Further on, in order to supplement the results, the frequencies of each rate, i.e., the mode has been considered as well. Namely, the factors that 67% of questioned users have rated with 4s and 5s have been considered as most influential. According to participants’ ratings, those factors are: audio quality, image quality and quality of service, as well going from more to less effective.

However, what differentiates this paper in comparison to the literature is that we have provided a list of IFs that were ordered by user perception of the strength of their impact on user’s QoE. This may serve as a useful input, in terms of what to focus on and what to enhance for stakeholders dealing with WebRTC based video calls (network providers, service providers, content providers, device manufacturers, etc.) when trying to improve their performance. Most of these IFs fall into category of system IFs, thereby confirming existing literature’s qualitative conclusions that the most influential factors in terms of QoE in this context comes from this class. However, having service price on a fourth place in the list, together with location, noise or movement in the first half of the IFs list, launches context IFs, as a group, shoulder to shoulder with system IFs, and should additionally motivate research community and stakeholders to investigate these factors and enhance their positive and suppress the negative effects.

In addition, in the subject questionnaire, we gave the opportunity to participants to give their opinion on the most influential factor and to suggest additional factors that may affect their satisfaction with the service. Gathered answers indicate that the list of examined factors is comprehensive and that factors identified as the most influential by the statistical analysis have been identified as most influential by the participants as well.

In the same way, we have determined that the least influential IFs are the ones that can be classified in human IF group: difficulties in using modern technologies, emotional state, time of the day, hand injuries, and speech difficulties, going from less to more influential. This justifies the lack of research which addresses this category of IFs (in comparison to system and context IFs) in context of user experience and QoE.

IV. Conclusion and Future Work

The advent of WebRTC enables the service providers of all types to rapidly and efficiently differentiate their business and service offerings. As this promising technology continues to proliferate, it becomes important to gain an in-depth understanding of the numerous influence factors which affect the user’s experience and its quality in the context of WebRTC video communication. To prevent users from getting unsatisfied with WebRTC video calling, we have identified the most and least influential factors according to examined users’ opinions. The list of influence factors that affect the QoE in the context of WebRTC video calling has been created and sorted by the impact strength. The list shows the dominance of SIFs, but launches CIFs on the same level, while confirming the relapsing importance of HIFs. This may be useful for stakeholders dealing with WebRTC based services to acquire knowledge that is necessary for improving the service performance. All this up-to-date information should motivate research community and stakeholders to consider these factors in more detail.

Therefore, the further investigation of key influence factors for different WebRTC based services, as well as understanding how they mutually correlate is planned for the future work due its importance for satisfying end user needs and expectations. Moreover, since the most influential factors have been considered as composite factors (e.g., audio quality, image quality, quality of service), it is desirable to decompose them into components, and examine
their impact on QoE (e.g., image quality may be decomposed into encoding, resolution, sampling rate, etc.). The knowledge of the effects of each component (sub-factor) can provide a deeper understanding which can be further utilized by interested stakeholders in order to improve user’s QoE.

Since today’s users are still not familiar with WebRTC based services, there is a reason to engage more effort in research activities to discover and remove existing disadvantages of this technology according to end user needs and expectations. Such research activities give the contribution in the process of adopting the WebRTC based services and successfully managing QoE in this context including all its components, i.e. modelling, monitoring, and optimization.

Is there any impact of human influence factors on quality of experience?

Abstract - The increasing popularity of real-time communication services has driven a rising interest in understanding the factors influencing the quality of experience (QoE). Many research activities aiming to accomplish this goal have addressed different influence factors (IFs), which may be classified into three categories, i.e., human IFs, context IFs, and system IFs. Although the importance of human IFs (HIFs) has been already emphasized, these factors have been considered to a limited extent, and due to lack of empirical evidence, they still remain not well understood. Therefore, this research has been motivated by the challenge to provide a deeper understanding of HIF’s impact on QoE in the context of the real-time communication services. In order to accomplish this and verify the conclusions derived from related work, we have conducted two experimental studies which consider voice over internet protocol (VoIP) and unified communication (UC) services. Experimental results show no existence of impacts of selected HIFs on the user’s overall QoE while using either VoIP or UC services. However, this highlights the need for further research on this topic due its importance for satisfying end user needs and expectations in the context of real-time communication services.

I. INTRODUCTION

The telecom industry is under a significant transformation. The real-time communication services are under a pressure as telecom market demands richer, higher value services available on any device, across any network, and with satisfactory performance. Hitherto, performance in the telecom industry has been typically addressed in terms of quality of service (QoS). However, the recent research in the field of quality of experience (QoE) [1]-[3] has shown that the traditional QoS mechanisms are not sufficient to satisfy end users, prevent their churn, and attract new customers or incline them to adopt new complex services and thereby support further technology development. Therefore, in order to improve users’ satisfaction and offer maximized quality while at the same time minimizing the costs, a deep understanding of the influence factors (IFs) that affect QoE is needed.

A QoE IF has been defined as “any characteristic of a user, system, service, application, or context whose actual state or setting may have influence on the quality of experience for the user” [4]. Although there are several approaches to the categorization of QoE IFs [1], [5], [6] we consider the classification proposed by EU Qualinet community which groups them into following three categories [4]: (1) human IFs; (2) system IFs; and (3) context IFs. In this paper, the focus is on the human IFs (HIFs) which present “any variant or invariant property or characteristic of a human user. The characteristic can describe...” [4]. These factors are divided into two sub-categories [7]: (1) low-level processing influence factors related to the physical, emotional, and mental constitution (e.g. gender, age, lower-order emotions, user’s mood, personality traits, motivation, attention level, etc.), and (2) higher-level cognitive processing influence factors (e.g. socio-economic situation, educational background, attitudes and values, expectations, needs, knowledge, previous experiences, etc.).

The low-level processing influence factors, especially those that are related to human perception of exterior stimulus, have the highest impact on QoE [7]. However, the previous research activities on HIFs were limited to the relatively easy to understand factors, such as gender, age, visual acuity, etc. These factors were not considered either as the main research focus or as independent variables whose influence on QoE is in detail investigated [8]. Therefore, this research has been motivated by the challenge to provide a deeper understanding of the selected HIFs, i.e. gender, age, prior experience, and emotional state, and their impact on QoE in context of real-time communication services. In order to accomplish this goal and verify the conclusions made by the authors addressed in the related work [9]-[35], we have conducted two experimental studies which consider voice over internet protocol (VoIP) and unified communication (UC) services.

The rest of the paper is organized as follows. Section II provides a state-of-the-art literature review in the field of HIFs and their impact on QoE. Section III describes the design of the experimental studies performed in order to examine the impact of selected HIFs on QoE in the context of the VoIP and UC services. It contains two subsections which give hypotheses, describe the experimental environment and provide result analysis. Finally, Section IV summarizes the conclusions and presents open issues for further research.

MIPRO 2017/CTI 557
II. A SURVEY OF HUMAN INFLUENCE FACTORS

Human influence factors may be defined as the “overall assessment of human needs, feelings, performance, and intentions” and thereby may be classified as subjective and objective factors on the basis of psychological and physiological factors [2]. The subjective factors are associated with both quantitative and qualitative aspects of human needs and requirements (e.g., ease of use, joy of use, usefulness, etc.). By their nature, they are psychological factors that take into account human perceptions, intentions and needs. In order to understand these factors, different psychological models (e.g., technology acceptance model (TAM), theory of planned behavior (TPB), etc.) may be used according to the nature of the service and environment [37]. On the other side, the objective factors are based on physiological (e.g., brain waves, heart rate, blood pressure, etc.) and cognitive aspects (e.g., memory, attention, human activity, human task performance, language, etc.). Since these factors are quantitative in nature, different physiological tools (e.g., body sensors, galvanic skin response (GSN), etc.) and human performance models (e.g., goals, operators, methods, selection rules (GOMS) model) may be used for their capturing.

On the basis of the foregoing, it is clear that human influence factors are highly complex because of their subjectivity and relation to internal states and processes. In addition, they are strongly interrelated and may also deeply interplay with other groups of IFs. Therefore, the more recent research activities on HIFs have gained the popularity resulting in the growth of literature and number of studies dealing with the influence of human factors on QoE. Nevertheless, the understanding of more complex HIFs and their impact on QoE is still relatively limited due to the fact that the wide range of these factors was marginalized by the research community for a long period of time [8].

The importance of HIFs’ influence on user satisfaction, experience, and its quality has been emphasized by several research studies [9]-[35]. Table I surveys a number of references concerning HIFs in order to obtain a “broader picture” on this topic and provide the brief analysis of several commonly considered HIFs. Although this survey should not be considered exhaustive, it aims to identify and select HIFs which are relevant for our further consideration. Based on the state-of-the-art literature review, the following HIFs are identified as commonly analyzed in research studies: cultural background [10]-[13], [26], [29] age [13], [15], [19], [26], [28], [33], [35], gender [13]-[22], [28], [32], [35], sensation [9], [23], perception [9], [11], [23], emotional state [20], [21], [23], [27], [31], [34], personality [10], [24], [25], [27] and prior experience [30]. However, these factors have been considered to the limited extent, and still remain not well comprehended.

Therefore, we have selected four HIFs, i.e., age, gender, prior experience, and emotional state, to be our main research focus and the independent variables whose influence on QoE will be investigated in the context of VoIP and UC services. The HIFs are selected on the basis that, according to Table I, age, gender, and emotional state are the most commonly analysed HIFs, whereas the prior experience is the rarest considered HIFs.

</table>
Giving the fact that a distinction can be made between factors that are stable and factors that have more dynamic nature [8], our research considers two stable factors, i.e., age and gender, and two more dynamic factors, i.e., prior experience and emotional state. As will be described in Section III, these factors are acquired at the beginning of each experimental study, since our research examines their impact on QoE in the context of VoIP and UC service (e.g., one research question is how emotional state affects the QoE, and not how VoIP or UC service usage affects the emotional state).

A comparative research studies on various real-time communication services show that there exist both age and gender differences in forming QoE. For example, as far as age is concerned, older individuals are more critical than younger ones, which may suggest that elderly people have higher requirements to QoE [15], [33]. However, the opposite results illustrate that older individuals tend to rate the quality more positively than younger ones [26], [35]. On the other hand, the research activities considering gender show that better performances of females are indicated in hearing sensitivity [17], memory localization facilities [18], or synchronization’s errors sensitivity [19], whereas the research results are in favour of males for localizing target sounds in a multi-source sound environment [16]. Nevertheless, it is shown that age and gender differences are insignificant in terms of QoE [28].

As indicated above, examples of HIFs that have more dynamic nature are emotional state and prior experience. The human emotional state may have a great impact on QoE and thereby it has recently gained importance which is demonstrated, for example, by incorporating it into speech QoE models [31] or investigating it through play gym games [34]. Despite its strong relevance for QoE [30], the impact of prior experience and the way in which it interlace with or depend on other IFs is still insufficiently understood. Giving the fact that prior experience, as well as other selected HIFs may interplay with other groups of IFs, their influence may be increased or decreased in accordance with the appearance of specific other IFs. Therefore, the motivation for this research lies in measuring the selected HIFs, in disentangling them, and understanding their influence on QoE.

III. EXPERIMENTAL STUDIES

To examine the impact of HIFs on QoE and verify the conclusions made by the authors addressed in the related work we have conducted two studies which included the testing of VoIP and UC services. The following two subsections provide more detailed discussion on the experimental studies and their results.

A. The impact of HIFs on VoIP

a. Introduction and Hypothesis

Based on the related work and reviewed literature, we derived the following four hypotheses. The hypotheses try to illuminate the existence of impacts of selected HIFs, i.e., age, gender, prior experience, and emotional state on user's overall QoE while he or she is using the VoIP service. We expect to find no impact of these factors on QoE, meaning that QoE will not change if these factors change.

H1.1: There is no impact of age on user's QoE when using VoIP service.

H1.2: There is no impact of gender on user's QoE when using VoIP service.

H1.3: There is no impact of prior experience on user's QoE when using VoIP service.

H1.4: There is no impact of emotional state on user's QoE when using VoIP service.

b. Description of the testing environment

The total of 30 participants has participated in the study (Fig. 1). Mostly those were the family members, friends, and colleagues and they have participated in the experiment on a good will basis, in their free time and for free. Experiments were conducted at authors’ homes (in Sarajevo, Tuzla, and Zenica).

All participants were given a task of registering, establishing, and terminating one VoIP call by using JITSI (https://jitsi.org/) after which they were asked to express their opinion regarding their QoE while using the VoIP service. The subjective evaluation of the test VoIP calls was performed by using the electronic evaluation questionnaire, which contained the part that was completed at the beginning of the experiment and it included the questions that covered the information related to the participant’s personal data, previous experience with VoIP service usage, and emotional state of the participant (considered HIFs), and the part that deals with the participant’s rating of the statement related to overall QoE when using VoIP service. The latter statement was a simple mean opinion score (MOS) scale used as the de facto standard in QoE Studies and specified in ITU-T Recommendation P.800.1. It must be noted that subjective QoE evaluation are to-date most commonly reported in terms of a single MOS value [36].

The experiment procedure lasted about 15-20 minutes and has included the three steps [36]: (i) introduction and clarification of the experiment tasks that need to be performed by the participants (8 minutes), (ii) participant training (5 minutes), and (iii) testing and rating of the experimental VoIP calls (5 minutes). All participants were asked not to think about their feelings during evaluation, but to be intuitive. As it could be concluded, the considered HIFs were differed in several groups. Namely, the factors of age and prior experience were considered in five abovementioned groups, while gender and emotional state in two.

c. Results analysis

In order to address the hypotheses (H1.1-H1.4) stating that differences in the age, gender, prior experience, and emotional state do not impact user’s QoE while using the VoIP service, we refer to the results of four one-way ANOVAs given in Table II. Independent variables (IVs) used for conducting this statistical examination are our selected HIFs, while the dependent variable (DV) is user's QoE. As previously mentioned, IVs are manipulated as follows: age and prior experience in five levels (groups), while gender and emotional state in two (Fig. 1). Based on the obtained results, one may conclude that there does not exist a strong and statistically significant impact (p>0.001) of user’s age, gender, prior experience, and emotional state on QoE when he or she is using the VoIP service. This implies that the hypotheses H1.1–H1.4 are supported.

B. The impact of HIFs on UC

a. Introduction and Hypothesis

Based on the related work and reviewed literature, we derived four hypotheses as well. The set tries to illuminate the existence of impacts of selected HIFs, i.e., age, gender, prior experience, and emotional state on user's overall QoE while he or she is using the UC service. We expect to find no impact of these factors on QoE, meaning that QoE will not change if these factors change.

H2.1: There is no impact of age on user's QoE when using UC service.

H2.2: There is no impact of gender on user's QoE when using UC service.

H2.3: There is no impact of prior experience on user's QoE when using UC service.

H2.4: There is no impact of emotional state on user's QoE when using UC service.

b. Description of the testing environment

The total of 96 participants has participated in the study (Fig. 2). As in the study described in previous subsection, mostly participants were the family members, friends, and colleagues and they have participated in the experiment on a good will basis, in their free time and for free. Experiments were conducted at authors’ homes (in Sarajevo, Tuzla, and Zenica).

All participants were given a task to register for using the UC service – Linphone application (https://www.linphone.org/), after which they had to: (i) change their presence status, (ii) send the message “How are you?” and receive the answer, (iii) establish an audio call lasting 30 seconds, and (iv) establish a video call lasting 30 seconds. Then, they were asked to express their opinion regarding their QoE while using the UC service. The subjective evaluation of the test UC service was performed by using the electronic evaluation questionnaire, which contained the part that was completed at the beginning of the experiment and it included the questions that covered the information related to the participant’s personal data, previous experience with UC service usage, and emotional state of the participant (considered HIFs), and the part that deals with the participant’s rating of the statement related to overall QoE when using UC service. As in previous study, the latter statement was the MOS scale.

The experiment procedure lasted about 15-20 minutes and has included the three following steps [36]: (i) introduction and clarification of the experiment tasks that need to be performed by the participants (10 minutes), (ii) participant training (5 minutes), and (iii) testing and rating of the experimental UC calls (2 minutes). All participants were asked not to think about their feelings during evaluation, but to be intuitive.

As it could be concluded, the considered HIFs were differed in several groups. Namely, the factors of age, emotional state, and prior experience were considered in three and five abovementioned groups, while gender in two.

c. Results analysis

In order to address this set of hypotheses (H2.1-H2.4) stating that differences in the age, gender, prior experience, and emotional state do not impact user’s QoE while using the UC service, as well as in previous subsection, we refer to the results of four one-way ANOVAs given in Table II.
using the cases of VoIP and UC service. The statistical analysis of data collected within emotional state, on user's QoE when using VoIP and UC selected HIFs, i.e. age, gender, prior experience, and conducted to obtain data for analysing the influence of existence of impact of HIFs on user's overall QoE by prepared. Further on, two experimental studies have been of-the-art literature in the field of the HIFs has been existence of impact of HIFs on user's overall QoE by supported. This implies that the hypotheses H2.1–H2.4 are emotional state on QoE when he or she is using the UC experience in five levels (groups) (Fig. 2). Based on the obtained results, one may conclude that there does not exist a strong and statistically significant impact (p>0.001) of user’s age, gender, prior experience, and emotional state on QoE when he or she is using the UC service. This implies that the hypotheses H2.1–H2.4 are supported.

IV. CONCLUSION AND FUTURE WORK

An enhanced understanding of human influence factors is a clear prerequisite for the successful management and optimization of end user experience. This means that there is a need to understand user’s QoE in this attractive and contemporary context, in order to maintain a satisfied customer base, prevent customer churn, and respond to upcoming challenges relevant to real-time communication services. Therefore, here lies the motivation for this paper which tries to provide a deeper understanding of the influence of human factors on QoE. The aim has been to experimentally investigate the existence of impact of HIFs on user's overall QoE by using the cases of VoIP and UC service.

In order to accomplish this, a brief survey of the state-of-the-art literature in the field of the HIFs has been prepared. Further on, two experimental studies have been conducted to obtain data for analysing the influence of selected HIFs, i.e. age, gender, prior experience, and emotional state, on user’s QoE when using VoIP and UC services. The statistical analysis of data collected within these experiments imply that there does not exist strong and statistically significant impact of user’s age, gender, prior experience, and emotional state on QoE either he or she is using VoIP or UC service.

However, the conducted experimental studies have certain limitations that may be overcome in the future work. Giving the fact that the impact of HIFs selected for our research study was found to be statistically insignificant, it is necessary to additionally investigate their impact when larger number of participants is included in the study in order to draw non-misleading conclusions. In addition, broader range of different HIFs may be taken into the consideration, as well as the relations between them in order to draw conclusions which may be helpful in a practical sense.

Extended AODV routing protocol based on route quality approximation via bijective link-quality aggregation

V.L. Prčić*, D. Kalpić**, D. Šimunić**
* Infoart d.o.o., Zagreb, Croatia

vprcic@infoart.hr

Abstract - Currently used routing protocols in mobile ad-hoc networks, such as those based on the ZigBee protocol, usually do not incorporate any notion of link-quality while searching for routes. While extensions to the AODV routing protocol with this in mind have been proposed, they usually use a single measure, such as SNR or RSSI to approximate the link-quality. Also, it is common that the process for determining the route between two nodes doesn’t make future route searches easier or quicker. In this work an extension to the standard AODV routing protocol is proposed, one that works with any well-defined link-to-link-quality assignment function and defines a route quality approximation approach that enables the maintenance of correct local measures needed for future route searches.

I. INTRODUCTION

We live in a world of never-ending scientific breakthroughs and advancements where bleeding-edge technology has seeped into ordinary lives, becoming the standard. Devices and accessories are so intricately interwoven with every-day activities that one can easily go about without being aware by the sheer amount of computer and electronic devices that surround us. It’s what makes it so easy to assume that radical, paradigm changing trends are all but depleted, done and behind us but is seems this is far from the truth. With recent advancements in miniaturization technologies that bodes well for the amount of computing power one can fit in a small volume of space, we are witnessing ordinary devices becoming “smart”, connected and interactive – a concept that can profoundly change the way we live.

For the moment, these devices do not speak the same language, which makes their integration difficult and reduces their scope of usability. A solution to this problem has been proposed by the IEEE in late 2004, a communication protocol named ZigBee, designed specifically for the use in wireless personal area networks (WPAN), that has since been refined multiple times to align itself with current technological trends. Such networks usually consist of a number of small devices running simple applications that collect or produce data and send it to a central point in charge of making the data readily available for the end client, usually uploading it to the Internet. The devices in question can vary from simple sensors that measure the temperature or humidity used either for personal or professional data aggregation, to home and industrial appliances. Usually, a ZigBee device can fall into one of three categories: ZigBee Coordinator (ZC), ZigBee Router (ZR) or ZigBee End Device (ZED).

The ZC devices are the most capable; they form the root of the WPAN, orchestrating the creation and mitigation of the network structure, but may also serve as a bridge to other networks. Along with the ZC devices, ZR devices fit the category of so called full function devices (FFD), devices that can run applications as well as participate in data transfer mechanism of the ZigBee protocol, while ZEDs fall into the category of reduced-function devices (RFD), meaning they can only run applications that produce or consume data, but play no further part in the node-to-node communication process.

A part of this communication process is the routing of packets from a device generating them to some other device in the network, usually the ZC device. ZigBee enabled devices are most commonly characterized as devices of low-power consumption – this makes them ideal for distributed data gathering since that can rely on a limited energy source for an extended period of time. However, the price to pay to attain such energy-efficient execution comes at a cost in the form of limited transmission and reception range, usually found to be somewhere in the interval between 10 and 20 meters, as well as limited bandwidth that peaks at a maximum speed value of 250 kbit/s.

To overcome these shortcomings, sending a packet of information using standard routing protocol defined by the ZigBee specification, the ad-hoc on-demand distance vector routing protocol (AODV) [1], usually implies making several “hops” between multiple ZR devices, where the probability of data loss increases with each such hop. Choosing the right route through which the packet is to be sent then becomes imperative for attaining a sufficiently high quality of service (QoS) level [2][3][4][5]. In an effort to resolve this, AODV is designed to choose routes with fewer such hops in a hope to minimize data loss, but does not always succeed. One might argue that the reason behind this is that not all hops can be treated equal and it is this notion, the notion of “hop quality” that is the basis of research described in this
work, and has already been incorporated into AODV from the start, as we well show in this article.

II. AODV AND ITS PROPOSED EXTENSIONS

When searching for a route between two nodes in a mesh topology network, in an effort to make the source node able to send information to the destination node, the source node starts by broadcasting a route request (RREQ), initiating the first phase of the AODV algorithm. This broadcasted request contains information about the source node, the identifier of the destination node and the identifier of the last node that forwarded the request. When a node receives a RREQ, it modifies it by replacing the identifier representing the last node that forwarded it with its own, before forwarding it further. This process continues up until the destination node receives the request. At that point, it sends a route reply (RREP), marking the second phase of the AODV protocol, but unlike the source node broadcasting the request, it sends it directly to the node it received the RREQ from. This node, in turn, sends it to the node it received the RREQ from and so on, until the source node is reached. In each of these steps, before sending the reply further, nodes store the routing information on how to reach the destination node - by specifying that, in order to do so, each must forward any future packages to the node it received the RREP in question.

To make the AODV protocol faster and more robust, additional actions occur in the first phase of the protocol. Each node that receives a RREQ, stores a reverse route to the source node. This makes it easier for future packages to be sent in the opposite direction, to the source node, and is mandatory for sending back a reply. Also, a node may choose not to broadcast a received request if it already has a valid route to the destination node, in which case it sends a RREP to the source node. For a route to be added into the node’s routing table, one of the conditions that must be fulfilled is that the number of hops it takes to reach the route destination via the new route must be smaller than that via a possibly preexisting route already in the routing table. Along with this, a number of conditions must also apply, but these conditions are all of the technical nature mandatory for the proper functioning of the routing algorithm itself leaving the before mentioned condition the only one that chooses a “better” route over another. This is to say that a form of route-quality dependent choice already inherently exists in the AODV algorithm, and we are simply building upon it. As such, problems concerning routing table instabilities that are common in network communications with any dynamic route adaptation scheme, like route flapping or route oscillations, should not arise with greater frequency than with the usage of the original AODV algorithm.

A number of protocols that incorporate a notion of link-quality into AODV have already been proposed [6][7][8][9][10], but we have found most of them make certain assumptions that do not necessarily hold in the general case, most notably the assumption that $q(a \rightarrow b) = q(b \rightarrow a)$, where $a \rightarrow b$ denotes the link from the node $a$ to node $b$, $b \rightarrow a$ denotes the reverse link, from node $b$ to node $a$, and $q(\cdot)$ denotes the link quality function. This assumption certainly makes the routing algorithm easier to implement, but does away with subtler concepts like load-balancing that can be otherwise achieved.

A few of the proposed protocols define the route quality as the minimum quality of all the links that constitute the route in question [11], or

$$Q(n_1 \rightarrow \cdots \rightarrow n_N) = \min_{i \in [1, N-1]} q(n_i \rightarrow n_{i+1}).$$

This definition is problematic because it prefers longer routes over short ones if only a single link in the shorter route is of low quality. Without going into which of these should be chosen, we propose a routing algorithm that makes such choices malleable.

III. NON-INVERTIBLE LINK QUALITIES

The assumption that a link between nodes $a$ and $b$ has the same quality, regardless of its direction, is a sound one, but only if the assumption of equal transmission and reception possibilities of both nodes is accepted as well. This would imply that all the nodes in a network are of the same type, able to transmit and receive packets with equal power consumption in all directions throughout the communication process. Since this is rarely the case, we can immediately see that this assumption sets ground for an unrealistic case.

Furthermore, making this assumption deprives us of implementing other behaviors that may improve overall communication quality. For example, one could implement a simple load balancing scheme by defining the link quality function to be inversely proportional to the average number of packets in the receiving node’s queue. Using such a link quality function would remove the load strain from heavily targeted nodes, and spread out the load, if possible, according to the network’s connectivity structure. Another example would be a link quality function that is proportional to the receiving node’s remaining energy level. Such a link quality function would decrease the number of packets that are sent through nodes with a low remaining energy level and redirect them to nodes with a high remaining energy level, thus prolonging the network’s current connectivity life span. Alongside these two local indicators, many more such indicators, like the average number of packets dropped by the transmitting node or the fact if a node is mobile of not, could be used to increase the overall QoS of a wireless network by making the link quality function dependent of them.

IV. AGGREGATED LINK-QUALITY

To give a proper definition of the bijective link-quality aggregation AODV (BLQA-AODV) protocol, we will reiterate the ideas of route and link notation, as well as quality function. A link $l_{a,b} \equiv a \rightarrow b$ can be seen an ordered pair of nodes $a$ and $b$ taken from the set of all nodes $\chi$. This forms a set of all links $\Lambda = \{a \rightarrow b: a, b \in \chi\}$. This set also contains the empty links $a \rightarrow a \equiv \emptyset, \forall a \in \chi$. A route can then be seen as an ordered sequence of nodes from $\chi$, or $r = n_1 \rightarrow n_{N}, i.e [1, N], n_i \in \chi$. For brevity, we denote “any combination
of nodes from $\chi^*$ as $\mapsto$, previously denoted as $\rightarrow \cdots \rightarrow$. Each link $a \rightarrow b$ is also a single hop route. Such routes can be added together by following certain rules. It holds that

$$n_1 \mapsto n_i \mapsto n_N = n_1 \mapsto n_i + n_i \mapsto n_N.$$  
(2)

Using this, we define route subtraction as

$$n_1 \mapsto n_i \mapsto n_N - n_1 \mapsto n_i = n_i \mapsto n_N,$$  
(3)

or equivalently

$$n_1 \mapsto n_i \mapsto n_N - n_1 \mapsto n_i = n_1 \mapsto n_i.$$  
(4)

So, using this notation, a route can be seen as a sum of links, or

$$n_1 \mapsto n_i \mapsto n_N = \sum_{j=1}^{N-1} n_j \rightarrow n_{j+1}..$$  
(5)

By using this notation, one can define a route quality function $Q(\cdot)$ that maps a route to a decimal value. Then, we can say that the BLQA-AODV protocol searches the route $\hat{r}$ such that

$$\hat{r}(a, b) = \arg \max_{r \in a \rightarrow b} Q(r).$$  
(6)

To calculate $Q(\cdot)$, one can define various criteria, but within the BLQA-AODV protocol, it is defined via the link quality function $q(\cdot)$ which maps any link $l_{a,b} \in \Lambda$ to a decimal value. To do so, first one must define a commutative associative operator $\otimes$, the aggregation operator, for which there exists an inverse operator $\oslash$ such that

$$Q(a \rightarrow b) \otimes Q(b \rightarrow c) = Q(a \rightarrow b \rightarrow c)$$  
(7)

and

$$Q(a \rightarrow b \rightarrow c) \oslash Q(a \rightarrow b) = Q(b \rightarrow c).$$  
(8)

Using the previous definition of a route as a sum of links, we can deduce that

$$Q(n_1 \rightarrow n_i \rightarrow n_N) = \bigotimes_{i=1}^{N-1} Q(n_i \rightarrow n_{i+1}).$$  
(9)

Finally, we will approximate the route quality function $Q(a \rightarrow b)$ as the link quality function $q(a \rightarrow b)$, by which we define the route quality approximation as the aggregated link-quality using the operator $\otimes$, or

$$Q(n_1 \mapsto n_i \mapsto n_N) = \bigotimes_{i=1}^{N-1} q(n_i \rightarrow n_{i+1}).$$  
(10)

The main advantage of this definition is that it allows us to calculate partial route quality, or:

$$Q(n_1 \mapsto n_N) = Q(n_1 \mapsto n_i \mapsto n_N) \oslash Q(n_1 \mapsto n_i).$$  
(11)

To make the approximated route quality definition useful, one must define how the link-quality function assigns values to links. The link quality function must be chosen so that the aggregated route quality is decreasing, that is, the inequality

$$Q(a \mapsto b) \otimes q(b \rightarrow c) \leq Q(a \mapsto b)$$  
(12)

must hold. We propose that the link-quality values are approximated by local values available at the destination node, such as values derived from packet reception process, like RSSI, SNR or bit-error, the number of packets in the destination nodes queue, current node battery level or any other such indicator.

V. APPLYING THE ROUTE QUALITY APPROXIMATION

All RREQ packets in BLQA-AODV have the addition of a current aggregated link quality. This means that the RREQ packet that emanated from node $n_0$ being broadcasted from node $n_{i-1}$ to node $n_i$ will contain the approximated route quality $Q(n_i \mapsto n_{i-1})$. After receiving the packet, node $n_i$ approximates the route quality $Q(n_{i-1} \mapsto n_i) \approx q(n_{i-1} \mapsto n_i)$ and calculates the new current aggregated route quality (ARQ)

$$Q(n_1 \mapsto n_{i-1} \mapsto n_i) = Q(n_1 \mapsto n_{i-1}) \otimes Q(n_{i-1} \mapsto n_i) \approx Q(n_1 \mapsto n_{i-1}) \otimes q(n_{i-1} \mapsto n_i).$$  
(13)

Then, it broadcasts the RREQ packet with the updated current aggregated route quality. Before doing so, the node $n_i$ stores the information about the broadcast, the same as in AODV, but adds to it the calculated current route quality for future reference.

Analogously to the AODV protocol, the rebroadcasting and the saving of the broadcasting information does not take place in certain conditions. For AODV, those include the new number of hops being smaller than any older, but in BLQA-AODV the current route quality must be greater than any previously encountered. Since the inequality condition (12) is being conserved, we are certain that the rebroadcasting will eventually stop because no cyclic routes will ever be attained since

$$Q(a \mapsto b \mapsto c \mapsto b) \leq Q(a \mapsto b).$$  
(14)

When the route request destination node receives the request, it sends the RREP to the source node containing the total route quality $Q(n_1 \mapsto n_N)$ via the node it received the broadcasted RREQ from. If it receives any additional RREQ packets, it will reply to them only if they contain a total route quality larger than the one it received earlier.

Upon receiving the RREP, each node $n_i$ calculates the quality of the route from that node to node $n_N$ using the identity

$$Q(n_1 \mapsto n_N) = Q(n_1 \mapsto n_1 \mapsto n_N) \oslash Q(n_1 \mapsto n_1).$$  
(15)

Then it can add the information of the route $n_1 \mapsto n_N$ to its routing table, together with the calculated route quality. Should later on such a node $n_1$ receive a RREQ packet for the same destination node $n_N$ from node $n_1$, that is, the request for route $m_1 \mapsto n_N$, it wouldn’t have to broadcast it further, but could send a reply to node $m_1$ with a route quality attained by the expression

MIPRO 2017/CTI

565
\[ Q(m_1 \rightarrow n_i \rightarrow n_N) = Q(m_1 \rightarrow n_i) \otimes Q(n_i \rightarrow n_N). \] (16)

The following pseudocode defines the described processes in a concise form.

```
calculate link quality \( q(n_{i-1} \rightarrow n_i) \)
calculate ARQ as \( Q(n_i \rightarrow n_{i-1}) \otimes q(n_{i-1} \rightarrow n_i) \)
IF already received RREQ for this broadcast THEN
  IF it has lower or equal current ARQ THEN
    return
  END IF
ELSE
  save broadcast info
END IF
IF current node is the destination THEN
  send reply
ELSE IF current node has valid route to destination THEN
  calculate total ARQ for route \( n_1 \rightarrow n_N \)
  send reply
ELSE
  broadcast request with updated ARQ
END IF
```

Pseudocode 1 – RREP packet receive function

- IF current node doesn't have route to destination THEN
  add it
ELSE IF existing route has lower or equal ARQ THEN
  update it
ELSE
  return
END IF
IF current node is not the source THEN
  IF current node has original broadcast info THEN
    forward reply
  END IF
END IF
END IF

Pseudocode 2 – RREQ packet receive function

VI. EXAMPLES

As we have seen in the previous chapter, by defining the operator \( \otimes \) and link quality function \( q(\cdot) \), the BLQA-AODV algorithm changes its definition of route quality and therefore its behavior.

By defining the link quality function as \( q(\cdot) = -1 \) and the aggregation operator \( \otimes \) as addition, we get the aggregated route quality definition as

\[ Q(n_1 \rightarrow n_N) = \sum_{i=1}^{N-1} -1 = 1 - N. \] (17)

This makes the route quality equivalent to the one defined in the unmodified AODV protocol, that is, the hop count.

Alternatively, we can define the aggregation operator as multiplication and the link quality function as the probability that the packet will be successfully sent between two nodes. Then the aggregated quality can be seen as the total probability a packet will be sent over a route, that is

\[ Q(n_1 \rightarrow n_N) = \prod_{i=1}^{N-1} P(n_i \rightarrow n_{i+1}) \] (18)

where \( P(n_i \rightarrow n_{i+1}) \) defines the probability of a successful packet transmission using the link \( n_i \rightarrow n_{i+1} \).

Additionally, we can define the link quality function in such a way that it is proportional to the inverse of the average number of packets a node has in its queue. Regardless of the aggregation operator, this will serve as a form of load balancing because routes that are not usually heavy on traffic will be chosen. In the same manner, the link quality function can be defined to be proportional to the nodes current energy level so routes containing nodes with higher energy levels would be preferred.

VII. FUTURE WORK

The current extension of the BLQA-AODV algorithm is based upon the assumption that the link quality function can assign different values to the same link depending on the link direction, that is

\[ q(a \rightarrow b) \neq q(b \rightarrow a). \] (19)

Should we make the assumption that the opposite holds, then the prospect of adding inverse routes as part of the route search process would be possible. Currently, it is not because the only way a node can know the quality of the link from it to a neighboring node is by sending a packet to the neighboring node and having it return the assigned quality. Should we make the mentioned assumption, it could get the link quality by simply receiving a packet from the neighboring node. This could make the algorithm have less packet overhead and as such is a notable path to consider, although it does reduce the possible scope of functionalities because the described behaviors like load balancing would not be possible.

VIII. CONCLUSION

The proposed extension to the AODV algorithm makes a solid foundation for future research. It gives an extendable framework for defining the behavior of the routing protocol in various networks where different conditions and assumptions may apply. Using specific knowhow of the network’s needs, one can define the routing protocol to be finely tuned to those needs, such as bandwidth maximization or energy consumption minimization. One can even use a link quality definition that is a combination of different indicators and combine it with a number of machine learning algorithms in an effort to optimize certain overall measures of a network.

[2] Bilel NEFZI, Ye-Qiong Song, Performance analysis and improvement of ZigBee routing protocol", IFAC Proceedings

Abstract — The transition from voice to data services has led to new trends in telecommunication business, and therefore the need to adjust legacy metrics and KPIs (Key Performance Indicators) that aims to point out the effects of these changes. In this paper, we give the review of development trends of new KPIs that provide greater insight into the use of data based services, as well as estimating the share of revenue that is obtained from these services. The importance of customer segmentation and correlation with KBOs (Key Business Objectives) is discussed. Special attention was paid to the situation of the market in Bosnia and Herzegovina and the need for trends monitoring in this area.

I. INTRODUCTION

Telecommunications companies are faced with the key changes in the market such as the explosive growth of data, a constant increase in the number of smart mobile devices and new applications, as well as changes in customers’ behavior and expectations. Although changes in the telecommunications industry brought increased demands for the transfer of data, there has been a decreasing in income and stagnation in the number of mobile users. Operators’ revenues are under the pressure because of the increasing rise in sophisticated demands of users and regulators and due to increasing competition of OTT (Over-The-Top) providers. As the market becomes saturated, a new investment business model cannot be based on the penetration and the number of new users. The legacy services such as voice and SMS are only applications in the world of data transfer. Thus the legacy metrics (per-user), such as: average revenue per user ARPU (Average Revenue per User), Churn rate, and Net Additions, do not give a real picture of the network. These metrics are relevant when voice was the main service and when each customer has owned a single mobile device. However, as customers have multiple types of mobile devices and use a variety of services, the company do not provide that existing metrics to obtain a complete picture of how subscribers use their devices and services. Operators will need to track success with the right KPIs that can shape their strategy for the long period.

The necessity of adapting existing KPIs to dynamic changes in the market has prompted many authors to deal with this problem. This paper presents the development trends of new KPIs in telecommunications companies. The second section summarizes the characteristics of the modern telecommunications market. In the third chapter is given an overview of KPIs evolution from the period when voice was dominant service to the period of maturity of data services. After that the importance of customer segmentation is discussed. At the end is given a use case with the example of new metrics selection in the specific market, as well as the benefits and challenges of multi-dimensional metrics selection.

II. MARKET TRENDS

Modern telecommunications market is characterized by the following features:

● The use of data based services is becoming the dominant mobile service. Monthly global mobile data traffic will be 30.6 EB (Exabyte EB=1 billion GB) by 2020, [1].

● The increase of the amount of data transferred does not mean an increase in revenues from data based services, Fig. 1.

● The total number of smartphones will be nearly 50% of global devices and connections by 2020. Because of increased usage on smartphones, smart traffic will cross four-fifths of mobile data traffic by 2020, Fig. 2.

● 4G technology is becoming the dominant technology on global market with 40.5% of connections and 72% of total traffic, Fig.3.
The number of M2M (Machine-to-Machine) connections increases rapidly as the number of multi-SIM service users. The impact of OTT applications and providers is becoming increasingly serious. The improving of the user experience is becoming more and more important.

The evolution of the telecommunications market has led to an environment with the saturation of voice and the rapid growth of data, which has imposed the need to define new business models and development strategies. The growing use of services such as the exchange of multimedia content, social networking, games, shopping over the Internet, and meteoric growth of OTT applications and rapid penetration of smartphones drove out services such as voice, text and data for less demanding applications. Telecommunications companies have large investments in infrastructure and technology, but they do not have the expected profit. Most of the operators are based their business strategy on reducing churn, and they offer flat-rate tariff models, fixed broadband, various service packages etc., which led to great use services based on high-speed data for a very small fee. This has led to decreasing ARPU in all world markets. With the loss of revenue from voice service as the growing use of VoIP, operators found that urgently need to develop strategies that help to monetize the increasing use of data based services. One way is better understanding of customer behavior and more efficiently CEM (Customer Experience Management).

As it is shown in [2] analysis of customer behavior and manage customer experience have become priorities for telecommunications companies, and investments are focused on improving the user experience higher than ever. The operators are changing their business models from a network-oriented to customer-oriented models [3]. This situation resulted in the redefinition of metrics that were indicators of quality of service, and performance indicators of the company.

III. THE EVOLUTION OF METRICS AND KPIs

A. Limitations of legacy KPIs

The evolution of the market is followed by evolution of existing KPIs and metrics in the new metrics that provide greater insight into the use of data based services, as well as estimating the share of revenue that is obtained from these services. The increasing use of data based services does not mean higher revenue from these services.

According to [4], the limitations of existing KPIs are as follows:

- Network Coverage, the legacy metric, which is losing its relevance due to the high penetration of smartphones and high-tech innovation solutions in developed markets, which are already saturated.
- Minute of use services (MoU), the legacy metric, which losing its relevance due to the growing popularity of VoIP traffic, flat-rate tariff models and various service packages.
- ARPU (Average Revenue per User) is a KPI that represents the average revenue per user, which is not the appropriate metric for multi-SIM users.
- Net Mobile Connection Additions is the number of new users reduced by the number of users who have left the network. It is a legacy metric, which losing its relevance due to the decreasing number of new subscribers. New business users in VPN groups, multi-SIM users and M2M connections do not mean an increase in this KPI by its definition.
- Market Penetration was initially defined as a KPI that measures and presents growth of core services (voice and SMS) on the market, in order to access to the market potential for the introduction of new services. But, this legacy metric does not successfully represent the full potential of the market for new services.
- Because of market development and the transition to data services, users can not be viewed in the same way as earlier because of new trends in the growth of M2M connections and the use of multiple devices per person.

B. Development of new KPIs

The legacy metrics and KPIs in the telecommunications industry are subject to significant changes due to external factors, but also because of the internal strategy of the company. The external factors include: new technologies, competition of OTT providers, market regulation, price reduction, increasing number of service providers and MVNO (Mobile Virtual Network Operator), changing in customers’ requirements. Internal strategies include new data-centric business models and new data services.

To overcome the limitations of existing KPIs that does not give a true picture of the emerging markets, in [4] and [5] are proposed the following KPIs:

- Data share of revenue indicates revenue share of data traffic in relation to the total revenue, which is very important since the service data represent a major part of the mobile operators offer.
- RGU (Revenue Generation Unit) metric scales revenue based on the number of services used by users (Multi-Service per User). This is very important from the point of analysis increase cross-selling and up-selling service offer.
- Since the MoU is losing its relevance, data usage per user becomes a metric that provides an insight on the amount of transferred traffic per user. This metric is particularly interesting from the point of billing.
• Machine to Machine Average Revenue per SIM - M2M ARP-SIM is an important metric to monitor the arrival of a growing share of M2M connections for that is expected a rapid growth in the future.
• As business metrics, instead of the ARPU, which has become irrelevant because of multiple devices per customer account, some operators as a measure of profitability of its offer measure the revenue with a new metric ARPA (Average Revenue per Account).

As an illustration, in Table 1 is presented the evolution of KPIs for wireless services in three phases: from the period in which voice was the dominant service to the period in which voice and data are equally presented, to the third phase of the evolution when data services are dominant with voice as an application. Acquisitions of customers, service delivery and business results are considered. For the first phase with voice as a primary service, as well as for the second stage of evolution when data services are getting more important, measuring the quality of service is still remained at the network level than at the application level. Only at the third stage of development services, new metrics are gaining in importance in the assessment of all aspects of the business, from the acquisition of customers to daily operations, [6].

Operators should consider a holistic approach to measuring service performance, because the end-to-end service quality not only relies on the performance of the network, but also other factors such as device and application performance. In a multi-dimensional approach, metrics and KPIs about network performance as well as segmentation of customer data (IMSI, time of the day, geo-location, age group, type of device, type of application, usage, habits, price sensitivity) etc. are necessary to enable operators to effectively assure services.

C. Customer segmentation

In [6] is proposed that operators have to access the segmentation of their customer base, and to control and analyze user behavior and expectations. When one user has multiple mobile devices and access to more services, operators must provide consistent user experience. Information about the type of content can be obtained from measurements such as the contents of the device (Content per Device) and the number of M2M connections per user (M2M Connections per User). Traditionally, customers were segmented on postpaid and prepaid customers. Another type of segmentation is per tariff models to business customers and individuals what allowed the operators a better understanding of the expected quality. The third type of segmentation is based on factors that are specific to the use of the service (per usage). To define a user-experience score, factors to consider include the user’s location, age group, price sensitivity, and frequently used applications. Network operators can construct a well-planned strategy to optimize their networks based on the regional user-experience score, while giving customers the best experience. These factors are as follows:

• Location: The types of applications and the level of service quality expected vary vastly between locations. The location can be seen as an urban, suburban or rural, or as indoor or outdoor. Data transmission has a different meaning in relation to the situation when the voice was the dominant service. That is because data has a visual aspect and the probability of accessing data services is greater in an indoor than an outdoor setting. For example, the probability of a request for transfer of data and the expected quality is the highest in indoor urban locations.

• Age group: Subscribers can be segmented by generations into seniors (birth year before 1946), baby boomers (birth year 1946-mid 1960s), Gen X (birth year mid 1960s-early1980s), Gen Y or millennials (birth year 1980s-2000s) and Gen Z (birth year after 2000s). This segmentation can give to operator good insights into the quality of service the network must deliver to the most important age group in that region, Figure 4.

• Price sensitivity: According to the consumption subscribers are divided into VIP customers and others who are viewed through consumption and habits, which correlates with the expected quality. For
example, for a group of business users in a specific region the operator must provide the highest quality services and the most reliable secure connection.

- Usage pattern: According to the use of the service users are divided into: users who predominantly use voice as a service and minimally data. Light users are checking e-mails and browsing the Internet. Medium users actively use social networks and often access the network. Heavy users extensively use video streaming and OTT applications.

Operators also can benefit from network analytics using customer micro-segmentation. With rapidly changing customer behavior and expectations, and increasing demand for personalization, operators need a better way to segment the market. One way is micro-segmentation. Micro-segments gather considerably smaller numbers of customers into groups based on application usage, device usage and geo-location. Operators can be better served their customers in various areas of their interest such as handling complaints, troubleshooting QoE issues, or providing micro-services tailored to their exact needs, [7]. Customer micro-segmentation technology empowers marketers to achieve deeper customer understanding and more effective customer marketing. Based on above given factors and using appropriate metrics and KPIs including user-experience score, the operator can get the insights for optimizing and tuning the network in accordance with the requirements of the users and identify services to target user groups, [8].

IV. CASE STUDY - SELECTION OF NEW METRICS

The selection of new metrics is affected by numerous factors which are determined by the specifics of the local and regional markets, technological developments and the competitive environment. In accordance with that appropriate KPIs are selected. The market in Bosnia and Herzegovina is very specific, [9]. It is characterized by the following factors: the three dominant national operators, the only telecommunications market in the region that is not implemented 4G/LTE technology, weak economic development and low ARPU in relation to the average ARPU in EU. At the end of 2015 the level of penetration of fixed telephony amounted to 20.45% and in the mobile telephony 89.63% with the dominant share of pre-paid users. There has been growth in the number of Internet users and at the end of 2015, penetration was 72.41%. Broadband services are increasing, so the number of broadband subscribers reached 99.72% of the total number of Internet subscribers. The most subscribers have access speeds of 2-10 Mbit/s. Data traffic is growing continuously, and the number of smartphones and OTT providers and applications are increasingly common in the market. Taking into account the above factors, it can be concluded that there is potential for further growth of the market. In that context, as the indicators for this specific emerging market can be taken the KPIs that are given in Table 2. They were chosen with a view to control customers and networks from the perspective of efficiency, the use of service and business results.

<table>
<thead>
<tr>
<th>TABLE 2: THE EXAMPLE OF NEW KPI SELECTION FOR B&amp;H OPERATORS.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Key Business Objective - KBO</strong></td>
</tr>
<tr>
<td>--------------------------------</td>
</tr>
<tr>
<td>Business processes improvement</td>
</tr>
<tr>
<td>Quality of service improvement</td>
</tr>
<tr>
<td>Sales increase (growth)</td>
</tr>
<tr>
<td>Revenue growth</td>
</tr>
</tbody>
</table>

Each of KPIs from Table 2 has to be correlated to the strategic objectives of the company described with Key Business Objectives (KBO): improving business processes, improving service quality and customer experience, increasing sales and operating income, strengthening the brand etc. Previously listed key performance indicators are the detailed indicators measured in real time that are measurable and support directly the KBO via Key Performance Objectives KPO, [10]. The example of that KPI-KBO mapping is given in Table 3.

<table>
<thead>
<tr>
<th>TABLE 3: KBO-KPO-KPI MAPPING.</th>

<tr>
<td>Sales increase (growth)</td>
</tr>
<tr>
<td>Revenue growth</td>
</tr>
</tbody>
</table>
Some of these metrics are already measured using tools for monitoring signaling and network control. The examples of service based metrics are given in the Figure 5. They are related to QoS per application and were obtained in real network environment using MasterClaw monitoring tool.

Figure 5. The examples of service based metrics, QoS per application.

V. BENEFITS AND CHALLENGES OF MULTI-DIMENSIONAL METRICS SELECTION

A multi-dimensional approach to monitoring, metrics selection and assuring the end user’s service quality can be the differentiator on competitive telecommunication market. Advanced analytics capabilities can support better capacity planning and traffic management as well as more effective service assurance to deliver a customer experience that retains subscribers and increases revenue. This approach should consider the following aspects: end-to-end network performance, including the end device, access, core network, the application servers, geo-location, age profile, the applications or services accessed by the customer, the customer’s identity, the device being used and the time period of usage. Since operators have large amounts of data about their customers, they can model the behavior of their users based of this data. In this area there are numerous challenges, because the data are collected and aggregated from various systems and processes. To take advantage of the enormous potential of this information, the operator must have a significant investment in the areas of data mining, warehousing and Big Data solutions.

Specificities of the market that affect the selection of appropriate KPIs are also barriers to compare the performance of telecommunications companies across the different markets. To avoid this disadvantage it is necessary to adopt a consensus on the choice of KPIs that are consistently able to follow on a global level. In this sense, it is not expected only from regulatory authorities to impose new metrics and methods of their measurements, but also the initiative of the operators, investors and market analysts to support the move toward greater consistency.

VI. CONCLUSION

In accordance with changes in the market, operators must select the appropriate metrics and KPIs that will follow new trends in the telecommunications industry to achieve long-term strategic goals and targets of the company. The selection of suitable KPIs depends on the operator’s ability to actually measure the indicators. KPIs that take into account the specificities of the market and customer requirements for quality of service are crucial in differentiating a company in a competitive environment. In very specific B&H telecommunication market it is very important continually monitoring the trends in this area and investing in appropriate tools that can support the implementation of new metrics and KPIs. Only a multi-dimensional approach in network analytics across multiple capabilities ensures a true end-to-end view of the service, enabling operators to improve service quality and overall customer experience. Modelling of new business processes and improving of KPI-KBO correlation are the challenges in our future work with the intention to realize greater business value.

Implementation and Testing of Cisco IP SLA in Smart Grid Environments

J. Horalek, F. Holik, V. Hurtová
University of Pardubice, Faculty of electrical engineering and informatics Pardubice, Czech Republic
josef.horalek@upce.cz, filip.holik@student.upce.cz

Abstract - Smart grid networks are becoming more and more commonly deployed due to their undisputed benefits. On the other hand, there is a high demand for reliability and functionality of these networks. This paper is analysing usage of the IP SLA for monitoring network state and collecting important information for potential problem detection and solving. The practical part of the paper presents implementation of the IP SLA into the smart grid network environment and its testing. The results from several simulated scenarios with different QoS classes, used within the smart grid networks, are discussed.

I. INTRODUCTION

Securing performance parameters and monitoring of network functionalities are two of the most important tasks of intelligent networks, in order to ensure their effective usage. Most of the backbone and local smart grid networks are using MPLS L3 VPN [1-5] due to its reliability and security. Implementation and testing of this technology in smart grid networks is the main point of this paper. Presented measurement can be used for confirming the SLA and for proactive problem solving of potential issues. The goal of the paper is to prove, if the Cisco proprietary solution for measuring performance parameters is a suitable technology in the industrial environment of smart grid networks built on Cisco devices [6,7]. Two types of measurements were conducted. In the first case, the priority class with g.729a codec, simulating communication of Intelligent Electronic Devices (IEDs); and in the second case, default class simulating standard communication of the same devices.

The paper is further organized as follows: the second section describes the implementation details of the Cisco IP SLA. This implementation is then thoroughly tested in the third section. The paper is concluded in the last section.

II. IMPLEMENTATION OF THE CISCO IP SLA

Cisco Internet Protocol Service Level Agreement (IP SLA) is a proprietary technology introduced by Cisco for effective monitoring of network traffic. It can be used for measuring network performance and performance critical parameters like packet loss, delay, and jitter. IP SLA can therefore detect and prevent problems, which can influence network functionality and performance [8,9]. This is one of the most important tasks in the environment of intelligent energetical networks. Effective monitoring and measurement of the complete network can be done using Cisco RTTMON with management information base (MIB) together with SNMP and IP SLA statistics. IP SLA can also be used for policy-based routing. This type of routing can adjust the direction of packet flows based on actual statistics, and therefore better utilize each link and ensure availability of critical parts of the network.

In order to conduct a measurement, the topology has to contain one Cisco router for packet generation (monitor) and one host, acting as a responder. The responder can be any IED with IP address [10], able to reply to requests (ICMP echo, or HTTP GET). These devices are common in smart grid networks. In the case that the responder is also a Cisco router (in the energetical networks typically a gateway between different areas), IP SLA can be better utilized because a larger number of critical parameters can be measured. The following data collection and presentation is realized with Network Management System (NMS). After successful configuration, the router is collecting results of each operation and save the results in a form of IOS RTTMON statistics. The router is then using SNMP NMS to collect proper information from MIB. From the technology perspective, IP SLA is using a concept displayed in Figure 1. Every operation is defining a type of packet generated by the router, source and destination address, and other values. The configuration also contains time, when each operation should be executed.

A. IP SLA Monitor (Generator)

Tests are defined on the IP SLA monitor. Based on the configured parameters of each test, the IP SLA is generating specific traffic, analysing the results and saving them for a future analysis over CLI or SNMP. The IP SLA monitor can be every Cisco router having IOS with a proper set of functions, depending on the chosen type of test. Processor load on the IP SLA monitor is a critical part for measuring different metrics, especially for recording timestamps. For this reason, a proper methodology has to be used in order not to exceed 30% of the router’s CPU utilization. It is therefore recommended to use a dedicated router just for the measurement, so the data traffic would not be influenced and the measurement will get more precise results.

B. IP SLA Responder

IP SLA responder is reacting on tests generated by the IP SLA monitor. The responder creates timestamps with packet received and packet send time and then includes them in the payload. These timestamps will allow the elimination of processing time on the responder from the
final measurement time as shown in Figure 2. As in the case of the monitor, the CPU utilization of the responder should not exceed 30%, so it is important to carefully choose the testing methodology.

$$RTT = T4 - T1 - \Delta$$

(1)

where: $RTT = \text{Round trip time}$

$T1 = \text{Timestamp 1}$

$T4 = \text{Timestamp 4}$

C. Multioperations Scheduler of IP SLA

Cisco IP SLA allows the use of a multioperations scheduler, which can monitor complex networks containing large number of probes, and is ideal for smart grid networks (containing tens to hundreds of IEDs). This scheduler can be turned on with the “ip sla group” IOS command. The scheduler allows the planning of a sets of IP SLA operations, which allows the monitoring of traffic in a uniformly distributed timeframe. The realization requires the specification of a range (ID) of each probe and the function can then being run at once. This feature helps minimize the CPU utilization and therefore to increase the network scalability. The function is using the following configuration parameters:

- Operation ID numbers – the list of all IP SLA probes and their IDs within a particular group.
- Group operation number – configuration parameter, containing the number of a particular group.
- Schedule period – the amount of time, for which the group of IP SLA operations is planned.
- Ageout – specify for how long the operations actively collecting information are held in a memory.
- Life – the amount of time for operation to actively collect information.
- Frequency – time after which every IP SLA is repeated.
- Start time – a time when the operation will start to collect information.

Figure 2. The system timestamps

### III. THE TESTING

#### A. The Methodology of Testing

The tests were based on ICMP and UDP implemented in IOS IP SLA. Because most of the smart grid networks are based on MPLS, the UDP jitter operation was selected for testing. This operation is primarily used for diagnosis of real-time application availability, which is essential for smart grid networks. This type of test is also the only one, able to measure with micro-seconds precision, which is important for critical infrastructure. The UDP jitter test is generating sequential information and timestamps for both the sending and the receiving sides. We have chosen two variants of UDP jitter for measuring performance metrics in MPLS L3 VPN infrastructure. These two tests can relevantly simulate proper data flows in smart grid networks. This includes link congestion when collecting data from IED devices and high priority control commands. These tests are:

- UDP jitter with g.729a codec, which is used for measuring in a priority class in a priority traffic (SLA-Voice).
- UDP jitter without a codec, used for measuring in non-prioritized classes (SLA-Normal).

In the case of SLA-Voice variant, data traffic can be separated from control traffic, making the measurement more relevant. In the case of SLA-Normal variant, direct behaviour in the class using a class-default queue can be observed. This corresponds with the process of IED data collection.

Table 1 shows that in the SLA-Voice variant, packets with 32B size will be generated for a 55 seconds with 100 ms intervals between packets and 5 seconds space between each test. This means, that the measurement is taking more than 90% from the complete measurement time length of 60 seconds. This test is not influenced by data flows between end devices like IEDs, but only by the link state. The test will be used only for measurement between substations due to its complexity.

In the SLA-Normal variant, packets with 32B length will be generated for 50 s with 500 ms intervals between

each packet and 10 seconds break between each test. This will ensure, that the measurement will run in more than 80% of the total timeframe of 60 seconds. This test is used for simulation of consumer traffic and parameters in the class-default (with DSCP CS0). This test will be applied in all experiments.

B. Design and Parameters

The measurement was realized on the testing topology depicted in the Figure 3.

Measurement type Provider Edge (PE) - Customer Edge (CE) measured SLA metrics between end stations, CE routers and core PE routers. For this type of measurement, hub and spokes design was chosen. The hub was represented by the IP SLA router (PE router) and spokes were represented by the substation end routers (CE routers). The goal of this measurement was to detect problems with communication technology, which can be rented from an external provider of network connectivity. This measurement can be therefore used for solving connectivity problems (like QoS transparency or packet loss) with the external connectivity provider. In the PE-CE type of measurement, only the SLA-Normal variant was chosen due to the possibility of high CPU utilization on the SLA monitor. This would result in a large increase of identical measurements. Classification of the IPv4 traffic will be conducted based on a DSCP parameter located in the IP header. QoS configuration was done using the same process level. Instead, the dedicated MPLS VPN was created, so tests in each core QoS classes could be conducted. Since each PE router was connected to all the other PE routers. From the MPLS point of view, the measurement was not realized on the global routing infrastructure. QoS in the core mesh, where every PE router was connected to all the other PE routers. From the MPLS point of view, the measurement was not realized on the global routing process level. Instead, the dedicated MPLS VPN was created, so tests in each core QoS classes could be defined. This test was aimed at detecting and solving problems within the core infrastructure. QoS in the core infrastructure was similar to PE-CE. The OUT-MPLS policy-map was created and applied on the output interfaces between PE routers. This policy-map contained three classes displayed in the Table 3.

Measurement type Customer Edge (CE) - Customer Edge (CE) was used for measurement of SLA metrics between end points and IEDs. The whole link was therefore monitored – from a single substation, via the whole infrastructure of the provider, to the next substation. This test can be used for the specification of maximum latency, jitter, or packet loss between the central system and a substation. In our case, the router CE1 was used as the monitor and CE2 as the responder. CE1 generated both types of measurements (SLA-Voice and SLA-Normal).

C. Results

Every scenario for diagnosis of Cisco IP SLA behaviour in the environment of smart grid networks on a simulated topology of energetical company, was tested after the configuration. A reference values were collected during the standard traffic. Tables 4 and 5 show parameters gathered from IP SLA probes. Measured data also shows times when the operation was conducted, the number of successful and unsuccessful operations, and the lifetime of the operation. Lastly, the one-way statistics are also available, allowing to analyse information for solving connectivity problems of the transport network.

Note: IPCIF = Calculated Planning Impairment Factor
Results for the scenario: Utilization data lines

The next scenario tested data link usage by an IED. In the high utilization, latency will increase, jitter will fluctuate more, and there can be some packet loss, influencing functionality and effectivity of data centers. QoS policy with the 5Mbit bandwidth between PE1-CE1 and PE2-CE2 was used for sufficient trustworthiness of the measurement. Data traffic was simulated using pings with the size of 1500 bytes and 0 time limit for the reply. This ensured a link congestion resulting in packet drops in a direction between CE1 and PE1.

Table 6 shows, that in a default class, there is packet loss due to the high traffic load. Unlike in original values, latency and jitter also increased. A direction in which packets are lost can be also detected – in our case it is from CE1 to CE2. Priority class SLA-Voice shows almost no change, proving good conditions of the link without any packet drops in a core or transit infrastructure.

Results for the scenario: Utilization of voice lines

The next tested scenario is focusing on lowering quality of the priority line – the voice in our case. This situation can happen if the communication between IEDs is using more bandwidth than what is assigned to the prioritized traffic. Bandwidth in the test was set to 100Kbit. A typical data flow with G729a codec is using approximately 32Kbit/s. That means, that three parallel transmissions can be realized at once and be fully functional. Simulation was again conducted with a ping tool and packets marked with DSCP EF. Collected data shows, that the priority class became saturated and packets from this class were dropped. The default class transferred practically no traffic, so there were no packets dropped there. The Voice class had a priority over the class-default, resulting in a possibility of delayed packets in the class-default. Despite the possible delay, no packets were dropped in this class.

The results of PE1-PE2 measurement in the SLA-Voice class are present in Table 7 and show increased latency. This however presents only a simulated situation, in the real environment, such traffic should not influence core infrastructure.

The measurement of SLA-Voice between CE1 and CE2 (Table 8.) shows decreased performance parameters for voice technologies and consequent packet loss. Latency rapidly increased to an average of 146 ms, 14 packets were lost, and MOS decreased while IPCIF increased.

On the other hand, SLA-Normal measurement between CE1 and CE2 clearly shows no packet loss. But as already mentioned, the situation where latency in the SLA-Voice priority class will increase, can happen as it happened in our case – to the average of 147 ms.

In both cases it is clear, that the voice traffic was generated from the consumer CE1, because the data drops and latency increased in the direction from the source (CE1) to the destination. This measurement evaluated each state, which can happen on a link. We can then detect in which traffic class is a potential problem and therefore to proactively react.

The goal of the paper was to show suitability of Cisco IP SLA implementation in the intelligent environment of smart grid networks. These networks, built on MPLS technology are realizing access into each sub-areas of the smart grid and also providing core data traffic forwarding. Measuring performance characteristics with the IP SLA is important for solution of problems, which can happen in these networks. The conducted measurement scenarios and their results clearly shows, that the IP SLA is a very effective technology for problem solving, while at the same time is providing detailed information about different communication parameters for various data types. This effect was tested during parameter measurement in specific traffic types. It was proven, that the IP SLA is a very complex tool for network monitoring. It allows us to supervise large number of services and traffic commonly used within intelligent networks like smart grid.

Fault management and Management Information Base (MIB)

O. Jukić, I. Hedi, I. Špeh
Virovitica College, Virovitica, Republic of Croatia
{oliver.jukic | ivan.hedi | ivan.speh}@vsmti.hr

Abstract - Fault management function mostly rely on SNMP protocol and SNMP agent capabilities, where SNMP agents are implemented over different network elements. Structure of management information is described in Management Information Base (MIB) for every single SNMP agent class. Hence, integrated management systems needs to implement different SNMP managers capable to communicate with number of different SNMP agents, obtaining management information from real telecommunication network. Those managers are often called access modules.

In order to decrease delivery time for SNMP management solutions, number of generic fault management MIBs are designed (e.g. Alarm Management Information Base). Theoretically, if different SNMP agents rely on the same management information base, only one SNMP manager (access module) is enough to manage different network elements. It is a logical way of thinking, if we consider that in real life different network elements share the same management information structure. For instance, alarm message from many different network elements consists of start time, probable cause, additional information, affected network element, etc. However, state of the art is not so idyllic, from the integrator’s point of view. Number of MIBs exist in real telecommunications network. In this paper we will make short research on MIBs implemented on different network elements, in order to detect real integrator position in network management solution’s development. At the end, solution is proposed for SNMP agent software development.

I. INTRODUCTION

“Fault management is one of the most relevant functional areas when we are talking about customer experience of service quality. When problem appears, network operator’s reaction time depends on many factors. One of the most important is to recognize problem root cause, based on unsolicited events coming from network” [1].

Two crucial terms within network management functional area are Manager and Agent. Their interaction is rather simple: manager controls number of managed objects via agent located close to those managed objects. That is how how management of network resources is achieved [2]. Manager-agent interaction is shown on figure 1.

Manager is software application serving as interface between the real world (e.g. network personnel dedicated for network management) and management information that agent will understood. Network management applications include some kind of graphical user interface usually. Management information is generally standardized and available to any network manager, respecting security issues (e.g. passwords). Agent acts as an interface between management information and real telecommunications network.

![Figure 1. Manager-agent concept](image-url)
they are called event reports. Unsolicited messages sending implicates agent’s built-in intelligence.

Manager is sometimes called managing system, while agent is called managed system [3].

For consistent manager-agent communication, following conditions must be fulfilled:

- there is communication infrastructure between manager and agent,
- communication protocol is defined,
- management information format is precisely defined and it is known to both manager and agent.

A. Simple Network Management Protocol

SNMP (Simple Network Management Protocol) is de facto standard in network management domain. It allows very simple set of network management operations [4]. First version, SNMPv1, was developed in 1988th by IETF (Internet Engineering Task Force). Next version, SNMPv2, is improved, but with a security issue unsolved completely. Finally, third version, SNMPv3, coped with that security issue.

Every node within MIB structure has its own number; specific node’s position can be unique defined as a “list” of all node’s numbers leading from the root to the specific node. Numbers within list are separated by sign “.”. That list of node numbers separated by full stop sign is called OID (Object Identifier). One example is: 1.3.6.1.4.1.14103.2.4.3.

Every company or organization is able to “reserve” its own branch within MIB root. Within own branch organization has full autonomy regarding sub-branches creation, deletion, naming and organization. MIB branch assignment is managed by international organization IANA (Internet Assigned Numbers Authority). Centralization of MIB branch assignment ensures uniformity of MIB branches on world level.

Message sequence in SNMP protocol is very simple and intuitive. SNMP manager sends management commands to SNMP agent (SET-REQUEST) or retrieve some management information from SNMP agent (GET-REQUEST). Those requests are followed by RESPONSE message from SNMP agent. On the other hand, when SNMP agent wants to send unsolicited message, it uses SNMP TRAP message to do it.

II. SNMP AND FAULT MANAGEMENT

A. Fault management

“Fault management primarily covers the detection, isolation and correction of unusual operational behaviors of telecommunication network and its environment” [7]. On network problem’s appearance, network generates large number of unsolicited notifications carrying information about malfunction; these notifications are also called events; in the fault management functional area these notifications are called alarms. For instance, in the case of transmission link failure, nodes from both sides of
transmission link will generate alarm (e.g. “Loss of signal”) [8]. All notifications are potential entries in a network management system.

B. Fault management notifications

ITU-T recommendation X.733 [9] provide the detail for the general parameters of the event reporting service, which is used to report events (“alarms” actually). The most important parameters are:

- event type;
- event information;

Event type categories the alarm. Five basic categories of alarm are specified. These are: communications alarm, quality of service alarm, processing error alarm, equipment alarm, and environmental alarm.

Event information carry notification specific information, processed later by network management system. The most important are:

- Probable cause
- Specific problems
- Perceived severity
- Additional text/information
- Notification identifier

Event type and event information, in addition to general event reporting parameters, such as managed object class, managed object instance and event time, are used to notify network management system about network alarm.

Consider the generic content of alarm message mentioned above, it is reasonable to expect that management information structure on different network element types may be the same. Implementation of any specific management agent may vary, but general alarm information structure is common.

C. Related work

There are number of papers that are focused on integrated fault management [1], [3], [8]. However, main idea in integrated management is to ensure appropriate “proxy” modules that will handle with different management information formats performing mediation function. Further, in [3] integrated management is considered as hierarchical system where system intelligence is spread among different management planes. However, we have not found relevant work handling with different MIB type comparison.

Hence, we’ve decided to convey small survey on different SNMP Management Information Base, for different network element types, and to compare it.

III. MIB COMPARISON

A. INC-MIB-AL

INC-MIB-AL is implemented on Nokia Siemens Network @vantage Commander v11.0 [10], which is part of core network. System alarms are forwarded in form of trap messages, while alarms are stored in alarm table. Alarm table entry has following format:

```
AlarmTableEntry ::= SEQUENCE {
    tiAlarmDateTime DISPLAY STRING,
    tiAlarmReportingObject OBJECT IDENTIFIER,
    tiAlarmFaultyObject OBJECT IDENTIFIER,
    tiAlarmEventTypeId INTEGER,
    tiAlarmSeverity INTEGER,
    tiAlarmErrorID INTEGER,
    tiAlarmEndKey INTEGER,
    tiAlarmDescription OCTET STRING,
    tiAlarmSequenceNumber INTEGER,
    tiAlarmSourceName DISPLAY STRING,
    tiAlarmSymbNEname DISPLAY STRING,
    tiAlarmNEtype DISPLAY STRING,
    tiAlarmNotificationID INTEGER,
    tiAlarmTransferID INTEGER,
    tiAlarmRepairText OCTET STRING,
    tiAlarmLongText OCTET STRING
}
```

Current alarm resynchronization on SNMP manager startup or reconnection is implemented. In that case, retransmission of the active alarms should be requested from SNMP agent (using SNMP SET-REQUEST).

B. X733GROUP-MIB

Siemens fixed telephony exchange EWSD is managed by Net Manager system [11]. SNMP agent implements X733GROUP-MIB [12]. As for @vantage commander, system alarms are forwarded in form of trap messages, while alarms are stored in alarm table. Alarm table entry has following format:

```
snmpAlarm NOTIFICATION-TYPE OBJECTS {
    neName,
    notificationId,
    severity,
    eventType,
    eventTime,
    probableCause,
    specificProblems,
    managedObjectClass,
    managedObjectInstance,
    ipAddress,
    trapName,
    originalAlarm
}
```

Current alarm resynchronization on SNMP manager startup or reconnection is implemented. In that case, retransmission of the active alarms should be requested from SNMP agent (using SNMP SET-REQUEST).
Further, it is allowed to request alarm with specific notification Id. It ensures unbroken alarm sequence on SNMP manager side. Finally, this SNMP agent sends alarm summary periodically to SNMP manager, or upon specific request.

C. OPENMIND-MOS-MIB

This MIB is implemented at SNMP agent on one implementation of SMS center module.

There is no active alarm table [13]. Hence, alarm resynchronization on SNMP manager startup or reconnection is not implemented. In the case of trap loss, there is no mechanism to recover missing alarm information.

System alarms are forwarded in form of trap messages. There is no unique format of alarm; every specific alarm type has its own parameters encapsulated within SNMP trap message.

D. TNMS-MIB

TNMS-MIB is used on Telecommunication Network Management System (TNMS), product by Siemens covering, among other, management of SDH multiplexers in transmission network.

System alarms are forwarded in form of trap messages, while alarms are stored in alarm table. Alarm table entry has following format (specific variable types are described in MIB document [14]):

```plaintext
EnmsAlarmEntry ::= SEQUENCE{
  enmsAlAlarmNumber Integer32,
  enmsAlSeverity PerceivedSeverity,
  enmsAlProbableCause ProbableCause,
  enmsAlClass AlarmClass,
  enmsAlServiceAffect Boolean,
  enmsAlState AlarmState,
  enmsAlTimeStampFromNE Boolean,
  enmsAlTimeamp EnmsTimeStamp,
  enmsAlEntityString DisplayString,
  enmsAlEntityType EntityType,
  enmsAlNEId NEId,
  enmsAlPortId PortId,
  enmsAlTPIdH TPId,
  enmsAlTPIdL TPId,
  enmsAlTPName DisplayString,
  enmsAlModuleId ModuleId,
  enmsAlProbableCauseString DisplayString,
  enmsAlNELocation DisplayString
}
```

Current alarm resynchronization on SNMP manager startup or reconnection is implemented. In that case, SNMP manager should make "walk" through MIB alarm table using SNMP-GET-NEXT command.

E. MIB comparison

Every of these four MIBs follows general alarm message structure, as described in section “Fault management notifications”: All alarms described above contain probable cause, perceived severity, affected managed object info, event time, additional information about alarm etc.

However, agents that implement management function are different applications, developed by different vendors. In parallel with SNMP agent development, MIB structure is defined also. Hence, for different network element types, there are four different MIB structures, regardless of fact that information content is almost the same.

Some SNMP agents ensure reliable message transmission, with resynchronization function implemented, some of they don’t. Short summary is shown in table 1:

<table>

IV. PROBLEM SOLUTION PROPOSAL

SNMP agents are pieces of software handling several functions. We will try to detect these functions in domain of fault management. First, it is necessary to handle all information from network element’s hardware and software. For instance, SNMP agent should recognize high CPU temperature, link synchronization problem or crash of software component. It must communicate with hardware. Further, based on information from network element, any unusual operational behavior should be recognized. SNMP agent should know when to trigger network element alarm and when to cancel alarming condition. Third, alarms should be stored in alarm database. It can be implemented as relational database (e.g. SQLite), or simple as a file. Finally, communication between SNMP manager and SNMP agent in both directions must be supported. SNMP manager request
management information from SNMP agent (SNMP-GET, SNMP-GET-NEXT), sets some management information (SNMP-SET) or receives unsolicited messages from SNMP agent (SNMP-TRAP).

Our proposal is to implement API (Application Programming Interface) that will be able to cope with SNMP support and alarm handling functions (figure 4). API will take care of alarm forwarding to SNMP manager, alarm database handling and processing of SNMP sets and requests from SNMP manager. For fault management function, API will use predefined and unique MIB. However, if SNMP agent handles any other data such as configuration, all of these data can remain in additional, specific MIB.

API should be integrated into existing SNMP agent software. All SNMP agent’s parts that are specific for monitored network element (e.g. communication with hardware and software as well as alarm condition detection) can remain unchanged (interrupted line on figure 4). However, after alarm start or end is recognized, appropriate API functions are called (programming interface I1 on figure 4).

Central part of API should be unified alarm structure. For instance, it can be realized as C++ class or data structure containing all alarm information. These information are mostly common for all MIBs analyzed in this paper, as we mentioned.

Since all SNMP agent’s parts that are specific for agent implementation may remain the same, minimum of changes in any SNMP agent software is needed to use proposed API structure. It means that cost of API implementation within existing agents is minimal.

V. CONCLUSION

In this paper we have made comparison between four different SNMP MIBs as well as SNMP agent functionalities implementation. Although all SNMP agents handle almost the same alarm information structure, all of MIBs analyzed have different format.

It requires different SNMP manager application for every single network element type. Consequence is increased delivery time for network management systems. It has influence on service delivery time plan which is related to telecom operator business results.

As recommendation for network elements’ and SNMP agents’ vendors, conclusion of this paper can be that unique Management Information Base could and should be used for fault management functional area. Thinking in that way, we have proposed API structure that can ensure unique SNMP support as well as management information format in fault management functional area, with minimum implementation cost.

Further work should be focused on API component development in order to prove that concept.

Distributed threat removal in software-defined networks

D. Samociuk*, A. Chydzinski *

* Institute of Informatics, Silesian University of Technology, Gliwice, Poland
e-mail address: {dominik.samociuk, andrzej.chydzinski}@polsl.pl

Abstract - We propose an architecture for distributed threat removal in software-defined networks. This is a novel design of a large network, in which security analysis must be performed. In the classic paradigm, the security analyzer is an entry device, connected serially with the rest of the topology. Obviously, this device may suffer from a high processing load. Therefore, it may create a bottleneck, when the arriving traffic is waiting for the security verification, before being forwarded to next devices in the network. In the proposed architecture, traffic is immediately forwarded towards all destinations, while the security analysis is carried out in parallel, resulting in offloading the entry security device. We show that the proposed solution reduces the bottleneck in the topology and increases the rate of the carried traffic, while ensuring the same, as in the classic approach, security level.

I. INTRODUCTION

Modern computer networks require several security solutions. Analyzers, qualifiers, classic firewalls and web-application firewalls, intrusion prevention systems and others, are used to ensure high level of security. They must be located on the route of the traffic (in-line deployment), what introduces delays in the delivery of packets, if they need to be in-depth analyzed for security purposes.

In general, the security of end users can be achieved using various mechanisms. For instance, the monitoring tools can be used to detect events before they cause safety hazards, the control mechanisms can help to delete hazardous components before they reach their destinations, the limiting mechanisms can facilitate cleaning up the topology and locating the threat. Companies must decide, which of the above mechanisms should be implemented in order to achieve the needed level of security.

At the same time, safety has to be carefully balanced in the network core. In particular, the impact of security mechanisms implemented in the network devices on the network performance has to be taken into account. As it was shown in [1], these mechanisms may induce non-negligible delays in data transmissions, mainly due to their serial location in relation to transfer path.

In [2], the dogma of the firewall was challenged, especially as a security mechanism for corporations. Obviously, the complete withdrawal of firewalls was not recommended, but some dubious situations were pointed, in which the safety mechanism create a bottleneck, or worse, a single point of failure of the entire network.

Web services, exposed to the outside of our network, are most vulnerable to security attacks (e.g., the denial of service). At the same time, these applications have a unique requirement for access to anyone, even unauthorized users. When the network service does not have the access control, it raises the question of how to implement the firewall. The firewall has not ceased to fulfill its role in the network architecture, but has become a heavy burden on the infrastructure performance. In modern networks, it is important to ensure security while preserving the performance and avoiding drastic delays.

Yet another issue is the fact, that modern networks are constantly moving the boundaries of their capabilities. It has not been that long since 1Gbps Ethernet was introduced. In the recent years however, technologies such as SaaS, IaaS, and PaaS have become popular, causing the extension of Gigabit Ethernet to the speed of 10Gigabit and 100Gigabit per second. There are also many factors driving the spike in performance requirements of network devices - from the Internet of Things, to the increasing demands for services of the *aaS type. However, as it turns out quite often, organizations undertake the infrastructure improvements and increase the throughput of the intermediate devices, only to find out that their security systems are not able to maintain transmission of data with the required speed.

We address this problem, by presenting a novel, parallel solution, in which the traffic is simultaneously being forwarded towards destinations, while the security analysis of packets is being carried out. Such parallel forwarding and analyzing of the data results in offloading the single device at the entry point, while ensuring the same, as in the classic approach, security. In our solution the entry device, instead of waiting for analysis to be finished, performs the forwarding immediately. If the threat is malicious, it will be dropped before the final delivery in one of the intermediate or edge switches, after they have received the appropriate control data with analysis results.

The paper is organized as follows. In Section 2, we discuss the related work. In Section 3, the novel architecture is presented and compared with traditional architectures. In Section 4, an OMNeT++ based simulator of the proposed threat removal mechanism is described in detail and the motivation behind the topology used in the tests is presented. In Section 5, we present and discuss the simulation results. Finally, Section 6 concludes the paper.
and presents our plans of future work related to the subject.

II. RELATED WORK

The combined topics of security and software-defined networking aspects have been studied in the following papers.

In [3,4], possible solutions to the problem of the lack of authentication, access control and creation of secure channel network architecture in programmable networks, were discussed. Namely, the applicability of three different protocols: Transport Layer Security, Secure Shell Tunnel and Host-to-Host IPSec, as the secure channel medium in software-defined networks with the OpenFlow protocol, was studied. The articles show that the implementation of one of the proposed solution would increase safety and reduce risks of attacks on an SDN topology. This is especially important when using the software-define network paradigm in wide-area networks.

Safe architectures of programmable network topologies, based on the OpenFlow protocol, were studied in [5,6].

FlowVisor [5] works as a transparent proxy between controllers and switches, in order to limit the rules created by the applications running on the controllers. The FlowVisor mechanism creates virtual topology divisions (slices), as combinations of switch ports, MAC addresses, IP addresses, Layer 4 ports or message types (ICMP), and then delegates control of these fragments to the various controllers. The role of FlowVisor in SDN topology is insulation the impact sent rules to specific part of the network. This means, that a rule created for one part cannot affect the traffic in the next division.

A similar concept is FortNOX [6]. This is a software extension, developed on the NOX controller, for checking (in real time) the flow of contradictory rules. It uses authentication, based on the roles of applications, using the OpenFlow protocol. (It concerns applications that want to modify the traffic in the network using the OpenFlow protocol, e.g. firewalls, intrusion prevention systems, etc.).

The difference between FortNOX and FlowVisor is that FortNOX is a single application controller, which operates in parallel, while FlowVisor operates independently of the controller (usually as a separate device in the network). Both of these solutions limit the possibility of introducing a security risk by untrusted controllers and applications. However, they are both based on the usage of the OpenFlow protocol and the assumption, that its communication channels are secure, which is not provided by default. This could be accomplished, however, by implementing the solutions proposed in [3,4].

The subject how to ensure the security of networks using the methodology of software-defined networks and the OpenFlow protocol was researched in [7,8].

NICE [7] is a system of protection against distributed attacks on the limitation of service. The tool for the detection of attacks is based on the graphic analytical models, capable of reconfiguring topologies in an emergency situation.

Moving Target Defense [8] is based on the fact that in the OpenFlow environment we can change frequently IP addresses of the internal devices, to prevent attacks and to reduce the reconnaissance carried out from external networks.

It must be stressed that to the best of the authors’ knowledge, there are no published results on analyzers in software-defined networks. Especially, we are not aware of works on the utilization of the SDN paradigm for enhancing the performance and functionality of classic analyzers and on the reduction of the bottleneck effects they generate now.

Moreover, there are no articles on the security-related behavior of software-defined networks in the wide area.

Figure 1. Classic network architecture and data flow through security device.
III. ARCHITECTURE

Traditional network architectures are not very well suited to meet the requirements of modern corporations, service providers and end users.

The classic data flow (Fig. 1) is as follows. The traffic entering the network (from the right) goes to the first switch and then to the analyzer, in which the first packet from every flow is analyzed (security check), while the rest of the flow is waiting in a queue. If the positive decision is made, the whole flow is forwarded and delivered to the destination. Otherwise, the whole flow is dropped.

In the proposed architecture (Fig. 2), we use the SDN paradigm, that decouples the network control and forwarding functions. Namely, the traffic entering the network (on the right) passes through the first switch, but a copy of the first packet from every new flow is forwarded to the analyzer. While the analysis is being performed, the whole flow is being forwarded towards the destination, without waiting for the analyzer’s decision. As soon as the analyzer reaches the decision about the new flow (drop or deliver), this decision is spread over the control plane, to all the programmable switches in the network. Therefore, a malicious flow can be dropped in every intermediate switch in the network. In the worst case, it is dropped in the last switch, before delivery to the end user - it is not allowed to deliver a flow to the end user without analyzer’s decision.

In this way, different flows may be queued in several different locations in the network, instead of one (entry point), while waiting for the analyzer decisions. These decisions are forwarded in control packets, carrying information whether a flow can be delivered, or must be dropped.

Comparing the new solution with the classic architecture, we may observe a few important differences, which are:

- volume of data that passes through the analyzer (only a copy of the first packet of a flow goes to the analyzer, instead of all data);
- type of packets forwarded (data + control data with the security decision sent once per flow, instead of pure data in the classic approach);
- physical connections (additional link between the first network switch and the rest of the network in the proposed solution, as presented in Fig. 2);
- queueing behavior of switches (every queue has three possible actions for each data flow: “deliver”, “drop” and “block”). The default action for a new flow is “forward” in all intermediate switches and “block” in the last-before-destination switches. After the analysis of the new flow is finished, every switch receives the control packet with the final decision on the flow, which is “deliver” or “drop”;
- switches, where the packets are queued waiting for the analyzer decision (multiple network switches instead of a single, entry device).

The main advantage of the proposed architecture is that the network is not idle (it is forwarding data) while waiting for the analyzer to finish its work. This reduces significantly the possibility of the bottleneck in the network entry point.

The cost we have to pay for this is the need for the programmable switches and the SDN controller.

IV. SIMULATION DESIGN

To simulate the proposed solution, the OMNeT ++ discrete event simulation framework was used (see https://omnetpp.org).

In fact, two separate simulators were implemented – one for the classic solution (Fig. 3) and one for the SDN-based solution (Fig. 4). For fair comparison, both simulators have common topology and network parameters (propagation times, link throughputs, buffer sizes etc.).

The topology used in the simulators was created to mimic the new laboratory of wide area network, named...
PL-LAB2020 [9-11]. PL-LAB2020 is an experimental network connecting six geographically dispersed, Polish research centers, namely:

- National Institute of Telecommunication;
- Warsaw University of Technology;
- Poznan Supercomputing and Networking Center;
- Silesian University of Technology;
- Gdansk University of Technology;
- Wroclaw University of Technology.

In the simulators, these research centers are denoted using their Polish acronyms, namely il, pw, pcss, psl, pg and pwr, respectively (see Figs. 3 and 4).

The network core consists of six Juniper ACX switches (acx_il, acx_pw, acx_pcss, acx_psl, acx_pg and acx_pwr in Figs. 3 and 4). These switches are connected via dedicated 10Gbit/s links, according to the schemes in Figs. 3 and 4. All the remaining, local links (e.g. acx_pw-sdn_pw) are of 1Gb/s throughput.

To simulate the geographical distribution of the PL-LAB2020 centers, the following core link propagation times were assumed: psl-pw: 25ms, pw-il: 19ms, pw-pcss: 21ms, il-pg: 29ms, pg-pcss: 29ms, pcss-pwr: 24ms, pwr-psl: 25ms. All the local links (e.g. acx_pw-sdn_pw) were assumed to have zero propagation time.

The entry point, as well as the analyzer and the SDN controller, are located in psl location, while four other locations are used as flow destinations: il, pw, pcss, and pwr.

In every destination, there is a programmable switch (in the classic architecture, it can be a standard switch) and a sink, for simulating an end user. The pg node is used only for forwarding the traffic.

Therefore, the final simulators, as shown in Figs. 3 and 4, consist of the following elements:

- **generator**, which generates multiple flows of packets, with predefined packet interarrival time distribution, flow size distribution, packet sizes and percentage of malicious flows;
- **sdn2_* devices** – programmable network switches, needed in the new architecture, with modified queuing capabilities and predefined buffer sizes;
- **sdn1_* devices, acx_*– standard network switches with predefined buffer sizes**;
- **analyzer**, which performs the security verification of packets. Namely, the first packet in every new flow is analyzed. When the decision based on the first packet is made, the whole flow is forwarded or dropped. In the proposed architecture, only a copy of the first packet of each flow is transmitted to the analyzer, while the original, complete flow is forwarded immediately. When the decision is made, the control packet is created and sent to all the switches, changing the default action for this flow to either “deliver” or “drop”;
- **sink_* - simulates an end user**.

Before the simulation results are presented, it is worth mentioning that we have considered also evaluating the performance of the proposed architecture using analytical methods. In particular, the potential method, [13-16], for finding characteristics of queues of packets in the system, was considered. Unfortunately, due to multiple queueing and control mechanisms involved, the mathematical analysis of the system is extremely hard – it seems to be beyond the current capabilities of the queueing theory. Therefore, we performed the analysis of the performance of the system using the simulations only.

In the future however, we are planning to implement and test the proposed solution in the PL-LAB2020 laboratory.

Figure 3. Classic architecture simulated in OMNeT ++.
V. SIMULATION RESULTS

The main purpose of all simulations was to find the maximum rate (in Mb/s) of the traffic arriving to the network, that does not cause losses of safe packets, due to buffer overflows. Naturally, both the classic and the new architecture were tested.

It is quite obvious, that the maximum allowed arrival rate depends strongly on the average time of analysis. Moreover, it depends on the average length of the flow, as only the first packet in each flow is analyzed. Therefore, three values of the average flow length were used (100, 200 and 1000), and two different average analysis times (0.003 and 0.0001s).

On the other hand, the maximum allowed arrival rate depends very little on the percentage of malicious flows. This is due to the fact, that the analysis time statistically does not depend on whether the packet is safe, or not.

In detail, the following parameters were used in simulations:

- packet interarrival time distribution: exponential;
- total arrival rate: varied from 0 to 1Gb/s;
- flow size distribution: exponential;
- average flow length (pkts): 100, 200 or 1000;
- packet size (bytes): 1500 or 9000 (Jumbo);
- control packet size (bytes): 64;
- buffer size at every switch (pkts): 10000;
- distribution of the security analysis time: exponential;
- average analysis time (s): 0.003 or 0.0001;

As the typical average value of the analysis time 0.003s was used. This value was chosen according to the speed of security devices common in contemporary enterprise networks.

The buffer size of 10000 packets was chosen following the bandwidth-delay product rule, which is well-known in buffer sizing. Assuming the packet size of 1500 bytes and a 10Gb/s link, this size allows for 120 ms of traffic buffering.

The total arrival intensity was manipulated by changing the average interarrival time between consecutive packets. The destinations of the arriving flows were assigned randomly, with equal probabilities for all available destinations.

Table I shows the maximum possible rate, for which we do not lose safe packets, in the case of 1500-bytes-long packets, the average analysis time of 0.003 second and three average flow lengths: 100, 200 and 1000 packets.

<table>
<thead>
<tr>
<th>mean flow size</th>
<th>classic solution</th>
<th>proposed solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>100 packets</td>
<td>282 Mb/s</td>
<td>359 Mb/s</td>
</tr>
<tr>
<td>200 packets</td>
<td>440 Mb/s</td>
<td>664 Mb/s</td>
</tr>
<tr>
<td>1000 packets</td>
<td>793 Mb/s</td>
<td>Line speed</td>
</tr>
</tbody>
</table>

The table demonstrates clearly, that the proposed solution provides significantly higher maximum rate for both short and long flows, assuming typical packet sizes and typical analysis times. Moreover, as can be can be noticed, where the classic architecture meets its limits for long flows (1000 packets), the proposed solution can still run with full line speed.

Having checked the typical case, we tested also the architectures in the case of very large packets.

Table II presents the maximum possible arrival rate, for which we do not lose safe packets, in the case of large frames, the average analysis time of 0.003 second and three average flow lengths: 100, 200 and 1000 packets.

<table>
<thead>
<tr>
<th>mean flow size</th>
<th>classic solution</th>
<th>proposed solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>100 packets</td>
<td>707 Mb/s</td>
<td>Line speed</td>
</tr>
<tr>
<td>200 packets</td>
<td>806 Mb/s</td>
<td>Line speed</td>
</tr>
<tr>
<td>1000 packets</td>
<td>953 Mb/s</td>
<td>Line speed</td>
</tr>
</tbody>
</table>
As we can see, the new solution outperforms the classic one in this case as well.

We also conducted some tests to find out, if our solution can be useful in use-cases other than security, e.g. in situations, where the average time of the analysis is very short. As a real-life example, the classification and/or marking of flows may serve - such operation can take about 0,0001s on average. Results of comparison of the maximum rate in such case are presented in Table III.

### TABLE III. Comparison of the maximum generator rate between the classic and the proposed solution for fast operations. Packet size 1500bytes, analysis/operation time 0,0001s.

<table>
<thead>
<tr>
<th>mean flow size</th>
<th>classic solution</th>
<th>proposed solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>100 packets</td>
<td>927 Mb/s</td>
<td>Line speed</td>
</tr>
<tr>
<td>200 packets</td>
<td>958 Mb/s</td>
<td>Line speed</td>
</tr>
<tr>
<td>1000 packets</td>
<td>990 Mb/s</td>
<td>Line speed</td>
</tr>
</tbody>
</table>

Similarly, the new architecture outperforms the classic architecture, though not that much as in the previous setups.

VI. CONCLUSIONS

Nowadays, network security mechanisms are becoming more important than ever. Moreover, the security devices must meet the rapidly increasing demands for serving large volumes of traffic. Inappropriate design of security mechanisms, devices or architecture may cause a huge decline in overall network performance, no matter how fast the network switching and transmitting mechanisms are.

We presented a possible solution for the bottleneck problem occurring in classic network topologies, caused by the security device.

Simulations proved that in distributed, SDN-based topologies, the proposed solution performs better than the classic solution. In all the tests, the level of security was the same in the classic and proposed architecture, but the maximum carried traffic was higher in the new design.

The benefit depends on the flow size distribution – the shorter the flows are, the more we gain. It also depends on the packet sizes in the same manner. Finally, it can be deduced that the benefit varies also with the number of destinations. Generally, the higher number of destinations is, the bigger the difference between the classic network and our solution is, in favor of the SDN.

As for the future work, the authors are planning to implement and test the proposed solution in a wide area networking laboratory.

ACKNOWLEDGEMENT: The infrastructure was supported by “PL-LAB2020” project, contract POIG.02.03.01-00-104/13-00. The work was carried out within the statutory research project of the Institute of Informatics (RAU2).

Abstract - Virtual Private Networks (VPN) are an established technology that provides users a way to achieve secure communication over an insecure communication channel, such as the public Internet. It has been widely accepted due to its flexibility and availability on many platforms. It is often used as an alternative to expensive leased lines. In traditional setups, VPN endpoints are set up in hardware appliances, such as firewalls or routers. In modern networks, which utilize Network Functions Virtualization (NFV), VPN endpoints can be virtualized on common servers. Because data encryption and decryption are CPU intensive operations, it is important to investigate limits of such setups so that feasibility of endpoint virtualization can be evaluated. In this paper, we analyze performance of two industry standard VPN implementations - IPSec and OpenVPN. We examine TCP throughput in relation to encryption algorithm used and packet size. Our experiments suggest that moving VPN endpoints from a specialized hardware appliance to a virtualized environment can be a viable and simple solution if traffic throughput requirements are not too demanding. However, it is still difficult to replace high-end appliances with large throughput capabilities.

I. INTRODUCTION

VPN has been an important technology since its creation in the mid-1990s. Point-to-Point Tunneling Protocol (PPTP) marked a starting point in the ability to connect remote computers to a common network. Since then, there have been many breakthroughs and innovations in the field, which resulted in competing technologies. As the technologies mature, it is important to focus on their comparison and evaluation of their viabilities in new networking use cases and paradigms. One such paradigm is Network Functions Virtualization (NFV) [1]. The NFV assumes moving network functions, such as a firewall, VPN endpoint, load balancer, etc. from specialized appliances to commercial off-the-shelf (COTS) servers. Often times the raw processing capabilities present a barrier to successful network function virtualization [2], [3].

Currently, there are two prevailing technologies used in the enterprise environments: IPSec and SSL/TLS based OpenVPN. Although IPSec is a de facto standard in VPN access, OpenVPN has been steadily gaining traction and is the only mature and widely used alternative to IPSec. The web proxy SSL/TLS based VPN access is not a network layer VPN tunnel and will not be discussed here.

Both, OpenVPN and especially IPSec, have been researched extensively, however, not much work has been done in comparing performance of the two in virtualized environments and on multi-core processors. For instance, Jaha and Libya in [4] evaluated relative performance of several VPN protocols on two operating systems, over wireless networks. Along with raw performance, they also investigated some QoS metrics. The authors findings were inconclusive as the results varied widely. Depending on the operating system in use, IPSec was from 8% slower than OpenVPN to up to 25% faster. This could suggest problems in their testbed or software and operating system implementation or configuration. Kotuliak et al. in [5] investigated differences between IPSec and OpenVPN, for different encryption algorithms. They showed that when using the 3DES encryption, IPSec was approximately 25% slower than OpenVPN. In case of Blowfish encryption, they were basically on par, but in case of AES, IPSec was 45% faster. The 45% difference is of greatest significance since AES is the new encryption standard and is replacing the aging 3DES and Blowfish. Instead of measuring raw network throughput, Voznak in [6] compared difference in bandwidth requirements for voice calls over OpenVPN and IPSec tunnels using AES encryption. He showed that packet payload size greatly influenced tunnel efficiency. Depending on voice codec used, payload size varied significantly and for very small payloads, IPSec required considerably less bandwidth than OpenVPN. In [7], Raumer et al. researched similar topics as this paper, but they limited their experiments to IPSec. They showed that, expectedly, network throughput is heavily dependent on packet size and that Intel’s AES-NI instruction set [8] brings huge throughput gains – in case of maximum size Ethernet frames, almost threefold.

In this paper, we will analyze and compare raw network throughput of IPSec and OpenVPN on COTS hardware to assess the viability of VPN endpoint virtualization. We will study several encryption algorithms and analyze the influence of packet size and hardware acceleration on the throughput.

This work has been supported in part by the University of Rijeka under the project number 16.09.2.2.05.
II. TECHNOLOGY OVERVIEW

There are two types of network layer VPN connections: remote access and site-to-site. Remote access VPNs are generally used to connect teleworkers or set up temporary tunnels, while site-to-site VPNs are used to set up permanent secure network layer tunnels between distant networks. A special case of VPN access are web based SSL/TLS VPNs [9]. They are based on establishing a secure SSL/TLS session between any web browser a user might have and a VPN gateway. Upon session establishment, the gateway offers client a list of available web applications from internal network for which a user has access privileges. The gateway establishes session to the selected web application and relays traffic between application server and the client. Although widely used and useful, the approach does not set up a secure network layer tunnel between two networks and is therefore not examined further. Instead, two most commonly used approaches are discussed and compared, namely, IPSec and OpenVPN.

A. IPSec

Internet Protocol Security (IPSec) is a collection of security protocols [10] designed by the Internet Engineering Task Force (IETF), with the aim of providing secure communication channels that spans, possibly, public or otherwise insecure Internet Protocol (IP) based networks. IPSec works by authenticating and encrypting each IP packet of a session. It provides data integrity and basic authentication and encryption services, which protect data from modification or unauthorized viewing. It operates on layer three (network layer) of the Open Systems Interconnection model (OSI) model and uses TCP protocol on the transport layer.

IPSec has become a de facto standard for setting up VPNs. Vendor acceptance has been wide and fast and it is currently available on mostly all hardware appliances with VPN capabilities. It offers high performance and its modular architecture allows for seamless integration of new algorithms. Since it is an open standard there are no vendor lock-in problems.

There are three primary components of IPSec:
- **Authentication Header (AH)**
- **Encapsulating Security Payload (ESP)**
- **Internet Key Exchange (IKE)**

AH is responsible for authentication and data integrity check, while ESP provides data confidentiality and encryption services. IKE serves as a protocol for negotiating algorithms, keys, and protocols and establishing security associations. Selection of algorithms for each of the components is up to a user to configure (Fig. 1).

Over the years, there were many software implementations of IPSec, most notable of which are FreeS/WAN and its forks Openswan and strongSwan, as well as Libreswan which is a fork of Openswan. In this paper, we will use strongSwan [11] as it is currently the most mature and actively developed IPSec implementation. It is an open source software, originally designed for Linux operating system, but also ported to Windows, Android, Mac OS X and other platforms. StrongSwan has full support for both IKEv1 and IKEv2 protocols.

B. OpenVPN

OpenVPN [12], [13] is an open source implementation of VPNs, which is, like IPSec, capable of setting up network layer tunnels in both site-to-site and remote access configurations. It appeared later than IPSec and, without the backing of large vendors, its development and acceptance has been slow, but in time it evolved and matured. Lack of support on network appliances has for long been a large disadvantage and limited its acceptance, nevertheless, it has still been steadily gaining traction. In light of the NFV paradigm, hardware support becomes less relevant and OpenVPN can now more easily compete with IPSec.

Unlike IPSec, OpenVPN can setup tunnels using both UDP and TCP protocols. This is an important consideration, as sending traffic over UDP tunnel can result in better latency when compared to a TCP tunnel [14]. Using UDP tunnels can also alleviate problems induced by IPSec on high delay and error prone links, such as satellite links [15]. Another advantage of OpenVPN is the ease of setup. Where IPSec is known for its complexity and steep learning curve, OpenVPN can be setup very quickly. It is easier to handle dynamic addresses and traverse firewalls and network address translation (NAT). The use of common networking protocols (TCP and UDP) for traffic tunneling makes it a desirable alternative to IPSec in situations where an ISP might intentionally block IPSec protocol.

Another difference to IPSec is that OpenVPN SSL/TLS tunnels operate at the transport and session layers of the OSI model. OpenVPN uses a custom protocol based on SSL/TLS for key exchange. It delegates services of both encryption and authentication to the OpenSSL library. This allows OpenVPN to use all the ciphers available in the OpenSSL package.

OpenVPN supports any operating system with an OpenVPN compatible VPN client, which nowadays is almost every OS, including Android.

![FIGURE 1: IPSec Framework](image)
C. AES-NI

Encryption is generally computationally very demanding. Current preferred standard for symmetrical key encryption is the Advanced Encryption Standard (AES). Traditional high throughput network appliances use special processors to offload AES encryption. The same approach was needed in COTS hardware if high performance were to be reached. For that purpose, Intel introduced AES-NI instruction set. Using AES-NI instructions can result in multiple fold increase in encryption performance. The instruction set is supported on all AMD x86 and x64 architecture processors since AMD Bulldozer Family 15h, and many Intel x86 and x64 processors. The full list of supported Intel processors can be found in [16]. Since both strongSwan and OpenVPN utilize AES encryption, we will analyze performance benefits of AES-NI on both technologies.

III. TEST SETUP

Testing was conducted on two HP ProLiant servers. Network connection was established by back-to-back connection using 10Gbps ethernet network interface cards (NIC). One machine was configured as a VPN server, while the other was used as a VPN client. Hardware and software specifications of the machines are shown in Table 1, while Fig. 2 shows the test setup.

To test performances in a virtualized environment, virtual machines were created to host tunnel endpoints. Since both physical servers ran on Linux operating system, KVM/QEMU [17] has been chosen as a virtualization solution. It is a full virtualization solution for Linux on x86 hardware. For operation, it requires a virtualization solution. It is a full virtualization solution system, KVM/QEMU [17] has been chosen as a virtualization solution. For operation, it requires a virtualization solution. It is a full virtualization solution system, KVM/QEMU [17] has been chosen as a virtualization solution. For operation, it requires a virtualization solution. It is a full virtualization solution system, KVM/QEMU [17] has been chosen as a virtualization solution. For operation, it requires a virtualization solution. It is a full virtualization solution system, KVM/QEMU [17] has been chosen as a virtualization solution. For operation, it requires a virtualization solution. It is a full virtualization solution system, KVM/QEMU [17] has been chosen as a virtualization solution. For operation, it requires a virtualization solution.

Virtual machines (VM) hosting VPN endpoints were identical (Table 1). Virtual NICs were connected to a 10Gbps physical port using Linux bridge. Each VM has been allowed to use two CPU cores. One core was assigned to a traffic generator, while the other was assigned to a VPN tunnel. As a traffic generator, the iperf3 tool was used.

Testing was performed on commonly used ciphers: AES, Blowfish, Camellia, and 3-DES. All test ciphers were in Cypher Block Chaining mode of operation (CBC). Testing procedure consisted of establishing a VPN tunnel between the server and client virtual machines, starting iperf3 server on the VPN server machine and sending TCP traffic over the encrypted tunnel from the client machine. Traffic generation was set to last for 60 seconds. Network throughput was measured for packet sizes in the range of 100 to 1500 bytes (the largest frame that can be sent over ethernet channel without getting fragmented).

The first set of tests was performed with AES-NI hardware acceleration disabled. In order to evaluate performance benefits of AES-NI, another set of tests was performed, but with AES-NI enabled.

Lastly, we tested how well do IPSec and OpenVPN scale on multi-core processors. To eliminate any influence of virtualization on test results and evaluate scaling efficiency of the software, the tests were performed by establishing VPN tunnels between physical machines, instead of virtual machines.

In all the tests, throughputs have been low enough such that a network card virtualization did not affect performance. As memory usage for VPN tunnels is low, maximum throughput is mostly constrained by a virtual CPU performance.

IV. RESULTS AND DISCUSSION

A. IPSec with AES-NI disabled

Figure 3 shows results for IPSec with AES-NI disabled. Depending on packet size, best performing ciphers were AES and Blowfish. At packet size of 1500 bytes, AES 128, AES 192, AES 256 and Blowfish achieved 415 Mbps, 387 Mbps, 370 Mbps and 338 Mbps, respectively. Camellia 256 was slower, with 303 Mbps, while 3-DES could only manage 116 Mbps. In 3-DES, to achieve reasonable security, DES algorithm is applied three times for each packet (encrypt-decrypt-encrypt). This procedure introduces processing overhead that results in a significant drop of network throughput.

As in all later tests, it can be seen that network throughput for small packets is significantly smaller than for large packets. For such types of traffic patterns, much larger number of packets needs to be sent to achieve the...
same throughput and, consequently, processing overhead grows exponentially.

B. **OpenVPN with AES-NI disabled**

In Fig 4., network throughputs achieved by OpenVPN with AES-NI disabled are shown. Again, AES is the fastest, while 3-DES is the slowest cipher. AES 128 and AES 192 are similar in performance and peak at 266 Mbps, but AES 256 is about 5% to 10% slower, depending on packet size. Blowfish and Camellia ciphers performed similarly and at 186 Mbps are about 30% slower than AES ciphers, while 3-DES could only manage 85 Mbps. It can be seen that OpenVPN is about 30% to 50% slower than IPSec, depending on the cipher used.

C. **IPSec with AES-NI enabled**

IPSec throughput with AES-NI hardware acceleration enabled is shown in Figure 5. AES ciphers most benefited from the hardware acceleration. For packet size of 1500 bytes, AES 128, AES 192 and AES 256 ciphers achieved 607 Mbps, 605 Mbps and 600 Mbps, respectively. An increase of between 40% and 64% in performance. What is also important to see is that previously noticeable difference in performance between AES 128 and AES 256 is significantly reduced. Camelia improved by 24% to 376 Mbps, while Blowfish showed little improvement and 3-DES showed no improvement at all from AES-NI.

D. **OpenVPN with AES-NI enabled**

Test results for OpenVPN with AES-NI enabled are shown in Figure 6. Camellia, Blowfish and 3-DES did not improve as a result of AES-NI being enabled. Throughput with AES ciphers is improved but not as much as in the case of IPSec. Overall, there is little difference in performance for different key lengths. For small packets, the difference is up to 10%, between AES-128 and AES-256. For packet size of 1500 bytes, AES 128, AES 192 and AES 256 ciphers resulted in 303 Mbps, 308 Mbps and 309 Mbps, respectively. The improvements over test case with AES-NI disabled are about 16%. Such a small improvement suggests that in the case of OpenVPN encryption is not the most limiting factor and that the bottleneck is somewhere else in a data path. StrongSwan’s IPSec implementation achieved almost double the throughput of OpenVPN.

E. **Software Scaling**

To test how well strongSwan’s IPSec implementation and OpenVPN scale, we modified the test setup such that traffic generation was taken off the servers. **Iperf3** was run on separate machines, which were connected over 10 Gbps network switch. For strongSwan, three tests were run. In the first run, a single CPU core was made available to the VPN tunnel. In the second run, all 4 cores were made available to the tunnel, and only a single tunnel (a single client) was used for all traffic. In the last run, 4 IPSec clients connected to a single IPSec server, which had all 4 cores available. Figure 7 shows achieved network...
throughputs. It can be seen that there is little difference in performance if a single tunnel or multiple tunnels/clients are used. Scaling with multiple clients is easier to solve, as each client can get a separate thread, but the results show that the strongSwan software efficiently scales even in a more difficult case of a single tunnel communication. Although all 4 CPU cores get utilized equally, the throughput is not proportional to the number of cores used and peaks at 1.4Gbps.

OpenVPN is not as good at scaling. It uses a single process and a single thread for all VPN tunnels of the same OpenVPN server instance. It means that it can only utilize a single CPU core. Although discussed by both developers and community, no multithreaded implementation has yet been released. Scalability can only be achieved by setting up one OpenVPN server instance per each available CPU core. The setup introduces configuration complexity and also requires careful distribution of VPN clients to server instances, such that traffic load on the instances is well balanced, which often makes the solution impractical. If only a single high throughput VPN connection is necessary, OpenVPN is not a viable option. Figure 8 shows achieved throughput in case of 4 OpenVPN server instances to which 4 clients are connected. Maximum throughput is about 27% less than is the case for strongSwan IPSec.

![Figure 7: IPSec achieved network throughputs](image1)

**FIGURE 7: IPSec achieved network throughputs**

![Figure 8: OpenVPN achieved network throughputs](image2)

**FIGURE 8: OpenVPN achieved network throughputs**

F. Results Summary

The test results showed that, in terms of raw network throughput, strongSwan IPSec implementation is clearly more capable than OpenVPN. As summarily showed in Figure 9, in the analyzed case of virtual VPN endpoints, it achieved higher throughput for each tested cipher, both when AES-NI enabled and AES-NI disabled. Of the tested ciphers, AES yielded the best throughput in all test scenarios. We showed that using processors with AES-NI instruction set can improve network throughput by 62% in case of strongSwan’s IPSec implementation and 16% when using OpenVPN.

On multi-core systems, strongSwan scales much better than OpenVPN. It can utilize all available CPU cores, regardless if only a single tunnel is used or traffic load is distributed between separate VPN tunnels. However, network throughput is not proportional to the number of CPU cores available. OpenVPN is single threaded so it does not scale, however, if applicable, it is possible to set up independent OpenVPN server instances, which run in separate processes and can, therefore, execute on different CPU cores.

V. Conclusion and Future Work

VPN endpoints are traditionally deployed on specialized network appliances, such as routers or firewalls/security devices. In this paper, we explored the viability of the endpoints virtualization on COTS hardware, with benefits in line with the NFV paradigm.

We find that VPN functionality of entry level appliances (up to about 1Gbps) can be easily virtualized even on low end servers. In most cases, both IPSec and OpenVPN will suffice. Although IPSec generally provides better throughput, OpenVPN has an advantage of setting up tunnels over UDP, which can lower latency and in special cases, such as satellite links, improve overall throughput.

On mid-range appliances, we expect throughputs of up to about 25Gbps. OpenVPN does not scale on multi-core systems so it is not suitable for such high requirements. StrongSwan’s IPSec implementation does scale and it can be used in the lower range of throughput requirements. Depending on a specific use case, and with proper
configuration and optimization, it, possibly, might also be used in the upper range.

When it comes to high-end security appliances, we currently cannot see any benefits of virtualization of their functionality on COTS hardware and we find it not to be a viable option.

In a future work, this study should be expanded to cover jitter and latency tests, as well as investigate network throughputs when UDP traffic is tunneled.

A Big Data Solution for Troubleshooting Mobile Network Performance Problems

K. Skračić, I. Bodrušić
Ericsson Nikola Tesla, Zagreb, Croatia
E-mail: kristian.skracic@ericsson.com

Abstract – Big Data has become a major competitive advantage for many organizations. The analytical capabilities made possible by Big Data analytics platforms are a key stepping stone for advancing the business of every organization. This paper illustrates the development of a big data analytics system for mobile telecommunication systems. The authors developed a solution for analyzing data produced by mobile network nodes which contain data relevant for predictive maintenance and troubleshooting purposes. The solution is built around the problem of working with small files in the Hadoop environment. The logs collected from mobile network nodes are small binary files between 5 and 15 MB in size. These binary log files need to be decoded to a readable format, and then analyzed to extract useful information. In this paper, the authors provide a benchmark of various scenarios for collecting and decoding the binary log files in a Hadoop cluster. As a result, the scenario with the highest performance has been used in the implementation of our solution. The developed solution has been built and tested on a live Hadoop cluster using real-world data obtained from several telecom operators around the world.

I. INTRODUCTION

The telecommunications industry is one of the largest and fastest growing industries in the world. Over the past few decades we have witnessed the change from 2G, 3G, 4G and now 5G in the near future [1]. With the rising demand for constant connectivity, the availability of telecommunication systems and their various components has never been more important. This trend is particularly apparent in the case of mobile networks. As shown in [2], during 2016 there were 7.5 billion mobile subscriptions in the world. The report in [2] estimates that in 2022 there will be 8.9 billion mobile subscriptions, 8 billion mobile broadband subscriptions and 6.1 billion unique mobile subscribers in the world. Mobile networks allow a subscriber to consume various telecommunication services via mobile phone from any place of coverage. Thus, they have become one of the most important resources today. This paper proposes a solution for analyzing data produced by mobile network nodes which contain information relevant for predictive maintenance and troubleshooting purposes.

As telecommunication systems are becoming larger and more advanced, it is necessary to constantly monitor and measure the performance of their various subsystems. However, larger networks and higher Internet access speeds carry with them the need to analyze larger amounts of data in a short period of time, in order to prevent network outages as soon as possible. Such requirements can be addressed by leveraging the analytical capabilities made possible by Big Data analytics platforms [3]. Apart from improved performance, Big Data can enable deeper analytics by providing access to historical data. For example, by storing network performance data it becomes possible to compare the current results with those obtained in past measurements. By storing the insight obtained through troubleshooting, it becomes possible to predict and prevent the same failures from happening again, or at least to shorten the response time when the same or similar failures present themselves again [4].

In this paper, the authors developed a Big Data solution for analyzing data produced by mobile network nodes, which contain important information used for troubleshooting purposes. The solution ingests large amounts of logs which contain network event information. The logs are gathered through an event-based monitoring (EBM) system, which is an embedded recording tool in the Ericsson EPG, SGSN and MME nodes [5].

This paper is organized as follows. Section II provides an overview of existing research on small files in the Hadoop environment, as well as the research on the applicability of Big Data solutions in the telecommunications industry. Section III shows the architecture of the developed solution and how the small files problem in Hadoop impacts it. Section IV shows the benchmark results for the scenarios laid out in Section III.

II. RELATED WORK

This section provides an overview of the results of existing research in the field of applying Big Data in the telecommunications industry, as well as previous work done on the analysis of small files in Hadoop.

A. Big Data Analytics Platforms in the Telecommunications Industry

Big Data solutions have become an important part of today’s industry for all types of businesses, such as finance [6], law enforcement [7], education [8] and others. To show the applicability of Big Data solutions in the telecommunications industry, we briefly summarized some existing use cases and their impact on the industry.

Telecom operators have access to large amounts of valuable data that can be used for various analytical use cases. The research in [9] shows a way to leverage Big
Data analytics for classifying subscribers based on their movement. Reusing existing data for new use cases such as this is the first step in data monetization, which is expected to become a major source of income for all types of businesses in the near future [10]. The work in [11] is able to predict customer churn for telecom operators, which has a direct impact on the operator’s profitability. Similarly, the work in [12] predicts customer experience when using over-the-top (OTT) applications such as WhatsApp or Viber.

As the Internet of Things (IoT) is evolving, it is expected to have an impact in the way telecommunications providers analyze the large amounts of sensor data such systems bring with them [13]. We would also like to note that the move to Big Data has a big impact on network infrastructure evolution, as such systems require higher link speeds to transfer the data form one node to another [14].

The solution developed in this paper is focused on mobile network performance troubleshooting. Thus, it is used to calculate various key performance indicators (KPIs) relevant for this domain. KPI measurement is frequently used by mobile operators and mobile network infrastructure vendors as a means to systematically search and identify network bottlenecks and anomalies [15].

B. Analyzing small files in the ad hoc environment

Hadoop is an open-source software framework used for distributed storage and processing of very large data sets [16]. The Hadoop distributed file system (HDFS) has been widely adopted as the standard for storing data in Hadoop based clusters [17]. In the Hadoop ecosystem, access to stored data is handled by a system called Namenode, which manages the file system namespace and regulates client access. First the client asks the Namenode for instructions on where to find the files it needs to read, as well as the location of a free block it can write to [18]. Figure 1 illustrates this process. DataNodes provide block storage and serve I/O requests from clients.

- correlations between small files are not considered for data placement;
- no optimization mechanism, such as prefetching, is provided to improve I/O performance

We would like to note that when small files are stored on HDFS, disk utilization is not a bottleneck. The research in [20] shows that a small file stored on HDFS does not take up any more disk space than is required to store its contents. More precisely, a 6 MB file stored with an HDFS block size of 128 MB uses 6 MB of disk space, not 128 MB.

HDFS is designed to read/write large files, and provides no optimization for handling small files. In cases where large amounts of small files are accessed directly in HDFS, a mismatch of accessing patterns will emerge [21]. HDFS will ignore the optimization offered by the native storage resource, which will lead to local disk access becoming a bottleneck [22]. Additionally, in such a scenario data prefetching is not employed to improve access performance for HDFS [22].

The research in [21] considers all files smaller than 16MB as small files, although no justification or proof were provided as to why this size was chosen as the cut-off point between large and small files in the context of HDFS. The research in [19] has quantified this cut-off point through experimentation. The study indicates that access efficiency starts to drop significantly with files smaller than 4.35 MB.

The small file processing problem in Hadoop has seen many different solutions with various levels of success, depending on the nature of the data. One of these is the merging of multiple small files into a single bigger file, which has shown some significant performance improvements [21], [23]. This paper explores different scenarios in which this solution can be applied to mobile network data. The scenarios are explained in more detail in the following sections.

III. SYSTEM OVERVIEW

This section provides an overview of the developed Big Data solution for mobile network performance troubleshooting.

A. Data Collection

Event data has been used for various troubleshooting purposes [5]. The event data is collected from EPG, SGSN and MME nodes within the core network. The environment is based on the Evolved Packet Core (EPC) [24], as shown on Figure 2. This study uses only event data generated by these nodes. The authors used an event-based monitoring (EBM) system, which is an embedded recording tool in the Ericsson EPG, SGSN and MME. We collected events on 2G, 3G and 4G networks.

The event data is collected in small log files which are between 5 and 15 MB in size, depending on the configuration. The overall size and and velocity of the logs depends on the size of the network (e.g. number of base stations/eNodeB, number of EPG, SGSN and MME.

![Figure 1. HDFS system overview](image-url)
nodes, overall network throughput). An average operator will generate around 200 GB of logs per day.

The log files are stored in a binary format which needs to be decoded to text (usually CSV) in order to be processed. After the decoding process, the files are up to 10 times larger than in their binary format. EBM logs contain information that documents successful and unsuccessful events for completed mobility and session management procedures.

As shown in the following section, the developed solution was tested on several small and large networks around the world.

*Figure 2 - Evolved Packet Core (EPC) schema*

**B. Architecture**

Figure 3 shows the architecture of the developed solution. Apache Flume is used to transfer the data from a network location to HDFS. Flume was chosen because it is a widely used distributed, reliable and available service for efficiently collecting, aggregating and moving large amounts of streaming event data [25]. The binary logs are usually dumped to a server, which is usually somewhere in the operator’s network. Using Flume, the binary logs are transferred to the cluster that hosts the proposed solution. Although the proposed solution can be deployed within the operator’s network, we argue that a centralized off-site deployment is more appropriate. A centralized approach enables data aggregation from various networks into a single cluster, and thus enriches the data with variety that comes from different network configurations and environments.

HDFS is used to store the raw binary log files until they are decoded. A MapReduce job is used to decode the binary files into CSV. The decoding process is explained in more detail in the following section.

The decoded CSV files are imported into an Apache Hive database [26]. Hive offers an SQL-like query language which enables data access. The developed solution has a number of Hive queries that calculate various KPI’s, which provide insight about mobile network bottlenecks. This is a quick method of finding out which parts of the network are worth looking into during troubleshooting. The results, or KPI’s calculated from such queries, are stored in a separate relation database, which is based on PostgreSQL. External applications can also connect to the Hive database and query the data to calculate KPI’s relevant for mobile network troubleshooting. One of the goals for this solution is to enable data mining. Mobile network experts can connect to the Hive database either through the Hive shell or by using a visualization tool like Tableau. Using the original measurement data stored in Hive, mobile network experts can extract new insight and get to the root cause of a problem. This is often not possible with aggregated KPI data because it hides much of the information it is derived from.

Hive provides several mechanisms for optimizing the storage of the data and query performance. The developed solution makes use of partitioning and bucketing functionalities offered by Hive. Partitioning in Hive is the process of horizontally dividing the data into a number of smaller and more manageable slices. Every partition is stored as a directory within a data warehouse table in Hive. The developed solution partitions the decoded CSV data based on the event identifier (or event name) attribute.

*Figure 3 – Architecture of the developed solution*

Bucketing is another technique of decomposing data into more manageable parts. This optimization method distributes the data evenly across multiple files. It is used to distribute and organize the table or partition data into multiple files so that similar records are present in the same file. The value of this column will be hashed into buckets by a user-defined number. Bucketing has many performance benefits, most notably faster Map side joins, more efficient grouping using “Group By” statements and more efficient sampling. As the developed solution is used by mobile network experts, such statements are used very often when accessing the Hive database directly.
The developed solution implements a MapReduce job to decode the binary files into the CSV format. The MapReduce job first reads the binary files in memory and then decodes them in parallel. The number of parallel decoding jobs is defined by the number of input splits in Hadoop. This is where the small files problem influences the developed solution. If each raw log file is decoded separately, it will have a negative performance impact. In the developed solution, we tried to influence the number of input splits by combining multiple raw log files into one larger file. More precisely, we tested the performance impact of using small files with the following scenarios:

- Scenario 1: the raw logs are stored as small files in HDFS and they are directly used as input splits in the MapReduce job. A custom Hadoop input reader is used to read the binary log files, which is based on the native RecordReader class in Hadoop (org.apache.hadoop.mapreduce. ecord reader)
- Scenario 2: the raw logs are combined into larger files, stored in HDFS and then decoded using MapReduce jobs. Each line in the combined file is a hexadecimal representation of the binary log file. In this scenario, Flume is used to combine the raw log files. Thus, a native Hadoop input reader is used (located in org.apache.hadoop.mapreduce. li .input.Te t input format)
- Scenario 3: the raw logs are combined into larger files, stored in HDFS and decoded using MapReduce jobs with only mappers and no reducers. Like in Scenario 2, each line in the input file contains a single file, and Flume is used to combine the raw log files

IV. RESULTS

For the purposes of this study, a Hadoop-based cluster was used to evaluate the developed solution. The cluster is based on the Hortonworks Data Platform (HDP) [27] and is composed of 10 servers (2 masters and 8 slaves). The master nodes have 2 model E5-2630 CPU-s, 128GB of RAM and 6 hard disk drives (HDD), each with 3TB of space. The slave nodes have 1 model E5-2623v3 CPU, 64GB of RAM, and 8 HDDs, each with 2TB of space. Each node runs on top of CentOS v7, which is installed on a separate SSD disk which is not part of the HDFS.

The input data was collected from several small and large networks around the world, including operators from Europe, North and South America, and Southeast Asia.

A. small files Decoding Benchmark

The combined files in Scenario 2 and 3 were grouped into larger files. Several performance tests were carried out on batches of 2, 9 and 33 GB of raw log files.

Table 1 shows how the decoder performs in Scenario 1, when the small log files are used directly. It can be seen that the MapReduce decoder is having difficulties processing even the smaller batches of 2 and 9 GB of raw logs. As stated in previous sections, the reason for this is the large number of small files that is imposing a heavy burden on NameNode memory. In contrast, Scenario 2 (Table 2) shows a significant performance improvement of the MapReduce decoder. Also, we used 18 reducers in Scenario 2, one for each event type available through the logging system.

Undoubtedly, the best performance was achieved in Scenario 3 by combining the input files into larger files and using map-only jobs (Table 3). The reason for such an improvement is that both the shuffle-sort and the reduce phases of the MapReduce job are skipped, thus drastically reducing the amount of processing power and memory needed to decode a large input file. For the largest batch of 33 GB, we can see that there is a 37% improvement compared to Scenario 2. We would like to note that this improvement increases with batch size (Figure 4). Figure 5 shows the performance gain for each scenario. The performance improvements rise with the batch size, which is traditionally not the case for solutions that are not based on Big Data.

The drawback of using the approach in Scenario 3 is that the output of the decoder is split into several smaller files which need to be imported into Hive. This is due to the way MapReduce jobs work. The intermediate results of the mappers are shuffled and sorted before being delivered to the reducers. By having only map jobs in our decoder, the unsorted intermediate results become the output. In contrast, when the reducers are used we can influence the number of files that will be generated. For example, each event type could be stored into a separate file. However, the files can easily be merged within Hive, as the output is textual (CSV). Also, the partitioning and bucketing in Hive restructures the physical layout of the data, so that the output of the map-only decoder does not influence the performance of the Hive queries.

B. Comparison with existing solutions

In order to clearly show the performance benefits when using big data solutions and technologies in this scenario, the study also shows the benchmark for decoding EBM logs without the proposed solution. Table 4 shows the performance benchmark on a single server, with the same hardware as the master node in the HDP cluster.

As shown in Table 4, the proposed solution is up to 6 times faster than existing solutions. The largest set of logs was unable to be measured since it was not possible with the existing solutions.

We note that the performance gains represent only one benefit of the proposed solution. The main advantage of the proposed solution is the ability to process a much larger set of logs than was possible with legacy solutions. Also, the proposed solution provides a way to continuously gather and store logs for deeper analytics, which was no the case with legacy solutions.

V. Conclusion

Big Data analytics can provide insight into the data available within the telecommunications industry. This paper demonstrates one use case in which analytics can be leveraged to improve the efficiency and value of troubleshooting in mobile networks. The main advantage of the developed solution is its ability to adapt to any new analytical requests, as well as the ability to adapt to changing input file sizes. More precisely, the results of this study show that the developed solution is capable of processing small files in an efficient manner within the Hadoop environment, which was not built for processing large amounts of small files. Additionally, the study shows that by skipping the reduce phase we can decrease the execution time of the MapReduce job used for decoding. This was shown to be the most time-consuming process. The developed solution was tested using log data collected in various small and large networks from around the world, which demonstrates its applicability for mobile network troubleshooting. The developed solution has proven that Big Data platforms are suitable for processing large batches of mobile network data, and that they bring significant performance and scalability improvements compared to traditional solutions. Future research may include the use of other Big Data tools that run on the Hadoop platform. Most notably, the use of Apache Cassandra instead of the Hive, and the use of Apache Spark as a replacement to the MapReduce decoder job.

Acknowledgment

This study was fully funded by Ericsson Nikola Tesla. The authors thank their leadership team for providing an environment in which it was possible to combine research and industry into one.

SIGNAL PROCESSING
Overlap Blocks in Reconstruction of Sparse Images

Isidora Stanković, Miloš Daković, Irena Orović
Faculty of Electrical Engineering, University of Montenegro
Dzordza Vasingtona bb, 20 000 Podgorica, Montenegro

Abstract—Images are commonly analysed by the discrete cosine transform (DCT) on a number of blocks of smaller size. The blocks are then combined back to the original size image. Since the DCT of blocks have a few nonzero coefficients, the images can be considered as sparse in this transformation domain. The theory of compressive sensing states that some corrupted pixels within blocks can be reconstructed by minimising the blocks sparsity in the DCT domain. Block edges can affect the quality of the reconstruction. In some blocks, a few pixels from an object which mostly belongs to the neighboring blocks may appear at the edges. Compressive sensing reconstruction algorithm can recognise these pixels as disturbance and perform their false reconstruction in order to minimise the sparsity of the considered block. To overcome this problem, a method with overlapping blocks is proposed. Images are analysed with partially overlapping blocks and then reconstructed using their non-overlapped parts. We have demonstrated the improvements of overlapping blocks on images corrupted with combined noise. A comparison between the reconstructions with non-overlapping and overlapping blocks is presented using the structural similarity index.

Keywords—compressive sensing, image reconstruction, overlapping blocks, gradient algorithm, noisy image

I. INTRODUCTION

An image is said to be sparse if it consists of only few nonzero coefficients in a transformation domain. A sparse image can be reconstructed with a reduced set of pixels. The processing and reconstruction of such images are examined within the theory of compressive sensing (CS) [1]–[9]. The theory of CS is widely used in various applications in the area of digital signal processing, since many real signals are sparse in a certain transformation domain. Numerous reconstruction algorithms for different kinds of signals have been developed within this field. They can be divided in several groups. The algorithm considered in this paper is from the group of algorithms based on the minimisation of the sparsity measure by using the gradient of the $L_1$-norm [10]. In this algorithm, the image is reconstructed in the spatial (pixels) domain. The corrupted pixels are detected, declared as unavailable (missing) and considered as the minimisation variables. This property makes the algorithm suitable for denoising of corrupted pixels in a noisy environment.

Common images have a small number of nonzero coefficients in the two-dimensional discrete cosine transform (2D-DCT) space. A reduced set of pixels can be used to reconstruct sparse images. Different reasons can cause that only a reduced set of pixels is available. One reason can be in heavy pixels corruption. Corrupted pixels may be declared as unavailable. Then the image is reconstructed using the CS methods. The impulsive noise is example of such a disturbance. It can appear due to analog to digital conversion errors, communication errors, dead pixels in image acquisition equipment, etc. Here we will consider a form of impulsive noise known as the salt and pepper noise with an addition of noise whose values are within the range of the original image pixels.

The paper is organised as follows. In Section II, theoretical background of sparse signal processing is presented. In Section III, the reconstruction algorithm is introduced. Section IV explains the idea of adding the overlapping block step. In Section V, the results and comparison using the structural similarity index is shown. In Section VI, conclusions are presented.

II. THEORETICAL BACKGROUND

Let us consider a grayscale image $I(m,n)$ of size $N \times N$. Based on the JPEG standard, we will split the image into blocks of size $B \times B$. We will assume that a image block starting at pixel $(m_0,n_0)$ is defined as

$$x(m,n) = I(m_0+m,n_0+n), \quad m, n = 0, 1, \ldots, B-1.$$  \hfill (1)

Its 2D-DCT representation is denoted by $X(k,l)$. The vector notations of the image blocks and their 2D-DCT are

$$x = \Psi X \quad \text{and} \quad X = \Phi x$$  \hfill (2)

where $\Psi$ and $\Phi$ are the transform and inverse transform matrices with rearranged elements of the 2D-DCT. Vectors $x$ and $X$ are obtained by stacking columns of the corresponding block pixels and 2D DCT transform.

The sparsity of one image block is $K < (B \times B)$. From the compressive sensing theory we know that, if an image is of a sparsity $K$, it can be reconstructed from less than $B \times B$ pixels/measurements. The measurements are denoted by $y$

$$y = [x(m_1,n_1), x(m_2,n_2), \ldots, x(m_M,n_M)]$$  \hfill (3)
where $M$ is the number of pixels_measurements used in a block. The relation between the values is $K < M < B \times B$. Our goal, in the sparse signal processing sense, is to reconstruct an image using the available pixels_measurements by minimising the sparsity, i.e.

$$\min \| X \|_1 \quad \text{subject to} \quad y = Ax$$

(4)

where $A$ is an $M \times N$ measurement matrix obtained from matrix $\Psi$ by selecting rows that correspond to the available pixels. The measurements are the available (uncorrupted) pixels in the image

$$y(i) = x(m_i, n_i).$$

(5)

Positions of the available pixels_measurements are $(m_i, n_i) \in \mathbb{M} = \{(m_1, n_1), (m_2, n_2), ..., (m_M, n_M)\}$. If we have an 8-bit $B \times B$ image block, corrupted with salt and pepper noise, the block can be then written as

$$x_a^{(m,n)}(m,n) = \begin{cases} 
  x(m,n), & \text{for } (m,n) \in \mathbb{M} \\
  0 \text{ (or 255)}, & \text{elsewhere}
\end{cases}$$

(6)

where 0 and 255 are salt and pepper noise. If an uniform noise is used then the values are between 0 and 255. In the next section we will present an algorithm used for the recovery of the noisy pixels.

III. RECONSTRUCTION ALGORITHM

The algorithm was introduced in [10], [11]. It is based on the minimisation of the gradient of corrupted pixels. Consider a corrupted image block as presented in equation (6). In the initial stage, we add an arbitrary value $\pm \Delta$ to the corrupted pixels

$$x_a^+(m,n) = x^{(p)}(m,n) + \Delta \delta(m-m_i, n-n_i)$$

$$x_a^-(m,n) = x^{(p)}(m,n) - \Delta \delta(m-m_i, n-n_i)$$

(7)

where $p$ is the iteration index. In the initial stage $p = 0$.

The arbitrary value $\Delta$ is usually the maximal uncorrupted pixel value, i.e. $\Delta = \max_{m,n}(y)$. For the corrupted pixels at positions $(m_i, n_i) \notin \mathbb{M}$ the gradient value is estimated as

$$g(m_i, n_i) = \frac{1}{2\Delta} \left( \| X_a^+ \|_1 - \| X_a^- \|_1 \right)$$

(8)

where $X_a^\pm$ are the 2D-DCT domain values of the signals in (7). Note that the gradient value for the uncorrupted pixels will be zero. Based on the gradient value, the corrupted pixel $x(m_i, n_i)$ is updated. Each corrupted pixel value is changed in the direction opposite of the gradient for a step $\mu$

$$x_a^{(p)}(m_i, n_i) = x_a^{(p-1)}(m_i, n_i) - \mu g(m_i, n_i).$$

(9)

Because of the shape of the gradient and norm-one sparsity measure, when the values are close to the true signal values, they will oscillate around the solution. The oscillations are proportional to the step size. When the oscillation is detected, the step sizes $\Delta$ and $\mu$ are reduced. These new parameters continue approach to the true signal values until a new precision is reached. The procedure is repeated until the desired reconstruction accuracy is achieved. One of the stopping criterion for the algorithm can be if the change in two successive iteration is smaller than some desired accuracy.

Note that only corrupted pixels (which are changed during reconstruction steps) contribute to this change. This is the basic reconstruction algorithm when the positions of the corrupted pixels are known (if, for example, the pixels are distinguishably corrupted).

If other noise types are used, then an additional step is proposed in [12], [13]. Since the positions of the corrupted pixels are unknown, we repeat Eq. (7) and (8) for all pixels (corrupted and uncorrupted). Each time we take the pixel with the largest gradient, reconstruct it and eliminate it from the array of possible values. This will be repeated until the error of two successful iterations is below an acceptable level.

IV. OVERLAPPING BLOCKS

Let us consider an image of size $N \times N$ and that we split the image in number of blocks of size $B \times B$. Each block has $M$ available/uncorrupted pixels. Within blocks we have corrupted pixels with salt and pepper noise and a uniform noise, whose values are similar to the uncorrupted pixels.

Assume that there are a few uncorrupted pixels at the edges which are not of the same or similar value as the other pixels in the block. These pixels mainly belong to the object of a neighbouring block. The compressive sensing theory looks for the sparsest possible solution as the reconstruction result. The sparsest solution of the considered block would be obtained by taking the uncorrupted pixels (which are part of the neighbouring object) as the corrupted ones, since these pixels significantly differ from the majority of the other uncorrupted pixels in that block. In this sense, a method will be falsely reconstruct these pixels as the pixels of similar values to the other pixels within the block.

To overcome this problem, we introduce the overlapping blocks. The idea is to take a bigger block to analyse the objects in surrounding blocks. Then we reconstruct the block and use only a smaller central part of the analysed block in the final image reconstruction. The method of overlapping blocks is suitable as an addition to the algorithms which are based on the detection and reconstruction of the noisy pixels itself, not the transformation domain coefficients.

As an illustration, let say that the block for analysis is of size $B \times B = 32 \times 32$. The size $B_o \times B_o$ will denote the size of the part which will be used in the final reconstruction. Obviously it must hold that $B_o < B$. We assume that we will use the central block of size $B_o \times B_o = 16 \times 16$. Illustration of this kind of blocks is presented in Fig. 1. Bigger blocks represent the blocks for analysis, which are of size $B \times B$, and smaller blocks are the blocks for final reconstruction. They are of size $B_o \times B_o$. Note that for the blocks which are at the edges of the whole image, we use the reconstruction from the edge analysis blocks.

V. RESULTS

In this section we will present reconstruction results using the method presented in the previous sections. Note that
idea of overlapping blocks can be considered as an improvement to the reconstruction algorithms for the edges of objects in images. The algorithm was tested using overlapping and non-overlapping blocks. It was tested on a grayscale $512 \times 512$ image “Lena” with $50\%$ of salt and pepper noise and $12.5\%$ of random noise. It is considered that $10\%$ of components in each block are nonzero in the 2D-DCT domain. The original image and the noisy image are presented in Fig. 2. The reconstruction without using overlapping blocks is shown in Fig. 3 (top). In the overlapping case the blocks for analysis are of size $32 \times 32$ and the part used for the final reconstruction is the central part of size $16 \times 16$. The result is shown Fig. 3 (bottom). The images zoomed in to the upper right corner are shown in Fig. 4.

A. Comparison

The comparison between the reconstructions using non-overlapping and overlapping blocks is presented using the localized structural similarity (SSIM) index. The SSIM index is a comparison parameter between two images. It is defined in [14] as

$$SSIM(x_o, x_r) = \frac{(2\mu_{x_o}\mu_{x_r} + c_1)(2\sigma_{x_o,x_r} + c_2)}{\mu^2_{x_o} + \mu^2_{x_r} + \sigma^2_{x_o} + \sigma^2_{x_r} + c_1} \quad (10)$$

where $x_o, x_r$ are the original and the reconstructed image, respectively. The values $\mu_{x_o}, \mu_{x_r}$ are the mean values of the images, $\sigma_{x_o,x_r}$ is the covariance between the two considered images, and $\sigma^2_{x_o}, \sigma^2_{x_r}$ are the variances of the two images. The values $c_1, c_2$ are used as stabilisation variables. If SSIM index is close to 1 the images are similar, if it is close to 0 they are not similar. The SSIM index of the zoomed images from Fig. 4 are shown in Fig. 5.

VI. Conclusions

A method for improving the reconstruction of noisy images using overlapping blocks is proposed. It is an improvement of the methods for reconstruction algorithms which are based on the detection of the corrupted pixels in spatial domain. The reconstruction of the images using non-overlapping and overlapping blocks is shown. The use of overlapping blocks improved results in the denoising of images.

Abstract—A method for reconstruction of sparse signals is presented in this paper. It is an improved version of the direct-search method for finding the set of non-zero coefficients representing the solution in sparsity domain. The proposed random search procedure is performed assuming the largest possible number of non-zero coefficients still satisfying the available measurements system. In the sparse signal processing and compressive sensing theory, this number should be smaller than or equal to the number of measurements. For each possible arrangement of the examined non-zero coefficients, the reconstruction is done by solving the system of equations in the least square sense, until the solution is found. Benefits of the proposed method are discussed. The calculation complexity improvement of the presented theory is confirmed with numerical examples.

Keywords — compressive sensing, signal reconstruction, direct search, sparsity

I. INTRODUCTION

A signal with a small number of nonzero coefficients (sparse signal) can be reconstructed from a reduced set of available samples/measurements [1]–[11]. The reduced number of measurements can be a consequence of various circumstances. It can occur as the result of a sampling strategy developed with the aim to reduce the storage requirements for the data. Measurements can be unavailable due to physical constraints or their intentional omitting due to a high noise corruption [11]. The analysis and reconstruction of sparse signals was the topic of many research papers [1]–[15]. Numerous reconstruction theorems and algorithms were developed [1], [2], [4]–[8].

Many signals in real applications can be considered as sparse in a certain transformation domain, meaning that the idea of sparse signal reconstruction can be exploited in different areas of signal processing. For example, digital images can be considered as sparse in the domain of discrete cosine transform (DCT), whereas radar ISAR data are sparse in the domain of two-dimensional Fourier transform [16].

One of the challenging topics in the compressive sensing is the optimal sampling strategy that will allow to reconstruct the signal with smallest possible number of available samples [12]. Various approaches are used to this aim, like those that minimize the coherence index of the isometry constant for a given signal transform. The direct search method provides exact reconstruction results if the unique reconstruction is theoretically possible. However, this method is computationally complex. For a large dimension of the reconstruction problem, number of available samples and sparsities, it is NP-hard and therefore not computationally feasible.

In this paper, we introduce an improvement in the computation of signal reconstruction by modifying the direct search strategy. It is known that for an observed sparsity level, compressive sensing algorithms, for instance \( \ell_1 \)-norm based or iterative, greedy, and other proposed algorithms [5], require a larger number of available measurements than the one required in \( \ell_0 \)-norm minimization. The aim is to overcome this issue by exploiting the possibility to reduce the number of trials in the direct search reconstruction procedure.

The paper is organized as follows. Basic compressive sensing definitions are presented in Section II. In Section III the direct search reconstruction algorithm is presented. The proposed, random search method, is introduced in section Section IV. Results and comparison are shown in Section V whereas the paper ends with concluding remarks.

II. BASIC DEFINITIONS

Let us consider a complex-valued discrete signal \( x(n) \) of length \( N \) and its corresponding transformation domain \( X(k) \)

\[
x(n) = \sum_{k=0}^{N-1} X(k) \psi_k(n), \quad X(k) = \sum_{n=0}^{N-1} x(n) \varphi_n(k),
\]

or in vector form \( x = \Psi X \) and \( X = \Phi x \). The inverse and the direct transform matrices are denoted as \( \Psi \) and \( \Phi \), respectively. We say that a signal is \( K \)-sparse in the transformation domain if the number of nonzero coefficients \( K \) is much smaller than the total length of signal \( N \), i.e., \( K \ll N \). Then a sparse signal can be reconstructed with \( M < N \) measurements. The signal with \( M \) samples/measurements available is denoted as \( y(m) \)

\[
y(m) = \sum_{k=0}^{N-1} X(k) \psi_k(m).
\]

Previous definition can be written in a vector form as

\[
y = AX
\]
where $A$ is the measurement matrix of size $M \times N$. It is formed based on the matrix $\Psi$, containing rows that correspond to the positions of the available measurements/observations, whereas the rows corresponding to the missing samples are omitted.

The sparse signal reconstruction can be defined as the solution of the optimization problem

$$\min ||X||_0 \text{ subject to } y = AX. \quad (4)$$

Having an undetermined system of linear equations defining the available measurements, the solution of the signal reconstruction problem is the one satisfying this system of equations, and being the sparsest possible. That is, the aim is to minimize the sparsity of $X$ using the available measurements $y$. This is achieved by exploiting a sparsity measure. A natural choice for this measure is the so-called $\ell_0$-norm which counts the number of nonzero coefficients in $X$, although not satisfying norm properties in a strict mathematical sense. However, this function is not convex and its minimization could be done only through a combinatorial search. Moreover, it can be easily shown that a direct combinatorial search is not computationally feasible for a reasonable length of the considered signal, its sparsity and number of available samples. This pseudo-norm is also very sensitive to the noise influence and quantization errors. This is the reason why, in practice and theory, more robust norms are exploited as sparsity measures.

The $\ell_1$-norm is the most frequent used norm since it is closest convex function to the $\ell_0$-norm. It is equal to the sum of absolute values of $X$. However, all norm-one reconstruction methods, as well as other standard algorithms developed within the fields of sparse signal recovery and compressed sensing, require more samples/measurements than the minimal possible number that can provide a unique signal reconstruction in theory. Motivated by this fact, we try to reduce the computational cost of the combinatorial approach, with the aim to obtain the results similar to the direct search in sense of the minimal required number of measurements needed for a successful unique reconstruction.

III. DIRECT SEARCH RECONSTRUCTION

Any problem described with (4) can be solved by a direct search over the whole set of possible values of nonzero coefficients positions. This procedure is defined as the direct search minimisation of the $\ell_0$-norm. Assume a vector $X$ with sparsity $K$. We try to detect indices of the nonzero values $k \in \{k_1, k_2, ..., k_K\}$ out of the set of all possible indices between 1 and $N$

$$k \in K \subset N \quad (5)$$

where $K = \{k_1, k_2, ..., k_K\}$, $N = \{1, 2, ..., N\}$. The vector $X_K$ contains assumed $K$ nonzero elements of $X$ at the positions from set $K$. The system

$$y = A_K X_K \quad (6)$$

with $M > K$ equations is solved by minimising the least square error

$$e^2 = (y - A_K X_K)^H (y - A_K X_K) = ||y||^2 - 2X^H K A^H K y + X^H K A^H K A_K X_K. \quad (7)$$

The minimum of the error is found from

$$\frac{\partial e^2}{\partial X_K^H} = -2A^H K y + 2A^H K A_K X_K = 0. \quad (8)$$

The solution is calculated as

$$A^H K A_K X_K = A^H K y \quad X_K = (A^H K A_K)^{-1} A^H K y. \quad (9)$$

For all solutions we check the error $y - A_K X_K$. The reconstruction of the signal $X$ is exact when the mean square error is equal to zero. The reconstruction is not unique if there is more than one solution.

IV. RANDOM SEARCH RECONSTRUCTION

In the direct search procedure we should check all combinations of $K$ nonzero out of $N$ coefficients in total. To find all possible combinations of $\{k_1, k_2, ..., k_K\} \subset N$, the total number of combinations is equal to

$$\binom{N}{K} \quad (10)$$

and it could be very large. The expected number of checked combinations is

$$T_d = \frac{1}{2} \binom{N}{K}. \quad (11)$$

Even though the direct search is an accurate method, it is computationally not feasible to get a solution for a large signal. For the random search procedure, we will consider a system with $M$ unknowns. Taking $M - 1 > K$ equations in a combination, less trials will be needed to find the solution. Let us consider a random combination of $M - 1$ nonzero positions. The new system is then

$$y = A_{sel} X_{sel} \quad (12)$$

with $M$ equations. If the considered combination includes all $K$ nonzero positions from $X$, then the system (12) of $M$ equations with $M - 1$ unknowns have the unique solution. Note that only $K$ coefficients in the solution are nonzero and remaining $M - 1 - K$ coefficients are zero valued.

Considering the new system (12), the probability that we find the solution is

$$P_s = \frac{\binom{N - K}{M - 1 - K}}{\binom{N}{M - 1}}. \quad (13)$$

The expected number of trials can be estimated as

$$T_r = \frac{1}{P_s} = \frac{\binom{N}{M - 1}}{\binom{N - K}{M - 1 - K}}. \quad (14)$$

608 MIPRO 2017/CTI
The improvement in speed of the proposed random search procedure compared to the direct-search is

$$S = \frac{T_d}{T_r} = \frac{1}{2} \binom{N}{K} \frac{(N-K)}{(M-K)} \binom{M}{K}. \tag{15}$$

The amount of the speed improvement will be illustrated by several examples in the next section.

V. EXAMPLES

**Example 1:** Let us consider a signal of length $N = 128$, having $M = 15$ available samples and sparsity $K = 7$. The total number of direct-search combinations for this case is

$$\binom{N}{K} \approx 10^{10}.$$ 

Probability that we guess solution by proposed method is

$$P_s \approx 3.6 \times 10^{-8}$$

whereas the expected number of trials equals

$$T_r \approx 2.75 \times 10^7.$$

The proposed method is $S \approx 1700$ times faster than direct-search (in average).

Let us now observe a signal having the same length $N = 128$, and $M = 31$ available samples with sparsity $K = 15$. Following the previous analysis, the calculation speed-up is

$$S \approx 7.7 \times 10^7.$$

The expected number of trials in the random search procedure applied in this case is

$$T_r \approx 8.5 \times 10^{10}.$$

**Example 2:** For signal of length $N = 128$ we vary sparsity $K$ from 7 to 60 and assume that the number of available samples is $M = 2K + 1$ for each observed sparsity. The speed improvement of the proposed method over the direct search, calculated according to (15) is shown in Fig. 1. The expected trials number is also calculated for both procedures, according to (11) and (14). The results are shown in Fig. 2.

**Example 3:** The main motivation to introduce an improved version of the direct search lies in the fact that standard sparse reconstruction algorithms, including those based on $\ell_1$-norm require a larger number of available samples for the recovery of missing samples than the reconstruction based on the corresponding direct search aiming to minimize the $\ell_0$-norm. In order to illustrate this issue, we observe a $N = 20$ length signal $K$-sparse in the discrete Fourier transform domain. The signal has the following form

$$x(n) = \sum_{i=1}^{K} A_i e^{i2\pi k_i}, \tag{16}$$

with amplitudes and frequencies having random values with uniform distribution, satisfying $0 \leq A_i \leq 2$ and $0 \leq k_i \leq N - 1$. Number of available samples was varied from $M = 1$ to $M = 19$ whereas for each number of available samples sparsity was varied from $K = 1$ to $K = 19$. Note that in cases when $K > M$ the reconstruction is not possible.

The proposed random search is compared with Orthogonal Matching Pursuit (OMP), a representative algorithm from the compressive sensing framework introduced in [5]. The random search procedure terminates when the solution is found, or the number of trials exceeds $\binom{N}{M-K}$. The experiment was conducted based on 100 independent realizations of signals with random missing samples positions and the probability of successful reconstruction is calculated.

The results are shown in Figs. 3 and 4. Comparing these results, it can be seen that the OMP-based reconstruction requires a larger number of available samples $M$ (for a given sparsity $K$) than the corresponding random search procedure. For example, in the OMP case with $K = 2$ accurate reconstruction in 100% of trials requires exactly $M = 9$ available samples.
In this paper we propose a method for sparse signal reconstruction based on the random search for \( K \) nonzero coefficient positions in the sparsity domain. Since we have \( M \) available measurements, in each trial \( M - 1 \) randomly selected positions are considered. If the considered combination includes all the nonzero coefficients, then the reconstruction is done successfully. Transform coefficients with wrongly assumed nonzero values are automatically set to zero using the partial sensing matrix pseudo-inversion involved in the signal reconstruction.

Taking more positions in one trial will converge to the solution faster than the direct-search procedure. The random search method is compared with the direct-search, showing noticeable improvement in the calculation cost. The basic motivation for this research is that standard algorithms from the compressed sensing framework require a larger number of available samples for the successful reconstruction than it is required by the direct search based reconstruction. This issue is illustrated in comparison with OMP algorithm. The obtained results confirm that the calculation improvements in the direct search based signal recovery represent important and open topics for further research.

VI. CONCLUSIONS

In this paper we propose a method for sparse signal reconstruction based on the random search for \( K \) nonzero coefficient positions in the sparsity domain. Since we have \( M \) available measurements, in each trial \( M - 1 \) randomly selected positions are considered. If the considered combination includes all the nonzero coefficients, then the reconstruction is done successfully. Transform coefficients with wrongly assumed nonzero values are automatically set to zero using the partial sensing matrix pseudo-inversion involved in the signal reconstruction.

Fig. 3. The probability of successful reconstruction using OMP as an example of standard sparse signal recovery algorithms. The results, shown for various \( K \) and \( M \) are obtained based on 100 independent realizations of signals with random missing samples positions, amplitudes and frequency positions. The signal length is \( N = 20 \).

Fig. 4. The probability of successful reconstruction using the proposed random search procedure. The results, shown for various \( K \) and \( M \) are obtained based on 100 independent realizations of signals with random missing samples positions, amplitudes and frequency positions. The signal length is \( N = 20 \).

A fast noise level estimation algorithm based on adaptive image segmentation and Laplacian convolution

Emir Turajlić
Faculty of Electrical Engineering, University of Sarajevo, Sarajevo, Bosnia and Herzegovina
emir.turajlic@etf.unsa.ba

Abstract - This paper proposes a fast algorithm for additive white Gaussian noise level estimation from still digital images. The proposed algorithm uses a Laplacian operator to suppress the underlying image signal. In addition, the algorithm performs a non-overlapping block segmentation of images in conjunction with the local averaging to obtain the local noise level estimates. These local noise level estimates facilitate a variable block size image tessellation and adaptive estimation of homogenous image patches. Thus, the proposed algorithm can be described as a hybrid method as it adopts some principal characteristics of both filter-based and block-based methods. The performance of the proposed noise estimation algorithm is evaluated on a dataset of natural images. The results show that the proposed algorithm is able to provide a consistent performance across different image types and noise levels. In addition, it has been demonstrated that the adaptive nature of homogenous block estimation improves the computational efficiency of the algorithm.

I. INTRODUCTION

Numerous image processing and computer vision algorithms require some means of accurate and computationally efficient estimation of noise variance from still images. Some of the applications of noise level estimation algorithms include image denoising [1-3], feature extraction [4] and edge detection [5]. In this paper, it is assumed that digital images are corrupted by additive white Gaussian noise (AWGN). Although, digital images can be corrupted by a range of different types of noise, such as the shot noise, the salt-and-pepper noise and the Poison noise, the estimation of AWGN variance from images remains the problem where much of the research effort is focused on.

Typically, the additive white Gaussian noise occurs as a result of image transmission, but it can also arise from image acquisition, storage and during some image processing operations. This type of noise is particularly challenging to estimate as it affects the entire image. In practice it is very difficult to discern to which degree the observed local variations can be attributed to the underlying image signal and to which degree they are associated with the corrupting noise signal. Due to the importance and the challenging nature of this research problem, over the years, various approaches for noise variance estimation have been developed. The most prominent approaches in spatial domain include block-based [6] and filtering-based noise estimation methods [7]. Block-based methods tessellate an image into a number of non-overlapping blocks. Commonly, they attempt to establish the homogenous image patches with little or no visual activity from which the local noise level estimates are obtained. Subsequent statistical analysis of these local noise level estimates leads to the final noise level estimation value. Conversely, the filter-based methods use some type of image filtering to suppress the underlying image signal and in doing so facilitate a more accurate noise level estimation. On the other hand, transform domain methods use a decorrelating transform to attain spectral decomposition of images and enable noise level estimation [8]. Here, the energy compactness of the decorrelating transform constitutes an important issue.

This paper presents a novel block-based algorithm for a fast and accurate noise estimation across a range of noise levels. The proposed algorithm is essentially a hybrid algorithm that relies on filtering as well as on block segmentation of images. Specifically, the proposed algorithm uses a zero mean Laplacian operator to suppress the underlying image signal from the noise corrupted image. Subsequently, a non-overlapping block segmentation is employed to estimate homogenous image regions. Here, the estimation process is adaptive in nature and is implemented in two distinct stages whereby the size of tessellation blocks is related to the initial noise level estimate. In this paper, the optimal relation between the size of the tessellation blocks and the observed noise signal is ascertained. The performance of the proposed method is evaluated on a dataset of natural images [9] and it is compared to the fast noise estimation of method, presented in [10], and the block-based noise estimation in singular value decomposition (SVD) domain [11].

The remainder of this paper is organized as follows. In section II, a brief overview of the fast noise estimation method [10] is presented. An overview of the block-based noise estimation in SVD domain [11] is presented in section III. Section IV presents the proposed noise estimation algorithm. Section V presents and discusses simulation results. Section VI concludes the paper.
The fast noise estimation algorithm [10] is a simple algorithm that entails only two steps. In the first step, a zero mean Laplacian operator is used to suppress the underlying image signal and to estimate the noise signal. The noise estimation operator is described by a following 3x3 mask:

\[
\begin{pmatrix}
1 & -2 & 1 \\ -2 & 4 & -2 \\ 1 & -2 & 1
\end{pmatrix}
\]

In the second step, the estimate of the standard deviation of Gaussian noise is obtained using the following relation [10]:

\[
\hat{\sigma} = \sqrt{\frac{\pi}{2}} \frac{1}{\alpha(W-2)(H-2)} \sum_{i,j} f(x,y) * h
\]

Clearly, this algorithm is designed with fast execution in mind. The simplicity of estimation comes at the cost of lower accuracy and estimation reliability.

III. NOISE ESTIMATION IN SVD DOMAIN

Singular value decomposition (SVD) is particularly applicable to the problem of noise estimation from images as the underlying image signal and additive noise can be well dissociated in the SVD domain.

A block diagram of the block-based noise estimation in SVD domain [11] is presented in Fig. 1 a). This method entails image segmentation via rectangular non-overlapping r x r blocks. Subsequently, a fixed number of randomly selected blocks is used to obtain a set of local noise level estimates. The procedure for obtaining local noise level estimates is essentially the same as the one described in [12], except that small rectangular image patches are used instead of the entire image.

The procedure is also illustrated in Fig. 1 b). Here, singular value decomposition is performed on an image block \(A\). An average of \(M\) trailing singular values \(s_j(i), 1 \leq i \leq r\) is evaluated to obtain a parameter \(P_A(M)\), where \(M\) constitutes a user defined parameter in a range \(1 \leq M \leq r\). Subsequently, the noisy image block is further corrupted by AWGN with \(\sigma^2 = 50\) to produce a block \(B\). The previously described procedure is repeated on the block \(B\) to yield \(P_B(M)\). Finally, the block-level estimate is evaluated according to:

\[
\hat{\sigma}_A = \frac{\alpha \hat{\sigma}^2}{2(P_B(M) - P_A(M))} - \frac{P_B(M) - P_A(M)}{2a}
\]

Here, the parameter \(\alpha\) describes the slope of linear relationship between \(P_A(M)\) and a noise level \(\sigma\). Parameter \(\alpha\) is required to be defined experimentally.

The implementation of this block-based noise estimation method in SVD domain requires a number of options and parameter values to be defined by a user. In this paper, these values are defined according to the recommendations made in [11] and [12]. For each image a total of 25 blocks are used to obtain local noise level estimates [11]. Here, each tessellation block is of fixed size 64x64 [11]. In addition, the number of considered singular values that are used in the process of producing a local noise estimates is set to \(M=3r=48\) [11], [12]. Finally, the parameter \(\alpha\) is defined as 4.86 [11].

IV. PROPOSED NOISE ESTIMATION ALGORITHM

A diagram of the proposed noise level estimation algorithm is presented in Fig. 2. The proposed method adopts features that are usually associated with both block-based and filtering-based approaches. Specifically, the proposed method implements the Laplacian convolution based on the operator \(h\) that is defined in (1), to suppress the underlying image signal. This feature is clearly associated with the filtering-based methods. On the other hand, the proposed method also employs rectangular block-based image tessellation to evaluate the homogenous image patches. However, the proposed algorithm evaluates the homogenous image patches in two distinct steps. In that sense it is different than the traditional block-based methods. It is inherently adaptive to the perceived noise level.

In the first step, the result of Laplacian convolution is tessellated into 64x64 non-overlapping image patches. From each image patch, the averaging procedure described in (2) is used to produce a local noise level estimate. The only difference is that the averaging is performed over a 64x64 image patch, instead of the entire image. The main results of the first stage in the noise estimation process are the initial noise level estimate \(\hat{\sigma}^{(1)}\) and the initial estimate of homogenous image regions \(B^{(1)}\). The initial set of homogenous image patches \(B^{(1)}\) corresponds to image blocks that exhibit the smallest local noise level estimates.
Figure 2. Block diagram of the proposed noise estimation algorithm with two distinct stages: 1) Laplacian convolution and initial noise estimation; 2) Adaptive homogenous area estimation and noise estimation.

Each local noise level estimate is associated with a particular homogenous image patch. Here, the number of homogenous image blocks is selected so that the total homogenous area corresponds to roughly (rounding) 15% of the total image area. On the other hand, the initial noise level estimate $\hat{\sigma}_n(1)$ is ascertained as the minimum value among the entire set of local noise level estimates.

In the second stage of the noise estimation process, the proposed method uses the initial noise level estimate $\hat{\sigma}_n(1)$ as the basis to perform further segmentation of homogenous image patches $B(1)$. Each rectangular block is segmented into even smaller image patches. The size of the new image segments, $r(2) \times r(2)$, is directly related to the initial noise level estimate $\hat{\sigma}_n(1)$ obtained in the first stage of the noise estimation process. Specifically, the relationship is of the form $r(2) = k \times \hat{\sigma}_n(1)$, where the optimal value of proportionality constant $k$ is experimentally evaluated. In order to have meaningful image segmentation the $r(2)$ values are also constrained to $3 \leq r(2) < r(1)$. The adaptive image segmentation ensures that when smaller amount of noise is observed, the image is tessellated into smaller blocks. Conversely, the higher the value of the initial noise level estimate, the bigger the size of segmentation blocks. Following the adaptive block segmentation, a set of local noise level estimates is obtained. In the similar manner as in the first stage of the estimation process, a new set homogenous of image blocks $B(2)$ is identified. The only difference is that the final number of homogenous blocks is set to denote 85% of all blocks that are derived over the area corresponding to the set of blocks $B(1)$. The averaging over the set of local noise level estimates associated with image patches $B(2)$ produces the final noise level estimate.

The proposed algorithm enables a very efficient two-stage estimation of homogenous image patches. Initially, a course segmentation based on the large 64x64 blocks is performed. A fraction of these blocks is identified as initial homogenous image patches. In the second stage, these homogenous image patches are further segmented based on the initial noise level estimates. This second stage image segmentation is performed over a fraction of the total image area as only the initial estimates of homogenous image patches are involved. The presented hierarchical two-stage image segmentation is expected to reduce the overall computational complexity of the proposed algorithm. In the following section, we will demonstrate that variable block size also improves the accuracy of noise estimation.

V. SIMULATION RESULTS AND DISCUSSION

In this paper, experiments are conducted on a subset of 40 images from the database of natural images [9]. Prior to any experiments, these RGB images are converted to grayscale. In addition, some experiments are performed on four standard test-images, presented in Fig. 3.

A. Proportionality Constant

The objective of the first experiment is to establish an optimal relation between the initial noise level estimate, as evaluated during the course image segmentation, and the size of the image blocks that are to be used in the second stage of image segmentation. It is assumed that this relation is linear, where $r(2) = k \times \hat{\sigma}_n(1)$, and it is only the value of the proportionality constant that need be ascertained.

The optimal value of the constant $k$ is evaluate in the following manner. The value of $k$ is varied between $k=1$ and $k=4$ in increments of 0.1 and the performance of the proposed algorithm is measured objectively, using the mean square error across the dataset of 40 images and the considered range of noised levels as the principal quality measure.
Here, MSE is defined as:

\[
MSE_k = \frac{1}{L \times N} \sum_{i=1}^{L} \sum_{n=1}^{N} (\hat{\sigma}_{i,n} - \sigma_n)^2
\]

where \(L=40\) denotes the size of the image data set and \(N\) describes the number of considered noise levels. Subscripts \(i\) and \(n\) denote the image index and noise index, respectively. Here, noise between \(\sigma_1 = 1\) and \(\sigma_{12} = 23\) in increments of 1. The results of the experiment showing MSE vs \(k\) curve is shown in Fig. 4. Clearly, the optimal value of the proportionality constant is \(k=1.9\) for which the MSE curve attains a global minimum value. Since, \(r^{(2)}(k) = 1.9 \times \hat{\sigma}_{n}^{(1)}\), we can ascertain the optimal linear relationship between area of the segmentation blocks and the initial noise variance value: \(r^{(2)}(k) \times r^{(2)} = 3.61 \times (\hat{\sigma}_{n}^{(1)})^2\). The proportionality constant value \(k=1.9\) is employed in all subsequent experiments and on all images to define the relationship between the initial noise level estimates and the size of the segmentation blocks used during the second stage of the noise estimation algorithm.

B. Estimation of Homogenous Image Regions

The homogenous image region estimation and the adaptive nature of image segmentation process is illustrated in Fig. 5. The presented results are based on the optimal proportionality constant value \(k=1.9\) and AWGN at \(\sigma=3\).

Here, the framed blocks denote the results of the initial homogenous region estimation via a course image segmentation, whereas the filled image patches denote the homogenous regions as estimated during the second stage of the noise estimation procedure. Note that, in each case, the initial homogenous region corresponds to the 15 % of total image region, whereas the final homogenous patches denote 85 % of the initial estimates. Visual inspection of the images, presented Fig. 5 and the corresponding results of Laplacian convolution indicate that the relative ranking among the local noise level estimates is to large extent correlated with the perceived level of visual activity. Hence, the estimated homogenous image patches are perceived as flat image regions, where most of the intensity variations can be attributed to the noise signal.

C. Performance Comparison

In the next set of experiments, the performance of the proposed noise level estimation algorithm is compared to the fast noise level estimation algorithm, presented in section II and the SVD domain based noise estimation algorithm, presented in section III. From here on, these two algorithms will be denoted as FAST and SVD, respectively. On the other hand, the proposed algorithm will be denoted as PR. The comparative analysis between the different noise level estimation algorithms involves a broad range of noise levels. Specifically, in each of the following experiments, the standard deviation of the additive white Gaussian noise is varied from \(\sigma = 1\) to \(\sigma = 23\) in increments of two.

Table I and Table II report the average estimation error results attained for each of the four test images. Here, for each image and considered noise level, the reported results denote the average estimation error obtained over 30 independent simulation runs. The bolded values indicate the best performing method for a particular noise level.

The results reported Tables I and II demonstrate that the proposed method outperforms the other two methods. In each case, these improvements are mostly evident when the proposed method is evaluated. The SVD algorithm offers the best performance for ‘Peppers’ image. On the other hand, the proposed algorithm constitutes the best option for all other images. In the case of test images with the highest degree of texture and underlying visual activity (‘House’ and ‘Baboon’), the proposed algorithm offers the best performance over the entire range of the considered noise levels.

Since these types of images are traditionally challenging for the types of algorithms that employ block-based noise estimation, the accuracy of noise level estimation can be attributed to the adaptive nature of image segmentation as well as to image filtering and suppression of the underlying image signal.

A more systematic evaluation of the considered noise level estimation algorithms is presented in the following experiment. Here, the noise level estimation algorithms are evaluated on a subset of 40 images from the dataset of natural images [9]. Prior to experiment, these RGB images are converted to grayscale. Again, the standard deviation of additive white Gaussian noise is varied from 1 to 23 in increments of two.

The performance of each method is evaluated in terms of the mean square estimation error (MSE) and the standard deviation of estimation error. The MSE is used to quantify the accuracy of the considered algorithms, while the standard deviation of estimation error is used to objectively evaluate the reliability of the considered algorithms. The results are reported in Fig. 6 and Fig. 7. The results clearly demonstrate that the proposed method, in comparison to the other considered algorithms’ exhibits higher levels of both accuracy and reliability. When considering the attained MSE values, it is clear that the proposed algorithm offers significant improvements in the accuracy of noise level estimation at nose levels. This property has been is also observed as part of our analysis of four test images. In addition, for most of the considered noise levels, the proposed algorithm attains the lowest standard deviation in estimation error values. This results indicates high levels of reliability of the proposed algorithm and its ability to provide a consistent performance across different image types and noise levels.

In the final experiment, the execution time of the proposed method is evaluated. The proposed method and the SVD method both employ image tessellation and use local noise estimates to ascertain the overall noise image estimate. In general, these methods are associated with a higher degree complexity compared to the FAST method. Here, FAST method entails only simple filtering and averaging operations, only. Consequently, they offer a much more accurate and consistent noise level estimation across images.

The execution times of the noise level estimation algorithms are evaluated on a dataset of ten 512x512 images. Here, images are corrupted by AWGN with $\sigma = 10$ and the total time required for each algorithm to perform noise estimation over the entire set is recorded. The result of the FAST method is used as the performance benchmark as it is expected to require the least amount of time to complete the task. The ratio of execution time of the SVD domain method compared to the FAST method is 3.31:1. On the other hand, the attained execution time ration of the proposed method in relation to the FAST method is 1.84:1. Clearly, the proposed algorithm is nearly twice as fast as

Figure 6. Mean square error evaluated across images for different noise levels.

Figure 7. Standard deviation of estimation error evaluated across images for different noise levels.
the block-based noise level estimation in SVD domain. The computational efficiency can be attributed to the efficient estimation of homogenous image patches. In comparison to the FAST estimation, the proposed algorithm, offers significantly higher levels of accuracy and reliability at the cost somewhat slower performance.

Thus, the proposed algorithm offers a high quality performance that is better or in certain cases at least comparable to the SVD domain method, while offering a faster execution time.

VI. CONCLUSION

This paper proposes a novel block-based algorithm for a fast and accurate noise level estimation. The proposed algorithm is in fact a hybrid algorithm that exhibits features that can be associated with both filter-based methods and block-based methods. The proposed method employs a zero mean Laplacian operator to suppress the underlying image signal from the noise corrupted image. In addition, it uses a non-overlapping block tessellation and adaptive image segmentation to ascertain homogenous image patches. These homogenous patches are used to obtain the local noise level estimates from which the final noise level estimate is produced.

The experimental results demonstrate that proposed algorithm offers high levels of accuracy and reliability across different images and noise levels. The ability to adaptively very the size of the image segmentation blocks is of particular benefit when the images are corrupted by a small amount of noise, where the traditional block-based methods tend to overestimate the noise levels in such instances.

dijana.ilisevic@mtel.ba, natasa.banovic-curguz@mtel.ba

Abstract - Software Defined Networks (SDN) and Network Function Virtualization (NFV) could be taken as a different expression of the overall transformation trend toward network softwarization which is deeply impacting and bringing Telecom and ICT Industry. These changes will have a broader impact on society, including aspects of regulation, policy, social impacts and new business model. A number of new stakeholders are involved in the realization of SDN/NFV driven architecture. Telecom companies are often regulated more than Internet players and this asymmetry represents a problem in terms of competitiveness and capability to deliver innovative services. In this article we have provided short overview of the most relevant stakeholder roles in future ICT industry. Afterwards, we have presented importance of regulation in future ICT environment which place huge impact on foster innovation and service delivery.

I. INTRODUCTION

The Fourth Industrial Revolution – digitization and internetization are already underway and is far cleverer than the previous because it is connect emerging technologies. This is blurring boundaries between physical, digital as well as transforming production, management and governance system in nearly every industry in every country. Digital transformation (DT) is a major driver for economic growth and has the potential to catalyze a country’s innovation, growth and development. Governments can accelerate or break this transformation and guide new digital mindset in this fast-changing area using ongoing digital transformation experiences.

All companies and governments will have to think about how to deal with this digital transformation and what their role in the newly growing digital ecosystems might be. Digital transformation takes beyond managing internal Information Technology (IT) applications. They need forecasting and business insight; they need to fully understand what transformation really means; and they need to understand the technology and how it will change their business value. Digital transformation is all about data, but its full value can only be delivered when adequate IT and technology form the infrastructure that seamlessly connects that data and enables its exchange – anytime and anywhere. This growing demand for connectivity will require companies to have broadband access and a high-speed infrastructure, which would result in a rise in spending for ubiquitous broadband (BB) access. A key foundation in digital society will be powerful Information and Communications Technology (ICT) infrastructure that support service delivery and foster innovation.

BB infrastructure puts telco sector in the heart of transformation process, but telcos are having a hard time because growth and profitability across the industry are in a downward spiral. First, consumers think that data services are too expensive and the experience is inadequate. Their needs for connectivity, bandwidth, reliability, and security are still not being met. Second, Internet service providers use telecom networks to serve their customers, but they think they are paying too much for bandwidth and data traffic throughput. Third, the governments are trying to cut the prices of telecom services. The EU is in the process of cancellation mobile roaming fees within Europe. Other governments around the world are trying to find ways to lower prices. The telecom industry can only become healthy when telcos themselves are healthy. In the same way, the industry can only complete its digital transformation once telcos have successfully gone digital. Telco companies and systems are connection-centric. Barriers have built up between their marketing, network management, and IT functions, and their front-end and back-end systems aren’t integrated. Contrarily, Internet companies keep their focus on their users, and have updated their organizations to quickly respond to user demands. As a result, a service that takes Internet companies a few months to develop and launch might take some telco companies one or two years. With such a long time-to-market, telcos can hardly stay ahead of the competition in the Internet era, where everyone is fighting for rapid iteration and innovation. DT will not only help telcos sharpen their competitive edge in new markets such as Internet of Things (IoT), video, and cloud, it will also support the cloudification of networks and operations systems to make telcos more agile. Telcos need the support of external enablers, and policy makers need to define issues of transitional and long-term period. Dynamic rules for capturing the full potential of future ICT networks can require redisinging or building new institutions, transformation of regulatory practice and governance, new skills and competencies, and significant changes to mindset and culture (legacy systems, institutions and processes).
From a technology point of view, we are going to see virtualized autonomous networks that are obviously moving into 4G, 5G, and it will be data centric and security-centric. The telcos of course are in danger of being pushed down into a dumb pipe because it is the Internet players that are developing increasingly strong customer relationships. Telecom companies are often regulated more than Internet players and this asymmetry represent a problem in terms of competitiveness and capability to deliver innovative services. Software Defined Networks (SDN) and Network Function Virtualization (NFV) could be taken as a different expression of the overall transformation trend toward network softwarization which is deeply impacting and bringing Telecom and ICT Industry. These changes will have a broader impact on society, including aspects of regulation, policy, social impacts and new business model. Detailed following of technological changes and trends, with understanding consequences it has on society as a whole, is the first step towards creation of advanced regulatory frameworks that can answer to modern trends in ICT sector.

II. FORECAST TOWARD ICT NETWORKS

A. Technology vision of future ICT networks

With the increase in traffic, content and applications, connectivity has become part of our work and life. From technology perspective competing standards requires much more complex networks scenario. The future network infrastructure have to support complete redesign of services and service capabilities, architectures, functions, access as well as connection security. The important challenges that must be addressed by 5G networks is higher capacity, lower E2E latency, massive device connectivity, reduced capital and operation cost and consistent Quality of experience (QoE) provisioning, [1]. New 5G architecture consisting of three generic services: extreme mobile broadband, massive of machine type communication and a spectrum toolbox, [2].

Moreover, the technological advances proposed for beyond 4G and 5G mobile networks still mostly focus on capacity increase, which is fundamentally constrained by the limited radio spectrum resources as well as the investment efficiency, and therefore will always lag behind the growth rate of mobile traffic. Unlike the communication resource, which is fundamentally limited by the bandwidth and power, the computing and caching (i.e., memory) resources are abundant, economical, and sustainable. Various attempts have been made to accommodate expanding mobile services through the use of sustainable non-communication resources. For example, to deliver multimedia contents (which constitute most of mobile traffic), proactive pushing through data caching has been proposed at both base stations and mobile terminals. In addition to use caching to provide “individualized” services to mobile users, savings in communication resources can also achieved through computing, in which contents intended for different mobile users are logically processed through coded multicasting or similar techniques, [3]. The three types of resources must be treated as equally essential and intrinsic in order for mobile systems to be scalable and sustainable. Instead of only the communication dimension, the capabilities of future mobile systems should be visualized by a native mobile 3C cube in which different services are supported by the 3C core functionalities. In order to analytically characterize the mobile 3C cube, first their metrics and mode of operations so that the impact of 3C can be quantified must be defined. In the native 3C form, the capability of the mobile network is determined by three vectors: Communication, Cache, and Computing.

The “communication vector” of the mobile system pertains to its ability to deliver information streams over an imperfect channel with given bandwidth and power. Its capability is measured by the data rate R (unit: bit per second per Hertz), with a relation with the system bandwidth and the signal power to noise ratio is well understood by Shannon’s capacity formula. Note that communication operations (e.g., modulations and channel coding) only protect but do not alter the information stream upon delivery. The “caching vector” of the mobile system pertains to its ability to buffer or store a certain amount of information (i.e., bitstreams) at nodes within mobile networks. Its capability is typically measured by the memory size (unit: byte). While neither protecting nor altering the information streams, caching operations introduce non-causality or time-reversal into the system, in turn increasing the system’s ability to deliver information over longer periods of time. The “computing vector” of the mobile system pertains to its ability to perform logic or algebraic operations across information streams. Unlike communication or caching operations, computing operations alter the information bits such that additional logic operations must be performed at the destination in order to recover the original information streams. By formulating “caching” as a form of non-causal operations and “computing” as a form of logic operations across information streams, the three native and complementary operations for mobile 3C systems has been established.

B. Stakeholders analyses

Softwarization will be a radical change of paradigm. Current telecommunications infrastructures have been exploited with purpose-built equipment designed for specific functions. In the future, network functions and services will be virtualized software processes executed on distributed horizontal platforms mainly made of standard hardware resources. Cost savings alone will not be enough to assure the future sustainability of the telecommunications industry (it is key to enable innovative service paradigms). Standards development organizations (SDOs), exist to assure the development of consensus-based, quality standards. These formal standards are needed in the telecommunications market to achieve functional interoperability. The standardization process takes years, and then a vendor still needs to implement the resulting standard in a product. This prevents service providers (SPs) who are willing to venture into new domains from doing so at a fast pace. With the development SDN and NFV, open source
technology is emerging as a new option in the telecommunications market. In contrast to SDOs, open-source software (OSS) communities create a product that may implicitly define a de-facto standard based on market consensus. Therefore, SPs are drawn to OSS, but they face technical, procedural, legal, and cultural challenges due to their lack of experience with open software development. The question therefore arises, how the interaction between OSS communities, SDOs and Industry Fora (IF) can be organized to tackle these challenges. A number of stakeholders are involved in the realization of this SDN/NFV-driven architecture, [4].

Most actors will perform more than one role at the same time. For example, traditional ISPs fulfill the role of infrastructure provider, virtual service infrastructure provider, and service provider. Users: Users, i.e. end/enterprise users, retail, or over-the-top (OTT) providers, request, and consume a diverse range of services. In general, users have no strong opinion about how the service is delivered as long as their quality of experience expectations is satisfied.

Service Providers (SPs) accommodate the service demand from users by offering one or multiple services, including over-the-top service and X-play services (e.g. triple play). The service provider realizes the offered services on a (virtualized) infrastructure via the deployment of virtualized network functions (VNFs). Virtual Service Infrastructure Providers (VSIPs) deliver virtual service infrastructure to SPs, meeting particular service level requirements by combining physical network and cloud resources into service infrastructure meeting particular SLA requirements implemented through NFV-enabled network applications. These network applications might involve resources (or network functions) that are either implemented in traditional network hardware, or as virtualized network functions, (NF). These are the result of an orchestration system that interacts with the network control system as well as the cloud control system. Infrastructure Providers (InPs) own and maintain the physical infrastructure and run the virtualization environments. By virtualizing the infrastructure, they open up their resources to remote parties for deploying virtual NFs. The reusable physical resources comprise all possible resource options (computing, storage, and networking), and they span the entire service delivery chain from the end-user gateway and set-top-box over the access, aggregation, and core network up to the cloud. Hardware Vendors provide the physical devices that are deployed by the infrastructure providers. The shift away from specialized equipment toward reusable, industry- standard high-volume servers, switches, and storage devices can reduce the total costs of InPs (furthermore, they cost less than manufacturer-designed hardware and increase flexibility). The hardware must provide an interface toward the controller systems. Software Vendors, including OSS developers, deliver the implementation of the logic that is used to optimally deploy the services on the physical infrastructure. Today a patchwork of specialized software products exists to realize that functionality. The most relevant software for the SDN/NFV architecture is those that focus on the following, as given in Figure 1, [4].

![Figure 1. Future software oriented SDN/NFV architecture](image)

For each of these, OSS communities have developed or are developing viable alternatives to proprietary software. SDOs and IF: The networking industry today is very much standards-driven to make a product or service safe (safety standards) and interoperable (interface standards), while making the industry as a whole more efficient.

C. Content delivery networks

How to effectively utilize these existing resources for massive content distribution is a fundamental question current and future networks must address. It is proposed that the leveraging of ubiquitous caching and computing at the wireless network edge will radically change future mobile network architecture, and can potentially solve the current bottleneck for massive content delivery. The recent trend toward network softwarization is transforming the networking industry into an open ecosystem, with three main stakeholders: users, operators and content providers, Figure 2, [5].

The business of wireless caching involves three key stakeholders that together form a complex ecosystem. The users of telecommunication services are primarily the customers and consumers of the content, but in the case of wireless caching they are also active stakeholders. Users might be requested to help in the form of contributing with their own resource (e.g., in the case of coded caching it will be memory and processing, or in device-to-device (D2D), caching it will also be relaying transmissions, and they will end up spending energy for the benefit of better performance. On the other hand, one could envision users employing D2D technology to enable caching without the participation of other stakeholders. Due to the complexities mentioned above, however, efficient wireless caching will require heavy coordination and extensive monitoring/processing. Hence, D2D approaches will be limited to restricted environments. The operators of telecommunication services
networks are well placed for wireless caching. Due to the particularities of coded caching and multi-access caching, operators are in a unique position to implement new protocols in base stations, affect the standards for new mobile devices, and develop big data processing infrastructure that can realize wireless caching. Nevertheless, for reasons related to encryption, privacy, and global popularity estimation, operators might not be able to install these technologies without the cooperation of the other two stakeholders.

Figure 2. Stakeholder’s analysis

The providers of Internet content are champions of trust from the user community. Apart from the security keys, they also hold extensive expertise in implementing caching techniques in core networks. From this advantageous position, they can positively affect the progressive evolution of caching in wireless networks. It promises to qualify network owners and providers, to increase the pace of innovation, diversify the supply chain for networking hardware and software, and drive the transformation of mobile networks into a highly capable platform in supporting emerging IoT and data science applications, among others. Mobile transport networks will play a vital role in future 5G and beyond networks. In particular, access transport networks connecting radio access with core networks are of critical importance. They will be required to support massive connectivity, super high data rates, and real-time services in a ubiquitous environment. To attain these targets, transport networks should be constructed on the basis of a variety of technologies and methods, depending on application scenarios, geographic areas, and deployment models.

D. Net Neutrality

5G is not just the next evolution of 4G technology; it is a paradigm shift. 5G is not only evolutionary (providing higher bandwidth and lower latency than current-generation technology); more importantly, 5G is revolutionary, in that it is expected to enable fundamentally new applications with much more stringent requirements in latency (e.g., real time) and bandwidth (e.g., streaming). 5G should help solve the last-mile/last-kilometer problem and provide broadband access at much lower cost because of its use of new spectrum and its improvements in spectral efficiency. Flexibility, ease of use, the dynamic nature of the network, Quality-of-Service, and anytime/anywhere availability, are some of the benefits for end users in this move to 5G. 5G is an enabler of exciting use cases that will transform the way people live, work, and engage with their environment. In the short term, 5G can support exciting use cases such as the IoT, smart transportation, eHealth, smart cities, entertainment services, etc. [6]. Net neutrality is “the principle that Internet service providers should enable access to all content and applications equally, regardless of the source, without favoring or blocking particular online services or websites” (Oxford Dictionary), [7]. Net neutrality is a highly politicized topic. Net neutrality debate should be extended to all the actors involved in the Internet delivery chain. Content delivery networks play a key role by storing content closer to users, thereby reducing transit costs and improving performance for that content; for device builders may introduce biases through the features of their products (possibly colluding with some other actors); and search engines (seen as service providers) directly affect the accessibility (visibility) of content. Regulatory Agencies therefore face the delicate task of defending fairness and universality principles in this complex ICT ecosystem, where ever changing technical and business conditions prevent (or considerably complicate) analysis and comparison.

III. ADVANCED REGULATION APPROACH

Digital transformation is accompanied by profound social and institutional changes. As a result, realizing the full potential of future ICT networks can therefore require redesigning of regulatory framework and even radical changes in adoption of innovation. The role of policymakers is to lead regulatory framework change, empower innovations and support effective adoption of new technologies. Ensuring affordable and competitive BB access (fixed and mobile) is essential. Managing of risks in DT is part of regulation framework: impact on job market, education, Public Safety, Green Energy, Privacy and Security, as given in Figure 3.

Figure 3. Regulation framework

Understanding future technology, policymakers must identify the key stakeholders/actors in creating ICT society. Policymakers must be aware of the critical role in recognizing limitations in current regulatory model and to support fast growing ICT industry. Reforms are essential to capture the ongoing technology changes and ensure their integration in society as a whole to achieve max
transformation impact. With the explosive growth of mobile devices, collecting user mobility information will generate huge amounts of data. Thus, big data analytics to extract the required mobility information is another challenge in mobility-aware caching. In order to take advantage of the user mobility pattern, some personal information (e.g., home locations and work place locations) may be divulged in the collected mobility information. This will certainly cause some concerns on privacy issues. Thus, how to extract useful user mobility information without touching individual privacy is important, [8]. Spectrum sharing is area where max efficiency is needed. 5G services will require novel and more complex ways of interaction and collaboration among operators. Spectrum sharing is one example of increased cooperation among operators, [2]. The use of exclusively licensed spectrum build the basis for mobile network operators to deliver good quality of service to their users. This type of spectrum usage should be prioritized, especially for applications requiring high reliability of data transmissions. However, as we are facing an exponential increase in the volume of wireless data traffic, we need to be prepared for supplementary solutions to serve the mobile users demand in space and time. The spectrum sharing enables include, for example, spectrum opportunities detection and dynamic frequency selection/dynamic channel selection, and use of a geo-location database. The energy efficiency can be considered at a device side or a network side, though the distinction will be blurred by the dual role of the mobile wireless devices in 5G. As networks densification continues to meet the capacity demands, it becomes increasingly important to implement new lean signaling procedures, to be able to activate and deactivate network nodes depending on the traffic load, or to switch off some of the node functionality in low load modes. The move to IP-based telecommunications expands the functions and features those telecommunications applications and services can provide. Nowadays, citizens are getting used to new ways of agile communications supporting media-enriched and context-aware information. However, the adoption of these evolved technologies in emergency communications between citizens and public authorities faces a series of barriers, including the lack of harmonized and interoperable solutions. Different initiatives worldwide are addressing the need for specifying a stable IP-based next generation emergency communications framework, [9].

A. Case study – regulation in Bosnia and Herzegovina

Telecommunications companies in Bosnia and Herzegovina are in quite unique position, since delivery of content and application services is possible only in 3G networks. Increasing user demands and competitive market creates a need to improve offered services as well as the degree of utilization of existing resources. In Bosnia and Herzegovina OTT providers are threats to three leading telecom operators. Decoupling of the service from the network have arisen and raised questions over the regulation framework that could answer to all future challenges. Innovative OTT services are cheaper than traditional but with low quality. The first regulatory issue refers to defining activities of OTT providers and to define online service such as voice telephony, SMS and television that can be regarded as potentially substituting for traditional telecommunications services such as voice, SMS and television. Specially designed regulatory legal act must protect users, considering that current acts in Bosnia and Herzegovina do not apply to the activities of OTT providers. Furthermore, detailed informing can contribute to user security.

IV. CONCLUSION

The role of a regulating agency is to recommend policies that guarantee widely accepted principles. The regulatory framework needs to evolve along with industry it regulates. It is up to the national policymakers to provide successful creation of ICT future that has a potential to transform society as a whole. This paper highlights the need for dynamic rules for capturing the full potential of future ICT networks, and can require redesigning or building of a better regulatory framework of fairness and the guarantee of fair competition among actors and the preservation of the motivation for investment toward satisfying end users better. Regulatory Agencies therefore face the delicate task of defending fairness and universality principles in this complex ICT ecosystem, where ever changing technical and business conditions prevent (or considerably complicate) analysis and comparison.

REFERENCES

Abstract - In the fast growth of mobile data services, rich services deliver a brand new experience to end users, and also bring about new opportunities for operators. Some applications, such as vehicular and industrial applications, demand a level of reliability that wireless communication systems typically are not able to guarantee. This paper provides a framework that enables these applications to make use of wireless connectivity only if the transmission conditions are favorable enough. In this paper, we will partially compare the fourth and future fifth generations of mobile networks and their applicability and were carried out measurements of data traffic amount and quality characteristics.

Keywords: Ultra-Reliable Communication, fifth-generation, mobile communication systems

I. INTRODUCTION

Few past years, there was been a tremendous surge in the demand for mobile and wireless connectivity, which is forecasted to grow exponentially within the near future. However, the Fifth-Generation (5G) mobile communication system [1] that is currently under discussion will not only have to cope with an increasing demand of traffic volume, but also provide a wider range of applications with new requirements in terms of reliability, availability and efficiency. Instead of integrating new radio access concepts such as Device-to-Device (D2D), Vehicle-to-Vehicle (V2V) communications, Massive Machine Type Communications (MMC), or Moving Networks (MN), the support of Ultra-Reliable Communication (URC) is seen as a key enabler for 5G communication systems [2].

Link reliability is the ability of a radio link to transmit and receive a certain amount of information successfully within a predefined deadline. System reliability is the ability of a system to accurately indicate the absence of link reliability to the application, and at the same time, to ensure the presence of link reliability as often as possible when required by the application [3, 4]. URC services such as road safety applications require very high rates within low deadlines circa 100 ms. Due to the sensitive nature of these applications, it is from very high importance to warn the application about the lack of link reliability according to the specific requirements of each application. Wireless communication systems are not designed to provide reliability at all times and in every reception scenario, as this would result in an overdesigned system with a very ineffective air interface in terms of data rate and power consumption. With this approach may harm the acceptance of URC services and restrict their usage. In this paper we define the URC concept in a general manner, i.e., without relying on details of any air interface requirement or radio transmission scheme. This method is motivated by the fact, that definition from the application point of view is required in order to allow URC services to be deployed in a wide variety of scenarios. From this point of view, the implementation details related to the wireless communication system are not included in the suggested URC concept.

The rest of the paper is organized as follows. Section 2 gives a brief overview and theoretical representation of the system concept for Ultra-Reliable Communication. Section 3 presents the conducted experimental measurements of data traffic amount and quality characteristics of two Bulgarian mobile operators. Section 4 concludes the paper.

II. KEY ENABLERS FOR 5G COMMUNICATION SYSTEMS

Despite the fact that it is practically impossible to ensure error-free wireless communication - it is feasible to derive boundary conditions for the transmission success. As illustrated in Fig. 1, the system concept for URC is based on a “Reliable Transmission Link” (RTL) that is set to transmit packets successfully and within a predefined deadline, and an “Availability Estimation and Indication” (AEI) mechanism that is able to reliably calculate the availability of the RTL under the corresponding conditions. Availability Indicator (AI) signals the outcome of the AEI to the application. An application requests an RTL by sending an Availability Request (AR) to the AEI. Depending on the implementation characteristics, the AR contains information such as the packet size, the maximum acceptable delay until successful reception or the maximum allowable error probability.

For the availability estimation, the AEI needs to monitor the channel conditions, e.g., by evaluating the Signal-to-Noise and Interference Ratio (SINR) and/or the ACK/NACK statistics of the retransmission protocols used at link level.
Typically, the AI is a binary value, i.e., either RTL available (AI=1) or unavailable (AI=0). After indicating the RTL availability, the application will be able to use it by transmitting data packets over the RTL (it is not shown in Fig. 1).

### A. Mathematical representation

In this section we formulate mathematically the URC concept by adopting a simple time-slotted model, in which each time slot (τ) corresponds to the time interval [t, t + \(D_{dt}\)], where \(D_{dt}\) is the maximum delay tolerated by the application. According to this definition is defined:

\[
RTL(τ) = \begin{cases} 
1, & \text{transmission is successful} \\
0, & \text{transmission not successful}
\end{cases}
\]  

(1)

For the availability indication is used a simple binary signaling format per time slot:

\[
AI(τ) = \begin{cases} 
1, & \text{AI}=1 \\
0, & \text{AI}=0
\end{cases}
\]  

(2)

where AI refers to availability of RTL for time slot τ (AI=1) and the non-availability of RTL for time slot τ (AI=0).

On Fig. 2 is shown the URC state transition probabilities divided into two stages. The principle of the URC concept is that an application should rely on the wireless communication only in those situation in which the link reliability is guaranteed with a certain probability. The AI indicates the availability of a RTL for time slot τ to the application, the probability of successful transmission for the time slot τ must be over a certain value, \(P_{UR}\), according to the application requirements. This criteria is refer as the ultra-reliable requirement, which can be expressed by (3):

\[
P_{\|\|} = Pr\{RTL(τ) = 1|AI(τ) = 1\},
\]  

(3)

where \(P_{\|\|} \geq P_{UR}\). The idea of the URC system design is to maximize the availability of the RTL under the predefined requirement:

\[
\max P_{I} = Pr\{AI(τ) = 1\}
\]  

s.t. \(P_{\|\|} \geq P_{I\|}\),

(4)

It can be concluded that there are two possibilities in order to improve the URC concept:

- improving the transmission model (\(Pr(RTL(τ) = 1)\));
- improving the estimation of the AI (\(Pr(AI(τ) = 1|RTL(τ) = 1)\)).

The first possibility can be achieved by more effective modulation and forward error correction (FEC) schemes, whereas the second possibility can be accomplished through more precise channel estimation and prediction methods.

It is interesting to note that the two probabilities \(P_{01}\) and \(P_{10}\) in Fig. 2 correspond to the Type I and Type II errors [5] in statistical probability analysis:

\[
P_{01} = Pr\{RTL(τ) = 0|AI(τ) = 1\}
\]  

(6)

\[
P_{10} = Pr\{RTL(τ) = 1|AI(τ) = 0\}
\]  

(7)

### B. URC system concept

In this section we will explain the URC concept by using a simple example based on the predicted SINR. We assume that the SINR for time slot τ is \(Γ(τ)\) and define that the transmission is successful for time slot τ if the corresponding SINR is larger than or equal to a given threshold \(Γ_1\) (\(Γ(τ) \geq Γ_1\)), which is given by the used modulation and FEC scheme including the use of retransmissions. The AEI signals to the application AI=1 if the predicted SINR for time slot τ, \(Γ_p(τ)\), is larger than or equal to the threshold \(Γ_1\) (\(Γ_p(τ) \geq Γ_1\)). We can formulate the optimization problem of the URC system model as:

\[
\max P_{I} = Pr\{Γ(τ) \geq Γ_1\}
\]  

s.t. \(P_{\|\|} = Pr\{Γ(τ) \geq Γ_1|Γ_p(τ) \geq Γ_1\}\),

(8)

where the Type I and Type II error can be expressed as:
\[ P_{qi} = \Pr \{ \Gamma_2(t) < \Gamma_1 | \Gamma_i(t) \geq \Gamma_i \} \quad (9) \]

\[ P_{qi} = \Pr \{ \Gamma_1(t) \geq \Gamma_1 | \Gamma_i(t) < \Gamma_i \}. \quad (10) \]

In this model, it would be possible to improve the URC concept by decreasing \( \Gamma_i \) by means of more robust modulation and FEC schemes, or by optimize the computation of \( \Gamma_i(t) \) in order to predict more accurately the availability of the RTL.

III. DATA USAGE AND TRAFFIC ANALYSIS

In this section we will compare two Bulgarian Mobile operators and their data traffic amount and quality characteristics, will describe the benefits of developing and implementing next generation mobile network standards and what are the key point which eventually needs improvement. To highlight the differences, the research was done in two different locations as follows:

- **Service Provider – Mid-size City** with approximately 76,000 citizens
- **Service Provider – Capital City**

Used for the study Base Stations (BS), from both Service Providers (SP) are from one and the same manufacturer. This approach, to compare two base stations from two different cities has selected to highlight the traffic usage, throughput and TBF Drop Rates in 2G/3G and LTE standards used in the selected BSs.

So far for Service Providers, the ultimate goal of network optimization is the improvement of user experience and enhance user satisfaction. Nonetheless, network optimization does not perfectly matches Quality of Service (QoS) improvement. Traditional network Key Performance Indicator (KPI) optimization largely deals with signaling, such as the Temporary Block Flow (TBF) establishment success rate and attach success rate. Although operators have been paying attention to them, these indexes cannot accurately reflect QoS. QoS indicators like “slow page loading”, “slow download rate” and “failure to open page” are indexes on the data service layer. As mentioned above, the TBF drop is KPI which is related to 2G data called GPRS/EDGE in GSM Network. TBF drop indicate how often the services is disconnected when GPRS or EDGE data Services are used [6].

A. 3G/UMTS

On September 1995, officially first GSM network in Bulgaria took place. It has been started working with six base stations covering a few central parts of the Capital City. The total number of active 3G/UMTS base stations, twenty years later in this country is nearly 5000. The 3G coverage reaches 96% of the areas in the country and 99% of its population.

The diagrams of current TBF drop rates in downlink and respectively uplink direction are shown on Fig.3 and Fig.4.

\[
\begin{align*}
\text{Time (Days)} & \quad 0 \quad 1 \quad 2 \quad 3 \quad 4 \quad 5 \quad 6 \quad 7 \quad 8 \quad 9 \quad 10 \quad 11 \quad 12 \quad 13 \quad 14 \quad 15 \quad 16 \quad 17 \quad 18 \quad 19 \quad 20 \quad 21 \quad 22 \quad 23 \quad 24 \quad 25 \quad 26 \quad 27 \quad 28 \quad 29 \\
\text{Throughput (Mbps)} & \quad 0 \quad 20 \quad 40 \quad 60 \quad 80 \quad 100 \quad 120 \quad 140 \quad 160 \quad 180
\end{align*}
\]

*Figure 3. Measured TBF Drop Rates in Downlink direction for a month*

As mentioned above, the statistics are from BSs, physically located in two different geographical locations.

As shown in Fig.3, the second Service Provider’s BS is either not optimally utilized or very precisely planned and implemented in the selected region, because of the low volume of TBF Drop Rate in downlink direction. Another parameter, which is from major importance for consumers and in which Service Providers are working to improve, is throughput. Large number of different throughput values for 3G/UMTS standard are known.

However, on Fig.4 and Fig.5 are depicted diagrams of currently measured throughput in Mbps.

The metrics are measured in uplink and downlink direction for a period of one month. In both figures, Service Provider 2 notably have wider throughput. In downlink, SP2 has peak value of 164 Mbps, where SP1 has just 20,5 Mbps and in uplink, SP2 has maximum value of 73,7 Mbps where SP1 has almost constant 12 Mbps with peak from only 14 Mbps.

\[
\begin{align*}
\text{Time (Days)} & \quad 1 \quad 2 \quad 3 \quad 4 \quad 5 \quad 6 \quad 7 \quad 8 \quad 9 \quad 10 \quad 11 \quad 12 \quad 13 \quad 14 \quad 15 \quad 16 \quad 17 \quad 18 \quad 19 \quad 20 \quad 21 \quad 22 \quad 23 \quad 24 \quad 25 \quad 26 \quad 27 \quad 28 \quad 29 \\
\text{Throughput (Mbps)} & \quad 0 \quad 10 \quad 20 \quad 30 \quad 40 \quad 50 \quad 60 \quad 70 \quad 80 \quad 90
\end{align*}
\]

*Figure 4. Throughput, measured in Megabits/s in Downlink direction for a month*

*Figure 5. Throughput, measured in Megabits/s in Uplink direction on monthly basis*
Last, but not least, Fig.6 represent graphical results of studied and analyzed Data Traffic from the two Service Provider’s Base Stations. Measured data traffic volume is for period of one month in Megabytes.

### B. Long Term Evolution

Since the summer of 2014 the fourth generation mobile internet (4G) started to be offered in Bulgaria. As of September 2015, Bulgarian customers using Long Term Evolution (LTE), which is Fourth Generation (4G) wireless broadband technology, are 0.3% of all Internet using mobile users. According to offered plans, the high-speed internet access can provide download speeds of up to 75 Mbps and upload speeds of up to 25 Mbps. The bandwidths used by the fourth generation mobile networks are 900, 1800, and 2100 MHz. In 2015, the 900 MHz band is divided among the largest three operators in the country and in early September 2015 the Commission for Regulation of Communications (CRC) announced that it will hold a tender for permits for using the 2,50-2,69 GHz band.

With high data speed, the LTE can provides downlink peak rates of 300 Mbps. Some of the advantages of LTE over 3G/UMTS are High Speed, High Capacity, better Spectral Efficiency and others [7, 8]. To compare the two standards and to present the advantages of using the LTE, we analyze the data from one Base Station running LTE and represent it graphically (Fig.7 and Fig.8).

### IV. CONCLUSION

Comparing the future fifth-generation mobile networks with current and the previous generations of mobile services were not so extremely sensitive in manners like delay. Expected characteristics for 5G networks are data rates of tens of megabits per second for tens of thousands of users; data rates of 100 megabits per second for metropolitan areas and significantly enhanced spectral efficiency, compared to 4G. To meet these specific requirements contemporary mobile networks should be improved in signaling efficiency, better coverage and to offer lower latency.

The expectations of fifth generation mobile networks are the mobile subscribers to grow even more, including D2D, V2V communication and Internet of Things (IoT), which demands a lot of improvements.

Abstract - In this paper, a comparison of Internet of Things protocols used for data transfer in Internet of Things constrained networks is presented. Setting up such a network with a large number of physical interconnected devices can be a challenge. In the IoT world, one of the main challenges is to efficiently support communication in constrained networks. This can be achieved using TT message queuing Telemetry Transport and CoAP Constrained Application Protocol protocols. Choosing the appropriate protocol can be difficult while developing IoT application. There are several conditions that need to be considered while determining which protocol should be used. In this paper, we will evaluate performance and compare these protocols through different scenarios.

Keywords: Internet of Things, data protocols, TT, CoA, communication

I. INTRODUCTION

Everyday growing number of objects connected to the Internet Worldwide has promoted the Internet of Things technologies and protocols as one of the most commonly used in the modern systems. IoT refers to the networked interconnection of everyday objects which are often equipped with electronic circuits and sensors [1]. In the IoT sense, these objects can refer to a wide variety of small devices embedded with electronics, software, sensors and network connectivity often integrated into larger systems, for example, transportation systems, smart cities, telecommunication networks, healthcare industry and many others. According to [2] Gartner says that 8.4 billion connected things will be used worldwide in 2017, up 31 percent from 2016. A total number of connected objects will reach 20.4 billion by 2020. Implementation of the IoT technologies extends system's ability to gather, analyze and distribute data and thus improve efficiency. Furthermore, IoT has made Internet sensory (temperature, pressure, vibration, light, moisture, stress) [3] thereby achieving improved monitoring, analyzing and tracking systems. During the implementation of the IoT technology, several things must be considered of which the most important are a hardware platform, network protocol and data protocol. Hardware requirements can be broken up into five main components: a power source and power management, processor and memory storage, ability to gather data from sensors and implemented modules for wireless communication. On the side of the connectivity between IoT devices, there are a variety of communication standards and protocols used, of which most widespread are IEEE 802.15.4, Internet Protocol version 6 (IPv6) and IPv6 over Low-Power Wireless Personal Area Network (6LoWPAN) [4]. Regardless the specific communication protocol used to deploy IoT network, all the IoT objects should make their data available to the other side, which can be another IoT object, application or the Internet. This can be achieved by sending the data to a web server or by employing the cloud through the use of Application Programming Interfaces with built-in functions for end-users [5]. This paper focuses on the data protocols that handle the communication and data transfer between the objects or applications. These protocols are application layer protocols that are used to send latest data or commands to servers which are responsible for forwarding or processing information. Choosing the appropriate protocol can be difficult while developing IoT application. There are several conditions that needs to be considered while determining which protocol should be used of which most important are the amount of data to send, the frequency of data transfer and hardware platform. Also, most of the IoT devices are installed in an isolated area where connection to the Internet is limited because it is realized over slow DSL connection or cellular network. In such environment, unreliability which reflects high packet loss rate is one of the main disadvantages [6].

II. IOT PROTOCOL STACK

There are several protocols proposed for M2M/IoT communication with a focus on mentioned constrained environments. Most frequently adopted protocols are MQTT (Message Queue Telemetry Transport) and CoAP (Constrained Application Protocol), XMPP (Extensible Messaging and Presence Protocol), RESTFUL Services (Representational State Transfer) and AMQP (Advanced Message Queuing Protocol). IoT applications can be simplified in the way of the error handling which can be done using these protocols [6].

Our main task is to test the performance of data protocols and compare them in different scenarios. Results can be helpful in determining which protocol should be used. After a brief description of MQTT and CoAP protocol, testing results are presented.
A. Message Queue Telemetry Transport (MQTT)

MQTT is a machine-to-machine (M2M)/Internet of Things connectivity protocol for use on top of the TCP/IP protocol stack which was designed as an extremely lightweight broker-based publish/subscribe messaging protocol for small code footprints (e.g., 8-bit, 256KB RAM controllers), low bandwidth and power, high-cost connections and latency, variable availability, and negotiated delivery guarantees [7]. In the hub and spoke model of Message-Oriented Middleware messaging server forwards messages from sensor devices to monitor devices [8]. In such architecture, a device whose main task is to continuously produce and send data to the server is defined as publisher. The central server, an MQTT broker, collects messages from publishers and examines to whom the message needs to be sent. On the other side, every device which had previously registered its interests with a server will keep receiving messages until the subscription is canceled (Fig. 2).

Using this architecture, publishers and subscribers do not need to know for each other which is one of the major advantages of this protocol. Devices that send data need not to know who are the clients that are subscribed for receiving data and conversely [9]. Further to this, the publishers and subscribers do not need to participate in the communication at the same time and do not need to be familiar with each other [10]. It is intended for devices with limited power and memory capabilities, where the network is expensive, has low bandwidth or is unreliable. One of the key requirements of an Internet of Things concept is low network bandwidth used to send data and minimal device resource requirements. While attempting to ensure reliability and delivery, MQTT has met these requirements [11]. This protocol has been applied in a variety of embedded systems. For example, hospitals use this protocol to communicate with pacemakers, oil and gas companies use it to monitor oil pipeline thousands of miles away. Facebook uses this protocol for messaging applications [12].

B. Constrained Application protocol (CoAP)

Usage of RESTful (Representational state transfer) Web services on the Internet has become an essential part of building applications. The work on Constrained RESTful Environments (CoRE) targets the realization of the REST architecture in a convenient form for the most constrained nodes (e.g., 8-bit microcontrollers with limited RAM and/or ROM) and networks (e.g., 6LoWPAN), Constrained networks (e.g., 6LoWPAN) supports the IPv6 packets fragmentation into small link layer frames, but this causes major reduction in probability of packet delivery. This effect solves Constrained Application Protocol (CoAP). CoAP aims to keep message overhead small, thus limiting the need of fragmentation.

Main goals of CoAP is to design a generic web protocol for the special requirements of this constrained environment, focusing on energy, building automation, and other machine-to-machine (M2M) applications. The goal of CoAP is to but realize a subset of REST common with HTTP, optimized for M2M applications. Although CoAP could be used for remodeling simple HTTP interfaces into a compact protocol, and more importantly it offers features for M2M such as multicast support, built-in discovery and asynchronous message exchanges.

CoAP has the following main features:
- Web protocol fulfilling M2M requirements in constrained environments
- UDP binding with optional reliability supporting unicast and multicast requests.
- Asynchronous message exchanges
- Low header overhead and parsing complexity.
- URI and Content-type support.
- Simple proxy and caching capabilities.
- A stateless HTTP mapping, allowing proxies to be built providing access to CoAP resources via HTTP in a uniform way or for HTTP simple interfaces to be realized alternatively over CoAP
- Security binding to Datagram Transport Layer Security (DTLS)
III. NETWORK ARCHITECTURES

A. MQTT client

Any IoT object can be MQTT client that sends or receives telemetry data. This could be any device from a microcontroller up to a server. The type of the MQTT client (subscriber or publisher) depends on its role in the system. It can produce or collect telemetry data. In both cases, MQTT client should first connect to a messaging server using a particular type of message explained in the following chapter. After the connection is successfully established, a client must declare himself whether he is a subscriber or publisher. To distinguish data sent by the publisher, a topic string is used. For example, a client can publish temperature and humidity values using a different string for each value (e.g. temp/25 or hum/40). On the other side, if an MQTT client wants to receive the data, he must subscribe to the specific topic. To make an MQTT client from a device, an MQTT library must be installed and connection to an MQTT broker must be established over any kind of network. For example, MQTT client can be a small computer (Arduino or Raspberry Pi) connected to a wireless network with a library strapped to the minimum or a typical computer running a graphical program. The client implementation of the MQTT protocol is simplified and very straightforward [13]. Client libraries can simplify the process of writing MQTT client applications. MQTT libraries are available for different types of programming languages and platforms, for example, JavaScript, PHP, C, C++, Android, iOS etc. For the initial implementation, Python library will be used.

B. MQTT server

An MQTT broker is a central device in mentioned hub and spoke model. The main responsibilities of an MQTT broker are handling communication between MQTT clients and distributing messages between them [6]. A broker can handle up to thousands connected MQTT client at the same time. When the message is received, the broker must find all the clients that have a subscription to the received topic [13]. It is responsible for receiving messages from the sensors connected to the device with implemented MQTT client library and forwarding it to the designated remote device. There are plenty other tasks and responsibilities that are handled by the broker. First of all, there is authentication and authorization of the clients for the security purposes. A client can send username and password within connect message that will be checked by the broker. On the broker side topic permission is implemented to restrict the client to publish or subscribe. Furthermore, for encrypted communication between the broker and the clients, TLS (Transport Layer Security) and SSL (Secure Sockets Layer) encryption are used, the same security protocol that can be used by the HTTP protocol [5]. It is also possible to implement custom authentication or authorization logic into the system [13]. There are several message brokers that implement MQTT protocol like Mosquito - open source MQTT v3.1/v3.1.1, Broker [14] and HiveMQ – an enterprise MQTT broker [13].

C. MQTT over protocols

Using MQTT over WebSockets every browser can be MQTT device. Due the publish/subscribe pattern of MQTT a real-time communication between end device (e.g. temperature sensor) and monitor device (e.g. a web application) is achieved. Using QoS 1/2 message will arrive on the client or broker at least once/exactly once. The broker will queue all messages which client misses when it is not connected. Messages which are retained on the server are delivered when a client subscribes to one of the topics instantly. Paho.js [15] implements this behavior and will be used in initial testing.

D. CoAP cloud system

Transport layer protocol which is used by CoAP is UDP (User Datagram Protocol) so each CoAP message occupies the data section of one UDP datagram. CoAP messages are exchanged asynchronously between CoAP end points. Packets order and retransmission depends on software stack. As already mentioned CoAP was designed according to the REST architecture and because of that it is similar to HTTP protocol so CoAP makes use of GET, PUT, POST, and DELETE methods in a similar manner like HTTP. Reliable message transmission is provided by marking a message as confirmable (CON). Recipient sends acknowledgment message (ACK), shown in figure 2.

A message that does not require reliable transmission (for example single measurement of sensor data) can be sent as a non-confirmable message (NON). CoAP also supports the use of multicast IP destination addresses, enabling multicast requests [16]. CoAP was usually designed to connect low power electronic devices (e.g. wireless sensors) with Internet based systems. In many cases data is collected for subsequent processing. A CoAP device is connected to a cloud-based system via an HTTP proxy using a standard CoAP-HTTP mapping, figure 3. Using a proxy/bridge adds an additional communication overhead and increases message latency.

![Figure 2. Reliable and non-reliable transmission with CoAP](image-url)
In CoAP, a sensor node is typically a server, not a client or it can be both. The sensor provides resources which can be accessed by clients to read or alter the state of the sensor. As CoAP sensors are servers, they must be able to receive inbound packets. To function properly behind NAT, a device may first send a request out to the server, as is done in LWM2M, allowing the router to associate the two. Although CoAP does not require IPv6, it is easiest used in IP environments where devices are directly routable.

IV. COMPARISON

Fig. 4 shows the frames sent in MQTT for one exchange. To establish a connection, TCP uses a three-way handshake (SYN, SYN-ACK, ACK). After TCP connection is established, MQTT protocol uses different messages for communication. There are 14 message types specified in 3.1 version of MQTT protocol. CONNECT (client request to connect to server), PUBLISH (publish message), PUBLISH (publish acknowledgment), SUBSCRIBE (client subscribe request) are some of the message types.

![MQTT data exchange](image)

One of the main differences between MQTT and CoAP can be found in the transport layer of the OSI model. MQTT runs on top of the Transmission Control Protocol while CoAP runs on top of the User Datagram Protocol. Although UDP is not reliable, CoAP provides its own reliability mechanism using „confirmable messages” and „nonconfirmable messages”. Former require an acknowledgment while latter do not need an acknowledgment [17].

MQTT is a many-to-many communication protocol for exchanging messages between multiple clients through a central broker. MQTT decouples clients by letting publishers to send messages and having the broker to decide to which subscriber the message will be sent. On the other side, CoAP network is primarily a one-to-one protocol for transferring state information between client and server. However, it supports one-to-many or many-to-many multi-cast requirements. This is inherent in CoAP because it’s built on top of IPv6, which enables multicast addressing for devices in addition to their normal IPv6 addresses [18].

For the purpose of the security, a username and a password can be sent inside of an MQTT packet. This can help simplify the authentication of individual clients in a network by reducing the number of keys that need to be distributed and managed in comparison to an exclusively key based system. Exchanged data can be encrypted using SSL or TLS, independently from the MQTT protocol [19]. Since CoAP is built on top of UDP, it cannot rely on SSL/TLS to provide security capabilities. To achieve security, CoAP uses Datagram Transport Layer Security (DTLS) which provides the same assurances as TCP.

In a simple point-to-point configuration between objects, MQTT and CoAP have similar performance characteristics, although broker-based routing requires an additional overhead when compared to a broker-less infrastructure such as HTTP or CoAP request. Additional overhead can be found in a request to a CoAP resource from HTTP client because it has to be forwarded via a

CoAP/HTTP proxy. It is recommended to use CoAP in systems where real-time performance and low latency are not a requirement. The single CoAP client can send the same request to multiple CoAP servers concurrently, which gives multicast characteristic to CoAP protocol. At the side of the hardware, Raspberry Pi model 3 is used. Main differences between RPi model 3 and prior versions are integrated wireless module (802.11n), integrated Bluetooth module (Bluetooth 4.1) and 1.2GHz 64-bit quad-core ARMv8 CPU. Using this type of RPi there is no need for additional modules for connecting end device to the network. For communication between clients and broker, Python language with Paho Python MQTT library is used. The library implements a client class that can be used to add MQTT support to RPi. For the purpose of CoAP testing, WebIoPi framework is used.

V. CONCLUSION

In this paper, a comparison of Internet of Things data protocols is given. IoT architecture is presented by describing the parts where application layer protocols are needed to handle communication. We have presented the most widespread application layer protocols in the IoT through the comparison among each other. Choosing the best appropriate protocol depends on several facts of which most important are: environmental conditions, network characteristics, the amount of data to be transferred, security levels, quality of service requests. CoAP network is primarily a one-to-one protocol for transferring state information between client and server while MQTT is a many-to-many communication protocol for exchanging messages between multiple clients. CoAP runs over UDP which means that communication overhead is significantly reduced. If constrained communication and battery consumption is not an issue, RESTful services can be easily implemented and interact with the Internet using the worldwide HTTP [5]. On the battery-run devices MQTT is more suitable. Additionally, if the targeted final applications require massive updates of the same value, MQTT protocol is more suitable. In a simple point-to-point configuration between objects, MQTT and CoAP have similar performance characteristics. Future work will be aimed at implementing MQTT and CoAP protocols in a lab environment and obtain an experimental comparison among them.

Digital Forensic Analysis Through Firewall For Detection of Information Crimes in Hospital Networks

Ayhan AKBAL*, Erhan AKBAL**
* Firat University/ Electrical-Electronics Engineering, Elazig, Turkey
** Firat University/ Digital Forensics Engineering, Elazig, Turkey
ayhanakbal@gmail.com

Abstract - Digital forensics analysis was done by taking a view of Firewall on the Firewall used in the hospitals, and the data that could create a criminal element were determined. As is known, all network traffic on the networks is over the firewall. For this reason, the traffic on the entire network is recorded on the firewall. When these records need to be analyzed in terms of forensic information and criminal elements should be detected, the records on the firewall should be analyzed without deterioration. For this purpose, the image of the firewall needs to be taken. However, in order to obtain images, it is necessary to calculate MD5 and SHA-1 HASH values with international validity, which confirm the integrity of the image. For this purpose, the Juniper SSG 550 firewall device used in Firat University Hospital will be analyzed. For analysis, FTK Imager program which is developed by AccessData firm and offered for free use will be used. This image will be analyzed with forensic tools such as forensics explorer.

II. DIGITAL FORENSIC AND ANALYSIS METHODOLOGY

A. Cyber-crime in Healthcare

With the digitization of the health sector, the health sector is increasing with cyber-crime [4]. In the last five years there have been a lot of cyber-attacks in the healthcare sector, and these cyber-attacks cost only US $ 6 billion [4]. People's personal information, address, credit card, health information about the patient is very important information. This information is different from other health information. The credit card information of the patient can be changed by canceling the credit card of the stolen patient. However, medical information about the patient cannot be changed at all. This makes medical data more important.

In the healthcare industry, hospitals or healthcare organizations have begun to use information technology more quickly to perform transactions. The systems followed by patients in intensive care have become accessible via the internet on many medical devices such as patient monitors, respiratory devices, temperature monitors.

However, these institutions are a clear target for cyber-attacks because their areas of expertise are health. The wired and wireless use of devices that store patient information, provide remote access, and the lack of specialist expertise or the management of non-expert systems leave health systems vulnerable. For this reason, it is also a very important issue to determine the criminal elements that control the data of health systems.

In this study, an example of how digital forensics analysis of firewalls, which are connection points of the hospitals to the outside world, is done.

B. Firewall

Firewall is a hardware based network security system that controls outgoing packet traffic on a network based
on a rule set. It is a device that keeps Internet traffic under control, with many different filtering features, including incoming and outgoing packets of computer and network. All incoming and outgoing packets pass through the firewall. For this reason, packets must be passed through the firewall during all attacks from outside the network. In this study, Juniper SSG 550 (Fig.2.1) firewall used in Firat University Hospital was used.

Juniper SSG550 line of secure services gateways consists of high-performance security platforms for regional branch office and medium-sized, standalone businesses that want to stop internal and external attacks, prevent unauthorized access and achieve regulatory compliance. A firewall performance and 500 Mbps of IPsec VPN performance, while the Juniper Networks SSG550M Secure Services Gateway provides 650 Mbps of state full firewall performance and 300 Mbps of IPsec VPN performance[6].

C. FTK Imager

It is a continuously developed digital data analysis and analysis program written by FTK ACCESSDATA. This program, which is very successful in transforming evidence analysis and evidence into concrete reports, is being used extensively all over the world, especially by security forces. The program is considered to be highly productive and functional, as well as evidence of the reports and data submitted to the court by all courts through this program.

FTK Imager Hash value found in terms of information, image date etc. Information. With the FTK Imager software, copies can be made in raw (dd), E01 (Expert Witness, Encase) and AFF formats. These images can then be analyzed in terms of forensic science and support filing formats such as FAT, NTFS, ext2, ext3 [7].

In this study, the image of Firewall was taken with FTK Imager. For this purpose, a write-locked UltraBlock USB3.0 Forensic Card Reader, shown in Figure 1, used in Forensic Computing Engineering Laboratories of Firat University [8].

D. Forensic Explorer

Forensic Explorer is a tool for the analysis of electronic evidence. Primary users of this software are law enforcement, corporate investigations agencies and law firms. Forensic Explorer has the features you expect from the very latest in forensic software. Inclusive with Mount Image Pro, Forensic Explorer will quickly become an important part of your forensic software toolkit [9]. Forensic Explorer combines a flexible graphic user interface (GUI) with advanced sorting, filtering, keyword searching, previewing and scripting technology. It enables investigators to: Manage the analysis of large volumes of information from multiple sources in a case file structure, Access and examine all available data, including hidden and system files, deleted files, file and disk slack and unallocated clusters, Automate complex investigation tasks, Produce detailed reports and Provide non forensic investigators a platform to easily review evidence[9].

E. Analysis Methodology

In this study, the file structure of the operating system used by the Juniper firewall device and the data analyzed by the firewall were analyzed. For this purpose, the storage unit of the active Juniper SSG 550 firewall device (Fig.2.3) Firewall uses 512 MB Compact Flash as the disk unit.
Images were taken with the FTK Imager program developed by ACCESSDATA. To do this, the Compact Flash disk on the Firewall is first removed and the UltraBlock USB3.0 Forensic Card Reader with write lock is inserted so that the evidence can not be changed. FTK Imager program The disk image operation has been started with the Create Disk Image menu. Later, source selection was made for the image to be taken in the program. At this stage, the physical source on which the software belonging to Juniper on the computer connected CF Reader is selected. After this process, CF Flash memory is selected from the list of physical drives in the computer. The CF image is taken in RAW (dd) format recognized by Forensic Explorer (Fig 2.4).

As shown in Figure 3.3, the file structure of the Firewall has been obtained in detail. The contents of these files can be viewed as HEX. When these files are examined, "golerd.rec" file contains log information to the firewall [11]. The firewall user information is stored in the "node_secret.ace" file [13]. The file "crushdump.dmp" is a file that records the data during execution for examining events occurring in the firewall. The "syscert.cfg" file contains system certificates. The "prngseed.bin" file and "license.key" file contains the license information for the Firewall [14]. The "envar.rec"
file contains the licenses received with the system when the system is being installed [11]. The "ns_sys_config" file contains all the settings that the users have defined on the firewall [12]. In the "dnstb.rec" file, all DNS information registered by the firewall can be accessed (Figure 3.4).

![Figure 3.4. dnstb.rec file detail](image)

IV. CONCLUSION

Forensic Computing has become an important element in recent years. For this reason, this has increased in studies. However, the high number of devices in the IT sector makes it difficult to analyze the products, which are a wide variety of manufacturers. For this reason, a forensic analysis of the firewall has been done in the literature.

As a result, the safety of the data is very important in hospitals where patient records are kept. Every year attacks are carried out in these data. When working on these data, it is necessary to perform forensic examinations in order that the data or configurations in the devices are correct and that the necessary work on the existing system can be done more easily and more accurately when a criminal element occurs. In this frame, the forensic examination of the Juniper Firewall SSG550M device within the Fırat University Hospital was made. As a result of this review, the Juniper Firewall file structure was accessed the device and analyzed without any changes to the data. All data of the Firewall has been accessed to the configuration that is active in the device, and to the data of users entirety. The file structure of the Firewall has been detected.

REFERENCES

Abstract— The goal of the paper is to assess the impact of node placement on its performance and throughput capacity. Furthermore, it explores optimal network node placements for wireless sensor networks (WSNs) with and without obstacles in a Wireless Sensor Network of a Home Sensing Environment. Influence of nodes' spatial distributions on the network performance is explored and the optimal nodes distribution on given conditions is given for three typical network spatial scenarios (no obstacles, minor obstacles and major obstacles). Then, the network performance is analyzed for each case and the results are compared.

Keywords— WSN; energy efficiency; network node placement; routing; network performance

I. INTRODUCTION

Network node placement is one of fundamental issues in wireless sensor networks (WSNs). Sensor nodes collaborate in a distributed and autonomous manner to dispatch the data they sense to specified data collection locations (data sinks), usually in an environment with no infrastructure [1]. In practice, it is common for the sensor nodes not to be placed evenly throughout the area, which has a great impact on the properties and performance of the network. Placing a large number of nodes into a limited region can result with considerable interference and deteriorate the networks' performance. If the nodes, on the other hand, are placed too sparsely, communication among them might prove to be challenging due to some nodes being out of range. Wireless sensor networks are often deployed in remote environments, and there are often many obstacles distributed in these areas. We define obstacles as areas where sensor nodes cannot be placed and through which the nodes cannot communicate directly. Thus, generally, obstacles have a negative impact on the network's performance since they constrain the distribution of sensor nodes and the transmission of packets. For example, in the case of a Wireless Sensor Network monitoring conditions in a closed space (e.g. Home Sensing Environment), electromagnetic wave signal can be attenuated significantly when passing through furniture, walls or floors, which could have a great impact on network performance [2]. Hence, there's a need to design the network node placement in such a way to minimize the impact of obstacles onto the network's performance. For example, in Home Sensing Environments, the capacity can be improved if fewer nodes are placed in areas shadowed by the obstacles [2]. The paper has following sections; in section II motivation for research and related work is given; in section III three different node placements are presented (with no obstacles, minor obstacles and major obstacles); in section IV results of simulations on each of the models are given and explained; in section V conclusions are drawn and further work is suggested.

II. MOTIVATION AND RELATED WORK

As the number of smart homes is rising exponentially, performance and quality of service (QoS) of wireless sensor networks comes into question, especially in the context of energy efficiency [3]. An example of modelling of WSN for Home Sensing Environments is given in [4]. Coverage-based node placement optimization [5] covers networks with linear topology while the topology control in energy-harvesting wireless sensor networks is given in [6]. Lastly, TRAST [7] presents trust-based distributed topology management for wireless multimedia sensor networks. The goal of this paper is to complement the works mentioned by assessing the impact of network node placement on its performance and throughput capacity by exploring optimal network node placement for wireless sensor networks (WSNs) with and without obstacles in a specific scenario - Wireless Sensor Network of a Home Sensing Environment, and to develop a better understanding of energy-related issues, performance and QoS in wireless sensor networks, and to help find novel approaches to networking in the future.
III. NODE PLACEMENT MODELS

Following scenarios (models) are considered: (1) no obstacles in the area; (2) area with minor obstacles (e.g. furniture); (3) major obstacles (e.g. walls). Area, the number of nodes and degree of the nodes are constant throughout all of the simulations; number of nodes \( N \) being one hundred, area being 30 x 50 meters and nodes’ degree being 8. When a node is not connected to every other node, messages have to go through intervening nodes to reach their final destination. The network topology can be described by the number of nodes and the interconnections among them. The degree of a node in a network is the number of connections it has to other nodes and the degree distribution is the probability distribution of these degrees over the whole network. Therefore, the degree is very important structural parameter of network topology. Following networks are not scale-free (where degree distribution asymptotically follows a power law and where a small number of nodes function as “hubs”). Instead, to distribute the traffic more evenly, all nodes have the same degree. Upon testing several topologies with different node degrees, the minimal number of links for achieving acceptable performance and number of hops in a network consisting of one hundred nodes proved to be eight. Furthermore, the simplest form of topology control, where all the nodes are assumed to have the same transmitting range \( r \), is the characterization of the critical transmitting range (CTR) [8]. In this case, the interest is in finding the minimum value of \( r \) for which the requirements of energy and consumption and network capacity are satisfied. This assumes there are no obstacles in the area where the nodes are deployed (1).

Second node placement assumes there are minor obstacles distributed in the area which correlates with, for example, furniture inside a room. Although the nodes cannot communicate directly through, minor obstacles can be bypassed from either side. This scenario is pictured above in Figure 2.

Third case assumes there are major obstacles distributed in the area. This can be explained as, for example, a wall between rooms inside a Home Sensing Environment. The nodes cannot communicate directly through, and the obstacle can be bypassed from one side only. The example of this kind of node placement is pictured above in Figure 3. Scenarios have all been generated and simulations performed in MATLAB and Simulink.

IV. SIMULATION AND RESULTS

The following simulations show nodes sending various types of data collected by sensors of a Wireless Sensor Network in a Home Sensing Environment, such as temperature, humidity or air quality. The longest routes, i.e. nodes furthest away from the sink are highlighted in
following examples. Nodes’ communication examples in each of the scenarios are given below in Figures 4 to 6, in each case the area monitored is 5 by 3 meters.

Figure 4 Longest path in WSN simulation in area without obstacles

Figure 4 pictures communication in WSN where there are no obstacles in area. The maximum number of hops needed (longest path) was, in this case, 5, while the average number of hops was 3.61.

Figure 5 Longest path in WSN simulation in area with minor obstacles

Figure 5 shows longest path in simulation for a WSN where there are some minor obstacles in the area. The longest path was 8. Average path length is, however, substantially lower (4.65).

Figure 6 Longest path in WSN simulation in area with major obstacles

In Figure 6, longest path in simulation of WSN with major obstacles in the area. The longest path was 6, and the average path was 4.87, making it the highest average among the three scenarios. The results of the simulation are summarized in the continuation of the article in Table 1, along with the network traffic for each case. Furthermore, it also affects the throughput of singular nodes, as shown on the following graphs. Figure 7 shows the number of messages for each of the nodes in area without obstacles. While the number of messages varies, the distribution is fairly even, the average number of messages per node being ~11, and maximum being 63.

Figure 7 Number of messages per node in area without obstacles

On the other hand, Figure 8 shows the number of messages for each node in the network in area with minor obstacles. It is apparent that the results are substantially different since several nodes have much higher number of messages exchanged. These nodes, as it was to be expected, are mainly in the central area, through which the majority of messages go through. In this case, the average number of messages per node is ~19, and the maximum equals 74. This
shows that changes in node placement due to minor obstacles can increase the number of messages exchanged among the nodes in the network up to approximately two thirds of the original traffic, in a network where there’s no obstacles in the area.

![Figure 8 Number of messages per node in area with minor obstacles](image)

Lastly, Figure 9 shows the number of messages for each node in the network in area with major obstacles. The results differ from the previous two cases, as only three out of one hundred nodes have exchanged significantly greater number of messages. The average number of messages per node is ~21, while only three nodes have exceeding values of 54, 87, and 99, respectively. All three nodes are located in the bridge area between the two parts separated by the obstacle and have up to four times more messages exchanged. This leads to a bottleneck situation and increases the total traffic significantly, up to 1.727 times in an area with minor obstacles and up to 1.91 times in an area with major obstacles. Another important issue is the possibility of overloading the nodes in critical areas in the last scenario where a small portion of nodes has exchanged up to four times more messages than average.

![Figure 9 Number of messages per node in area with major obstacles](image)

The results in Table 1 (below) clearly show even minor obstacles cannot be ignored while defining a node placement of a wireless sensor network with the average time necessary for a message to be exchanged being 1.288 times more in areas with minor obstacles and 1.349 times more in areas with major obstacles (in comparison to an area where there are no obstacles present). Furthermore, the total traffic also increases, up to 1.727 times in an area with minor obstacles and up to 1.91 times in an area with major obstacles. Another important issue is the possibility of overloading the nodes in critical areas in the last scenario where a small portion of nodes has exchanged up to four times more messages than average.

<table>
<thead>
<tr>
<th>WSN without obstacles</th>
<th>Longest path / average path (number of hops)</th>
<th>Time comparison for message exchange</th>
<th>Average number of messages per node / increase in total traffic</th>
</tr>
</thead>
<tbody>
<tr>
<td>WSN with minor obstacles</td>
<td>5 / 3.61</td>
<td>1x</td>
<td>~11 / 1x</td>
</tr>
<tr>
<td>WSN with major obstacles</td>
<td>8 / 4.65</td>
<td>1.288x</td>
<td>~19 / 1.727x</td>
</tr>
<tr>
<td>WSN with major obstacles</td>
<td>6 / 4.87</td>
<td>1.349x</td>
<td>~21 / 1.91x</td>
</tr>
</tbody>
</table>

The following table shows traffic distribution among the nodes in the networks.

<table>
<thead>
<tr>
<th>WSN without obstacles</th>
<th>Maximum number of messages in a single node</th>
<th>Number of nodes having 2x the average traffic</th>
<th>Number of nodes having 4x the average traffic</th>
</tr>
</thead>
<tbody>
<tr>
<td>WSN with minor obstacles</td>
<td>63</td>
<td>17</td>
<td>0</td>
</tr>
<tr>
<td>WSN with major obstacles</td>
<td>74</td>
<td>9</td>
<td>0</td>
</tr>
<tr>
<td>WSN with major obstacles</td>
<td>99</td>
<td>3</td>
<td>2</td>
</tr>
</tbody>
</table>

The traffic is distributed much more evenly in the case where there are no obstacles in comparison with the third case. This would further suggest there’s a need to resolve the bottleneck issue that occurs by increasing the number of
nodes placed in this particular area as this would increase energy efficiency. Further analyses are needed to verify and continue the work of network optimization.

V. CONCLUSION

The optimal nodes’ spatial distribution should be studied for specific obstacles distributions in the area. Then, these optimal solutions for different nodes’ distributions provide energy efficient wireless sensor network. Results from this work indicate even minor obstacles cannot be ignored while defining node placement of a wireless sensor network in a Home Sensing Environment. Minor and major obstacles impact the network’s performances significantly, in terms of throughput, total traffic and time necessary for the message to be delivered. Another issue is a possibility of overloading the nodes in critical bridge areas that a large part of the messages needs to go through. These results provide us a foundation for further work of network optimization and protocol design. Further in-depth analyses for network areas with different nodes' distributions are needed.

Abstract: The activity of mining always had an element of risk associated with it. Miners often had to encounter challenging underground environment which sometimes result in injuries and fatalities. Some portion of them can be attributed to error caused by human carelessness. More often the cause of these accidents can be attributed to the ambient conditions. In this paper, we design a mine safety system using wireless sensor networks with measurement of parameters such as temperature, air-flow, humidity, noise, dust, and gas concentration. These six ambient characteristics have been identified as hazardous to the health and safety of the mine worker. From the experimental results obtained, an accurate mine safety system is achieved by design of various sensors. The temperature sensors, humidity sensor, airflow sensor, and noise sensor achieved an accuracy of 94.45%, 98.55%, 85.4%, 99.14% alternatively. Besides, the dust sensor has a resolution of 0.003mg/m³ and the gas sensor show a resolution of 0.9ppm which is close to the required resolution of 1 ppm.

Keywords: mining industry, sensor systems, temperature measurement, humidity measurement, airflow measurement, noise sensor measurement, wireless sensor networks

I. INTRODUCTION

The concept of mining has been around since the beginning of civilization; our ancestors used stones, ceramics and later metals found close to earth’s surface to make tools and weapons. The activity of mining always had an element of risk associated with it. Miners often had to encounter challenging underground environment which sometimes result in injuries and fatalities. Some portion of them can be attributed to error caused by human carelessness. More often the cause of these accidents can be attributed to the ambient conditions underground.

The ambient conditions underground are extremely difficult to monitor without placing someone’s life at risk [1]. This type of first hand monitoring endangers the life of the observer which is not ideal. The International Organization of Standard proposes the ISO 45001 standard which benefits both miners and the economy [2].

Wireless sensor technology if implemented in mines can improve the safety of mines considerably by eliminating the need for human testers inside the mines. A wireless sensor network consist of a number of sensor nodes [3] [4] distributed around various locations in the mine communicating with each other [5] [6]; they form a non-invasive mine safety system. Moreover, wireless sensors provide a considerable reduction in wiring [7] which can be damaged during mine blasting; sensors also provide real-time measure of the mining environment [8].

Due to the dangerous and potentially unsafe mining practices there exists a relationship between hazard, latent danger and accident [9].

The wireless sensor network discussed in this research work considers star and mesh network topologies. The ambient characteristics measured in our research work include temperature, air-flow, humidity, noise, dust, and gas concentration. These six ambient characteristics have been identified as hazardous to the health and safety of the mine worker. In other words, each of these characteristics can be solely or collectively responsible for incurring a risk to a mine worker. The idea of our system is not to mitigate an accident but rather to detect a hazard early and provide a control output to alleviate latent danger. This output could be a decision by the active mine manager to call all miners out of the mine for a temporary period, or a visual alarm system that can provide a timely warning when conditions become unstable.

Our research work takes advantage of available wireless technologies, which will not only monitor the conditions inside the mine but also be used to provide a noise mapping feature which will output a noise protection scheme for the workers, and provide ventilation switching to regulate air in the mine. Current related works in place do not consider noise or humidity as a parameter for measurement as in [10] [11]. It also provides an enhanced snapshot of the condition inside the mine at any given time.

II. PROPOSED SYSTEM

Our proposed system consists of Measurement nodes and a Data collections station. The measurement node consists of different sensors which detects the values of temperature, humidity, gas concentration, air-flow and noise levels. These measured values are transferred to the data collection center using a wireless network. Each of these sensors has their own respective signal processing circuits. The input from the sensor is sampled by the micro controller, which forms the central processing Unit (CPU) of the measurement module. The microcontroller also has a timer which determines the delay between two sensor sample readings. A wireless communication module is also integrated into the microcontroller for transmitting data to the data collection station. The
The proposed system uses ZigBee 802.15.4 wireless protocol for wireless communication.

The data collection station has also a wireless communication module and a microcontroller. The data collection center has the necessary hardware and software capabilities to process, display and store these data values. Data collection stations display the measured sensor values in the GUI of the laptop. The data collection station’s tasks also include developing safety schemes for the mine workers using the sensor data collected.

The three control outputs that will be created by this proposed system are:

- Visual Indicator on Central Computer
- Noise Protection Scheme
- Ventilation Switching

Controlling a hazardous situation involves using the results of monitoring and performing some control output driven by these results to avoid latent danger.

The first two outputs will assist the mining supervisor or equivalent to employ existing safety policies by showing the output of the collected data at the data collection center at the central computer.

The noise protection scheme will be implemented purely in software. This scheme will take a predefined visual map of the mine and combine it with the noise values measured in each different segment of the mine. This scheme will then subsequently provide the miners with a guide of which areas in the mine are noisy. The switching module will use the data from the system namely the outputs from the gas and air-flow sensors to provide a switching mechanism to switch on a ventilation unit (a fan). This module will take a control signal from the microcontroller and a domestic AC input and provide an AC power point where the ventilation unit can be powered from. The temperature, air flow and humidity sensors are created using the first principles. The dust and gas sensors used in our work are off the shelf components.

III. SYSTEM DESIGN

A. Temperature Sensor

This sensor is used to measure ambient air temperature. There are a variety of different methods which can be used to design temperature sensor from first principles, the two alternatives which were considered are the use of a thermistor and the use of a thermocouple. After evaluating these two alternatives in the context of this project it was decided that a thermistor based temperature sensor will be designed.

Thermistor we used has a resistance of 2000 ohms at 25°C. We measured the resistance of the thermistor at three different temperatures. In order to find the correct load to provide the best range of measurement a range of different values were simulated for the load. It was found that a 1000 ohm resistor was best. This is shown in Figure 1.

B. Humidity Sensor

Humidity sensor is used to measure the ambient humidity in its surroundings. There are different methods which can be used to design humidity sensor from first principles, the two different methods we considered are resistive and capacitive type humidity sensors. Since resistive type sensors have a higher dependence upon exposed temperature and are more vulnerable to damage from dust and pollution a capacitive type approach has been chosen for the humidity sensor.

The sensor used in our work is the Honeywell HIH-4000 series humidity component. This sensor has a typical current draw of 200 µA [12]. The voltage across the sensor will vary depending on the water vapour it is exposed to. The microcontroller used in our work can have an operating voltage of 5V, so we improved on the off the shelf humidity sensor with voltage range (0.8V – 3.8V) by designing an operational amplifier. This increased the resolution of the measured humidity. The figure given below, Figure 2, shows the amplifier circuit current drain simulation circuit.

C. Air Flow Sensor

Air flow sensor is used to measure the ambient air flow in its surroundings. Different techniques can be used to design air-flow sensor from first principles. The rotation based approach has been chosen for our work.

The air flow sensor is built from the first principle by using a three cup anemometer and slotted optical switch.
The air flow sensor can be divided into two parts the electronic component and the mechanical component consisting of the cup anemometer. The slotted optical switch used in our work is OPB804.

![Figure 3. Theoretical relationship between linear wind speed and RPM](image)

The optical switch consists of a phototransistor and an LED. The near IR light emitted by the LED is detected by the phototransistor which causes a voltage change from low to high. The mechanical part has a small metal piece mounted on the bearing of the anemometer. When the arm rotates, the metal crosses the slot of the optical switch, each time this happens one revolution is observed. The timer in the microcontroller is used to calculate the corresponding rotations per minute (RPM). Theoretical relationship between linear wind speed and RPM is given in Figure 3. The airflow sensor calibration setup is shown in Figure 4.

![Figure 4. Airflow Sensor Calibration Setup](image)

D. Noise Sensor

A noise sensor is used to determine the ambient sound levels in its surroundings. It is designed and implemented using the first principle.

In our system in order to convert noise (sound) into a usable metric for the system, a microphone is used to capture the analog variances with sound changes. The output of the microphone is fed into the filter and amplification circuit which gives a constant voltage which can be measured by the controller. The measured sound levels are considered noise because they negatively affect the employees of the mine.

E. Gas Sensor

Gas sensor is used to measure the concentration of ambient gas in its surroundings. In a mine we measure the concentration of methane gas. We implement gas sensor using an off the shelf component called Figaro TGS2611-C00.

The heater (RH) voltage is applied to the heater element in order to maintain the sensing element at a specific temperature which is optimal for sensing. The circuit voltage is applied to allow for a voltage to be measured across the load resistor. Figure 5, shows Gas Sensor Resistance to Gas Concentration. The measured voltage is converted into gas concentrations using mathematical modeling.

![Figure 5. Gas Sensor Resistance](image)

F. Dust Sensor

Dust sensor is used to measure the concentration of dust in its surroundings. We use an off the shelf optical type dust sensor Sharp GP2Y1010AU0F. This sensor measures the dust concentration in the air by assessing the intensity of light.

The sensor requires a square wave input, to achieve this we use the PWM output of the microcontroller. Figure 6, shows the simulation on OrCAD to find the current draw of the peak detector. Figure 7 shows, Dust Sensor Driving Signal and Output.

![Figure 6. Dust Sensor Peak Detector Current Drain Simulation](image)

G. Design of the System

The final design [15] is implemented using a set of PCBs. The sensor nodes needs to be mobile so they are battery operated. The collection node is static so they are...
powered by a suitable power supply. Each node utilises a
dsPIC30F4011 microcontroller [16, 17] which has the
required hardware and software functionalities. XBee
Series 1 Pro acts as the ZigBee wireless interface [18,19,
20] for data transmission. The graphical user interface
provides the visual output of the parameters measured by
our system.

IV. RESULTS, OBSERVATION AND DISCUSSION
We subjected our system to various tests which
focuses on a specific subsystem. Different tests on
various sections are discussed in the subsections below.

A. Testing the Temperature Sensor
The parameters that are considered for this test
include the reference temperature measured by the digital
thermometer and the temperature measured by the
prototype system [21, 22]. The reference value measured
is compared against the prototype’s measured value. We
exposed our test setup to different environments. These
environments provided different ambient conditions. The
ambient values are sampled from the prototype system
and compared against the reference value measured on
the digital thermometer. The results obtained from the
experiment for testing the accuracy of the measured
temperature are shown in Table 2 and Table 3 below.

The first observation made is regarding the error
obtained on each temperature measurement made, when
compared to the reference temperature. The error
percentage of the measurement made will be calculated
using the equation for relative error given below.

\[
\text{Relative Error} = \left( \frac{\text{measured value} - \text{reference value}}{\text{reference value}} \right) \times 100
\]

of 9.51%, if the same calculation is done for sample
number 6 the result is 5.55%. This shows that the
temperature measurement from the prototype system has
a worst case accuracy of 89.01% and a best case accuracy
of 94.45%.

This resolution obtained from the result is 0.105°C. The
obtained resolution of the temperature exceeds the
specification of 0.5°C. The range of the temperature obtained (2-45°C) also exceeds the specification of the
range of 20-35°C. This range is determined while the
accuracy is being tested.

B. Testing the Humidity Sensor
The parameters that are considered for this test
include the reference humidity measured by the digital
hygrometer and the humidity measured by the prototype
system. For resolution test the ambient humidity is varied
in small increments. The ambient values are sampled
in the prototype system and compared against the reference value measured on the digital hygrometer. The
result of the humidity sensor accuracy test is shown in
Table 4 and Table 5. The results show that, the humidity
sensor measures humidity in the required range with a
worse case accuracy of 98.55% accuracy which is in line
with the required specifications.

C. Testing the Air Flow Sensor

The parameters that are considered for this test include the reference airflow measured by the digital anemometer and the airflow measured by the prototype system. The airflow is varied in small increments. The results show that the airflow sensor measures the magnitude of airflow in the range of (0 - 15m/s). The magnitude of the error increases with the increase in the wind speed. For 5m/s the worst case error percentage is 2.4% (average = 1.45%). For 10m/s the worst case error percentage is 11.5% (average = 10%). For 15m/s the worst case error percentage is 14.6% (average = 12.5%). This resulted in a worst case accuracy of 85.4% (average = 90.5%). This worst case accuracy will only be applicable for airflow magnitudes near the 15m/s magnitude with lower magnitudes showing better accuracy. Therefore this sensor does meet the specification for range of measurement. The airflow resolution test is completed using 3 trials of 2 measurements. The results across the trials gave the similar airflow resolution output. So the test-retest reliability of the airflow resolution is high for this system. The result shows that an average resolution of 0.045m/s which exceeds the expectation of 0.5m/s.

D. Testing the Noise Sensor

The parameters that are considered for this test include the reference noise measured by the digital sound level meter and the noise measured by the prototype system.

During testing different sounds are made to elevate the sound level. This level is different for a set of measurements to measures different values. The reference sound is noted and compared to the sound level measured from the prototype system. The results show that sound level measurement from the prototype system has a worst case accuracy of 89.53% and a best case accuracy of 99.14%.

The fluctuation in the observed sensitivity of the noise measurement system shows that only 80% of the tests conducted produced a relative error percentage lower than 5%. This shows a promising trend for the sensor. There are however the remaining 20% of the results which are greater than 5%. The lowest value that can be measured is 50 dB SPL, below this value, the sound level is almost silent. This noise sensor is able to measure to 95 dB SPL, this meets the required specification. The noise sensor resolution test is completed using 3 trials of 2 measurements. The result of the resolution test is given in Table 7. The result shows a resolution of 0.23 dB SPL which exceeds the specification of 5 dB SPL.

![Figure 8. Gas Sensor Range Test Results](image-url)
result of the gas sensor’s resolution test is given in Table 8. The result shows a resolution of 0.9ppm which is close to the required resolution of 1 ppm.

F. Testing the Dust Sensor

The parameter that is considered for this test is the measured dust concentration. The measured value is obtained from the electronic circuitry and software implemented. The results obtained from the experiment for testing the accuracy of a measured dust concentration is shown in Figure 9. This figure shows the functioning of the dust sensor as well as the maximum value that could be measured using this experiment. The result of the resolution test for the dust sensor is given in Table 9. The results show a resolution of 0.003mg/m³ which is higher than the required expectation of 0.5 mg/m³. The result is still good as the threshold value for the dust concentration/crystalline silica is limited to 0.1 mg/m³[13][14].

V. CONCLUSION

In this paper, we designed wireless sensor networks consisting of temperature, air-flow, humidity, noise, dust, and gas sensors to improve the safety of mines considerably by eliminating the need for human testers inside the mines. Each of these characteristics can be solely or collectively responsible for incurring a risk to a mine worker. The wireless sensor network discussed in this research work considers star and mesh network topologies. We also takes advantage of available wireless technologies, which will not only monitor the conditions inside the mine but also be used to provide a noise mapping feature which will output a noise protection scheme for the workers, and provide ventilation switching to regulate air in the mine. From the experimental results obtained, an accurate mine safety system is achieved by design of various sensors. The temperature sensors achieved an accuracy of 94.45%, humidity sensor achieved an accuracy of 98.55%. The airflow sensor measures accuracy of 85.4%, the noise sensor has a worst case accuracy of 89.53% and a best case accuracy of 99.14%. The dust sensor has a resolution of 0.003mg/m³ which is higher than the required expectation of 0.5 mg/m. The result of the gas sensor shows a resolution of 0.9ppm which is close to the required resolution of 1 ppm.

BUSINESS PROCESSES AND BUSINESS ECONOMY
Replication of Virtual Network Functions: Optimizing Link Utilization and Resource Costs

Francisco Carpio, Wolgang Bziuk and Admela Jukan
Technische Universität Braunschweig, Germany
Email:{f.carpio, w.bziuk, a.jukan}@tu-bs.de

Abstract—Network Function Virtualization (NFV) is enabling the softwareization of traditional network services, commonly deployed in dedicated hardware, into generic hardware in form of Virtual Network Functions (VNFs), which can be located flexibly in the network. However, network load balancing can be critical for an ordered sequence of VNFs, also known as Service Function Chains (SFCs), a common cloud and network service approach today. The placement of these chained functions increases the ping-pong traffic between VNFs, directly affecting to the efficiency of bandwidth utilization. The optimization of the placement of these VNFs is a challenge as also other factors need to be considered, such as the resource utilization. To address this issue, we study the problem of VNF placement with replications, and especially the potential of VNFs replications to help load balance the network, while the server utilization is minimized. In this paper we present a Linear Programming (LP) model for the optimum placement of functions finding a trade-off between the minimization of two objectives: the link utilization and CPU resource usage. The results show how the model load balance the utilization of all links in the network using minimum resources.

I. INTRODUCTION

Network Function Virtualization (NFV) is a new paradigm that virtualizes the traditional network functions and places them into generic hardware and clouds, as opposed to the designated hardware. The placement of the virtual network functions (VNFs) can happen either in remote data centers (DC) or by deploying single servers or clusters of servers. Placing VNFs in remote data center can lower the cost of deployment, but is known to typically increasing the delay and create churns of network load, due to the fix and often remote location. Installing new mini data centers inside the network can mitigate the distance-to-data center problem. At the same time, the deployment of new servers forming small data centers in regular nodes requires new investment costs, which requires a gradual upgrade of the network. Therefore, the optimal placement of these servers in the network is a must for network operators to reduce the operational costs.

While most of the current work concentrates on the optimal placement of VNFs under some specific objective minimizing the network costs under some specific resources constraints, e.g. costs of power consumption or the number of physical servers, less effort has been on addressing the network load balancing problem with VNF placement. In this paper, we address, jointly, the network load balancing and resource cost problem with VNF placement, where the concept of VNF replications is used to find a trade-off between network load balancing and network costs. The Fig. 1 illustrates the idea, whereby we assume a service chain, which is composed of non-replicable VNFs and a variable number of replicas, may be split to one or more parallel sets of an ordered sequence of VNFs towards the service end-point. The major advantage is to split the traffic flows in a controlled way such that network traffic load balancing can be optimized when the service is running. As commonly in network services, the service chain starts with a non-replicable VNF, e.g. a load balancer or gateway, and is allocated in a dedicated data center which generates service requests, while the rest of the functions are allocated on small servers, maintaining the sequence order. To find the optimum placement of servers required for the deployment of VNFs, we formulate the problem as an Integer Linear Programming (ILP) model.

The rest of the paper is organized as follows. Section II presents related work. Section III describes the reference architecture. In Section IV, the related optimization models are described. Section V analyzes the performance and Section VI concludes the paper and discusses future research.

II. RELATED WORK

Early work in [1] studies the optimal VNFs placement in hybrid scenarios, where some network functions are provided by dedicated physical hardware and some are virtualized, depending on demand. They propose an ILP model model with the objective to minimize the number of physical nodes used, which limits the network size that can be studied due to complexity of the ILP model. In [2], a context-free language is proposed for the specification of VNFs and a Mixed Integer Quadratically Constrained Program (MIQCP) for the chaining and placement of VNFs in the network. The paper finds that the VNF placement depends on the objective, such as latency, number of allocated nodes, and link utilizations. In mobile core networks, [3] discusses the virtualization of mobile gateways, i.e., Serving Gateways (S-GWs) and Packet Data Network Gateways (P-GWs) hosted in data centers. They analyze the optimum placements by taking into consideration the delay and network load. In [4], the authors also propose the instantiation and placement of PDN-GWs in form of VNFs.

Unlike previous work, we solve the VNF placement problem by considering VNF replications which is the novel idea that we already proposed in [5]. In this work, we extend [5] to solve the optimum placement of VNFs by minimizing the network cost while maximizing load balancing with constraints on the available resources in mobile core networks. Therefore,
we propose a more realistic approach to enable an scalable growth of the mobile data traffic over years. This paper also includes a new traffic model of end-user traffic generated in the Radio Access Network, which previous paper did not consider. We also consider multiple VNFs placement per node with replications, which is a novel idea.

III. REFERENCE ARCHITECTURE

The NFV architecture is basically described by three components: Services, NFV Infrastructure (NFVI) and NFV Management and Orchestration (NFV-MANO). A service is the composition of VNFs that can be implemented in virtual machines running on operating systems or on the hardware directly. The hardware and software resources are provided by the NFVI that includes connectivity, computing, storage, etc. Finally, NFV-MANO is composed of the orchestrator, VNF managers and Virtualized Infrastructure Managers responsible for the management tasks applied to VNFs.

In NFV-MANO, the orchestrator performs the resource allocation based on the conditions to perform the assignment of VNFs chains on the physical resources. The sub-task running in the orchestrator, known as VNF Forwarding Graph Embedding (VNF-FGE) or VNF placement problem, tries to find the optimum place to allocate VNFs with regard to some specific objective, such as minimization of computation resources or power consumption, network load balancing, etc.

A. Gateway Virtualization: The EPC Use-Case

In the focus area of VNF placement problem, we propose to study a concrete scenario from legacy mobile systems, namely the Evolved Packet Core (EPC) networks, where we believe that the VNF placement in Service Function Chaining can bring most benefits. The proposed case study is shown in Fig. 1. The Serving Gateway (S-GW) and PDN Gateway (P-GW) are connected to e-NodeB and send the end-user traffic towards Internet. This traffic usually requires various additional services, currently deployed using traditionally embedded network functions, such as load balancers (LB), TCP optimizers (TCP_opt), firewalls (FW) and NATs. Considering the virtualization of the S-GW and P-GW on small data centers, as proposed in [3], both the data-plane and control-plane functions of the current legacy gateways are moved to an operator’s datacenter. At the places of the legacy gateways, an off-the-shelf network element (NE) is used to redirect the traffic from the origin access point of the Radio Access Network (formely done by the S-GW) to the DC and from the DC to the external backbone interface, which is, in the most cases, the former place of the P-GW. Typical VNFs related to control-plane functionalities of the S-GW and P-GW can not be further distributed on the network. In contrast, due to the large traffic volumes handled by the data-plane, parallel transmission paths can be used in the transport network, and thus, VNFs related to data-plane functions with high intensives tasks, e.g. TCP optimizers or Performance Enhancement Proxies (PEP), may also be replicated and be used in parallel at different network locations, as proposed in [6]. Thus, we study the chaining and virtualization of the additional functions related to the data-plane on different physical locations in the mobile core network. The number of required replicas will be in relation with the network traffic demands. Therefore, by knowing how many replicas are necessary we can place them to maintain an optimum network load balancing. On the other hand, the usage of additional network locations increases the number of required DCs, increasing the network costs. To this end, we define the problem as finding the optimum placement for these functions subject to the network costs while at the same time load balancing the network.

B. Network Traffic Model

In a real network, not all services will be virtualized at once. Thus in this paper, we assume two kinds of network traffic, defined as the background traffic and data center traffic. This is illustrated in Fig 2. The background traffic is related to the legacy not virtualized services and the traffic is generated from each core node to the rest of nodes and routed by a traditional network core protocol, e.g. IP routing. The virtualized services are responsible for the data center traffic. This traffic is generated at the S-NEs (former S-GW places) and has to be transported towards the Internet gateways (P-NE’s at former P-GW locations), as shown in Fig. 1. Since the
latter category of traffic, usually TCP connections, is generated by end users, it has to traverse a set of network functions to match the required service before accessing to Internet.

In our approach, we assume that the background traffic can be generated randomly and forwarded following the rules of a specific Traffic Engineering (TE) model defined by the traditional single path destination oriented IP routing. The TE model written in form of ILP formulation (detailed in the next section) minimizes the link utilization of all links in the network using a linear cost functions approach. Once the background traffic is load balanced, it will not be affected by the control of the data center traffic, but it has to be considered as a fixed input parameter for the next model called Resource Allocation (RA). This model is used to allocate optimally VNFs in the network trying to minimize the cost associated to the used resources, maximizing the network load balancing. The optimum placement of VNFs and replicas can provide the optimum locations for the data centers, which will be responsible for the instantiation of VNFs in the network.

IV. OPTIMIZATION MODELS

This section formulates the Link Capacity Dimensioning, TE and RA models as optimization problems subject to a set of constraints, as described next. The notation of all parameters and variables is summarized in Table I.

A. Link Capacity Dimensioning Model

This model allows the initial link dimensioning with the aim to minimize the required capacities for a given topology and a given traffic matrix. The set of available capacities are defined as an input parameter, such as, 10, 40 and 100 Gbps:

\[
\text{Minimize: } \sum_{\lambda} \sum_{t \in L} C_{\lambda}^{t} \quad (1)
\]

The constraint (2) assures that for the given link traffic (left side) the capacity of each link is dimensioned according to an over-provisioning factor \( \vartheta \), commonly used for fault tolerant operation or demand forecast. So, \( \forall \lambda \in L \):

\[
\sum_{\lambda} \sum_{t \in L} \lambda \cdot R_{\beta_t} \cdot t_{\lambda}^{l} \leq \vartheta \cdot \sum_{t \in L} C_{\lambda}^{t} \cdot t
\]

(2)

Each link can only take exactly one of the available capacities:

\[
\forall \lambda \in L : \sum_{t} C_{\lambda}^{t} = 1
\]

(3)

Finally, the next constraint assures that every traffic demand exactly uses one admissible path:

\[
\forall \lambda \in L_{\beta} : \sum_{p \in P_{\lambda}} R_{\beta_t}^{l} = 1
\]

(4)

B. Traffic Engineering Model

The TE model minimizes the utilization cost of all links in the network given as

\[\text{Minimize : } \sum_{\lambda} \sum_{t \in L} K_{\lambda} \quad (5)\]

where the cost of every link is related to its link utilization \( U_{\lambda}^{TE} \) and defined by the resulting value from all linear cost functions \( y_{\lambda}(U_{\lambda}^{TE}) = a_{\lambda} \cdot U_{\lambda}^{TE} - b_{\lambda} \) as follows:

\[
\forall \lambda \in L, \forall y \in Y : K_{\lambda} = y\left(U_{\lambda}^{TE}\right)
\]

(6)

where constants \( a_{\lambda} \) and \( b_{\lambda} \) are chosen in a way that the slope of the incremental cost values \( y_{\lambda} \) approximately follows an exponential function [7]. The link utilization is given by

\[
U_{\lambda}^{TE} = \sum_{\lambda} \sum_{p \in P_{\lambda}} \frac{\lambda \cdot R_{\beta_t}^{l} \cdot t_{\lambda}^{l}}{c_{\lambda}}
\]

(7)

The summation takes into account each traffic demand \( \lambda \) out of the set of all background demands \( \lambda_{\beta} \) whose specific path \( p \in P_{\lambda} \) is traversing link \( l \), divided by the link capacity. The only routing constraint for this model assures that every traffic demand exactly uses one admissible path:

\[
\forall \lambda \in L_{\beta} : \sum_{p \in P_{\lambda}} R_{\beta_t}^{l} = 1
\]

(8)

MIPRO 2017/CTI
C. Resource Allocation Model

The second optimization model, called RA model, uses a similar objective function as the previous model, but adding a new term using the binary variable \( F_n \) (1 means the node is used by at min 1 VNF, 0 no VNF is assigned) which minimizes the number of nodes that are allocating VNFs subject to the constraints explained below:

\[
\text{Minimize} : \alpha \left( \sum_{l \in L} K_l \right) + \beta \left( \sum_{n \in N} F_n \right)
\]

Both terms are weighted by \( \alpha \) and \( \beta \) parameters to enable the desired tradeoff between load balancing and network costs. In this paper we restrict to use them as selection parameter for one of the objective functions. Although, we only consider these two variables to reduce computing complexity, additional parameters such as network delay or power consumption, already considered for future extensions of this work, could be added to the model.

Differently to the TE model, in this model, for each service chain \( s \in \mathcal{S} \) a total number of \( \| \Lambda^s \| \) traffic demands \( \lambda \in \Lambda^s \) are defined, where each of them could not split and has to be forwarded over one specific path \( p \in \mathcal{P}^s \), which is taken into account by binary variable \( R_{p}^{\lambda,s} \) (is only 1 if path \( p \) is used by demand \( \lambda \)). Furthermore, the number of paths \( \| \mathcal{P}^s \| \) may be different than the number of demands. Thus, without the usage of VNF replicas all demands of a service chain must use the same path. As a result, the link utilization due to the RA model is given by:

\[
U_{l}^{RA} = \sum_{s \in \mathcal{S}} \sum_{\lambda \in \Lambda^s} \sum_{p \in \mathcal{P}^s} \lambda \cdot R_{p}^{\lambda,s} \cdot \frac{t_{l}}{c_l}
\]

In the RA model, the linear utilization cost functions take into account the superposition of the fix given background TE traffic with the RA traffic specified as:

\[
\forall l \in L, \forall y \in \mathcal{Y} : K_1 \geq y \left( U_{l}^{TE} + U_{l}^{RA} \right)
\]

Because each demand has to be assigned to a path, the routing constraint is given by

\[
\forall s \in \mathcal{S} : \sum_{\lambda \in \Lambda^s} \sum_{p \in \mathcal{P}^s} R_{p}^{\lambda,s} = \| \Lambda^s \|
\]

Then, to know if a specific node is being used or not, the binary variable \( F_n \) will only be 1 if \( \geq 1 \) VNFs are assigned to a node \( n \), which is assured by the constraint:

\[
\forall n \in \mathcal{N} : \sum_{s \in \mathcal{S}} \sum_{v \in \mathcal{V}} F_{n}^{v,s} \frac{W}{V} \leq F_n \leq \sum_{s \in \mathcal{S}} \sum_{v \in \mathcal{V}} F_{n}^{v,s}
\]

where the binary variable \( F_{n}^{v,s} \) indicates, if VNF \( v \) from service chain \( s \) is allocated to node \( n \). \( W \) is a large constant to assure, that the left side of the equation is always less than 1. The next constraint (14) assures that a certain traffic demand \( \lambda \) can only use a path \( p \) if the requested service chain

\[
\forall s \in \mathcal{S}, \forall p \in \mathcal{P}^s, \forall \lambda \in \Lambda^s : R_{p}^{\lambda,s} \leq R_{p}^s
\]

Furthermore, the number of admissible paths for each service chain \( s \) is constrained by the number of replicas. Then, for \([0, 1, 2, ..., r_{max}] \) replicas, each service chain can use at maximum \( [1, 2, 3, ..., (r_{max} + 1)] \) paths to forward traffic, i.e.,

\[
\forall s \in \mathcal{S} : 1 \leq \sum_{p \in \mathcal{P}^s} R_{p}^s \leq r_{max} + 1
\]

Therefore, with no replicas, a certain service chain can only use one path, while increasing number of replicas, the number of admissible paths proportionally increases. Then, for each activated path in service chain \( s \) defined by \( R_{p}^s \), the next constraint allocates all VNFs of the service chain:

\[
\forall s \in \mathcal{S}, \forall p \in \mathcal{P}^s, \forall v \in \mathcal{V} : R_{p}^s \leq \sum_{n \in \mathcal{N}} F_{n}^{v,s}
\]

On the other hand, the sequence order of VNFs in the service chain has to be maintained. Then, for a certain path \( p \), the function \( v \) can not be allocated in the node \( n \), if the previous function \( v - 1 \) is not already allocated in any of the previous nodes of the same path. So, \( \forall v \in \mathcal{V}, \forall p \in \mathcal{P}^s, \forall n \in \mathcal{P} \):

\[
\left( \sum_{m=0}^{n} F_{m}^{(v-1),s} \right) - F_{n}^{v,s} \geq R_{p}^n - 1 \quad when \quad v > 0
\]

The next two constraints limit the maximum number of VNFs that can be allocated in the network. First, the maximum number of VNFs allocated in some specific node \( n \) is constrained by the parameter \( w_{max} \):

\[
\forall n \in \mathcal{N} : \sum_{s \in \mathcal{S}, v \in \mathcal{V}_s} F_{n}^{v,s} \leq w_{max}
\]

Second, if a certain function \( v \) can be replicated \( r_v \), then, the maximum number of replicas is constrained by the maximum number of active paths \( R_{p}^s \). If the function can not be replicated, then can only be placed once. So, \( \forall s \in \mathcal{S}, \forall v \in \mathcal{V} : \)

\[
\sum_{n \in \mathcal{N}} F_{n}^{v,s} \leq r_v \sum_{p \in \mathcal{P}^s} R_{p}^s + 1 - r_v
\]
To improve the load balancing feature using replicated VNFs, we introduce an additional constraint. In the proposed replication model, we exclude the case where two selected paths $p_1$ and $p_2$ from the service chain $s$ are choosing the same shared node $n$ to place the same function (original and replica). So, following the example shown in Fig. 3, $v_2$ and $v_{2,rep}$ can never be allocated in the same node $n$. Then, for $\forall v \in V_s$, $\forall p_1 \in P_s$, $\forall p_2 \in P_s$, $\forall n_1 \in p_1$, $\forall n_2 \in p_2$:

$$R^a_{p_1} + R^a_{p_2} + 2F^{v,s}_{n} \cdot r_v \leq 3 \quad \{ \begin{array}{l} n_1 = n_2 = n \\
 v \neq 0 \neq V_s - 1 \end{array} \} \quad (21)$$

This constraint is added for all pairs of admissible paths of each service chain. To reduce the computing complexity, only link dis-joint paths are taken into account.

V. PERFORMANCE EVALUATION

In this section, we show the results of four different scenarios: 1) network load balancing (minLB), 2) minimization of network costs (minNC) given by the number of required data centers (DCs), 3) minimization of network costs with limited number of VNFs per DC (minNC_constr) and 4) network load balancing with limited number of DCs to place VNFs and limited number of VNFs per DC (minLB_constr). The LP models are implemented using the Gurobi Optimizer [8] and the topology (26 nodes and 84 links) is chosen from SNDLib website [9] and shown in Fig. 4.

The background traffic is randomly generated for each source-destination node pair within the interval [1, 4] Gbps. Since the allocation of VNFs is known to be NP-hard, we restrict to 9 eNBs and 3 internet gateways placed in the network, which are responsible for the data-center traffic (see Fig.4). Unlike other proposals, where the traffic can not be split, each eNB generates 10 traffic demands of 4.4 Gbps to its associated gateway, which can be routed along different paths. For the link dimensioning, the background and data-center traffic is optimally load balanced by solving the TE model, where the GWs are not virtualized and placed at the original locations. Based on the traffic flows, we assume an overprovisioning factor of 1.2, which are chosen from different granularities (2.5, 10, 40, 100 and 200 Gbps).

For the RA model the background traffic is routed over the single path derived above, which yields the partial link utilization $U^{TE}_l$. Only the DC traffic is now optimally routed, possibly using parallel paths. All traffic demands between NEs are handled by one service chain. The service chain analyzed is shown in Fig. 2, which is composed of VNFs (i.e. S-GW, P-GW, LB), which can not be replicated, VNFs (i.e. TCP-optimizer) and VNFs (i.e. Cache PEP), which can be replicated, and finally, VNFs (i.e. LB, FW, NAT), which again can not be replicated. Depending of the optimization objective, all VNFs may be placed in the same or in different DCs. We assume the location of the DCs and the assignment of the VNFs to DCs are the variables to optimize.

A. Network Load Balancing vs Minimum Network Node Costs

We study optimization results obtained for the exclusive minimization of the load balancing (minLB, $\alpha = 1, \beta = 0$) and exclusive minimization of the network costs (minNC, $\alpha = 0, \beta = 1$). In the Fig. 5, we show the comparison of the average link utilization, maximum link utilization, number of used DCs and maximum number of VNFs per DC with no replication, with one and two replicas, respectively. Due to Eq.(16) the number of replications are restricted to the maximum value $r_{max}$, later shown in the figures as replicas.

For the minNC scenario we observe expected results. Due to the cost optimization, all VNFs are placed in 3 DCs traversed by the same single path between NEs. Thus the average and maximum link utilization is maintained constant for any case. The maximum number of VNFs per DC for the NC scenario changes if one VNF replication can be used (see Fig. 5c), although the optimized value of the objective function remains the same. This comes from the fact that the solution is only unique with respect to the number of used DCs and not to the number of assigned VNFs per DC, which is an important behavior and for further studies.

On the other hand, in the minLB scenario, the average link utilization increases with replication (Fig. 5a) because of the optimization model tries to decrease number of overloaded links using longer paths with underutilized links, as can be seen from the reduction of the maximum link utilization (Fig. 5b). In more detail Fig. 6 shows a histogram of the link utilization, which verifies, that an increment of the available parallel paths to forward traffic decreases the number of overloaded links due to replication. The improvement between one and two replicas is not significant, but it is totally dependent on the chosen topology. The effect of the objective function (9) is quite important, as can be seen from the chart embedded in Fig. 6. On the other hand, as shown in Fig. 5c, the number of used DCs increases, due to for longer paths more DCs are required to allocate replicas.

B. Network Optimization under DC and VNF Constraints

In the minNC case, the objective is to minimize the number of used DCs without restricting the number of VNF per DC. However, in a realistic case the number of VNFs allocated to a virtual machine (VM) will be restricted by the available computation resources, e.g. the service processing time. Furthermore, the number of VMs per DC will be constrained as well. However, due to our small scale example we will
deal with this problem by constraining the maximum number of VNFs per DC to 8 VNFs. The solution of the constraint optimization problem minNC_constr results into 6 DCs, which doubles the network costs compared to the previous case (Fig. 5c). Due to the increased number of DCs, the use of VNF replications offers some advantages, as shown in Table II. The constraint reduces the average number of VNFs (avg-vnf) per node and further, the usage of replicas allows to use some alternative paths in parallel, reducing the average path length (in hops). Consequently, the total network traffic decreases as well as the average link utilization.

Finally we want to optimize the load balancing under constraints given by the maximum number of usable DCs as well as the maximum number of VNFs per DC, where the constraints are taken from the optimal results given by the minNC_constr problem. In Fig. 7, we show the results for the histogram of the link utilization. Here, we can see that one replica is still able to improve the load balancing, but due to the small example with less effect.

VI. CONCLUSIONS

Since VNFs can only be placed onto servers located in data centers, the traffic directed to these DCs has not only significant impact on the network costs but also on the load balancing. To enable a cost efficient DC placement jointly with network load balancing, we introduce the VNF placement with replications in this paper, and especially how the replications of VNFs can help to load balance the network. For future work, we will extend this model to allow more variables to optimize and work with more scenarios.

Abstract – This paper presents results of an analysis of the impact of the human resources changes in Scrum teams. Four Scrum teams were tracked (two developments and two quality assurance) along with their productivity and performance. Analysis showed that human resources changes have a significant impact on the entire team and its behavior. Their effort increased by adding overtime hours. In the same time, their performance and effective work decreased, which is reflected on the quantity of work that can be billed to the client. The analysis shows that it takes, in average, three sprints (each lasting fourteen days) for new team members to fully adjust to the team development process and acquire a business knowledge needed for maximum productivity. Teams whose members have been working together longer period and who have more senior members can adjust to team shifts more quickly. The analysis also showed a correlation between quality assurance and development team – when development team had extra utilization due to overtime, quality assurance team had an increase in overtime hours almost proportionately.

I. INTRODUCTION

In 2001, 17 software development leaders created the "Manifesto for Agile Software Development" [1]. One of the principles behind the Agile manifesto is that the best architectures, requirements, and designs emerge from self-organizing teams[2]. Manifesto addresses many points in software development but the main point is that teams require autonomy to achieve excellence. However, the Agile Manifesto does not prescribe steps on achieving the goals [1][3]. Instead, it is necessary for an organization to use a more specific framework like extreme programming, Scum, Kanban, etc. Scrum is the most popular one[4][5].

Scrum is designed in an attempt to not only increase productivity of the team and the quality of the end product but to increase the job satisfaction as well by creating a comfortable workplace. The goal of Scrum is to shift focus to the team itself in an attempt to address team members concerns which, in turn, should bring higher quality product [2].

The six core Scrum principles are [3]: empirical process control, self-organization, collaboration, value-based prioritization, time-boxing and iterative development. Scrum principles are non-negotiable and must be applied [3]. It is obvious that all Scrum principles are easier to follow with a strong and coherent team, which has been working together for longer period. Job related skills are crucial but soft skills and ability of the team to create a friendly work environment is just as important for Scrum team.

A key strength of Scrum lies in its use of cross-functional, self-organized, and empowered teams [4]. To fully utilize those strengths, it is crucial to enhance and later preserve the productivity and efficiency of the team. During the relatively short history of Scrum, many collaboration tools have been developed in an attempt to track and evaluate the team performance. They help the team and management in organization, planning, tracking the project progress and detecting bottlenecks. However, there are variables in Scrum that are not that easy to track, measure and react to. In general, control of some aspects of agile software development is based on experience from practice, like stable velocity [6] or predicting change requests [7], etc. Human resource (HR) issues is an example of those be a challenging factor for every Scrum project[8][9].

Preserving a stable and well organized Scrum team for longer period on dynamic job market (especially in IT sector) is becoming increasingly difficult. Scrum teams, at some point, are facing changes in human resources. This study is focused on analyzing their ability to react on these changes. New team member can disrupt agile principles. It is difficult for a team member to prioritize work on the bases of business value without proper business knowledge. Team can have problems with self – organization, as they are unaware of the knowledge and capacity of new members. Collaboration can suffer as new members may lack soft skills etc. [10][11]. Coherent and stable team will ultimately deliver higher quality products.

The Scrum aims for a quick delivery of viable product – team must be able to quickly respond to any changes in business process and implement the support for the business flow inside the application they are building. This concept can result in an absence of detailed documentation [12]. Newcomers most overcome this obstacle before becoming a useful team member. The absence of documentation means that the team members are the sole owners of business logic [13]. Changes in human resources inside the team could result in a cascade effect of productivity loss on team level as team members might be forced to dedicate additional time to compensate during the knowledge transfer phase [13]. On top of that, the quality of the product can drop since an increase in number of bugs can happen due to the lack of business logic knowledge.

Considering all the above, an argument can be made that human resources changes have a negative impact on productivity of Scrum team.
the team. This case study attempts to determine how exactly this affects the team by using credible metrics to measure the team performance during this period.

II. CASE STUDY

To determine how the HR changes are affecting Scrum teams we have conducted an analysis where we tracked four teams during the course of 19 sprints. Two of the teams were development (DEV) teams while two were Quality Assurance (QA) teams. All teams worked on the same project for the same client. Team changes were tracked along with their productivity and their billable utilization (percentage of work which can be actually billed to client).

The focus of the analysis was on the development teams. QA teams were tracked to show the correlation between the two. Reasoning for HR changes was not considered - analysis focuses only on parameters that could be precisely measured.

A. Team organization and Scrum in case study

Sprint lasts for 14 days for all teams analyzed. They are synchronized so all teams begin and end their sprint at the same time. First day of the sprint includes sprint retrospective where team evaluates previous sprint and establishes points of improvement. New members are most often presented on the first day of the sprint. Sprint planning occurs day before the end of the sprint or on the last day. Sprint demo, where new features developed are presented to client, occurs at the end of each sprint. Team members from all teams (both DEV and QA) are present. After the product demo, development team implements feedback from client, if any. After that the product will be deployed to QA environment for testing. Once the quality assurance is completed, all significant notes from the QA teams implemented the process continues on UAT (staging) environment. In this environment, all items are tested again and regression testing takes place. This is the phase where client can conduct their own tests. Any item can be returned to development team for additional work from any of these stages.

Production release occurs every month and includes development work from two sprints. The code is thoroughly tested and ready to be shipped to the end users. Figure 1 shows the release cycle and responsibilities of each team during the process. Some of the involvement is amended for clarity (for example, client is involved in development and QA phase if required by the team).

B. Metrics used

In this analysis, we measured three key parameters: resource utilization (referred simply as utilization), billable utilization and quality for the development teams.

- Resource utilization – a percentage of planned work vs. actual work done on team level. Planned utilization takes into account all planned activities and absence of team members (holidays and unpaid and annual leaves). It does not, however, include any unplanned activity such as sick leaves or unplanned personal leaves. Ideal utilization would be 100% but it is often difficult to achieve, especially in teams with more team members. For teams analyzed in this study, fluctuations in utilization percentage are not a cause for concern for management as long as it does not affect the billable utilization. However, if the team utilization raises above 100% this means that overtime work hours were needed and should be addressed to determine the cause.

- Billable utilization – utilization streamed toward fulfilling client requirements for the software. All activities from which client does not gain short term benefit are considered as non – billable. These may include company administration activities, in – company meetings, internal and external trainings (unless explicitly requested by client to comply with the immediate needs) etc. It is important to note that Scrum activities count as billable utilization (daily Scrum meetings, sprint retrospective, sprint demos etc.). Ideal billable utilization is 100% which is the maximum. Non – billable utilization does not represent the time “wasted”. It only means that this time cannot be invoiced to client.

- Quality – is calculated for the development team as a measure of backlog items (BI) completed in a sprint without QA or end user finding any issues in implementation. The formula for calculating quality is: \[100 \times (BI\ done / BI\ Failed)\]. For the QA team, it is calculated with the same formula but using the number of bugs found by QA team and those found by client (usually on UAT environment and in production). QA team quality was not considered in this analysis.

![Figure 1. Release cycle for the Scrum teams in case study](image-url)
There are several important points to note on Table I. All teams had HR changes during the time analyzed. All teams, except QA 1 had team members leaving the team. DEV 1 team not only had most changes in team but the team size doubled during the time analyzed (from three to six). There was a total of 13 HR changes in this team, one more than all other teams combined. DEV 2 and QA2 had smaller team changes and kept the original number of team members. QA1 team had an increase of team members by 50% - two new team members joined and none left.

Also, we had two occurrences of multiple team member changes in a single sprint. In sprint 5 DEV 1 experienced major changes with two team members leaving and three joining in. QA2 team had similar situation in sprints 12 and 13 with two members leaving and two joining the team.

Table II shows all measured parameters per team and sprint, along with the HR changes count for comparison. It can be seen that with every team members change there is a notable change in parameters measured.
Figure 2 shows utilization, billable utilization and quality for DEV 1 during the 19 sprints which were analyzed. DEV 1 is especially interesting as it had the most HR changes, as stated previously. It can be seen that each change was followed by decline of billable utilization. Also, for each outgoing member (four occurrences) we have an increase of utilization when compared to previous sprint, which indicates overtime work. Billable utilization is decreased with each new incoming HR in average by 16%, while utilization increased by 4% in average.

When it comes to team members leaving the team, there were no significant changes in billable utilization (negative trend of -0.4%). It also had an effect on utilization which was increased by 12%. Quality dropped by 6% in average when new team members joined, while it dropped by 1.5% when team members left the team.

The most significant is sprint 5 when team experienced a major HR changes, followed by another two in following two sprints. Major fall of billable utilization, increase of utilization and a notable drop in quality can be seen. Parameters were slowly stabilizing until the sprint 13 when new changes were made.

DEV team 2 had less HR changes which can be observed on Figure 3. As a result, the team had significantly less oscillations in parameters measured. However, even though this team consists of more experienced members when compared to DEV 1, it also had troubles adjusting to HR changes.

In average, billable utilization dropped by 5.5% when new team members joined while utilization increased by 1.5%. When team members left the team, billable utilization dropped by 2%, in average, while utilization was increased by 1.5%. Meanwhile, quality actually increased by 1% in both cases, meaning that team leveraged the seniority of both incoming and existing team members.

However, although the HR changes affected the DEV2 team, it can be observed that the team adapted faster when compared to less experienced DEV1, even managing to increase quality, while DEV1 had significant drop.
QA teams showed similar trends to DEV teams. QA1 team had an average drop in billable utilization by 24% when new members joined, which can be observed on Figure 4. Utilization increased by 1% at the same time. In average, three sprints were needed for new members to reach billable utilization of the team members already in place. No team members left the team during the period analyzed.

QA2 team had the most HR changes after DEV1 team, with three members joining and three leaving the team. As expected, billable utilization dropped by 11.1% in average with new team members but it increased by 1.5% when they had team members leaving. Utilization was reduced by 5.5% and increased by 3% for team for incoming and outgoing team members respectively.

III. DISCUSSION

Team with more experienced members handles the HR changes better and manages to “recover” faster. Their utilization does not increase significantly while less experienced team has more issues and suffer from increased utilization during the sprints following the HR changes.

Utilization, measured as a percentage of planned work and work done, is an important parameter to observe. Fluctuation in any direction is not desirable, especially when monitoring the HR changes. Rise in utilization means that team members spent more time introducing the new members to business processes and as a consequence, they worked overtime to compensate so that the sprint goals can be achieved. Lower utilization, in most cases, means that sprint goals were not achieved.

Although utilization above 100% may not look like a serious indicator, a simple calculation proves otherwise. For example, in a team consisting of four members, assuming that the sprint has 10 work days with 8 work hours each, it brings us to a total of 320 work hours per sprint which represents the ideal utilization of 100%. If the utilization is increased by 10% that means each team member has additional work day on top of 10 existing.

Figure 4. Trend of measured parameters in comparison with HR changes per sprint for QA 1 team

Figure 5. Trend of measured parameters in comparison with HR changes per sprint for QA 2 team
Impacts that this might have is a motivation for future research.

It is also important to observe a correlation between the development team’s utilization and the one of the quality assurance, which is to be expected. This can be clearly seen during the last three sprints – whenever the development teams were over – utilized, quality assurance were over – utilized almost proportionately.

Apart from the impacts which are measurable and presented above, HR changes, especially unexpected and unplanned, happening during the sprint had a negative effect in fulfilling the sprint goals and commitment made to the client. In all cases analyzed this lead to the sprint re-planning and, in some cases, adjusting the scheduled release dates. This can reduce the client satisfaction since their own plans for the end product might be affected as a result.

IV. CONCLUSION

Conclusions of the case study are presented in bullets below:

- Changes in human resources have significant negative effect on the team as a whole.
- Team utilization change after HR changes goes both ways, depending on whether the team choses to work overtime to compensate. In three out of four team’s utilization was increased when compared to previous sprints.
- Billable utilization (work actually billed to client) drops by 14% in average in the sprint when new team members are introduced but tends not to significantly change when team members leave.
- Quality for the development teams drops by 5.5% in average in sprint when new team members are introduced, while it drops by 1.5% when team members leave.
- A correlation between QA and DEV team’s utilization has been established - when DEV team was significantly over utilized, QA was over - utilized almost proportionately.
- It takes, in average, three to four sprints for the team to consolidate and return to previous values measured, provided that no new HR changes take place.
- To maintain product quality, high billable utilization and reduce the risk of over-utilization it is crucial to maintain the stable and coherent Scrum team for as long as possible.

V. FUTURE RESEARCH

This analysis did not account for in-sprint re-planning nor does it include any mid – sprint requirements which might affect all the parameters analyzed above. Motivation for future research is to track all related variables to provide more insights into performance fluctuations of scrum teams. As previously noted, effects of over – utilization on product quality and ultimately, job satisfaction should be analyzed.

Also, the reasoning between the human resources changes was not considered. The study can be improved by comparing the impacts of team members leaving the team voluntary (team/project change, pursuing job opportunities in other companies etc.) in comparison to leaving because they failed to meet company quality standards.

Sažetak - U radu su predloženi model i instrumenti mjerenja pojedinih elemenata/komponenti društveno odgovornog poslovanja kao i stupa društveno odgovornog poslovanja i stupnja razvijenosti konkretno-odgovornih sposobnosti poduzeća. Na temelju toga dan je model povezanosti stupnja razvijenosti društveno odgovornog poslovanja i stupnja razvijenosti konkurske sposobnosti poduzeća. Uz pomoć modela analiziralo se utjecaj na utjecaj ekonomske, društvene i ekološke komponente na razvijenost ključnih kompetencija (opipljivi resursi, neopipljivi resursi i organizacijske sposobnosti) koji su izvor konkurske prednost, donosni sposobnosti poduzeća. Istraživanjem se želi povećati razumijevanje važnosti društveno odgovornog poslovanja i opseg znanja o njemu u kontekstu povećanja konkurskog poslovanja poduzeća. Empirijska istraživanja provedena su formuliranim anketnim upitnikom na uzorku od 76 velikih hrvatskih poduzeća u 2011. godini. Rezultati istraživanja su ukazali na pozitivnu međuovisnost ovih dvaju pokazatelja.

I. UVOD

Društvena odgovornost pomaže poduzeću u izgradnji ugleda, osigurava motiviranost i zadovoljstvo zaposlenika kao i širu društvenu prihvaćenost, jača konkurentske sposobnosti i dugoročno omogućava brži poslovni razvoj poduzeća. U tom smislu uvijek poduzeća uz financijsku, moraju imati i vjerojatno imaju i održivi razvoj.

II. MODEL STUPNJA RAZVJENOSTI DRUŠTVENO ODGOVORNOG POSLOVANJA

Klasifikacija DOP-a je predstavljena u obliku matrice pokazatelja inicijalnih ciljeva koji se mogu iskoristiti kao polazna točka za razvoj pokazatelja održivosti i metoda procjene zadovoljenosti ciljeva i načela DOP-a. Osnovna klasifikacija područja DOP-a koja odražavaju ciljeve i načela DOP-a je dana u SFA1A dokumentu " An introduction to CSR": Ekologija; Društvo (ljudska prava i prava radnika, zdravstvo, društvena pitanja) te Ekonomija (etičko poslovanje, upravljanje). Navedena područja DOP-a predstavljena su od strane eminencitnih udrugstv koje se bave razvojem DOP-a kao što su "Business in the Community", "CSR Europe", "Business Leader Forum" itd. te su postali dio raznih nacionalnih i regionalnih programa. DOP više predstavlja univerzalni skup regulativa i potrebnih znanja vezanih za svako poduzeće pojedinačno. Potrebno je definirati taj skup osnovnih pokazatelja za svako područje DOP-a.

Osnovna matrica DOP-a se sastoji od ekonomske, društvene i ekološke matrice. Svaka matrica definira osnovne tematike DOP-a koje predstavljaju najbolja iskustva koja vežemo uz odgovarajuće pokazatelje DOP.

A. Ekonomska matrica DOP-a

Ekonomska matrica u prvom redu podrazumijeva etičko poslovanje, transparentno upravljanje i sudjelovanje u globalnom partnerstvu.

B. Društvena matrica DOP-a

Društvena matrica u prvom redu podrazumijeva ljudska prava i radne norme, zaštitu zdravlja i društvena pitanja.
C. Ekošća matrica DOP-a

U današnje vrijeme od poduzeća se očekuje integracija odgovornosti za okoliš na svim razinama poslovanja: iznalaženjem održivih rješenja u iskorišćavanju prirodnih resursa; smanjenjem otpada, zagađenja i štetnih emisija; poboljšanjem učinkovitosti i produktivnosti na svim poljima, pogotovo na području upravljanja vodom, energijom i sirovinama.

III. MODEL STUPNIJA RAZVIJENOSTI KONKURENTSKE SPOSOBNOSTI PODUZEĆA

Resursni pristup strategiji

Slika 1. Resursni pristup strategiji [3]
Operacijska djelotvornost poduzeća je potrebna jer u suvremenim uvjetima poslovanja predstavlja standard tržišnog natjecanja. Međutim, ona nije činitelj razlikovanja među suparnicima. Strategija je ta koja stvara pretpostavke dugoročnog opstanka poduzeća sa obzirom da se temelji na identificiranju izvora razlikovne odnosno konkurentske prednosti te na izgradnji i održavanju konkurentske prednosti.

Uz pretpostavku da je kreiranje komp socijske strategije odziv na opaženu ekonomsku prijetnju (Zadek, 2006) [4], u ovom poglavlju može se prikazati teorijski model koji omogućava poimanje društvene odgovornosti kao strateškog kreatora konkurentske prednosti. Osnovni elementi modela društvene strategije: tržišne prilike, unutrašnji resursi i kompetencije, organizacijske vrijednosti, industrijska struktura i dionici, moraju biti povezani sa temeljnim poslovanjem kompanije (Burke i Logsdon, 1996; Husted 2003; Zadek 2005). Djelovanje kompanije mora biti usmjereno i na društvena pitanja, odnosno na stvaranje strategije fokusirane na društvenu dimenziju konkurentsnosti, društveni utjecaj lanca vrijednosti i generička društvena pitanja (Porter i Kramer, 2006) [5]. Nakon formuliranja društvene strategije, možemo preći na formuliranje konkurentske prednosti koju je kreirala ova strategija, što je pokazano na slici 2.

Slika 2. Teorijski model- izvori konkurentske prednosti (izradili autori)

Uzimajući u obzir vezu između resursne teorije konkurentske prednosti (Barney, 1991) [6] i teorijskih i empirijskih dokaza određenih poslovnih prednosti, povezanost društvene odgovornosti i konkurentske prednosti manifestira se kroz izravni utjecaj među njihovim odgovarajućim elementima, što rezultira jačanjem reputacije i imidža kompanije, motivacijom zaposlenika, zadržavanjem izuzetnih pojedinaca, stvaranjem vrijednosti i boljih ekonomskih performansi usklađivanjem društvene odgovornosti i kompanijske strategije kroz inovativne i učinkovite društvene projekte, bolje socijalne performanse, bolje ekološke performanse te jačanjem kompanijskog upravljanja. Ovi elementi su nematerijalni resursi kompanije te kao takvi ključni čimbenici za stvaranje konkurentske prednosti ukoliko imaju sljedeće karakteristike: vrijednost, rijetkost, nepotpuna imitabilnost, nedostatak strateških ekvivalenta (Barney, 1991; Grant, 1991) [6] i [7].

Također je važno naglasiti da legitimnost ovim elementima daje i društvo i da bi se to dogodilo, djelovanje DOP-a mora biti u skladu sa društvenim očekivanjima. Formulirajući društvenu strategiju poduzeća, organizacija može ostvariti konkurentska prednost ukoliko u obzir uzima i društvenu odgovornost.

Dakle, ovim gore navedenim teorijskim modelom možemo između ostalog postići integraciju strateškog menadžmenta društvene odgovornosti u temeljno poslovanje i strategiju kompanije.

Pod pojmom „resursa“ mogu se obuhvatiti različiti oblici imovine kojima poduzeće raspolaže, te ih koristi za postizanje poslovnih ciljeva, odnosno implementaciju planova. S aspekta postizanja konkurentske prednosti na temelju resursa trebalo bi spomenuti kako se pod resursima podrazumijevaju fiksni proizvodni faktori specifični za pojedino poduzeće, a ne varijabilni faktori koje je lako nabaviti na tržištu (popis standardiziranih sirovina, nestručne radne snage itd.). Grant (1991) [7] ima stajalište o tome kako konkurentska prednost poduzeća ovisi o dvjema temeljnim čimbenicima: trajnosti (održivosti) resursa i sposobnosti poduzeća za stvaranje profita (ekonomske rente) na temelju posjedovanja dotičnih resursa.

U Collinsovom članku (1994, str. 145) navodi se da se (strateška) *spособност* može prosuditi kao atribut (snaga) poduzeća za učinkovitije obavljanje određene aktivnosti,
odnosno efikasnije korištenje raspoloživih resursa, iz čega, pod uvjetom raspolaganja usporedivim resursnom bazom, poduzeća u posjedu (strateških) sposobnosti stječu konkurentska prednost. U tom kontekstu se može prihvatiti i „generička definicija“ (strateških) sposobnosti poput „svojstava organizacije kao kompleksnih rutina društvenog karaktera koje određuju razinu efikasnosti s kojom poduzeće transformira inpute u outpute“ (Collis, op. cit.). To bi značilo da sposobnost nastaje kao rezultat kompleksnih interakcija između i unutar opipljivih i neopipljivih resursa. Sposobnost je kapacitet kompanije elektronskim putem posredovati poduzeću omogućiti servisu, odgovornosti te svemu drugom što nekom vrhunskoj kvaliteti, inovacijama, organizaciji poslovanja, konkurentnoj prednosti u trenutku tri do četiri k Godina. Co. preporučuju da kompanija posjeduje u svakom kompaniji konkurentske prednosti umjesto krajske prednosti. Slika 3. Model (matrica) povezanosti stupnja razvijenosti društveno odgovornog poslovanja i konkurentske sposobnosti poduzeća

Istražit ćemo kako društveno odgovorno poslovanje, s obzirom na svoju razvijenost u poduzeću, utječe na konkurentske sposobnosti samog poduzeća. Do govora na ovo pitanje dolazi se međusobnim križanjem elemenata razvijenosti društveno odgovornog poslovanja sa pojedinim elementima konkurentske sposobnosti poduzeća (sa njihovim podelementima). Rezultat međusobnog križanja navedenih komponenti/elemenata i podele poduzeća je 3x8 matrica koju su sami izradili autori.

V. REZULTATI EMPRIJSKOG RAZMATRANJA

možemo zaključiti da je društveno odgovorno poslovanje u istraživanim poduzećima znatno razvijeno. To smatramo dobrim rezultatom za poduzeća u Republici Hrvatskoj koja na kraju rezultatski gledano ulažu u razvoj društveno odgovornog poslovanja u zadovoljavajućoj (znatnoj) mjeri.

Također je donijet finalni zaključak je li i koliki je stupanj razvijenosti konkurentske sposobnosti u istraživanim poduzećima. U slijedećoj tablici rezimirani su svi sumarni rezultati razvijenosti konkurentske sposobnosti po pojedinim podelementima u istraživanim poduzećima.

**Slika 5. Ukupna razvijenost konkurentske sposobnosti [11]**

Iz tablice VI vidljivo je da se od spomenutih triju podelementa, s obzirom na srednje vrijednosti, nešto malo više od ostalih, ističe razvoj neopipljivih resursa po svojoj aritmetičkoj sredini. Medijan i mod svih triju podelementa su približno isti. Za razvoj neopipljivih resursa se može zaključiti, uzimajući u obzir srednje vrijednosti i rezultate obrađene u prethodnom tekstu, da je ipak bliži razvijenosti opipljivih resursa u znatnoj mjeri dok se za preostali podelement- razvoj organizacijskih sposobnosti može zaključiti da ipak više nagnje djelomičnoj (donekle) razvijenosti.

Za ukupnu razvijenost konkurentske sposobnosti u istraživanim poduzećima, može se zaključiti da je ona na visokoj razini. U prilog ovakvom zaključku svjedoči aritmetička sredina sa vrijednošću 3,6, te medijan koji iznosi 3,56. Osim toga, slika 5, koja pokazuje distribuciju istraživanih poduzeća s obzirom na ukupnu razvijenost konkurentske sposobnosti, također ukazuje na spomenuti zaključak. Možemo uočiti da skoro 60% istraživanih poduzeća ima ukupnu konkurentska sposobnost koja je razvijena u znatnoj mjeri ili u potpunosti u odnosu na 40% istraživanih poduzeća koja imaju osrednju (donekle) ili neznatnu razvijenost. Slika 5 vidljivo je da je sama distribucija istraživanih poduzeća pomaknuta prema

**Slika 4. Ukupna razvijenost društveno odgovornog poslovanja [11]**

Sveukupno gledajući razvijenost društveno odgovornog poslovanja u istraživanim poduzećima, njena aritmetička sredina iznosi 3,63. Medijan, druga srednja vrijednost 3,66, tj. prosječno gledano društveno odgovorno poslovanje je između donekle do razvijeno u znatnoj mjeri, s tim da ova srednja vrijednost je ipak puno bliže razvijenosti u znatnoj mjeri. Treća srednja vrijednost, tj. mod ima vrijednost 4,8, odnosno 4, ako gledamo ovu varijablu kao grupiranu varijablu, što bi značilo da najveći broj istraživanih poduzeća u uzorku ima znatnu razvijenost društveno odgovornog poslovanja.

Slika koja prikazuje distribuciju istraživanih poduzeća, s obzirom na sveukupnu razvijenost društveno odgovornog poslovanja ukazuje na distribuciju koja je ipak blago pomaknuta prema desno, odnosno prema vrijednosti 4 (razvijenosti u znatnoj mjeri). Pokazano je da oko 43% istraživanih poduzeća ima razvijen DOP u znatnoj mjeri. Naime, skoro 60% istraživanih poduzeća je razvilo DOP u znatnoj mjeri do u potpunosti, u odnosu na oko 40% istraživanih poduzeća koji su razvili DOP neznatno do donekle. Imajući u vidu upravo iznesen

Možemo zaključiti da je društveno odgovorno poslovanje u istraživanim poduzećima znatno razvijeno. To smatramo dobrim rezultatom za poduzeća u Republici Hrvatskoj koja na kraju rezultatski gledano ulažu u razvoj društveno odgovornog poslovanja u zadovoljavajućoj (znatnoj) mjeri.

Također je donijet finalni zaključak je li i koliki je stupanj razvijenosti konkurentske sposobnosti u istraživanim poduzećima. U slijedećoj tablici rezimirani su svi sumarni rezultati razvijenosti konkurentske sposobnosti po pojedinim podelementima u istraživanim poduzećima.

**TABLICA VI. UKUPNA RAZVJENOST KONKURENTSKE SPOSOBNOSTI**

Iz tablice VI vidljivo je da se od spomenutih triju podelementa, s obzirom na srednje vrijednosti, nešto malo više od ostalih, ističe razvoj neopipljivih resursa po svojoj aritmetičkoj sredini. Medijan i mod svih triju podelementa su približno isti. Za razvoj neopipljivih resursa se može zaključiti, uzimajući u obzir srednje vrijednosti i rezultate obrađene u prethodnom tekstu, da je ipak bliži razvijenosti opipljivih resursa u znatnoj mjeri dok se za preostali podelement- razvoj organizacijskih sposobnosti može zaključiti da ipak više nagnje djelomičnoj (donekle) razvijenosti.

Za ukupnu razvijenost konkurentske sposobnosti u istraživanim poduzećima, može se zaključiti da je ona na visokoj razini. U prilog ovakvom zaključku svjedoči aritmetička sredina sa vrijednošću 3,6, te medijan koji iznosi 3,56. Osim toga, slika 5, koja pokazuje distribuciju istraživanih poduzeća s obzirom na ukupnu razvijenost konkurentske sposobnosti, također ukazuje na spomenuti zaključak. Možemo uočiti da skoro 60% istraživanih poduzeća ima ukupnu konkurentska sposobnost koja je razvijena u znatnoj mjeri ili u potpunosti u odnosu na 40% istraživanih poduzeća koja imaju osrednju (donekle) ili neznatnu razvijenost. Slika 5 vidljivo je da je sama distribucija istraživanih poduzeća pomaknuta prema
desno, tj. prema razvijenosti konkurentске sposobnosti u znatnoj mjeri (vrijednost 4).

Slijedeća analiza prikazat će rezultate temeljene na korelacijskim testovima. Korelacija oznakačava vezu između dvaju obilježja (varijabli) kod koje je past/pad jednog obilježja popraćen u većoj ili manjoj mjeri rastom/padom drugog obilježja, ovisno o predznaku i veličini koeficijenta korelacije [12]. Korelacijski testovi, osim što daju odgovor da li postoji korelacija i koliki je koeficijent korelacije, također odgovaraju na pitanje da li je ta korelacija statistički značajna [12]. S obzirom na činjenicu da je analiza obuhvaćala parove redoslijednih i numeričkih obilježja, korišten je Spearmanov koeficijent korelacije, primjereniji za parove obilježja ovakvog tipa [12]. Ukoliko je $\alpha \geq 0.05$ to znači da ne postoji statistički značajna korelacija između dviju varijabli, dok ukoliko je $\alpha < 0.05$ to znači da postoji statistički značajna korelacija između dviju varijabli. U ekonomiji koeficijenti korelacije (r) govore o: $0 < r < 0.5$ => slobodna korelacija; $0.5 < r < 0.8$ => srednje jakom korelaciji; $0.8 < r < 1$ => jaka korelacija.

**TABLICA VII. POVEZANOST RAZVJENOSTI DRUŠTVENO ODGOVORNOG POSLOVANJA I RAZVJENOSTI KONKUREN茨KE SPOSOBNOSTI U ISTRAŽIVANOM PODUZEĆIMA [11]**

</tr>
</tbody>
</table>

*Correlation is significant at the 0.05 level (2-tailed).*

*Correlation is significant at the 0.01 level (2-tailed).*

Što se tiče međuovisnosti sveukupne razvijenosti društveno odgovornog poslovanja i razvijenosti podelemlena razvoja konkurentске sposobnosti, poduzeća može se primijetiti da ona ima najveće utjecaj na razvoj neopipljivih resursa ($r = 0.699$) gdje govore o srednji jako korelaciji. Njena međuovisnost sa ostalim podelementima razvoja konkurentске sposobnosti također govori o srednje jako korelaciji. Značajno je utvrditi da se postoji pozitivna korelacija (koeficijent korelacije $\alpha \approx 0.000$) na razini povjerenja od 99%. Što se tiče međuovisnosti sveukupne razvijenosti društveno odgovornog poslovanja i sveukupne razvijenosti konkurentске sposobnosti poduzeća može se vidjeti da se opet radi o gotovo savršenoj korelaciji što se tiče statistički značajnosti ($\alpha \approx 0.000$) na razini povjerenja od 99%. Koeficijent korelacije $r = 0.657$ ukazuje na srednje jako korelaciju. Drugim riječima, ukoliko raste ukupna razvijenost društveno odgovornog poslovanja u poduzećima, taj rast će u srednje jako meriji pratiti i rast ukupne razvijenosti konkurentске sposobnosti tih poduzeća.

VI. ZAKLJUČAK

Sveukupno gledajući rezultate teorijskog i empirijskog istraživanja razvijenosti društveno odgovornog poslovanja i konkurentске sposobnosti poduzeća pokazano je da razvijenost društveno odgovornog poslovanja u poduzećima, sa svojim pojedinih dimenzijama (i podelementima) pozitivno utječe na stupanj razvijenosti konkurentске sposobnosti tih poduzeća i obrnuto.

Rezultat ovog istraživanja (uz ograničenja s obzirom na veličinu uzorka, vrijeme provedbe istraživanja, nedostatke metode anketnog upitnika, nedostatka definiranja sveobuhvatne literature o društveno odgovornom poslovanju) će, nadamo se, biti od koristi svima koji se bave problematikom implementiranja društveno odgovornog poslovanja, s obzirom da je napravljeno vrlo malo istraživanja u praksi koja bi mogla potvrditi traženja povezanost sa poslovnim performansama. Lako je u Hrvatskoj prepoznata važnost društveno odgovornog poslovanja malo je onih koji ga pravilno integriraju u poslovne prozore. U vremenu kada je sve više dokazana kako društveno odgovorno poslovanje nije uzažaladan trošak nego direktna investicija u konkurentnost, kada on prestaje postojati samo na dobrovoljnoj bazi, poduzeća sve više prepoznaju da nešto moraju učiniti, ali ne znaju i što. Zbog toga se nadamo da će naš rad biti korak u smjeru prema prepoznavanju nužnosti implementacije društveno odgovornog poslovanja, ali i upozorenje svima nama da i sami možemo sudjelovati u stvaranju klime koja će pogodovati svim dionicima društva.

**LITERATURA**

**Uloga standarda u postupku redizajna poslovnih procesa telekom operatora**

Darko Markulin, Kristina Musa, Ljerka Pisačić, Ana Mršić

I. UVOD

Dobro dizajnirani procesi osniva se na uspješnu implementaciju poslovnih procesa u složenoj okolini sustava za podršku. Značaj modeliranih i dokumentiranih poslovnih procesa vrlo je velik i u slučaju zamjene postojeće poslovne podrške. Bez dobro modeliranih poslovnih procesa nije moguća efikasna analiza postojećih poslovnih procesa te definiranje optimalnih poslovnih procesa koji će se podržavati kroz nove sustave za podršku.

II. ZNAČAJ I MODELIRANJE POSLOVNIH PROCESA

Definirani, dizajnirani i dokumentirani poslovni procesi od vitalnog su značenja za svakog telekom operatora. Ovo se odnosi kako na poslovne procese definirane u sklopu određenog poslovnog područja, na primjer poslovnii procesi za OSS sustave podrške (Operations Support System), tako i na E2E (s kraja na kraj) poslovne procese. Ukoliko postoje dobro dizajnirani i dokumentirani poslovni procesi koji opisuju i definiraju operativne poslovne procese, kao što su procesi provisioninga (uključenje, promjene i isključenje telekomunikacijskih usluga) i procesi uklanjanja grešaka, postoje i preduvjeti za efikasne sustave podrške. Takvi sustavi omogućuju implementaciju novih procesa ili promjene u postojećim procesima u kratkom vremenskom roku te učinkovitije upravljanje troškovima kompanije i ljudskim resursima.

Telekomunikacijski poslovni procesi trebaju osigurati sve potrebne akcije u cilju realizacije i aktivacije telekomunikacijskih usluga. Automatskom aktivacijom svih potrebnih mrežnih resursa postiže se vrlo brza i efikasna realizacija telekomunikacijskih usluga. Da bi se postigli potrebni preduvjeti za uspješnu primjenu ovakvih definiranih telekomunikacijskih poslovnih procesa potrebno je, kao preduvjet za dobro dizajnirane poslovne procese, imati dokumentirane poslovne procese uz primjenu nekih od jezika koji se uspješno koriste za njihovo modeliranje, kao što su BPMN, UML i EPC. Optimalni model poslovnog procesa za realizaciju telekomunikacijske usluge treba osigurati stručnjacima iz poslovne domene dobro razumijevanje poslovnih procesa i uspješnu analizu u cilju pronalazačenja poboljšanja u njihovom odvijanju, a isto tako i stručnjacima iz IT domene da se na temelju takvog modela mogu uspješno izrađivati tehničke specifikacije na temelju kojih se izvode promjene u sustavima za podršku.

Modeliranje poslovnih procesa te njihovo dokumentiranje dobiva na značaju kao cijelo u slučaju zamjene postojeće poslovne podrške. Dobro modelirani i dokumentirani poslovni procesi omogućavaju efikasnu analizu postojećih poslovnih procesa, otkrivanje uskih grla u njihovom odvijanju te definiranje optimalnog tijeka aktivnosti u cilju realizacije telekomunikacijske usluge što je vrlo značajno u postupku razvoja novih sustava za podršku. Time se i osiguravaju pozicije za donošenje odluka kod optimizacije poslovanja tvrtke. Dobro opisani procesi nužni su za bilo koju statičku ili dinamičku promjenu u sustavima za podršku.
(simulacija) analizu procesa koji se odvijaju u pojedinim organizacijskim jedinicama kompanije.

Prilikom modeliranja poslovnih procesa u sklopu projekta kojim se uvodi nova ili optimizira postojeća sistemska podrška treba težiti primjeni postojećih standarda za modeliranje telekomunikacijskih poslovnih procesa kao što je eTOM (Enhanced Telecom Operations Map) definiran od strane TM Forum (Tele Management Forum). Time se, uz prilagodbu uvjetima odvijanja poslovnih procesa svakog pojedinog telekomunikacijskog operatora, koriste iskustva drugih telekomunikacijskih operatora, telekomunikacijskih standardizacijskih tijela i proizvođača telekomunikacijske opreme.

III. POSLOVNI PROCESI ZA REALIZACIJU TELEKOMUNIKACIJSKIH USLUGA

S aspekta realizacije telekomunikacijske usluge kroz aktivacije elemenata telekomunikacijske mreže i uz pomoć OSS sustava kojima se upravlja odvijanjem poslovnog procesa mogu se razmatrati četiri osnovne kategorije poslovnih procesa:

A. Uključenje telekomunikacijske usluge
B. Promjene na telekomunikacijskim uslugama
C. Otklanjanje smetnje na telekomunikacijskoj usluzi
D. Isključenje telekomunikacijske usluge

Ovi se procesi pokreću na temelju zahtjeva korisnika kreiranjem naloga u CRM (Customer Relationship Management) sustavu. Potrebne informacije se putem definiranog sučelja između CRM i OSS sustava šalju u OSS sustav u sklopu kojih se kroz definirani proces osigurava potrebni slijed akcija za realizaciju telekomunikacijskih usluga. Uz potreban slijed akcija potrebno je osigurati odgovarajuće podatke za realizaciju akcija bilo da se akcije izvršavaju automatski kroz definirana sučelja, bilo da ih izvršavaju akteri poslovnog procesa.

Telekomunikacijske usluge kao što su govorna usluga, usluga pristupa Internet mreži i IPTV (IP Television) spadaju u usluge širokog tržišta i karakteristika procesa za realizaciju tih usluga su velik broj pokrenutih procesa, predefinirani slijed akcija, potreba za visokom razinom automatizacije kod aktivacije mrežnih elemenata i potreba za brzom realizacijom usluga. Primjeri takvih procesa su uključenje govorne usluge, promjena brzine na usluzi za brzom realizacijom usluga. Primjer takvih procesa su uključenje govorne usluge, promjena brzine na usluzi za brzom realizacijom usluga.

IV. MODELIRANJE POSLOVNIH PROCESA KROZ ETOM STANDARD

eTOM je inicijativa TMF-a kojom se donosi model ili okvir za poslovne procese korištene od strane davatelja usluga ili ostalih sudionika u telekomunikacijskoj industriji [1]. eTOM opisuje sve poslovne procese davatelja usluga i analizira ih na različitim razinama detalja o visokom značaju i prioritetu za poslovanje. eTOM okvir može se koristiti kao alat za analizu postojećih ili razvoj novih procesa. eTOM okvir za poslovne procese je referentni okvir za kategorizaciju svih poslovnih aktivnosti davatelja usluga [1]. Najčešće se kategoriziraju poslovnice elemente koji sadrže poslovne aktivnosti tako da se elementi mogu kombinirati na različite načine u cilju implementacije E2E (s kraja na kraju) poslovnih procesa.

Na slici 1 procesi telekom operatora podijeljeni su na horizontalne i vertikalne grupacije [1]. Horizontalne grupacije međusobno odjeljuju operativne i ostale funkcionalne procese. Na primjer, odjeljuju operativne prodajne poslove vezane uz upravljanje korisničkim podacima i nalozima (Cutomer Relationship Management) od operativnih poslova vezanih uz upravljanje i aktivaciju usluga (Service Management & Operations).

Vertikalne grupacije predstavljaju E2E procese potrebne za podršku korisniku i upravljanje poslovanjem. eTOM je prvenstveno fokusiran na osnovne korisničke operativne procese provizioniranja, otklanjanja smetnji i naplate (Fulfillment, Assurance and Billing - FAB). Ostali operativni procesi (Operations Support & Readiness) odjeljeni su od FAB real-time (u stvarnom vremenu) procesa. Procesi koji nisu namijenjeni za direktnu podršku korisnika (Strategy, Infrastructure and Product) odjeljeni su od operativnih procesa.

U [2] je identificirano sedam korisnički orijentiranih procesa i ti procesi počinju na temelju kontakt a korisnikom i završavaju s ispunjenjem njihovog zahtjeva:

A. Request to Answer (zahtjev za informacijom)
B. Order to Payment (zahtjev za novom uslugom)
C. Request to Change (zahtjev za promjenom na usluzi)
D. Usage to Payment (korištenje i naplata usluge)
E. Termination to Confirmation (zahtjev za isključenjem usluge)
F. Problem to Solution (zahtjev za otklanjanje greške)
G. Complaint to solution (prigovor na pružanje usluge)

U radu je dan primjer modeliranja procesa koji spada u kategoriju Order-to-payment procesa. Ovaj proces bavi se svim aktivnostima koje pretvaraju zahtjev kupca ili prihvaćenom ponudom u proizvod s povećanjem korištenja. Otvoren je pravac komunikacije korisničkog nalog, pokretanje odgovarajućeg usluznog procesa i prelazak naloga na uslužni sloj. Nakon uspješne realizacije usluga korisnički nalog se zatvara i provjerava se korisničko zadovoljstvo. U ovom scenariju je relevantan za usluzni sloj bogat modeliranj poslovnih procesa. Ovaj proces bavi se svim aktivnostima koje pretvaraju zahtjev kupca ili prihvaćenom ponudom u proizvod s povećanjem korištenja.
1 i 2 dano je mapiranje procesa na eTOM razinu 2 i tijek procesa na razini 3 [2].

V. PRIMJER MODELIRANJA POSLOVNOG PROCESA U SKLPOPJU ZAMJENE OPERATIVNE PODRŠKE

Na slici 3 prikazan je primjer modela poslovnog procesa za uključenje telekomunikacijskih usluga preko tehnologije digitalne pretplatničke linije (ADSL). U modeliranju se kao alat za modeliranje koristi struktura i elementi UML dijagrama aktivnosti. Ovakav način modeliranja baziran je na scenarijima i modulima [3], [4] i uspješno se koristi u modeliranju postojećih poslovnih procesa proz OSS sustave za podršku u HT-u. Scenarij je jedan od poslovnih procesa koji se odvija kroz OSS sustave za podršku i sastoji se od modula predstavljenih podprocesima kao što je na slici 4. Scenarij se sastoji od modula koji se mogu dalje delomponirati na podprocese, a i mogu sadržavati akcije i poslovna pravila potrebne za pravilno odvijanje procesa. Na taj se način postiglo fleksibilno i jasno dizajniranje procesa za realizaciju telekomunikacijskih usluga [3]. No, ovaj model dizajnira poslovne procese koji se odvijaju kroz OSS sustave poslovnog područja i nije sastavni dio modela E2E poslovnog procesa za realizaciju telekomunikacijske usluge, a time i nisu jasno definirane odredine koje se protežu kroz BSS sustave za podršku. Da bi se uspješno implementirali novi sustavovi koji upravljaju poslovnim procesima kroz sve poslovne domene potrebno je definirati model kojim se uspješno modeliraju procesi kroz te sustave za podršku (BSS, OSS, Billing).

Prema eTOM standardu, proces realizacije usluga preko tehnologije digitalne pretplatničke linije, prikazan na slici 2, u uslužnoj je domeni podijeljen na više funckjskih blokova. To su „Issue Service Order“ (izdavanje servisnog naloga), „Track & Manage Service provisioning“ (praćenje i upravljanje realizacijom usluge), „Allocate Specific Service Parameters to services“ (aloaciranje specifičnih usluznih parametara usluzi), „Implement, Configure & Activate service“ (implementacija, konfiguracija i aktivacija usluge), „Test Service End-to-End“ (testiranje usluge s kraja-na-kraj) i „Close Service Order“ (zatvaranje uslužnog naloga). Ti funckjski blokovi pripadaju 3. razini eTOM procesnog modela (slika 2) i kroz njega je proces jasno podijeljen na osnovne cjeline u sklopu E2E poslovnog modela. Na slici 5 je, zbog jasnote prikaza, prikazan dio podprocesa modeliran u alatu Arts [5] korištenjem EPC jezika za modeliranje. Struktura modela je, iako se koriste različiti elementi i princip izmjenjivanja događaja i akcija, slična strukturi modela prikazanog na slici 4. No, ono osnovno što ih razlikuje je to što je ovaj model dio E2E modela poslovnog procesa koji se proteže kroz sve poslovne domene koje sudjeluju u realizaciji telekomunikacijske usluge. Ovač model je obogaćen i dodatnim elementima kao što su ulazni i izlazni podaci potrebni za akciju, akteri koji izvršavaju akciju, sustavi koji su potrebni za izvršavanje akcije, …

Dobiveni model poslovnog procesa kroz modeliranje uz pomoć eTOM standarda omogućava jasno sagledavanje E2E procesa počevši od same interjekcije s korisnikom, preko aktivacije potrebnih mrežnih resursa, pa do naplate realiziranih usluga. Kroz modeliranje procesa preko funkcionalnih blokova dobiva se podloga za definiranje akcija koje se mogu na fleksibilni način koristiti u više različitih poslovnih procesa te za definiranje točaka u procesu gdje je potrebno definirati sučelje između različitih sustava za podršku koji pripadaju istim ili različitim poslovnim domenama. Primjer za to je definiranje informacija koje je potrebno razmijeniti između BSS i OSS sustava u sklopu kreiranja naloga za aktivaciju mrežnih elemenata u cilju realizacije uključenja telekomunikacijske usluge. Uz pomoć ovakvog načina modeliranja te uz odgovarajuća način implementacije poslovne podrške kojom se upravlja procesom, može se dobiti fleksibilno rješenje u kojem promjena u pojedinim procesima ili implementacija novih procesa ima što je moguće manji utjecaj na preostale poslovne procese.

VI. ZAKLJUČAK

Značaj dobro modeliranog poslovnog procesa na području realizacije telekomunikacijske usluge je vrlo velik. U radu je, kao prijedlog jednog od načina modeliranja poslovnog procesa, dan primjer modeliranja procesa za realizaciju usluga preko tehnologije digitalne pretplatničke linije (ADSL). Model realiziran korištenjem UML dijagrama aktivnosti nastao je na temelju dogodovišnog iskustva autora na području modeliranja i dizajna poslovnih procesa. No, postojeći model, iako predstavlja dobru osnovu za implementaciju poslovnih procesa u postojeće sustave za podršku, ne omogućava detaljniju analizu i definiranje uslužnih elemenata u procesu što je vrlo bitno u projektima kao što je IT transformacija koja se trenutačno provodi u HT-u. Ovim se radom želi, kroz primjer IT transformacije, ukazati na potrebu korištenja provjerenih standarda i alata u modeliranju poslovnih procesa kako u postojeće, tako i u nove sustave za podršku. Daljnji tijek projekta pokazat će uspješnost primjene i definiranje smjera u kojem je potrebno ći i svakom modeliranim poslovnim procesima.

Sporazum o razini usluga i upravljanje razinom usluga u informacionim tehnologijama uz podršku mehanizma CobiT

mr Dušanka Glamočanin, dipl.inž.el.
Mtel, Banja Luka, Bosna i Hercegovina
e-mail: dusanka.glamocanin@mtel.ba

Sažetak - U današnje vrijeme razvoj ekonomije je najčešće diktiran uslugama koje se traže i isporučuju korisnicima. Organizacije sve više uživaju od direktnih isporučioca usluga, ali i trećih strana za različite usluge u informacionim tehnologijama. Međutim, organizacije često nisu zadovoljne uslugama koje dobijaju. Ponekad su zavisne od trećih strana čija budućnost je neizvjesna, posebno u ovom periodu koji karakterišu velike ekonomske promjene. U ovom radu biće prikazano kako organizacije mogu parirati takvom problemu koristeći Sporazume o razini usluga – Service level agreements SLAs i Upravljanje razinom usluga – Service level management SLM, uz podršku mehanizma CobiT (Control Objectives for Information and related Technology).

I. UVOD

Prema Fondacijama za sporazum o razini usluga – Foundations of Service Level Agreement, upravljanje razinom usluga je „disciplinarna, proaktivna metodologija i procedure koje se koriste kako bi se osiguralo da se isporuče adekvatne razine usluge prema svim IT korisnicima, poštujući poslovne prioritetе i prihvatljivu cijenu“ [1] [2]. Service-level agreement (SLA) ili Sporazum o razini usluga je dogovor između dvije ili više strana o razini, kvalitetu i odgovornosti prilikom pružanja usluga. Pri tome je potrebno definisati uslugu koja se pruža, način mjerenja kvalitete, način upravljanja uslugom, garancije i slično [3].

Da bi se provelo upravljanje razinom usluga – SLM (Service level management) prvo mora da bude uveden SLA. SLA je dio ugovora između davaoca usluga i korisnika usluge. Svrha SLA je da ustanovi mjerljive razine uspješnosti sa ciljem da se postigne obostrano razumijevanje vrste i razine usluge koja se zahtijeva [4].

II. DEFINICIJA SLA I SLM

Uopšteno govoreći, postoje 3 glavna tipa SLA: in-house, ekstermi i interni. Razlike između ovih tipova se odnose na strane koje su uključene u definisanje SLA. Prvi i najčešći tip SLA je in-house SLA. U nastavku teksta, in-house podrazumijeva sve što je vezano za,

dolazi iz ili se dešava unutar organizacije To je sporazum postignut između in-house davaoca usluge, kao što je IT sektor i in-house klijenta ili sektora, kao što je marketing, finansije i sl. Sljedeći najčešći SLA je eksterni SLA. To je SLA između eksternog davaoca usluge (treće strane) i organizacije. Na kraju, interni SLA se koristi od strane davaoca usluge za mjerenje uspješnosti grupa unutar iste organizacije [5]. Bez obzira koji tip SLA je izabran, pregovaranje o sporazumu treba da obavi multidisciplinarni tim sa iskustvom s jednakom zastupljenošću obje strane, korisnika i davaoca usluga. Mnogi pregovarači sa strane korisnika pregovaraju o najboljem usluzu po minimalnoj cijeni, dok pregovorači sa strane davaoca usluga nastoje da postignu dogovor, najčešće po cijeni kojoj je usluga debe, kako bi učestvovali u dijeljenju troškova sa minimalnim naporom i uz maksimalnu zaradu. Traženje balansa između ove dvije pozicije je bitno, ali veoma komplikovan posao kako bi se postigao zadovoljavajući SLA i SLM [6].

SLA postaje neophodan dokument između davaoca usluga i korisnika jer usluga može biti označena kao „loša“ ili „dobra“ samo ako je usluga tačno definisana i određena. Dalje, kroz SLA se formalizuju potrebe i očekivanja organizacije i usluga kao vrsta garancija za obje strane. U tom smislu, potencijalna neslaganja su smanjena i dat je tačan pregled prioriteta usluge i njihove isporuke [7].

Sam SLA je u suštini dokument formiran oko određenog broja ključnih ili suštinskih komponenta (Tabela 1), koji su diskutovane i složene u organizacije, kao korisnici usluge i davaoci usluge. Rokovi/trajanje i obim/predmet kroz SLA se definisaju kao period koji će SLA pokriti i vrsta usluge koja je predmet sporazuma. Važno je, dakle, identifikovati šta nije predmet SLA (elementi koji su isključeni ili nisu predmet sporazuma) [8].

Ciljevi razine usluge opisuju razine obaveza koje se odnose na različite usluge oko kojih su se složile korisničke grupe i davaoci usluga, kao što su raspoloživost, izvođenje (brzina, spremnost na odgovor, tačnost), razine opterećenja, sigurnost, održavanje i kvalitet. Da bi se omogućilo da korisničke grupe i
davaoci usluga razumiju ciljeve razina usluga, ključno je napraviti razliku između tehničkih razina usluge i poslovnih razina usluge. Dok poslovne razine usluge predstavljaju zahtjevavanu uslugu u poslovnom smislu, tehničke razine usluge je prevode u tehničke zahtjeve.

Indikatori razine usluge specifičiraju metrike i statistike kojima razine usluge mogu biti mjerene [9].

Dalje, treba da se definishe ko će tačno izvršiti ključna mjerenja i kako će ona biti provedena. Kada su metrike definisane, bitno je uzeti u obzir objektivne metrike (brojeve), kao i subjektivne metrike (kao što je perception korisničke grupe). U mnogim SLA, opisuju se i validiraju samo objektivan kriterijum i metrike, što ponekad vodi do bumih i beskrajnih diskusija između organizacija i davaoca usluga. Dalje, klauzule za neizvršenje usluga definisu šta se dešava kada davaoc usluga ne postigne ciljni SLA kao što je definisano (upozorenje, korektivne akcije, finansijski penali, procedure za eskalaciju). Opcione usluge (dodatne usluge koje nisu obezbijedene u trenutku definisanja sporazuma) takođe mogu biti uključene, kao i izvještavanje i administrativne procedure koje treba da budu definisane (npr. uloge, odgovornosti, komunikacione procedure i učestanost sastanaka). Treba da budu uključeni pregled/azuriranje procedura i procesa da bi se omogućila identifikacija i odgovarajuća implementacija svake zahtijevane izmjene (npr. drugi indikatori, novi tehnološki razvoj, novi organizacioni ili servisni zahtjevi i promjene u organizacionoj strategiji). Redovna revizija SLA je ključni faktor za uspjeh, budući da su organizacije i njihove usluge po svojoj prirodi dinamični. Konačno, i formalna saglasnost treba da bude uključena u SLA [10].

**III. SLA I SLM KROZ COBIT**

CobiT je mehanizam koji pomaže u definisanju i upravljanju razine usluga koristeći SLA i SLM [12]. CobiT je okvir za vođenje i upravljanje IT preduzeća, razvijen od strane instituta za upravljanje IT sektorom. To je proizvod rada razvojnog tima neprofitnog, nezavisnog udrženja ICASA (Information Systems Audit and Control Association). Verzija CobiT5 uključuje najnovija razmišljanja u tehnikama vođenja i upravljanja IT produženja, te pruža globalno prihvaćen načela, prakse, analysičke alate i modele kako bi se povećao značaj i povjerenje u IT. Okvir verzije CobiT5 definisne trideset četiri IT procesa, koji obuhvataju četiri IT domena – planiranje i organizaciju, akviziciju i implementaciju, isporuku i podršku i nadgledanje.

U nastavku su navedena četiri IT domena i procesi identifikovani u CobiT-u, a koji su bitni za provođenje SLA i SLM.

**Planiranje i organizacija:**

- Definisati strateški plan
- Definisati informacionu arhitekturu
- Odrediti tehnološke smjernice
- Definisati IT organizaciju i međusobne veze
- Upravljati IT investicijama
- Usaglasiti ciljeve menadžmenta i smjernice
- Upravljati ljudskim resursima
- Osigurati usaglašenost sa eksternim zahtjevima
- Procjena rizika
- Upravljanje projektima
- Upravljanje kvalitetom

**Akvizicija i implementacija:**

- Identifikovanje automatizovanih rješenja
- Sagledavanje i održavanje softvera
- Sagledavanje i održavanje tehnološke infrastrukture
- Razvijanje i održavanje procedure
- Instalacija i akreditacija sistema
- Upravljanje promjenama

**Isporuka i podrška:**

- Definisati i upravljanje razinama usluga
- Upravljanje uslugama trećih lica
- Upravljanje učinkom i kapacitetom
- Obvezbjeđenje kontinuirane usluge
- Obvezbjeđenje sigurnosti sistema
- Identifikovanje i dodjeljivanje troškova
- Edukacija i treningi za korisnike
- Pomoć i savjetovanje kupaca
- Upravljanje konfiguracijom
* Upravljanje problemima i incidentima
* Upravljanje podacima
* Upravljanje opremom
* Upravljanje operacijama

**Nadgledanje:**

* Nadgledanje procesa
* Procjena adekvatnosti interne kontrole
* Pribavljanje nezavisne verifikacije
* Osigurati nezavisnu reviziju

CobiT definiše jedan cilj visoke razine za svaki proces, a 3 do 30 detaljnih kontrolnih ciljeva. Ovi kontrolni ciljevi sadrže izjave o željenim rezultatima ili svrhe koje treba da budu postignute implementacijom specifičnih kontrolnih procedura unutar IT aktivnosti i omogućuje jasnu politiku za IT kontrolu.

Jedan od IT procesa identifikovan unutar okvira je definisanje i upravljanje razina usluga (domen isporuke i podrške). Zbir kontrolnih ciljeva za ovaj IT proces je naveden u nastavku teksta. Ovi kontrolni ciljevi naglašavaju značaj SLA okvira i potrebu za usaglašavanjem komponenta SLA. Trebaju se uzeti u obzir procedure za izvršavanje, nadgledanje i izvještavanje. Ugovori se trebaju redovito revidirati. Konačno CobiT kontrolni ciljevi naglašavaju potrebu za programom kontinuiranog poboljšanja SLA.

**IV. KONTROLNI CILJEVI**

A. **Kontrolni cilj visoke razine**

Potrebno je vršiti kontrole definisanja i upravljanja razinama usluga, preko IT procesa, koje zadovoljavaju poslovne zahtjeve, kako bi se postigao zajednički stav o zahtjevanoj razini usluge. To se omogućuje kroz uspostavu sporazuma o razini usluge kojima je usaglašavan programa za izvršavanje, nadgledanje i izvještavanje. Ugovori se trebaju redovito revidirati. Konačno CobiT kontrolni ciljevi naglašavaju potrebu za programom kontinuiranog poboljšanja SLA.

**B. Detaljni kontrolni cilj 1: SLA okvir**

Uprava treba definisati okvir za promociju formalnih SLA i definisati minimalne sadržaje kao što su dostupnost, pouzdanost, uspješnost, kapacitet za rast i razine podrške koje se pružaju korisnicima. Korisnici i IT funkcija moraju imati pisani sporazum koji opisuje razinu usluge u kvalitativnom i kvantitativnom smislu i definiše odgovornosti obje strane.

C. **Detaljni kontrolni cilj 2: SLA aspekti**

Treba da se postignu eksplicitni aspekti koje SLA treba da pokrije (npr. raspoloživost, pouzdanost, uspješnost).

D. **Detaljni kontrolni cilj 3: Procedure izvršenja**

Uprava treba provesti procedure kako bi se osiguralo da su način i odgovornost za definisanje i uredavanje odnosa (npr. čuvanje sporazuma) između svih uključenih strana utvrđeni, koordinirani, održavani i komunicirani sa svim odjelima kojih se tiču.

E. **Detaljni kontrolni cilj 4: Nadgledanje i izvještavanje**

Treba biti imenovan menadžer razine usluga, koji je odgovoran za praćenje i izvještavanje o ostvarenju navedenih kriterija uspješnosti usluga i svih problema koji se javljaju prilikom rada.

F. **Detaljni kontrolni cilj 5: Pregled – revizije SLA i ugovori**

Treba biti provedeni redovni postupci pregleda SLA i temelja ugovora s davaocima usluga treće strane.

G. **Detaljni kontrolni cilj 6: Naplative stavke**

Uprava treba uključiti odredbe za stavke koje se naplaćuju u SLA, čineći moguće uštede na razini usluga u odnosu na cijenu.

H. **Detaljni kontrolni cilj 7: Program za poboljšanje usluge**

Proces kojim bi se osiguralo da se korisnici i menadžeri razina usluga redovito slažu oko programa za poboljšanje usluge, odnosno razine usluga, a koje je troškovno opravdano.

V. **MODEL ZA MJERENJE ZRELOSTI PROCESA**

Da bi se odgovorilo na potrebe menadžmenta za kontrolu i mjernost IT procesa, CobiT obezbeđuje vodič za nadgledanje koji sadrži alat za pristup i mjerenje IT okruženja u organizaciji, kroz trideset četiri IT procesa. Vodič za nadgledanje uključuje modele zrelosti (MM - maturity models), koji su temeljeni na modelima CMM/CMMI (Capability Maturity Model/Capability Maturity Model  Integration). Vodič za nadgledanje uključuje još i faktore koji su kritični za uspjeh (CSFs – critical success factors), ključne indikatore cilja (KGI – key goal indicators) i ključne indikatore učinka (KPIs - key performance indicators) za svaki proces [13].

Model zrelosti je način bodovanja koji omogućuje organizaciji da postigne svoju zrelost za određen proces nepostojeći (0) do optimizovan (5). Alat nudi razumljiv i jednostavan način da se odredi stvarna i željena (u skladu sa strategijom preduzeća) pozicija, i
omogućuje organizacijama da pozicionira sebe imajući u vidu najbolji način rada i standardne smjernice. U tom smislu, može se identifikovati razlika između željenog i stvarnog stanja, te definirati konkretnе aktivnosti kako bi se primakli željenoj poziciji. Kada je urađena procjena zrelosti, bitno je složiti se sa osnovnim principima mjerenja zrelosti. Moguće je pomjeranje na viši stupanj zrelosti samo kad su ispunjena sva stanja opisana u određenom stupnju zrelosti. Model zrelosti za definisanje i upravljanje razinama usluga, koji su srbirno dati u tabeli 2, određuju da je organizacija na stupnju zrelosti 1 za taj proces kad postoji svijest o potrebi za upravljanjem razinama usluga, ali je proces neformalan. Organizacija dostiже stupanj zrelosti 5 kada su sve razine usluga u kontinuitetu ponovo procjenjivane tako da osiguravaju poduđaranje IT i poslovnih ciljeva.

Rezultati istraživanja koje je provela ISACA u 2002. godini otkrivaju da je stupanj zrelosti za definisanje i upravljanje razinama usluga za većinu organizacija pozicioniran od 2 do 2.5. Propuštanje kroz filter po veličini, geografiji i industriji otkriva da velike kompanije, kompanije koje rade na globalnom principu, organizacije u finansijskom sektoru i IT davaoci usluga dostiže prosječno viši stupanj zrelosti (između 2.5 i 3) u definisanju i upravljanju razinama usluga [14]. Ovi podaci mogu biti veoma koristan reper ili ocjena ili oznaka kvaliteta za organizacije kada procjenjuju da su razine usluga usklađene s strateška poslovna jedinica i IT, ali oni su neformalni i nisu revidovani. Izvještavanje o razini usluge je nepotpuno. Kada je urađena procjena stvarnog stanja, te definisati konkretne aktivnosti kako bi se ostvario željeni cilj usluga koja se pruža korisniku. Razine usluga su kontinuirano ponovo procjenjivane tako da osiguravaju kontinuitetu ponovo procjenjivane tako da osiguravaju dostigla stupanj zrelosti 5 kada su sve razine usluga u odnosu na najbolji način rada čiji samit potrošača je pokriven i snažan it proces u kojem se dosta svjedake pružaju. Ključni faktori učinka su procesno upravljani, pri čemu se veliki naglasak stavlja na isku stva, a pokazuju koliko dobro IT proces omogućuje da se dostigne željeni cilj [15].

A. **Ključni indikatori zrelosti**

Faktori koji se mogu smatrati da su kritični za uspjeh IT procesa, su:
- razine usluga su izražene u poslovnim terminima krajnjeg korisnika, kad god je to moguće;
- analiza korijena uzroka je provedena kada dođe do povrede razine usluge;
- vještine i alati su dostupni da pruže korisne i pravovremene informacije o razi; uslugu;
- oslanjanje kritičnih poslovnih procesa na IT je definitano i pokriveno u SLA;
- odgovornosti za upravljanje IT procesima je povezano s razinama usluga;
- IT organizacija može identifikovati izvore odstupanja troškova;
- dostavljena su detaljna i dosljedna objašnjenja odstupanja troškova;
- na raspolaganju je sistem za praćenje i provođenje individualnih izmjena.

B. **Ključni indikatori cilja**

Ciljevi koji treba da se ostvare su:
- strateška poslovna jedinica objavljuje da su razine usluga usklađene s ključnim poslovnim ciljevima;
- prisutno je zadovoljstvo kupca da je razine usluge u skladu sa očekivanjima;
- stvarni/budžetirani odnos troškova je u skladu s razinama usluga;
- postotak svih kritičnih poslovnih procesa koji se oslanjaju na IT je pokriven sa SLA;
- postotak ponovo pregledanih SLA je u dogovorenom intervallu ili nakon značajnih promjena;
- odjava partnera koji su omogućavali financiranje za pravljenje razine usluge;
- postotak IT usluga koje zadovoljavaju SLA. Ovo su ujedno i ključni indikatori cilja.

C. **Ključni indikatori učinka**

Ključni indikatori učinka za IT procese su:
- rezolucija kašnjenja zahtjeva za promjenu u razini usluge;
- frekvencija istraživanja zadovoljstva korisnika;
- kašnjenje u rješavanju problema razine usluge;
- koliko puta su u traženom roku izvršene analize uzroka odstupanja procedura za razine usluge;
značaj iznosa potrebnih dodatnih sredstava da bi se isporučila definisana razina usluge.

Važan je uzročno-posljedični odnos između ključnih indikatora učinka i ključnih indikatora ciljeva. Ako ključni indikatori ciljeva, kao što su zadovoljstvo kupaca da je razina usluge distigli očekivanja, i ključni indikatori učinka, kao što je vremenski pomak od rješavanja zahtjeva promjene u razini usluge, nisu usaglašeni, teško će se dostići željeni rezultati. Analiza ključnih indikatora učinka, bez ključnih indikatora ciljeva može dovesti do značajnih ulaganja bez odgovarajućeg mjerenja koja pokazuju da li je odabrana efektivna SLM strategija. Neki ključni indikatori učinka će, naravno, imati veći utjecaj na određene ključne indikatore ciljeva u usporedbi s drugima. Važno je identifikovati najvažnije ključne indikatore cilja za određena okruženja i pažljivo pratiti ključne indikatore učinka koji najviše doprinose tome.

VII. ANALIZA SLA KORIŠTENJEM OKVIRA COBIT U UGOVORIMA O ISPORUCI IT USLUGA U BIH

U nastavku teksta, izvršena je analiza i samoprocjena (self-assessment) SLA i SLM u ugovorima za IT usluge, korištenjem CobiT mehanizma.

Ugovorom o korištenju usluga servisnog centra 24x7 IT operatera i jedne banke u Bosni i Hercegovini, definisane su sve suštinske komponente SLA, navedene u drugom poglavlju ovog rada, osim: procedura za sigurnost, procedura za reviziju, administriranje, pregled/azuriranje i imovine. Jasno je definiran kontrolni cilj u smislu održavanja i tehničke podrške softverskog rješenja 24x7 za elektronsko bankarstvo koje se sastoji od aplikativnih rješenja i modula. Od 7 detaljnih kontrolnih ciljeva koji treba da budu definisani po preporuci CobiT, navedeno je 5 (nisu navedeni pregled – revizije SLA kao i program za poboljšanje usluge). U ovaj IT proces ima četvrti stupanj zrelosti za definisanje i upravljanje razina usluga, tj. po CobiT preporukama je upravljiv i mjerljiv. Identifikovani su kritični faktori uspjeha, ključni indikator ciljeva je ujedno i kontrolni cilj. Ključni indikatori učinka se ne mogu potpuno otkriti iz SLA. Davaoc usluge je dostavio tražene informacije na upit. Ključni indikatori učinka za određena okruženja i pažljivo pratiti ključne indikatore učinka koji najviše doprinose tome.

SLA i SLM su efektivni mehanizmi za organizaciju kojima se ublažavaju problemi nepostizanja odgovarajućih razina traženih usluga. Uvodenjem SLM procesa u organizaciji izbjegavaju se problemi da se ne dobije usluga koja se zahtijeva i da razine usluga budu isporučene u skladu sa uslovima poslovanja. Uspostavljanje efektivnog i djelotvornog SLM procesa je složen i težak zadatak, koji zahtijeva iskusne i multidisciplinarne resurse. CobiT je koristan i podržavajući mehanizam za definisanje i implementaciju zrelog SLM procesa, identifikujući kontrolne ciljeve, modele zrelosti, ključne indikatore cilja, ključne indikatore učinka i kritične faktore uspjeha, kako bi se omogućilo što efikasnije postizanje poslovnih ciljeva. Ovaj rad ima za cilj da pojasni predloženi model koji ima potencijal da vremenom bude dominantan mehanizam za definisanje i implementaciju SLM procesa, u skladu sa novim naučnim sadašnjostima iz ove oblasti, kao i zahtijevima tržišta.

Synergy of ITIL methodology and help users systems

Ivan Ivosić
Croatian Electricity Company d.d.
Zagreb, Croatia
ivan.ivosic@hep.hr

Abstract - Information and communication technology, services and corporate security shape modern working places creating new added values. The development of technology markets and new innovations impose phrase how to lead IT and thereby be successful. The article describes and develops pragmatism and interdisciplinary of information systems of companies with the help of ITIL methodology. The construction of the help users system can improve business, but it is not easy to provide safety and legal economic regulator. Social and political system defines a new user and its function and role and the challenge is to balance customer needs and IT engineering support in a globalized world where is the thin dividing line between work and private.

I. INTRODUCTION

In recent years office management is made easier with the help of information and communication technology. The synergy of different professions is wanted to act efficiently and cost – effectively in a working environment that is created and developed. The challenge for computer scientists and managers is how to design, develop and maintain working place in a manner that allows safe and proper relationship with colleagues, tasks and used tools. The computer with paper and stationery has become irreplaceable in many corporations today and it may be said that the workers are aware of the significance and importance of provided information communication services. Computer scientists are thinking about the methods that create new added value for the company so they invented ITIL[1] methodology that is not standard, but the framework by which it can create and maintain a knowledge base of different IT solutions across the different processes that are implemented in the company. (IT – Information Technology – generally refers to management of information systems with the help of technological solutions, ITIL – Information Technology Infrastructure Library - a set of knowledge and business experience for IT Service Management (ITSM) that performs IT services in accordance with business needs)

II. SERVICES AND ITIL

II. 1. Service

Services are from immemorial time a term that describes the effort. It is not measurable, but it is inevitable in the sense that the time is used for well-being and sometimes to negative. In the last twenty years information and communication technology was respected bond and guiding community in the work, that the computer, cell phone and Internet services change the paradigm of behaviour of staff members and customers. ITIL methodology is not the standard, but quality demystifies services of client and computer information system.

II. 2. Service strategy [2]

Strategic analysis of the industry, public and state-owned enterprises, banks and other companies can’t ignore the fact that the information and communication technology is the future business and therefore the investment in the development of local computer networks contributes to a successful corporate social responsibility. The system of the company can be created, developed and built with the help of ITIL methodology. The production strategy is basis where services are designed to provide the support to financial management and demand management process where the experts analyse the market and form a flexible portfolio of services.
II. 3. Service design [3]

Architects and moderators devote most attention to the design of specific service that works on the foundations of operational work through service level management process to the relations with suppliers when it comes to interaction with the external environment and availability and capacity management processes where the internal control is established criteria for the same pragmatism. A quality of the methodology is established for the business continuity and information security management as high as possible. The specific phase is spreading knowledge about a specific service and its possible range in the business information system of the company through the service catalogue management process. Synergy of existing design processes develops services and benefits for the system by reducing the negative impact on the enterprise work.

It is necessary to provide the logistics and security of the communication channel between the working premises of computer experts and end users where they aren’t be deprived of pleasant and comfortable work after returning to their workplace. An important link between design and service operation is transfer of technical and business knowledge for solving the specific situations in the company. Change management process in coherence with release and deployment management manages time and allows to IT experts space for the smooth and save processing tasks for each individual case. Database of client equipment staff builds information systems in the company and creates intellectual capital of organizational units, while an IT worker with help of the service validation and testing process has the opportunity to test life cycle of IT service.

II. 5. Service Operation [5]

IT operations personnel can control their services a number of ways. The first and basic process of control is event management which creates services of certain value in the portfolio companies. Related processes are request fulfillment and access management where user’s aspirations are being modelled in accordance with the system policies in the establishment of a functional work environment and in synergy with key enterprise business processes. But we should not neglect the incident and problem management process that reveals the unwanted situations of hardware and software topics in the company.

II. 6. Continual service improvement [6]

Phase continual service improvement is working on cooperation and development of all phases of the ITIL methodology. Management on the one hand through various reports can measure the usefulness of each process and can estimate value of investment returns whereas computer scientists improve process by use of different methodologies (e.g. PDCA – Plan Do Check Act management method for the control and quality improvement of processes and products[7], CMMI – Capability Maturity Model Integration – a model of maturity and quality of application support[8]).

III. THE CONSTRUCTION AND DEVELOPMENT OF A HELP USER SYSTEM

Happy user is a satisfied customer and each working position for which is provided the use of information and communication technology requires careful consideration and analysis. Service Desk can be a function of the organizational unit that relieves the work of certain teams and integrates catalogue of IT services. Based on the specific services defined in the IT strategy and in accordance with business requirements it is desirable to define the specific working teams who are willing to help in telecommunications systems, system support system, in technical assistance to end users and in the development program activities.

The responsibilities of individual levels of support can be analysed in organized and structured manner in the establishment of a modern and information conscious companies. Service Desk team can be a logical organization who establishes new services or improves existing ones. One level of responsibility provides insight into the events that are introduces into the system of enterprises (for example – procurement and configuration of computer, phone or cell phone). The purpose of that level is management of authentication process, respectively the preparation and training of workers for the next level of IT support. On the different level technically trained staff allows authorized end-user work in a safe and proper way acting normally on the user’s location. The next level support is ultimate invisible for the user, but not unimportant as it allows system and application support and the inclusion of equipment in the safe and correct way in local area network. The synergy of the levels support enables full control of the working process with the help of information and communication technology that establishes the definition and evaluation of standard procedures for a more comfortable work as computer scientists and so end users.

Each help user system in their own way systematize mutual relations, powers and the principle of action and it
is not possible to standardize the methodology. The following shows the possible organization of IT business support in the company:

a. Computer technical support works on processes and activities:
- Training of workers for the first work with computer equipment
- Replacement of worn-out computer equipment with new where workers create new added value for the company
- Hardware and software upgrade in the client system of the company
- The disposal of used equipment and preparing the same for the process of repeated allocation, expenses or donations

b. Telecommunications technical support works on processes and activities:
- Training of workers for the first work with telecommunication equipment
- Replacement of worn-out telecommunications equipment with new where workers create new added value for the company
- Hardware and software upgrade in the client system of the company
- The disposal of used equipment and preparing the same for the process of repeated allocation, expenses or donations

c. System support works on processes and activities:
- Inclusion of user authorization in the computer system of the company
- Control mechanisms for safe and proper end-user work on the client equipment
- Hardware and software upgrade in the computer system of the company
- Exclusion of user authorization in the computer system of the company

d. Application support works on processes and activities:
- Inclusion of user authorization in the specialized applications of the company
- Control mechanisms for safe and proper end-user work on the specialized applications
- Software upgrades of applications
- Exclusion of user authorization in the specialized applications of the company

The challenge of any IT-conscious company is work on the definition of boundary parameters of authority and responsibility for the different IT teams. Continuous work on yourself and on your team allows better interpersonal relationships and creates the framework of normal communication with members of other teams. Only then it can be formed the basis of quality help that is a precondition for the correct IT support.

IV. THE USER IN THE CLIENT INFORMATION SYSTEM

The technology of the present is changing the way of thinking and business approach. Innovative models of new and existing enterprises are created in relation to the finances of the owner and the mission and vision of the company. We distinguish large business information systems that are geographically dispersed and that build infrastructure of computer system in an organized and disciplined way and smaller companies where it is all centralized in one place. But, one thing never changes and that is the system user or employee.

Client information system is simply for planning and maintenance, but it requires the continuous development of communication skills of informatics experts for comfortable direct relationship with the customer during the establishment of certain service. The next time flow chart demystifies specific development phases of user desires and possible scenarios of the life cycle of equipment (Picture 1).

a) End user will get specific equipment for use with the help of standardized communication channels – entrance, exit, requirements management
b) During the handover of equipment employee in theory by his signature on the assignments document guarantees and warrants that he will use the equipment for work in a safe and correct manner – booking of equipment in the books of companies, amortization
c) In the initial phase of establishing a new service it is possible that computer scientists (application and system support) are working on concrete settings for authorized work on the system and with specialized applications – the establishment of a functional work environment and user workplace
d) In the next phase the user (lawyer, economist, sociologist, psychologist..) on a stand-alone mode uses the default privileges for continued work in the computer network – the maintenance of equipment
e) The user during work may be faced with unpleasant situations where it is desirable that the user solves the incident and at the very least looks for help in the
case of endangering the business continuity process – the setting up of business continuity
f) While working user can specifically improve their business – hardware or software upgrade
g) In the final stage of using the particular equipment the user will be discharged with same – the disposal of the equipment

![ITIL processes diagram](image)

- Unprofessional and unknown work with information and communication technology
- (not)ethical working staff
- Lack of experience in time management and crisis situations

Opportunities
- Security and control in the management of business processes
- Better organization
- Pragmatism at work

Threats
- The physical alienation of equipment
- Unauthorized work in the Wide Area Network
- Trading with confidential information

The possible range of analyzes of user rights and personal desires leads to the rational conclusion that user don't need to be afraid of stories about good and bad sides of using technology, already he should be continuously directed on the good. With own professional approach and the control of the working process end user will contribute to the quality in business at mutual pleasure of his superiors and computer experts.

V. THE SYNERGY OF ITIL, IT AND BUSINESS

The principles of efficiency, economy and security of information systems[10] raise the quality level of complete business system. The legal view of the development of technical and functional processing activities of information and communication technology enhances the reputation and honour of the system and the same is better prepared for the work and activities in the corporate environment. At some point the end user has a need for computer equipment, but he doesn’t have the sense and knowledge of the effort that is invested in the strategy, design, preparation and transition of the same. The legal aspect of informatics experts with information and communication technology is reflected in the handover of equal or higher quality than the existing one. ITIL provides guidance to information officer for work, but it takes work on a continuous adjustment of the ITIL processes with key business processes of the company. Work on IT principles contributes to the creation of the better and more efficient decision support systems and business will be easier to control with the help of a sophisticated information and communication technology (picture 2).
The business information systems (human resources) are built in a way which each company has its own story and system activity. ITIL processes can help in the integration of products. The article describes the ITIL methodology that describes the processes of creating, maintaining and abolition of IT services. The service architecture presented in the paper is designed to build highly important trust and loyalty between computer experts and end users. The possibility for the development of client responsibilities (in cooperation with interdisciplinary professional development of informatics experts) is envisaged.

The future is in the innovative services and the question is how they can be incorporated into daily operations without diminishing the effort and the will of information and engineering staff for pragmatic management of the same.

The challenge is to develop the business potential of the marginal utility of information and communication technologies with legal – economic regulation use of the same.

Sinkronizacija SDH mreže HŽ Infrastruktura

Krunoslav Cazin1#, Tomislav Pušec2#
1 HŽ Infrastruktura/Informatika, Zagreb, Hrvatska
2 tomi@hzinfra.hr, # krunoslav.cazin@hzinfra.hr

Sažetak - Za multipleksiranje i prijenos digitalnih signala u transportnoj mreži HŽ Infrastruktura koristi se tehnologija sinkrone digitalne hijerarhije (SDH, Synchronous Digital Hierarchy). SDH kao transparentna i krajnje pouzdana komunikacijska infrastruktura nadograđivala se usporedo s razvojem optičke okosnice telekomunikacijske mreže HŽ Infrastruktura. Sinkronizacija SDH mreže HŽ Infrastrukture također je imala svoj razvojni ciklus: od početne faze praktički bez sinkronizacije, preko sinkronizacije E1 signalom iz SDH mreže mađarskih željeznica pa do sadašnjeg stanja gdje sinkronizaciju osiguravaju tri SSU jedinice za distribuciju sinkronizacijskog signala (SSU, Synchronisation Supply Unit) s prijamnicima signala sustava globalnog pozicioniranja (GPS, Global Positioning System). Višegodišnjim praćenjem rada SDH mreže HŽ Infrastrukture uočavaju se promjene postavki sinkronizacije, koje su već implemenirane u ovom radu. Prikazat će se promjene postavki sinkronizacije mreže o kojima će se detaljno govoriti u ovom radu.

U početku svoje eksploatacije SDH mreža je služila samo za međusobno povezivanje telefonskih centrala i udaljenih korisnika putem E1 signala. Kako su se unutar SDH mreže E1 signala prenosili isključivo govorni kanali koji su relativno robusni po pitanju nesinkroniziranosti, a djelomično i zbog tadašnje organizacije HŽ Infrastrukture, nisu primjećivani problemi u sinkroniziranosti SDH mreže. Promjenom organizacije tako da je unutar HŽ Infrastrukture formirana jedna služba za područje cijele Hrvatske koja se brine, između ostalog, i o SDH mreži te je primijećivana problemi u sinkroniziranosti SDH mreže. Na osnovu uočenih nedostataka pristupilo se analizi tadašnje konfiguracije mreže te nedostaci u sinkronizacijskoj infrastrukturi i njene sinkronizaciji.

I. UVOD

Topologija SDH mreže (Slika 1.) HŽ Infrastruktura slijedi topologiju mreža željeznickih pruga. S obzirom na to da se SDH mrežom povezuje relativno mali broj međusobno udaljenih korisnika, u odnosu na javne telekomunikacijske mreže, za izgradnju SDH mreže bi trebalo potrebno uložiti znatna sredstva. Takva topologija mreže ima za posljedicu i složenu sinkronizaciju iste.

II. ANALIZA

Prilikom analize postavki sinkronizacije SDH mreže u HŽ Infrastrukture posebno pažnja dana je restauraciji sinkronizacijskog signala u slučaju prekida pojedinih veza (tokova sinkronizacijskog signala) i mogućoj pojam sinkronizacijskih petlji u tim slučajevima kao i broju koraka u kojem svaki pojedini SDH multipleskor dobiva referentni sinkronizacijski signal kako u normalnom radu, tako i prilikom prekida pojedinih veza.

Ukoliko bi prilikom simuliranja prekida pojedinih veza došlo do pojave sinkronizacijskih petlji u nekom dijelu SDH mreže to bi značilo da postavke sinkronizacije u tom dijelu mreže nisu dobro konfigurirane.

Slika 1. Topologija SDH mreže HŽ Infrastruktura
Prekid pojedinih tokova sinkronizacijskog signala simuliran je na dva načina:

- brisanjem reference iz tablice upravljanja sinkronizacijom pojedinog SDH multipleksora,
- promjenom kvalitete reference u tablici upravljanja sinkronizacijom pojedinog SDH multipleksora.

Analiza broja koraka rađena je na temelju teorije grafova, pomoću matrice susjedstva i njezinih potencija. Čvorovi grafova predstavljaju elemente SDH mreže, SDH multipleksore i izvore sinkronizacijskog signala (PRC ili SSU). Veze između čvorova grafa predstavljaju sinkronizacijske veze. Kako većina SDH multipleksora može primati referentni sinkronizacijski signal iz više smjerova, prilikom kreiranja matrice susjedstva uzimane su u obzir samo one sinkronizacijske veze koje imaju najveću kvalitetu i naižiš prioritet. Sinkronizacijske veze između pojedinih elemenata SDH mreže s manjom kvalitetom i/ili nižim prioritetom uzimane se u obzir samo u slučaju kada je simuliran prekid veze s većom kvalitetom i višim prioritetom ili je ta veza označena da ne koristi. što je broj kojim se označava kvaliteta i/ili prioritet veći ta sinkronizacijska veza ima manju kvalitetu i/ili niži prioritet.

Analizom je izračunat broj koraka u kojem svaki pojedini SDH multipleksor prima sinkronizacijski signal od SSU-a. Također je naznačeno od kojeg SSU-a dolazi signalizacijski signal. Aplikacija za izračun broja koraka napisana je u Microsoft Access-u te su matrice susjedstva prikazane kao tablice u bazi podataka. Matrica susjedstva, tj. tabla, ima N redova i stupaca, pri čemu N predstavlja broj SDH multipleksora čiji je ID jednak 8 i 9 (Slika 5.).

Prekid pojedinih tokova sinkronizacijskog signala simuliran na dva načina:

- matematičkim modelom i
- izravnim algoritmom kreira matricu susjedstva

A. Izračun koraka sinkronizacije

Množenjem matrice susjedstva i njezine treće potencije dobivamo četvrti korak sinkronizacije. Kod četvrte potencije matrice susjedstva (Slika 6.) vidimo da su sva polja u prvom retku jednaka nuli, što znači da više ni jedan mrežni element ne prima referentni sinkronizacijski signal. Izračunavanje potencijal matrice susjedstva vrši se do one potencije kod koje više ne postoji ni jedan mrežni element koji prima sinkronizacijski signal. To znači da su svi mrežni elementi primili sinkronizacijski signal ili da jedan ili više njih nije sinkroniziran.

**B. Analiza početnih postavki sinkronizacije**

Analiza početnih postavki sinkronizacije u SDH mreži pokazala je da svi SDH multipleksori sinkronizacijski signal PRC kvalitete dobivaju iz SSU Zagreb bez regeneracije istoga u SSU Knin. Unosom podataka u aplikaciju i izračunom broja koraka sinkronizacije dobiveni su sljedeće vrijednosti koje karakteriziraju početnu konfiguraciju:

\[ A_{\text{max}} = 11, \quad \sum A = 365, \quad N = 61, \quad \bar{\alpha} = 5.98 \]

Iz dobivenih vrijednosti za početne postavke vidi se da maksimalni broj koraka sinkronizacije iznosi jedanaest, što je u granicama propisanim ITU-T preporukom G.803 [3]. Iako je maksimalni broj koraka sinkronizacije u propisanim granicama, zbog krivih postavki sinkronizacije na SDH multipleksoru Knin sinkronizacija SDH mreže nije se odvijala kako je bilo zamišljeno. Tok referentnog sinkronizacijskog signala početnih postavki prikazan je Slikom 7.

**SSU Zagreb**

\[ A_{\text{max}} = 10, \quad \sum A = 242, \quad N = 48, \quad \bar{\alpha} = 5.04 \]

**SSU Knin**

\[ A_{\text{max}} = 5, \quad \sum A = 45, \quad N = 13, \quad \bar{\alpha} = 3.46 \]

Podatkovni prsten između Vrhovina i Gospića poslužit će za grafički prikaz toka referentnog signala u normalnom radu i nakon restauracije sinkronizacijskog signala prilikom simuliranja gubitka referentnog sinkronizacijskog signala. Na slici 8. vidi se tok referentnog sinkronizacijskog signala u oba smjera. Isti slučaj bio je na svim podatkovnim prstenima na relaciji Zagreb – Knin i na ostalim dijelovima SDH mreže gdje imamo dva linka kapaciteta STM-16 kao vezu između dva SDH multipleksora.
Sporedni linkovi su kapaciteta STM-4 i na njima je obostrani tok sinkronizacijskog signala dozvoljen samo na jednom kraju podatkovnog prstena.

Simuliranjem gubitka referentnog sinkronizacijskog signala uspostavio se je novi tok sinkronizacijskog signala koji je prikazan Slikom 9. iz koje se vidi da je SDH multipleksor Vrhovine kako novi izvor referentnog sinkronizacijskog signala odabrao sinkronizacijsku referencu s prioritetom 11 te da je došlo do pojave sinkronizacijske petlje Gospić → Vrhovine → Gospić.

Slika 9. Završetak restauracije toka sinkronizacijskog signala – početna konfiguracija

Osim ovih problema uočeni su još neki manji nedostaci u konfiguraciji pojedinih SDH multipleksora koji su se uglavnom svodili na nepostojanje zaštitnog puta sinkronizacijskog signala, tj. sinkronizacijski signal mogao se je primati samo iz jednog smjera.

III. OTKLJANJE UOČENIH NEDOSTATAKA

Analizom je utvrđeno postojanje dva velika nedostatka početnih postavki sinkronizacije SDH mreže u HŽ Infrastrukturi. Prvi je pojava sinkronizacijskih petlji unutar svih podatkovnih prstenova koji se nalaze između SDH multipleksora Zagreb GK i Knin. Drugi je nedostatak logična posljedica prvog, a to je da SSU Knin u slučaju kvara SSU Zagreb ne preuzme na sebe sinkronizaciju SDH mreže, osim u slučaju prekida optičkog kabela između SDH multipleksora Padene i Knin. Oba nedostatka proizlaze iz krivo konfiguriranih postavki sinkronizacije pojedinih SDH multipleksora. Neki se nedostaci mogu otkloniti na jednostavan način dok je za rješavanje drugih, poput pojava sinkronizacijskih petlji i nemogućnost sinkroniziranja cijele SDH mreže iz SSU Knin, potrebno poštivati određena pravila.

Model prstenaste mreže [1], [2] na Slici 10. prikazuje kako se pomoću pravilne konfiguracije tokova sinkronizacijskog signala i SSM [2] (SSM, Synchronization Status Message) poruka može izbjeći pojava sinkronizacijskih petlji. Na Slici 10 postoje dva kružna tokova referentnog sinkronizacijskog signala, primarni i sekundarni. Pojava sinkronizacijskih petlji sprečavanje se tako da svaki tok bude prekinut na onom SDH multipleksoru iz kojeg je krenuo. U normalnom radu tok referentnog sinkronizacijskog signala je SDH 1 → SDH 2 → SDH 3 → SDH 4 → SDH 5 → SDH 6 i prekida se na ulazu SDH 1. U slučaju gubitaka ulaza s prioritetima 1 i 2 na SDH 1 uspostavlja se sekundarni tok referentnog sinkronizacijskog signala SDH 4 → SDH 3 → SDH 2 → SDH 1 i SDH 4 → SDH 5 → SDH 6.

Poštivajući pravila prikazana Slikom 10. pristupilo se rekonfiguriranju sinkronizacije cjelokupne SDH mreže, a posebna pažnja dana je tokovima referentnog sinkronizacijskog signala u podatkovnim prstenovima između Zagreba i Knina. Sinkronizacija mreže je konfigurirana tako da dio mreže sinkronizacijsku dobiva iz SSU Zagreb, a dio iz SSU Knin. U slučaju kvara jednog od njih ili gubitka GPS signala mreža bi prešla u master-slave mod rada i onaj SSU koji bi radio ispravno sinkronizirao bi cijelu mrežu.

Slika 10. Model prstenaste mreže s protekcijom petlje – dva ulaza
Nakon završetka restauracije uspostavljena su dva smjera referentnog sinkronizacijskog signala: Vrhovine → Gospić → Perušić i Vrhovine → Ličko Lešće.

Izračun proveden aplikacijom za novu konfiguraciju sinkronizacije SDH mreže dao je sljedeće vrijednosti:

SSU Zagreb
\[ A_{\text{max}} = 9, \sum A = 168, N = 37, \bar{A} = 4,54 \]

SSU Knin
\[ A_{\text{max}} = 5, \sum A = 84, N = 24, \bar{A} = 3,50 \]

Može se primijetiti da je srednji broj koraka sinkronizacije manji nego prije početka analize i donekle uravnotežen. Zbog topologije SDH mreže (Slika 1.) teško se može postići da srednji broj koraka bude jednak na oba SSU-a.

U slučaju kvara SSU Zagreb sinkronizaciju cijele SDH mreže preuzeo bi SSU Knin te su pomoću aplikacije dobivene sljedeće vrijednosti:

\[ A_{\text{max}} = 15, \sum A = 429, N = 61, \bar{A} = 7,03 \]

U slučaju kvara SSU Knin sinkronizaciju cijele SDH mreže preuzeo bi SSU Zagreb te su pomoću aplikacije dobivene sljedeće vrijednosti:

\[ A_{\text{max}} = 11, \sum A = 369, N = 61, \bar{A} = 6,05 \]

Novu konfiguraciju sinkronizacije u normalnom radu ima manji maksimalni i srednji broj koraka, što je bilo i za očekivati jer je sada sinkronizacija SDH mreže raspoředena na dva SSU uređaja. Kvar SSU Zagreb, u novoj konfiguraciji sinkronizacije, bi imao za posljedicu porast maksimalnog i srednjeg broja koraka sinkronizacije u odnosu na stanje prije analize. Iako bi prilikom kvara SSU Zagreb maksimalni broj koraka zadovoljavao ITU-T, preporuku G.803, on bi bio na samoj granici preporučene vrijednosti. Ovo je posljedica promijenjenih tokova sinkronizacijskog signala na nekim SDH multipleksorima između SSU Zagreb i SSU Knin. I u ovom slučaju je malena vjerojatnost kvara SSU Knin, već je vjerojatnije da bi zbog gubitka GSP signala radio kao SSU, a to bi značilo da bi tada broj koraka sinkronizacije od SSU Knin ponovo kretao od jedan.

IV. UGRADNJA SSU VINKOVCI

Porastom IP servisa koji se prenose SDH mrežom, a koji imaju ishodište u SDH multipleksoru Vinkovci ukazala se potreba za ugradnju još jedne SSU jedinice. Problem nije predstavljao broj koraka sinkronizacijskog signala već nepostojanje drugog optičkog kabela. Prekid optičkog kabela bilo gdje na relaciji između Dugog Sela i Vinkovaca imao bi za posljedicu da SDH mreža prema Vinkovcima ostane bez referentnog sinkronizacijskog signala. Kako se cjelokupno upravljanje stabilnim postrojenjima električne vuče iz centra daljinskog upravljanja u Vinkovcima obavlja IP servisima preko SDH mreže, teža nesinkroniziranost u toj mreži imala bi za posljedicu opadanje kvalitete servisa. Kako se ne mogu postići srednji broj koraka radija kao SSU, a to bi značilo da bi tada broj broja koraka sinkronizacije od SSU Knin ponovo kretalo od jedan.

Od provedene analize sinkronizacije SDH mreže pa do trenutka kada se krenulo u nabavu novog SSU-a za Vinkovce mreža je nadograđena s novim SDH multipleksorima i u određenoj mjeri je prekonfigurirana njena topologija kako bi se izbjeglo ulančavanje podatkovnih prstenova. Ugradnja SSU Vinkovci odmah je uključila i osam SDH multipleksora za koje se znalo da će se ugraditi nakon ugradnje SSU Vinkovci. Tok referentnog sinkronizacijskog signala buduće konfiguracije SDH mreže prikazana je Slikom 13.
Simulacija provedena aplikacijom dala je sljedeće vrijednosti:

SSU Zagreb
\[ A_{\text{max}} = 6, \Sigma A = 139, N = 39, \bar{A} = 3,56 \]

SSU Knin
\[ A_{\text{max}} = 5, \Sigma A = 89, N = 25, \bar{A} = 3,56 \]

SSU Vinkovci
\[ A_{\text{max}} = 5, \Sigma A = 42, N = 15, \bar{A} = 2,8 \]

Iz dobivenih rezultata može se vidjeti da predložena konfiguracija sinkronizacije nakon nadogradnje SDH mreže i ugradnje SSU Vinkovci ima manji maksimalni broj koraka sinkronizacije. Vidi se i da je srednji broj koraka sinkronizacije donekle ujednačen za svaki SSU. Iz dobivenih rezultata može se zaključiti da je predložena konfiguracija nakon nadogradnje SDH mreže ispravna.

V. ZAKLJUČAK

Izračun broja koraka sinkronizacije pomoću matrice susjedstva, prije analize sinkronizacije SDH mreže i nakon njenog rekonfiguriranja, omogućio nam je uvid u postignuta poboljšanja po pitanju maksimalnog broja koraka sinkronizacije i srednjeg broja koraka sinkronizacije. Pomoću ovog algoritma možemo prije svakog većeg rekonfiguriranja SDH mreže testirati predviđene postavke sinkronizacije. U trenutku pisanja algoritma za izračun broja koraka sinkronizacije nismo znali koje uvjeti treba postaviti kako bi algoritam mogao vršiti i provjeriti da li dolazi do pojave sinkronizacijskih petlji te u tom trenutku to nije bilo moguće ustanoviti pomoću aplikacije.

Iz provedenih analiza, kako početnog stanja tako i predloženih rješenja, može se zaključiti da je neophodno sljedeće:

- pravilno određivanje prioriteta sinkronizacijskih referenci,
- poštivanje pravila za protekciju sinkronizacijskih petlji i
- poželjno je da svi elementi SDH mreže podržavaju SSM poruke.

Ispunjavanje navedenih uvjeta osigurat će pouzdanu sinkronizaciju SDH mreže. Osim toga važno je da djelatnici koji rade na konfiguriranju i održavanju SDH mreže budu upoznati s problemima sinkronizacije kako bi što učinkovitije otklonili moguće nedostatke. Poželjno je i da svaki SDH multipleksor referentni sinkronizacijski signal može primati barem iz dva smjera (izvora) koji su jednake kvalitete.

Rastom SDH mreže analiza sinkronizacije mreže i predviđanje kritičnih situacija postaje sve složenija. Koliko god se trudili postavkama i uređajima osigurat sinkroniziranost cije mreže, u stvarnosti se teško može postići njezina sinkroniziranost u svim uvjetima. Osim nepredviđenih situacija za neke situacije ni ekonomski isplativo osigurati sinkroniziranost. Cilj je sinkronizacije postići što pouzdaniju sinkroniziranost mreže u svim situacijama, a u skladu s tehničkim i ekonomskim mogućnostima. One situacije koje nisu pokrivene postavkama sinkronizacije, mogu se riješiti kvalitetno obučenim djelatnicima koji održavaju SDH mrežu, koji će u što kraćem roku ispravno intervenirati i gubitak prometa kroz mrežu zbog sinkronizacije svesti na najmanju moguću mjeru.

Abstract - Optical fiber technologies gradually expanded into areas, which enabled creation of new hybrid applications. These applications show special features, which precede the success. Special category of optical interferometric systems with possibilities of many applications in these areas. Combination of gyroscope with optical fiber interferometer based on principle of Sagnac interferometer is able to create optical fiber gyroscope system. The basic criterion for this activity is creation of Sagnac effect in optical fiber. This phenomenon is needed for detection of direction and speed of rotation. The point of this article is design and testing optical fiber gyroscope system in program environment OptSim.

Key words – Fiber optical gyroscope, OptSim, Sagnac effect

I. INTRODUCTION

Devices which were based on well-known different types of systems are very popular nowadays. One of these devices is optical fiber gyroscope. Interferometers were developed for monitoring and examination of different parameters of devices. Every type of examined device is based on different physical principle. Therefore, it was necessary to develop different type of interferometers, which would be able to examine these physical parameters. Nowadays four types of interferometers are well known. They are Michelson, Mach-Zehnder, Fabry-Perot and Sagnac. Principles of these interferometers were described many years ago, however they potential is fully exploited just today. Combination of new type of devices based on new technologies and state-of-art materials brings new possibilities for analysis.

Expansion of optical fiber technology opened many possibilities for transmission of optical beams through glass or plastic medium. Optical fiber gyroscope system based on Sagnac interferometer is combination of glass transmission medium and well-known system. Sagnac interferometer was based on transmission of optical beam between optical mirrors. The use of optical mirrors prevented usage in small applications. Combination of interferometers and some devices lead to new possibilities for exploration of properties. Optical fiber gyroscope allows examination of non-optical properties such as location, rotation and other properties of optical fiber gyroscope module. We designed optical fiber gyroscope in OptSim program to be able to confirm and show creation and impact of Sagnac effect in optical fiber. This optical fiber is the basic part of optical fiber gyroscope system. Optical fiber gyroscope can be classified as optical sensors. Construction of this optical sensor is fully optical, because all of the components which are used sensor are optical and opto-electronic [1-2].

II. OPTICAL FIBER GYROSCOPE

The design of optical fiber gyroscope must reflect conditions for optical transmissions. This module can be created from single mode optical fiber, optical laser with adequate value of emitted optical power and APD (Avalanche Photodiode) or LD (Laser Photodiode) photodiode as detector [1-2].

The principle of this optical sensor is exploration and comparison of phase shift of optical signal spread in optical fiber. Module created in the program OptSim is represented by real optical gyroscope module. This model describes the differential phase shift which is caused by Sagnac effect. It occurs between two optical signals. First modulated optical signal is spread in the clockwise direction (CW) and second signal is spread in counter-clockwise direction (CCW) in optical fiber wound into a coil shape. Sagnac effect is a phenomenon in the interferometer, which in this case occurs at circular rotations of the optical fiber. The optical signal in form of light beam is split into two light beams that propagate in opposite directions in the area and interference are caused by recombination of individual light beams. The entire process takes place in an optical fiber, which is used both as a transmission medium, but also as a component in which operates Sagnac effect [1-4].

The phase difference depends on the constant representing the Sagnac effect \( \varphi_S \), which is proportional to the scalar product of the vector rotation speed \( \Omega \) and vector space \( A \) through bounded route:

\[
\varphi_S = \frac{4\pi}{\lambda} \varphi_S \Omega, \quad (1)
\]

but now the actual area A is N-fold the area of a single loop. It is represented by equations (2,3):

\[
\varphi_S = \frac{8\pi NA}{\lambda c} \Omega, \quad (2)
\]
\[ \varphi_s = \frac{2\pi LD}{\lambda c} \Omega, \quad (3) \]

where \( \lambda \) is wavelength, \( D \) is the diameter of coil, \( L=\pi ND \) is the fiber coil length, \( A=\pi D^2/4 \) is the area of the single fiber loop, and \( N \) is the number of loops \([1-4]\).

Range of phase measurement of \( \pm \pi \) rad around zero corresponds to an unambiguous operating range of \( \pm \Omega \pi \).

Fig. 1 shows rotation rate for this case.

Sensitivity and efficiency of optical fiber gyroscope depends on length of optical fiber and diameter of optical coil \([1]\). These parameters affect phase of rotation, which is given by equation (4):

\[ \Omega_s = \frac{\lambda c}{2L \cdot D}, \quad (4) \]

where \( L \) is length of optical fiber, \( D \) is diameter of coil, \( \lambda \) is wavelength of light, \( c \) represents speed of light in vacuum. Considering values of these parameters enable division of optical fiber gyroscope by the sensitivity \([5-7]\).

A very high sensitive optical fiber gyroscope has values of parameters given by Table I \([1]\).

<table>

</tbody>
</table>

Efficiency and sensitivity depends on type of chosen configuration. Every configuration offers different properties. In the next part we create model of optical fiber gyroscope in program OptSim \([8-9]\).

III. DESIGN OF OPTICAL FIBER GYROSCOPE IN OPTSIM

OptSim program was chosen for purposes of simulation. Usage of blocks present in OptSim is enables describe of physical model of optical fiber gyroscope system. Model created in OptSim is exact copy of real experimental model. Each block is based on parameters and variables. The most important of them are type of used light source, length of optical fiber, diameter of optical coil and other important properties.

Design schema of optical fiber gyroscope contains following three parts:

- laser source,
- I-FOG optical fiber loop,
- signal detection.
A. Analysis of each parts

1) Blocks of part optical source
Basic construction blocks of this part:
- BB Source (Broad Band Source),
- Optical Attenuator,
- Polarization Transformer,
- Optical Monitor – optical monitor of interim results,
- Property map – monitoring power of laser,
- Multiplot – it allows viewing of the individual signals on the beam.

Optical signal propagates from optical source towards optical attenuator. Block of optical attenuator is connected with block of polarization transformer. These signals could be examined and analyzed in the block named as “Property map”, which purpose is monitoring power of laser and changes of optical power in time. The second block which allows examining amplitudes of outputting signals is named as “Multiplot”. Each variable was configured in regard to construction of real physical optical fiber gyroscope system. Parts of optical source are displayed on Fig. 2. The example of configuration of optical source blocks is shown in Table VII.

![Figure 2 Part optical source.](image)

**TABLE VII Configuration of block BB – Source and block CW – Laser**

<table>
<thead>
<tr>
<th>Block</th>
<th>Description</th>
</tr>
</thead>
<tbody>

<td>BB – Source (Broad Band – Source)</td>
<td>Radiated Power 20mW</td>
</tr>
<tr>
<td>CW – Laser (Continuous Wave – Laser)</td>
<td>Used wavelength 1531nm</td>
</tr>
</tbody>
</table>

The next applied blocks are optical filter, increase of optical noise, normalization of optical power, optical attenuator, and transformation of polarization.

2) I-FOG Optical fiber loop
Optical fiber loop is basic part of optical fiber gyroscope system. Primary function of this part is simulation of creating of Sagnac effect in optical fiber. Due to this phenomenon it is possible to examine parameters of optical signal, which is spread in optical fiber wound into a coil shape. As the primary block of optical gyroscopic system was used optical fiber loop containing 16 blocks. Three of these blocks are named as SigPlt2, 4, 8 (Signal Plot) and represent analyse of signal. Four blocks named as ExtMod1-4 (External Modulator) are used as modulators of optical signals. Two blocks ElecGen2 (Electrical Generator) generate electrical signal on base of PRBS (Pseudorandom Binary Sequence). Blocks of OptSplit (Optical Splitter) and OptCombiner (Optical Combiner) creates splitting or merging of optical beams. Two blocks named as PM_Fiber_CW (Polarization Maintaining Optical Fiber in Clockwise) and PM_Fiber_CCW (Polarization Maintaining Optical Fiber in Counterclockwise) represent type of single mode optical fiber with polarization maintaining. Type of considered optical fiber is SMF28, which satisfies conditions for usage in our case. Sagnac effect is ensured using block named as Sagnac Effect and block named as Phase_Shift ensure phase shifting of signals in one branch. Design this part is shown in Fig. 3.

![Figure 3 FOG optical fiber loop.](image)

**Table VIII. shows example configuration of signal generator [10-11].**

</tr>
</tbody>
</table>

3) Signal detection
The part of signal detection is designed to process signals obtained from I-FOG. This configuration can be seen on Fig. 4. Processing and analysis of signals takes place here. The basic block for which this configuration is designed is
created by detector, filter (ElecFilt – Electrical Filter), monitoring block (OptMon – Optical Monitor), blocks of multiplot (MultiPlot) and signal analyzers (SigPlt – Signal Plot). As the detector is considered APD (Avalanche Photodiode) photodiode.

In Table IX, configuration of photodetector block is shown.

<table>

IV. CONCLUSION

The design of interferometric optical fiber gyroscope in program environment “OptSim” is based on parameters of real components, which are available in laboratory of optoelectronic systems at Department of electronics and communications of University of Technology Košice. The created configuration consists of three parts, and each of them contains more configuration blocks. The configuration of each block it is made as it could be seen in tables. Once configured, compiled and tested signal waveforms were obtained, as it could be seen on Fig. 5. This figure shows phase changes of signal and impact of Sagnac effect in optical loop. When examining changes of key parameters of gyroscope module as length of used optical fiber, speed of rotation lower and higher signal phase changes could be observed.

This phenomenon happened in each case. The objective of the experiment was creation of interferometric optical fiber gyroscope system in which phase changes created by Sagnac effect are demonstrated.

Value Based Service Design Elements in Business Ecosystem Architecture

Darije Ramljak
IBM Croatia Ltd/IBM Global Business Services
Zagreb, Croatia
darije.ramljak@hr.ibm.com

Abstract - Enterprises are increasingly being exposed to a number of changes stemming from the overall business environment and their collaborative network of users and partners. Current techniques and models created by using standard frameworks such as Enterprise Architecture are not able to cover relevant design aspects required for service interactions, thus new design elements and aspects stemming from new concepts such as Ecosystem Architectures are being introduced.

This paper focuses on introduction of innovative method and models for service design and selection in complex ecosystem environments by focusing on value oriented aspects used in service composition.

I. INTRODUCTION

The term business architecture is usually associated with intra-enterprise definition of elements required to link the enterprise business strategy and its operational aspects. By definition, business architecture is “a blueprint of the enterprise that provides a common understanding of the organization and is used to align strategic objectives and tactical demands”. The business architecture is one of the key aspects of many Enterprise Architecture (EA) frameworks, such as Zachman and TOGAF, to name a few. By using EA frameworks, one can specify certain business related elements, architectural building blocks (ABBs), to depict the enterprise business capabilities in a form of business ABB elements and relations among them.

The market environment and its changes bring various constraints and challenges for a successful functioning of an enterprise and EA alone, while providing a great starting point, is not sufficient to provide a framework and a method to devise a complex environment and interactions beyond the enterprise boundaries, hence we introduce the concept of an enterprise ecosystem.

An ecosystem is a complex web of interdependent enterprises and relationships aimed to create and allocate business value [1]. Ecosystems are broad by nature, potentially spanning multiple geographies and industries, including public and private institutions and consumers.

Ecosystems are structurally complex environments comprising participants and their interactions. They have unique rules of engagement and share significant market characteristics. Ecosystem participants/partners can create value through innovating products, services, or experiences and they must collaborate to create and deliver something of mutually beneficial value. In effect, value creation and value capture reflect a networked, dynamic, everyone-to-everyone process of exchange and the main difference to standard value chains is that ecosystems produce more value as a whole, than the sum of the individual participants acting independently.

In a nutshell, ecosystem enablers are mandating efficient means of product creation, collaboration, data exchange, and interconnection of systems. Thus, APIs become the main technology and conceptual building blocks to create new ecosystem operational platforms and environments.

In this paper, we are introducing an innovative method and models for service design and selection in complex ecosystem environments by focusing on value oriented aspects used in service composition. Value orientation is based on a concept of value network [2] and define it as a value creating system in which all involved stakeholders in the ecosystem “co-create value”. Since “value co-creation” is the ultimate objective of services, the method should firstly focus on high-level service value models, i.e. the identification of service participants (ecosystem participants), their value expectations and value exchange relations.

The starting point of the proposed method is the high-level business ecosystem architecture definition and service value model, which is described by service value network in a form of associated service attributes.

Value model is defined as an UML profile with defined stereotypes and is further transformed into a property graph representing the attributed service design model and one of the potential execution transformations is defined as an RDF model, capable of being queried as well as serving as a foundation for service execution models.

Majority of recently published papers dealing with the problem of service design and composition are mostly focusing on the technical issues such as interface matching, semantic service description and semantic service discovery. Several of web services discovery approaches use the tagging concepts to annotate the service descriptions [7] and utilize tags to analyze the service similarity and provide the best service match [8], but these approaches focus primarily on the technical service attribute aspects and augmentation of the discovery and selection approach based on user service tagging. In this
paper, we use tagging technique as a means to transfer business ecosystem defined goals and value attributes into service descriptions to enhance the service clustering process and streamline the final service selection based on service skyline approach.

The proposed approach is aiming on the creation of the value oriented method for the definition of flexible, business aligned services to enhance the cumbersome process of API composition and assembly.

This paper is organized as follows. Section II gives a description of Service design and the role of Enterprise architecture in decisioning process. Section III introduces the model and a method for value based service design. Section IV presents the process of service selection based on the value elements. Section V is a case study. The conclusion and future work are presented in section VI.

II. ENTERPRISE ARCHITECTURE AND SERVICE DESIGN

In the context of this paper, an “enterprise” is defined as a collection of organizations having the same set of goals and/or the same common denominator. In this sense, an enterprise could be a government agency, government apparatus as a whole, a corporation, a corporate sector or just a department [11].

Definition of the “enterprise” in the context of Enterprise Architecture can depict the whole enterprise, including all of its information systems, and/or a specific domain within the enterprise. In both cases, architecture comprises several information systems and several functional areas within the enterprise.

ANSI/IEEE Std 1471-2000 defines architecture as the “fundamental organization of a system, embodied in its components, their relationships to each other and the environment, and the principles governing its design and evolution” [10].

According to the aforementioned definitions, Enterprise Architecture (EA) is understood as (1) the fundamental organization of a government agency or a corporation, as a whole or in part as a division or department; and (2) the principles governing its design and evolution. EA models represent either As-Is or To-Be architectures of an actual government agency or corporation. EA frameworks provide the following:

- meta-models for EA description,
- methods for EA design and evolution,
- a common vocabulary for EA,
- optionally, reference models as templates or blueprints for EA design and evolution

EA approach is hierarchical and it usually means that „IT follows the business”, starting with strategic business positioning, then defining appropriate organizational processes and structures, and finally specifying the information system that is appropriately supporting business requirements.

Most EA frameworks differentiate the following layers [11]:

- Business Architecture – represents the fundamental organization of the enterprise from the business strategy point of view. Typical artifacts in this layer are organizational structures, business goals, business functions, business processes and business services.
- Information Architecture – represents the set of main informational entities and their relationships within the problem domain on which the EA focuses on. It is comprised of a business data model, logical data model, requirements for the interoperability from the data point of view, etc.
- Application Architecture – describes the main application system types required for data processing and business process support. The term application is not depicting a computer based system, it is formulated as a logical functional group managing the data elements defined in the Information Architecture and providing support for the business functions defined in the Business Architecture.
- Technological Architecture – provides a technological view of the entire system. It is comprised of the definition of technological elements, called architectural building blocks (ABBs) and their allocation to different technological architectural layers, depending on the desired approach for the definition of information system's technological infrastructure. ABBs are not representing the technological solution itself, they are technology independent and are defining the main technological characteristics and properties for a particular physical implementation.

A very important concept introduced in the definition of Business architecture is the notion of Component Business Architecture (CBA) [4]. The decomposition of the entire enterprise into well defined and discrete components enables a clear separation of concerns, and the definition of business services offered within the enterprise or to the ecosystem. The concept is based on the Component Business Modeling (CBM) method [12]. CBM as a methodology is more comprehensive in terms of facilitating the transformation of the enterprise, while the new concept of CBA is more focusing on alignment of business services, business processes, and the service oriented information systems. One of the purposes of creating the business components is also the need to break complex business processes into manageable parts that have clearly defined boundaries (component boundaries) and interfaces (component services).

CBA differentiates the ecosystem wide, inter-component and intra-component processes. Inter-component processes are describing how the enterprise-wide processes are being choreographed using the business services provided and/or required by the business components. It also defines the value creation and value capture requirements as a set of constraints, i.e. circumstances in which the enterprise is willing to be a part of the ecosystem. Value capture and
value creation flows are proposed to be modeled in a form of a value network.

Intra-component processes, on the other hand, are describing how the business service’s logic, within the component that offers it, is defined in a form of processes and sub-processes (usually depicting the service that needs to be exposed from Systems of Record).

III. THE MODEL FOR VALUE BASED SERVICE DESIGN

In order to define the elements (attributes) required to associate business and user value characteristics to particular services, a new model for service design are being introduced in this paper.

The model comprises two main layers, business and service layer. The business layer is built upon the CBA model of business and application architecture and introduces the Value Offering concept. The Value Offering is key element in the translation of ecosystem business strategy and intent and is containing definitions for each value attribute proposed by the business component. Value itself can be created and captured by using the service that “realizes” the Value Offer.

![Figure 1 - Value Based Service Model](image)

The Value Offering’s attributes are directly linked and typed based on the Business Area and Business Component category types, ensuring that model can introduce specific industry/domain standards for value elements definition.

The Service Layer is focusing on detailed service design and each Service entity is defined by Service Capability and Service Quality elements. Service Capability is defining functional aspects and provision of specific functionality by service execution, while Service Quality is focusing on non-functional service descriptions.

By having Service Capabilities and Service Qualities linked to Value Offering, the model is ensuring that Service Capabilities are defined based on the ecosystem business architecture components and convey the strategic intent of the ecosystem participant to lower, “execution” layers.

Each Service Capability will be realized in a form of a service “tag”, that will enable easier classification and service discovery and matching algorithms. Tags are, in essence, an annotation mechanism to enrich the service description and to provide enough information for the service selection and composition based on definition of business value provided by the service.

Service Quality elements will provide additional dimension for service description and by focusing on non-functional service qualities, provide additional selection and composition criteria.

By using both, Service Capabilities and Service Qualities, each ecosystem participant will be able to discover and select appropriate services and provide a composition pattern to co-create and capture the value provided by the interaction with the service of an ecosystem service provider.

IV. SERVICE SELECTION

The proposed method uses the analysis of service capabilities as in a form of service tag, for which the String representation is used and we can apply content analysis of various service capabilities and compare the ecosystem service user request with existing ecosystem service descriptions. Service capabilities in a form of service tags have a direct traceability back to the originating business ecosystem value offerings and thus create a link to business value strategy defined for the entire ecosystem.

In some related research [5], services are selected depending on a predefined objective function. In this case, a weighting mechanism is leveraged where service users express preferences over different characteristics (parameters) as numeric weights. The composite service gaining the highest value is selected and returned to the user.

As it proved to be very challenging to transform user preferences into numeric weights, some researchers have tried solving the problem using the dominance relationship between services [6] (also called skyline). With dominance relationship between services, for a task, only skyline services are selected for further composition, reducing the number of candidate services.

This paper proposes a method where initial service selection is based on service clustering by utilizing service tags (service capability) comparison and the next stage is to find the skyline service within the service clusters to finalize the service selection process.

A. Service Clustering

For each service capability, a service tag or a set of tags is defined and we can mark a service \( s_1 \) with a tag set
\[
T_1 = \{t_1, t_2, \ldots, t_n\},
\]
and a service \( s_2 \) with a tag set
\[
T_2 = \{t_1, t_2, \ldots, t_n\}.
\]

We can define the service similarity based on the service capabilities tags as:
\[
sim(s_1, s_2) = \frac{|T_1 \cap T_2|}{|T_1 \cup T_2|}
\]
Service capabilities and tag similarities are not necessarily a single value for all service capabilities, and we can define several tag sets for multiple service capabilities. Service tag is a String representation of a capability, where capability can be a single Name-Value pair or a complex map of N-V pairs. Each service similarity based on a tag set can be further used as a single value preference for service skyline and finding Top-k services.

### B. Service Dominance Definition

Given a set of d-dimensional points, a point $p$ is said to dominate another point $q$ if it is better than or equal to $q$ in all dimensions and better than $q$ in at least one, denoted as $p < q$. The skyline points are the subset of points that are not dominated by other points [3]. In a scenario of improving composition and assembly of services with proposed skyline technique, given a predefined value network schema, top-k skyline services are selected for each required value flow between ecosystem participants and composed into a composite service flow.

**Definition 1. Service Dominance**

A service $ws_i$ is defined as a dominate another service $ws_j$ on $Q$ if and only if $\forall q_j \in Q, ws_i.q_j \geq ws_j.q_j$ and $\exists q_i \in Q, ws_i.q_i > ws_j.q_i$.

**Definition 2. Service Skyline**

A service $ws_i$ is a skyline service if and only if there does not exist a service $ws_j \neq ws_i$ dominating $ws_i$. Service skyline could also be called full skyline or free skyline.

**Definition 3. Value Preference Service Dominance**

Given a value preference space $P$, a service $ws_i$ is said to dominate another service $ws_j$ on $P$ if and only if $\forall p_i \in P, ws_i.p_i \geq ws_j.p_i$ and $\exists p_i \in P, ws_i.p_i > ws_j.p_i$.

**Definition 4. Value Preference Service Skyline (VPS)**

A service $ws_i$ is a skyline service on $P$ if and only if there does not exist a service $ws_j \neq ws_i$ dominating $ws_i$ on $P$. We use $s\text{-VPS}(WS,P)$ to denote the set of skyline services in $WS$ on $P$, where $s$ represents the number of attributes in $P$. $s\text{-VPS}(WS,P)$ can be abbreviated as $s\text{-VPS}$ or $VPS$.

The first two definitions describe skyline services over full service characteristics dimension, and Definition 3, 4 show what a value preference skyline service is. Given an $l$-dimensional value preference space $vi$ and $d$-dimensional service characteristic space $Q$, when $l = d$, the value preference service dominance is equivalent to the original dominance in full skyline.

**C. Finding top valued services**

Using VPS, top-k candidate services for each task are selected for the further composition. In order to rank services in a same candidate service class, a score is computed for each service under a user preference space $P$, denoted as $score(ws)$ for the service $ws$. The score is computed as follows: $score(ws) = \sum_{j=1}^{d} ws.q_j$, where $q_j \in P$, $0 \leq ws.q_j \leq 1$ and $ws.q_j$ is the parameter value after normalization.

For selecting top-k services, a dominant number is defined for service ranking. For the service $ws$, its dominant number is equivalent to the number of services dominated by $ws$ in VPS.

V. Case Study

The new model and approach can be applied in any complex organization going through the digital transformation of their current information system landscape and moving towards the ecosystem collaboration platform. The government/public sector of a particular state or city is one such organization, and is taken under consideration for this case study. The government sector is usually comprised of a large number of government agencies, ministries, and public institutions. Each of those government organizations are continuously going through IT transformations in order to comply with new regulations, new laws that has been passed, etc. The problem with this continuous adaptation of Information systems is that the interoperability between those organizations is becoming very difficult. In addition, multiple new service consumers and service providers are emerging, such as small startup companies eager to harness the power and value of the open data that governments provide and using this insight to create new services for government entities and citizens. This is effectively becoming a new ecosystem where all participants, government entities, citizens and commercial entities are providing and consuming services simultaneously.

This problem is being addressed by the new combination of EA elements and service value design approach, where the business decomposition starts from the overall government, dividing the business responsibilities for each agency and ministry, defining them as business components interacting in the government business ecosystem. Definition of government CBA is important step in defining Value Offerings being offered by business components and services.

Services describe the actual conversation between government organizations (components), and the establishment of the overall Information architecture gives a common vocabulary for this conversation. Government business model is defining all entities within the government business horizon and is one of the main drivers for better interoperability between government agencies. Each government organization is comprised of a large number of internal components that comprise its CBA.

After defining the CBA for the entire ecosystem, government-wide and for each organization, and defining value offerings and services, the mechanism for the service selection and composition is ready to be used by the new ecosystem participants.

Our case study is focused on a creation of a new business ecosystem where the City and local government would have a lead ecosystem role, with a goal to attract various startups as potential ecosystem participants to focus on a value creation and value capturing in the smart/connected cities domain, specifically on improving current services for citizens.

Based on the Smart/Connected City CBA, that would decompose the domain into business components with
associated key activities, processes, business entities and KPIs, utilizing ITU-T Smart Sustainable Cities elements.

The new business goals (e.g. “Improve the city Net Promoter Score for 5%”) for the new model would be associated with dedicated business component. This business goal would be further derived into new Value Offering (e.g. “Successful service execution rate”, “Positive feedback rate increase” or “Location based POI recommendation success rate”). Each Value Offering would further define specific service capabilities (full model is beyond the scope of this paper) that the ecosystem would need to provide and create an environment where ecosystem participants can state their own goals and intents and be able to discover and compose new services to satisfy ecosystem goals and intents.

VI. CONCLUSION

In this paper, a novel model for linking ecosystem business architecture and value capture with service design and representation of service capability parameters as tags, required for improvement of service composability and assembly, is given. As majority of the related work in this field is focusing on semantic matching and service discovery based on attribute names from the pure technical service description or manual user tagging of service capabilities, with extremely inconsistent quality of business value offerings and capability descriptions across a number of services, we believe that the model we introduce is providing the necessary structure and mechanisms for efficient service discovery and service composition in a relatively open ecosystem environment.

Benefits of the new approach were presented in the form of a new method for deriving the ecosystem participant’s strategic intent into value co-creation and finding the relevant services exposed and offered by the same ecosystem to use the service for value capture and realization. Value oriented elements are defined in a form of a Value Offering and subsequently Service Capabilities. The proposed method used tag similarity and clustering techniques combining with finding Top-k services in the service skyline.

This approach will be further realized using the UML stereotype pattern analysis that will enhance the translation from business to service model and enhance the matching of services in the ecosystem.

REFERENCES

Abstract - Recent theoretical studies of communication systems show much interest on high-level modulation, such as M-ary quadrature amplitude modulation (M-QAM), and most related works are based on the simulations. In this paper, a simulation model to study various M-ary QAM modulation techniques is proposed. The simulation model is implemented in Matlab/Simulink environment and BERTool in conjunction with the model is also used. Simulation for 64-QAM and 256-QAM modulation techniques is done. The effect of the phase noise on the constellation diagram for both M-QAMs is examined. The impact of changing the power of the input signal, phase noise and frequency offset on Bit Error Rate (BER) performance of 64-QAM and 256-QAM is also studied. The simulation results in terms of the constellation diagram and the BER curve under various conditions are presented and analyzed.

Index Terms—Additive White Gaussian Noise (AWGN), Bit Error Rate (BER), BERTool, M-ARY Quadrature Amplitude Modulation (QAM), Matlab, phase noise, Simulink.

I. INTRODUCTION

As the digital communication industry continues to grow and evolve, the applications of modulation techniques continue to grow as well. This growth, in turn, spawns an increasing need to seek automated methods of analyzing the performance of digital modulation types using the latest mathematical softwares. The Amplitude Shift Keying (ASK), Frequency Shift Keying (FSK) Phase Shift Keying (PSK), and Quadrature Amplitude Modulation (QAM) are the basic forms of the digital modulation techniques [1]-[3]. With the fast development of modern communication techniques, the demand for reliable high data rate transmission is increased significantly, which stimulate much interest in modulation techniques. The requirements for spectral and power efficiency in many real world applications of the modulation lead to the necessity of using the modulation techniques other than binary modulation. Modern modulation techniques exploit the fact that the digital baseband data may be sent by varying both envelope and phase/frequency of a carrier wave. Because the envelope and phase offer two degrees of freedom, such modulation techniques map baseband data into four or more possible carrier signals. Such modulation techniques are known as M-ary modulation [4], [5], since they can represent more signals than if just the amplitude or phase were varied alone. In an M-ary signaling scheme, two or more bits are grouped together to form symbols and one possible signal is transmitted during each symbol period. Usually, the number of possible signals is \( M = 2^m \) where \( m \) is an integer. Depending on whether the amplitude, phase or frequency is varied, the modulation technique is M-ary ASK, M-ary PSK, or M-ary FSK [4]-[6]. The modulation that alters both, amplitude and phase is M-ary QAM [4], [7], [8], [11]. Different bandwidth efficiency at the expense of power efficiency can be achieved using M-ary modulation techniques. M-ary modulation schemes are one of most efficient digital data transmission systems as it achieves better bandwidth efficiency than other modulation techniques and give higher data rate. In order to improve the performance of M-ary modulation techniques, always a need of studying and analyzing the unwanted effects caused by different factors on their characteristics exists.

In this paper, two variants of M-ary QAM, namely 64-QAM and 256-QAM, are studied in Matlab/Simulink environment. The studies are done in terms of effects caused by such factors as input signal power, Additive White Gaussian Noise (AWGN), phase noise and frequency offset on behavior of these modulations. Constellation diagrams and Bit Error Rate (BER) curves for mentioned variants of M-QAM are obtained and analyzed.

II. M-ARY QAM

QAM is the encoding of the information into a carrier wave by variation of the amplitude of both the carrier wave and a „quadrature” carrier that is 90° out of phase with the main carrier in accordance with two input signals. That is, the amplitude and the phase of the carrier wave are simultaneously changed according to the information needed to transmit. It is such a class of non-constant envelope schemes that can achieve higher bandwidth efficiency than M-PSK with the same average signal power [4].

Mathematically, M-ary QAM can be written as shown in [9]

\[
s_{kl}(t) = A_k \cos(2\pi f_c t + \theta_l), \quad k = 1, 2, \ldots M_1, \quad l = 1, 2, \ldots M_2,
\]

where \( A_k \) is the signal amplitude, \( \theta_l \) is the signal...
phase, $M_1$ is the number of possible amplitudes of the carrier, $M_2$ is the number of possible phases of the carrier, and $f_c$ is the carrier frequency.

The combined amplitude and phase modulation, results in the simultaneous transmission of $\log_2(M_1M_2)$ bits per symbol.

M-ary QAM is one of the widely used modulation techniques because of its efficiency in power and bandwidth [4], [6]. A variety of forms of QAM are available and some of the more common forms include 16-QAM, 32-QAM, 64-QAM, 128-QAM, and 256-QAM. QAM is in many radio communications and data delivery applications [6], [7]. Some variants of QAM are also used for many wireless [5], [12] and television and cable modem applications. Variants of QAM and 256-QAM are often used in digital cable domestic broadcast applications [10] for example, 64-QAM is used in some specific applications and standards [4]. For delivery applications [6], [7]. Some variants of QAM are available and some of the more common forms include 16-QAM, 32-QAM, 64-QAM, 128-QAM, and 256-QAM. QAM is in many radio communications and data delivery applications [6], [7]. Some variants of QAM are also used for many wireless [5], [12] and cellular [5], [13] technology applications.

Because of the widely use in modern communication systems, M-QAM modulation technique needs to be continuously studied, especially in terms of factors that affect its performance.

III. M-QAM PERFORMANCE MEASURES

A. Constellation Diagram

The constellation diagram provides a graphical representation of the complex envelope of each possible symbol state, and also is an important visual tool in evaluating a performance of M-QAM modulations. The x-axis of the constellation diagram represents the In-phase component of the complex envelope and the y-axis represents the Quadrature component of the complex envelope. For

$$I \times J \quad \left( M = I \times J, \quad I = 2^{(m-1)/2}, \text{ and } J = 2^{(m+1)/2} \right)$$

rectangular QAM constellation, each message point can be represented as

$$x = x_I + jx_Q$$

(2)

where $x_I$ is the In-phase component and $x_Q$ is the Quadrature component of the point $x$.

The components, $x_I$ and $x_Q$ are given by

$$x_I \in \{ \pm d, \pm 3d, \ldots \pm (I - 1)d \}$$

(3)

$$x_Q \in \{ \pm d, \pm 3d, \ldots \pm (J - 1)d \}$$

(4)

If 2$d$ is the Euclidean distance between two adjacent signal points and $E_b$ is the bit energy, $d$ can be expressed in terms of $E_b$, $I$ and $J$ as [9]

$$d = \sqrt{\frac{3E_b \log_2(I \times J)}{I^2 + J^2 - 2}}$$

(5)

For the case of M-ary square QAM (5) becomes

$$d = \sqrt{\frac{3E_b \log_2(M)}{2(M-1)}}$$

(6)

The distance between the signals on the constellation diagram relates to how different the modulation waveform are, and how well a receiver can differentiate between all possible symbols when random noise is present.

B. Bit Error Rate Probability

BER is a performance measurement that specifies the number of bit corrupted or destroyed as they are transmitted from its source to its destination. Several factors that affect BER include bandwidth, signal-to-noise ratio (SNR), transmission speed and transmission medium. The definition of bit error rate can be translated into a simple formula:

$$BER = \frac{\text{Number of bit errors}}{\text{Total number of bits sent}}$$

(7)

BER can also be defined in terms of the probability of error (POE) [13] and expressed as

$$POE = \frac{1}{2} \left[ 1 - \text{erf} \left( \frac{E_b}{\sqrt{2}N_0} \right) \right]$$

(8)

where erf is the error function, $E_b$ is the energy in one bit and $N_0$ is the noise power spectral density. At that, the error function erf is different for the each of the various modulation methods. This is because each type of modulation performs differently in the presence of noise [14]. It is important to note that POE is proportional to $E_b/N_0$, which is a normalized form of SNR.

The performance of each modulation is measured by calculating its BER or POE with assumption that systems are operating with additive white Gaussian noise (AWGN). Knowledge of the BER enables other parameters of the communication systems, such as power, bandwidth, etc to be tailored to enable the required performance to be obtained.

C. Noise

The term noise refers to unwanted electrical signals that are always present in electrical systems. Particularly, in terms of communication systems, noise can be defined as any unwanted energy tending to interfere with the proper reception and reproduction of transmitted signals.

In digital communication systems, noise may produce unwanted pulses or perhaps cancel out the desired ones.
Noise may introduce serious mathematical errors in signal analysis and limit the range of systems for a given transmitted power. It can also affect the sensitivity of receivers by placing restrictions on the weakest signals to be amplified. All these are some of the effects of noise on signals and communication systems at large [15].

1. Additive White Gaussian Noise (AWGN)

   In communication systems, the most common type of noise added over the channel is the Additive White Gaussian Noise (AWGN). AWGN is the effect of thermal noise generated by thermal motion of electron in all dissipative electrical components i.e. resistors, wires and so on [16]. Mathematically, AWGN is modeled as a zero-mean Gaussian random process where the random signal “z” is the summation of the random noise variable “n” and a direct current signal “a” that is

\[ z = a + n. \]  

(9)

The probability distribution function for this Gaussian noise can be represented as follows

\[ p(z) = \frac{1}{\sigma \sqrt{2\pi}} \exp \left[ -\frac{1}{2} \left( \frac{z-a}{\sigma} \right)^2 \right]. \]  

(10)

where \( \sigma^2 \) is the variance of \( n \).

The higher the variance of the noise, the more is the deviation of the received symbols with respect to the constellation set and, thus, the higher is the probability to demodulate a wrong symbol and make errors.

The model of this noise assumes that its power spectral density \( G_n(f) \) is flat for all the frequencies and is denoted as

\[ G_n(f) = N_0/2. \]  

(11)

The factor 1/2 in (11) is included to indicate that the power spectral density is a two-sided power spectral density and indicates that half the power is associated with positive frequencies and half with negative frequencies.

This type of noise is present in all communication systems and is the major noise source for most systems with characteristics of additive, white and Gaussian. It is mostly used to model noise in communication systems which are simulated to determine their performance. This noise is normally used to model digital communication systems which can be replaced with other interference schemes.

2. Phase Noise

   Phase noise is a type of noise that affects the phase of carrier signals. Here, the noise (whose phase is random) causes the phase of the carrier signal to be random. When phase noise is introduced into a carrier signal, it causes angular displacement of the carrier signal. Phase noise is associated with oscillators. In M-QAM modulations, phase noise is usually generated when the constellation points oscillate.

Phase noise like other noises can only be described statistically, because of its random nature and is typically expressed in units of dBc/Hz at various offsets from the carrier frequency. This is usually referred to as Phase Noise Level Density (PNLD) [17] and it can be expressed mathematically as

\[ \text{PNLD} = -10\log(I/I_0) \]  

(12)

where \( I \) = noise intensity level in dB and \( I_0 = 10^{-12} \) is a reference noise intensity level.

IV. M-ARY QAM SIMULATION MODEL

Simulink [18], developed by Math Works, is an environment for multi-domain simulation and model-based design for dynamic and embedded systems. It provides an interactive graphical environment and a customizable set of block libraries that enable to design, simulate, implement, and test a variety of time-varying systems, including communications, controls, signal processing, image processing. Simulink is integrated with Matlab [19], providing immediate access to an extensive range of tools for algorithm development, data visualization, data analysis, and numerical computation.

In this paper, a baseband simulation model of M-ary QAM is implemented in Matlab/Simulink environment. The model is shown in Fig. 1. The Simulink model is a graphical representation of a mathematical model of a communication system that generates a random signal, converts it into a binary representation, modulates it using QAM, adds noise (AWGN and phase noise) to simulate a channel, demodulates the signal and finally converts it into an integer representation. The model also contains blocks for calculating and displaying the BER and SER and the scatter plot of the modulated signal. In addition, the BERTool in conjunction with the Simulink model is used to evaluate the performance of each QAM technique through plotting the BER versus the Eb/No. BERTool is an interactive Graphical User Interface (GUI) that invokes the simulation for Eb/No specified range, collects the BER data from the simulation, and creates a plot. In BERTool, three ways of simulations are possible, that are: theoretical, semi-analytical and Monte Carlo. To invoke the BERTool, the command "BERTool" needs to be entered in main command window of Matlab.

The blocks and the lines in the model describe mathematical relationships among signals and states.

The simulation model allows studying the effects of input signal power, phase noise and frequency offset on performance of various M-QAM modulation techniques in terms of their constellation diagram and BER curve.

V. SIMULATION RESULTS AND DISCUSSIONS

The model, shown in Fig. 1 is extracted into BERTool and tested in Monte Carlo for 64-QAM, as well for 256-QAM.
To take into account the presence of phase noise, in addition of AWGN, phase noise is also added as a source noise, assuming that PNLD = -60 dBc/Hz. Furthermore, the input signal power is set to 1 W and the frequency offset is set to 200 Hz, respectively. The only exceptions are cases, where the studies are done with more than one value of these parameters.

Before running the simulation to study the effect of phase noise on constellation diagram for each of two modulations, the value of signal-to-noise ratio (Eb/No) in the AWGN channel is set to 100 dB, such that the channel itself will not have any effect on the modulated signal.

A. Results for 64-QAM

The first Scatter Plot Scope1 displays the constellation diagram shown in Fig. 2. Because of high value of Eb/No (Eb/No=100 dB) in the channel, this constellation diagram is almost the same as the original constellation diagram which is presented in [3].

The effect of phase noise on the modulated signal is illustrated by the result of the second Scatter Plot Scope2. The constellation diagram for PNLD = [-60 -70] dBc/Hz is presented in Fig. 3 and Fig. 4, respectively.

The constellation diagram in Fig. 3 shows a significant angular displacement/distortion of the modulated signal for PNLD of -60 dBc/Hz. The reduction of the phase noise level density with 10 dBc/Hz (from -60 dBc/Hz to -70 dBc/Hz) results in the reduction in the angular displacement, i.e., to a higher quality of the constellation diagram, which is obvious in Fig. 4.

To study the impact of changing the power of the input signal on the noise variance and therefore on the bit error rate, BER as a function of Eb/No is simulated. The simulation is performed for values of the input signal power [0.5 1.0 2.0 4.0] W in the presence of phase noise (PNLD=-60 dBc/Hz). For each value of the input signal power a result in the form of BER graph, as shown in Fig. 5, is obtained. The simulation result illustrates that as the power of the input signal increases, the error rate also
increases. This is due to the proportional relation between the signal power and the noise variance [14] which relation is implemented in the AWGN Channel block (see Fig. 1).

Figure 3. Constellation diagram of 64-QAM for Eb/No=100 dB and PNLD=-60 dBc/Hz.

The effect of phase noise on BER performance of 64-QAM is studied, as the values of the PNLD are varied from -50 dBc/Hz to -70 dBc/Hz, in step of -10 dBc/Hz. For each value of PNLD, as well, for case without phase noise (in the presence of AWGN only), a BER curve versus Eb/No is obtained. The result is represented in Fig. 6.

As can see in Fig. 6, the higher the phase noise level density, the higher the BER simulated value at a fixed Eb/No value. For example, at Eb/No=18 dB, the value of BER obtained for PNLD of -50 dBc/Hz is 6.3476E-2 while if the noise level density is reduced to -70 dBc/Hz, there is a significant reduction of the BER value (the value obtained equals 1.5873E-5). Moreover, it is observed from the simulated curves, that the BER curve for PNLD of -70 dBc/Hz gets close to the curve without phase noise (in the presence of AWGN only).

Figure 4. Constellation diagram of 64-QAM for Eb/No=100 dB and PNLD=-70 dBc/Hz.

BER as a function of the Eb/No ratio, at various offsets from the carrier frequency is simulated, too. The values of the frequency offset are varied from 100 Hz to 300 Hz, in step of 100 Hz. The simulation is performed with PNLD equal to -60 dBc/Hz. For each value of the frequency offset a BER as a function of Eb/No is obtained. The result, in the form of graphs, is displayed in Fig. 7. How is seen in Fig. 7, at low SNRs (Eb/No under of 8 dB), the three BER curves almost coincide. For values of a Eb/No ratio over 10 dB, the obtained BER curves more and more get away from each other with increasing Eb/No. As is expected, it is observed in Fig. 7, that an increase of the frequency offset increases the BER value at a fixed Eb/No ratio. In other words, the BER curve for a frequency offset of 100 Hz outperforms the BER curve for a frequency offset of 200 Hz and 300 Hz.

Figure 5. BER vs. Eb/No for 64-QAM at different phase noise level densities and without the presence of phase noise.

Figure 6. BER vs. Eb/No for 64-QAM at different phase noise level densities and with the presence of phase noise.
respectively. For example, the change of the frequency offset from 100 Hz to 300 Hz at Eb/No=18 dB and PNLD=-60 dBc/Hz, causes the BER value increase from 5.5531E-4 to 7.1251E-3.

Figure 7. BER vs. Eb/No for 64-QAM for different values of the frequency offset.

B. Results for 256-QAM

Constellation diagrams and BER curves for 256-QAM, are simulated under the same conditions as for 64-QAM using Simulink model in Fig. 1.

The constellation diagram displayed by the first Scatter Plot Scope1 in Fig. 8 is almost the same as the original constellation diagram that is shown in [1]. The similarity is due to the high value of the Eb/No ratio in the channel (Eb/No=100 dB).

Figure 8. Constellation diagram of 256-QAM for Eb/No=100 dB and without the presence of phase noise.

The Scatter Plot Scope2 placed after the Phase Noise block gives different result for each PNLD value. Resulting constellation diagrams for PNLD=-60 dBc/Hz and PNLD=-70 dBc/Hz are displayed in Fig. 9 and Fig. 10, respectively. It is obvious from Fig. 9 and Fig. 10 that the reduction of the phase noise level density from -60 dBc/Hz to -70 dBc/Hz, results in a significant reduction in the angular displacement.

The dependence of the BER on Eb/No ratio for different values of the input signal power is also examined. The value of the input signal power is varied from 0.5 W to 4 W. With each variation, the model is simulated. The set of the simulated BER curves for values [0.5 1 2 4] W of the input signal power is presented in Fig. 11. It can be seen in Fig. 11 that with increasing the input signal power, the BER also increases. This is due to the proportional relation between the signal power and the noise variance [14] which is equivalent to proportionality between the signal power and BER ratio. The numerical results, obtained with Eb/No=18 dB and PNLD = -60 dBc/Hz, show that the increase of the input signal power from 0.5 W to 4 W, results in an increase of the BER value from 1.3095E-4 to 5.8251E-2.

Figure 9. Constellation diagram of 256-QAM for Eb/No=100 dB and PNLD=-60 dBc/Hz.

Figure 10. Constellation diagram of 256-QAM for Eb/No=100 dB and PNLD=-70 dBc/Hz.
To study the effect of phase noise on BER performance of 256-QAM modulation technique, the phase noise level density is varied in the same way as for 64-QAM modulation technique. Simulation of BER curve for each of values [-50 -60 -70] dBc/Hz of a PNLD is performed and the result is shown in Fig. 12.

As can be seen, the BER curve is moved upward with increasing of the frequency offset. That means the increase of the frequency offset affects negatively the BER curve. It is also evident, that the three BER curves are nearly identical up to Eb/No=10 dB. For values of Eb/No, which are over 12 dB the curves are gradually moving away one from another.

VI. CONCLUSIONS

A simulation model to study 64-QAM and 256-QAM modulation techniques is built using the Simulink tool that is integrated in the Matlab environment. Also, the BERTool under Matlab is used to evaluate the performance of both modulation techniques through plotting the BER versus Eb/No. The model can not only be used for 64-QAM and 256-QAM modulation techniques, it can also be used for the other QAM order (for example, for M = [4 8 16 32 128 512, etc.], as well for a platform to simulate other modulation techniques, such as M-PSK, DPSK, etc.

The simulation results show that the phase noise affects constellation diagram. The effect of phase noise on constellation diagram, results in an angular displacement of the modulated signal. It can be seen from Figs. 3, 4, 9 and 10 that the points do not lie exactly on the constellations because of the added noise. The radial pattern of points is due to the addition of phase noise, which alters the angle of the modulated signal. Moreover, the effect of phase noise on constellation diagram increases with an increase of phase noise level density, as well with an increase of the modulation order.

The simulations show that the BER for both type (64-QAM and 256-QAM) modulations decreases with increasing value of Eb/No. The higher the Eb/No value, the better the BER based on data generated by the computer simulation model.

According to the results of the simulations it is possible to conclude that as the QAM order increases, the simulated BER values also increase. In case of 256-QAM the BER is greater than in case of 64-QAM as constellation points come closer.

It follows from the simulation results, that all the
specified factors (AWGN noise, input signal power, phase noise, and frequency offset) affect the BER performance of M-QAM (M=64 and 256) modulation techniques. At that, increasing each one of them results in a BER increase. In fact, how it can be seen in Fig. 6 and Fig. 12, for a PNLD value greater than -60 dBc/Hz there is no a significant change in the BER value with increasing the Eb/No.

Finally, it can be concluded that 64-QAM has better BER and phase noise performance than 256-QAM.

INVITED PAPER
Okvir za digitalnu zrelost i procjena digitalne zrelosti škola u Hrvatskoj

N. Begićević Redep i I. Balaban
Fakultet organizacije i informatike, Sveučilište u Zagrebu
nina.begicevic@foi.hr, igor.balaban@foi.hr

U ovom radu opisana je metodologija razvoja Okvira za digitalnu zrelost škola (ODŽŠ) u Hrvatskoj, pripadajući mjerni instrument, te je dan pregled rezultata procjene razine zrelosti škola. Okvir zajedno s pripadajućim instrumentom i on-line aplikativnim programskom potporom predstavlja jedinstveno i sveobuhvatno rješenje za procjenu digitalne zrelosti škola i davanje smjernica za podizanje digitalne zrelosti. Okvir je organiziran u 5 osnovnih područja podijeljenih na 38 elemenata od kojih je svaki opisan s 5 razina zrelosti u obliku rubrike. Prvo testiranje mjernog instrumenta digitalne zrelosti izvršeno je na 151 školi u Hrvatskoj.

I. UVOD

Koncept digitalne zrelosti škola postaje sve više značajan zbog vrlo brzog razvoja i sve veće važnosti informacijsko-komunikacijskih tehnologija (IKT) u obrazovanju. Europska komisija je također poznala važnost digitalne zrelosti, te kroz niz programa podržava razvoj digitalne zrelosti škola (npr. [10] i [13]). Digitalno zrelošć škole za potrebe ovog istraživanja definiramo kao škole s visokom razinom integracije IKT-a, istezatamaño pristupu koji mora biti planiran i upravljanju školom i u obrazovnim procesima. Korištenje sistematiziranim pristupom korištenja IKT-a u škole s visokom razinom integracije IKT-a, digitalno zrele škola za potrebe ovog razloga je potrebno identificirati područja i elemente koji doprinose digitalnoj zrelosti škola, kako bi se mogao planirati napredak u integraciji, a korištenju digitalnih tehnologija (vidjeti npr. [1]).

Problem je prepoznat i u Republici Hrvatskoj te se kroz projekt "E-Škole: Uspostava sustava razvoja digitalno zrelih škola u RH (pilot projekt)" financiranog sredstvima europskih fondova (voditelj CARNet) nastoji primijeniti cjeloviti pristup informatizaciji školskog sustava u svrhu stvaranja digitalno zrelih škola za 21. stoljeće (vidjeti [5]). Za informatizaciju školskog sustava i održivost projekta neophodna je usklađenost implementacije infrastrukturnih i uslužno-obrazovnih dijelova projekta. Kako bi se ostvarila usklađenost potrebano je jedinstveni koncept koji bi sve navedeno obuhvatio, a to je koncept okvira digitalne zrelosti škole.

Trenutno postoji nekoliko okvira koji opisuju digitalnu zrelost obrazovnih institucija (npr. [6], [7], [9], [10], [11]). No, provedena kvalitativna analiza u okviru projekta je pokazala da nijedan od njih nije prikladan za prikaz i opis digitalne zrelosti škola (vidjeti [4]). Isto tako ne postoji sveobuhvatni koncept koji obuhvaća okvir, instrument za procjenu i programsku potporu procesa procjene digitalne zrelosti škola.

Temeljem analize postojećih okvira, te niza drugih metoda razvoja okvira te uzimajući u obzir zahtjeve projekta e-Škole, razvijen je Okvir za digitalno zrele škole (ODŽŠ), instrument za samoprocjenu i vanjsku (ekspertnu) procjenu, te pripadajuća on-line programskoga podrška. ODŽŠ se sastoji od pet glavnih područja, te 38 elemenata od kojih je svaki opisan s pet razina zrelosti. Samoprocjena i vanjska procjena su provedeni na 151 školi u Hrvatskoj koristeći mjerni instrument i on-line programsku potporu kako bi se utvrdila trenutna razina digitalne zrelosti škola u pilot projektu, te kako bi se ispitalo razlike između samoprocjene škola i vanjske procjene uz pomoć vanjskog tima za procjenu sastavljenog od eksperta u e-obrazovanju. Nakon provedenog istraživanja, svaka škola je dobila uvid u rezultate te individualne preporuke za poboljšanje kroz on-line aplikativnu potporu.

II. OKVIR ZA DIGITALNU ZRELOST ŠKOLA

Okvir za digitalnu zrelost škola namijenjen je osnovnim i srednjim školama u RH s ciljem ispitivanja mogućeg napretka u integraciji i efikasnom korištenju digitalnih tehnologija te prepoznavanja područja za poboljšanja u kontekstu okvira digitalne zrelosti škola. Okvir je razvijen u okviru projekta e-Škole od strane CARNeta i Fakulteta organizacije i informatike i detaljno je opisan u [3] i [4].

A. Razvoj Okvira

Razvoj okvira za digitalnu zrelost škola ovdijao se od listopada 2015. do lipnja 2016., a imao je za cilj identificiranje područja i elemenata digitalne zrelosti škola te prepoznavanje područja i elemenata ključnih za podizanje razine digitalne zrelosti škola. U razvoju okvira primijenjena je složena metodologija, koja je prvenstveno bila kvalitativna, a obuhvaćala je niz metoda i instrumenta poput kvalitativne analize postojećih okvira i strateških dokumenata, anketa, polustrukturnih istraživačkih intervjuja, metode sortiranja karata, fokus grupe i dr.

U prvom fazi razvoja provedena je kvalitativna analiza postojećih 15 okvira za procjenu digitalne zrelosti s ciljem odabira onih okvira koji ispunjavaju uvjete...
potrebne za razvoj ovkira za procjenu digitalne zrelosti osnovnih i srednjih škola u Hrvatskoj. Temeljem te analize odabrana su dva okvira koja su činila osnovicu za stvaranje Okvira za digitalnu zrelost škola primjenjivog u hrvatskom obrazovnom sustavu: a) DigCompOrg [10], europski priznati okvir za digitalnu zrelost obrazovnih institucija i b) eLearning Roadmap [6], alat koji se vrlo uspješno koristi u Irskoj u svrhu certificiranja digitalno zrelih škola. DigCompOrg je prije sve generički i vrlo općenit model koji propisuje područja i indikatore digitalno kompetentnih obrazovnih institucija, no autori sugeriraju prilagodbu ciljnoj domeni i kontekstu [10]. Zbog toga je u analizu uključen eLearningRoadmap, alat koji najvećim dijelom implicira samo e-obrazovanje i tehnologije vezane uz takav oblik učenja, omogućuje školama testiranje trenutne razine u smislu e-obrazovanja, te im daje smjernice za unapređenje. Na slici 1. prikazana je usporedba osnovnih područja razvijenog ODŽS-a sa DigCompOrg-om-i eLearningRoadmapom.

Slika 1. Usporedba Okvira za digitalnu zrelost – glavna područja

U drugoj fazi razvijena je prvina inačica okvira temeljen na kvalitativne analize dva identificiranina ranije spomenuta europska modela, ekspertnog znanja te fokus grupa na kojem su sudjelovali predstavnici osnovnog i srednješkolskog obrazovanja.

U trećoj fazi došlo je do prilagodavanja okvira hrvatskom obrazovnom kontekstu, a pri tome se koristilo više različitih metoda kao što je metoda sortiranja karata i rada u fokus grupi te polustrukturni intervju s ravnateljima i drugim predstavnicima hrvatskog školskog sustava. Rezultat ove faze je detaljni opis temeljnih područja i pripadajućih indikatora digitalne zrelosti škola u RH. Definirano je i pet razina digitalne zrelosti škola po uzoru na [12] i [2].

U četvrtoj fazi razvijena je rubrika za određivanje razine zrelosti za svaki od identifikatora po uzoru na [8], te je napravljeno matematičko modeliranje kako bi se razvila metrika za izračun ukupne razine zrelosti škola. U ovoj fazi aktivno se je provodilo revidiranje elemenata po svim razinama zrelosti na temelju strukturirane diskusije s predstavnicima CARNet-a i ravnateljima nekoliko škola u RH.

U petoj fazi razvijena je završna inačica Okvira i prijedlog mjernog instrumenta za procjenu digitalne zrelosti škola, točnije upitnik za samoprocjenu digitalne zrelosti i upitnik za vanjsku procjenu te sustav za unos i prikaz rezultata. Upitnik je primijenjen za mjerenje digitalne zrelosti škola prema krajnjem korisniku i mapiranje u rubiku.

B. Područja i elementi okvira

Jezgra Okvira za digitalno zaleće školje je strukturirana u pet područja karakterističnih za obrazovni sustav u domeni osnovnih i srednjih škola pri čemu se svako od tih područja odnosi na različite aspekte integracije i korištenja digitalnih tehnologija. Temeljna područja su (vidi sliku 1): 1. Planiranje, upravljanje i vodstvo (sedam elemenata), 2. IKT u učenju i poučavanju (sedam elemenata), 3. Razvoj digitalnih kompetencija (sedam elemenata), 4. IKT kultura (sedam elemenata) te 5. IKT infrastruktura (10 elemenata).

Područja, kao i elementi unutar područja nisu međusobno isključiv i disjunktivni. Oni su komplementarni i međusobno povezani, te na taj način tvore cjelinu. U nastavku sažeto prikazujemo glavna područja Okvira te pripadajuće elemente:

1. Planiranje, upravljanje i vodstvo: Ovo se područje Okvira digitalne zrelosti škola temelji na postojanju vizije i/ili strateških smjernica integracije IKT-a na razini cijele škole, ali i šire koje su izražene u školskim dokumentima kao što su npr. Godišnji plan i program rada škole i Školski kurikulum. Kroz strateško pozicioniranje određuje se stupanj integriranosti IKT-a u učenju i poučavanju, ali i u poslovanju, odnosno upravljanju školom što pridonosi većoj transparentnosti poslovanja i opće dostupnosti i primjenjivosti obrađenih podataka. Elementi su: Vizija, strateške smjernice i ciljevi integracije IKT-a, Plan i program razvoja škole s aspekta IKT-a, Upravljanje integracijom IKT-a u učenju i poučavanju, Upravljanje integracijom IKT-a u poslovanju škole, Upravljanje podacima prikupljenima putem informacijskih sustava, Regulirani pristup IKT resursima i Primjena IKT-a u poučavanju učenika s posebnim odgojno-obrazovnim potrebama.

2. IKT u učenju i poučavanju: Razina i kvaliteta primijene IKT-a u učenju i poučavanju je važan segment digitalno zrelih škola koji obuhvaća digitalnu zrelost odgojno-obrazovnih djelatnika i učenika. Kroz svijest o svim koristima i razinama primijene IKT-a u učenju i poučavanju, potrebno je i pomno isplanirati tu primjenu gdje tehnologija mora biti u službi pedagoške i odgojno-obrazovnih ciljeva. Područje opisuje potrebnu razinu i kvalitetu primjene IKT-a u učenju i poučavanju kao važan segment digitalno zrelih škola koji obuhvaća digitalnu zrelost odgojno-obrazovnih djelatnika i učenika. Elementi su: Osvještenost, Planiranje, Primjena, Digitalni sadržaji, Vrednovanje učenika, Iskustvo učenika, te Posebne odgojno-obrazovne potrebe.

3. Razvoj digitalnih kompetencija: Kako bi se što produktivnije primjenjivao IKT u učenju i poučavanju, kao i u segmentima koji se tiču poslovanja škole, odgojno-obrazovni djelatnici i ostali djelatnici trebaju unaprjeđivati svoje digitalne kompetencije. Isпитuje stanje i razvoj digitalnih kompetencija kako bi se što kvalitetnije primjenjivao IKT u učenju i poučavanju, kao i u segmentima koji se tiču poslovanja škole. Elementi su: Osvještenost i sudjelovanje, Planiranje, Svrha stručnog
usavršavanja, Samopouzdanje u primjeni IKT-a, Digitalne kompetencije učenika, Posebne odgojno-obrazovne potrebe i Informalno učenje.

5. IKT infrastruktura: Ovo se područje Okvira digitalne zrelosti škola temelji na opisu infrastruktura kao temeljnog čimbenika odgovornog za odvijanje i posredovanje u novoj digitalnoj praksi, te proširene granica prostora za učenje (iz fizičkog u virtualni). Elementi su: Planiranje i nabava, Mrežna infrastruktura, IKT oprema u školi, IKT oprema za odgojno-obrazovne djelatnike, Programski alati u školi, Tehnička potpora, Održavanje opreme, Centralno mjesto pohrane digitalnih dokumenata i obrazovnih sadržaja, Sustav informacijske sigurnosti i Kontrola licenciranja.

C. Razine digitalne zrelosti

Za svaki element Okvira za digitalnu zrelost uspostavljene su razine zrelosti od 1 do 5 za utvrđivanje digitalne zrelosti škola. U Okviru za digitalno zrelo škole utvrđene razine zrelosti su sljedeće:

- Razina 1: Digitalno neovisna
- Razina 2: Digitalno početna
- Razina 3: Digitalno osposobljena
- Razina 4: Digitalno napredna
- Razina 5: Digitalno zrela.

Uz svaku od razina dati su opisi razine zrelosti koji služe kao generalni opisnici i pokazatelji općenitih karakteristika pojedinih razina zrelosti za svaki od elemenata unutar pojedinog područja. U nastavku donosimo kratki opis svake od razina.

Razina 1: Digitalno neovisna

U školi ne postoji svijest o mogućnostima primjene IKT-a u učenju, poučavanju i poslovanju škole i odgovornostima za primjenu IKT-a u učenju i poučavanju. Vrijednosti i dugoročni ciljevi primijene IKT-a u učenju i poučavanju i poslovanju škole nisu uopće ili su samo manjim dijelom uključeni u strateško planiranje, upravljanje i vršenje škole. Postoji svijest o potrebi razvoja digitalnih kompetencija odgojno-obrazovnih djelatnika i učenika, no praksa kontinuiranog usavršavanja digitalnih kompetencija još uvijek ne postoji. Odgojno-obrazovni djelatnici i učenici imaju na raspolaganju IKT resurse samo u određenim prostorijama škole, ukljucujem od okviru nastave. IKT infrastruktura (mreža, računala i dr.) nije na zadovoljavajućoj razini funkcionalnosti u školi.

Razina 2: Digitalno početna

U školi postoji svijest o mogućnostima primjene IKT-a u učenju, poučavanju i poslovanju škole, ali samo određeni broj odgojno-obrazovnih djelatnika primjenjuje IKT u učenju i poučavanju. Vrijednosti i dugoročni ciljevi primijene IKT-a u učenju i poučavanju i poslovanju škole nisu uopće ili su samo manjim dijelom uključeni u strateško planiranje, upravljanje i vršenje škole. Postoji svijest o potrebi razvoja digitalnih kompetencija odgojno-obrazovnih djelatnika i učenika, no praksa kontinuiranog usavršavanja digitalnih kompetencija još uvijek ne postoji. Odgojno-obrazovni djelatnici i učenici imaju na raspolaganju IKT resurse samo u određenim prostorijama škole, ukljucujem od okviru nastave. IKT infrastruktura (mreža, računala i dr.) nije na zadovoljavajućoj razini funkcionalnosti u školi.

Razina 3: Digitalno osposobljena

U školi postoji svijest o mogućnostima korištenja IKT-a u učenju, poučavanju i poslovanju škole te se u tom smjeru razvijaju strateški dokumenti koji se provode i u praksi. Odgojno-obrazovni djelatnici razvijaju svoje digitalne kompetencije, izrađuju digitalne sadržaje te uvode inovativne načine poučavanja. Pristup različitim IKT resursima je moguć u većini prostorij, a odgojno-obrazovni djelatnici imaju na raspolaganju i periferne uređaje koje mogu koristiti i izvan učionica. Financijska sredstva za održavanje opreme i tehničku podršku su u pravilu osigurana. Odgojno-obrazovni djelatnici škole aktivni su u online komunikaciji i prezentaciji sadržaja, te imaju iskustva u projektima orijentiranih na IKT.

Razina 4: Digitalno napredna

U školi se vrlo jasno prepoznaju prednosti IKT-a u svim aspektima djelovanja te djelatnici škole integriraju viziju i dugoročne ciljeve primjene IKT-a u sve svoje strateške dokumente i planove koji se provode i u praksi. Odgojno-obrazovni djelatnici koriste IKT za naprednije načine poučavanja i vrednovanja znanja te štite autorskim pravom vlastite sadržaje. Postoji i zajednički repozitorij sadržaja koji mogu koristiti odgojno-obrazovni djelatnici i učenici. Planira se i izravna kontinuirana usavršavanje odgojno-obrazovnih djelatnika za stjecanje digitalnih kompetencija te se doprinosi razvoju istih kompetencija i kod učenika. Pristup različitim IKT resursima je moguć u većini prostorij škole, a nabavka te održavanje IKT resursa je planirana. Odgojno-obrazovni djelatnici škole su aktivni u IKT projektima te su vrlo aktivni u online komunikaciji i prezentaciji digitalnih sadržaja. Provodi se kontrola licenciranja programskih potpore i vodi se računa o sigurnosnim aspektima korištenja IKT resursa.

Razina 5: Digitalno zrela

U školi se vrlo jasno prepoznaju važnost primjene IKT-a u učenju, poučavanju i poslovanju škole. Djelatnici škole provode integraciju vizije i dugoročnih ciljeva primijene IKT-a u sve svoje strateške dokumente, kao u i u sve aspekte svog djelovanja. Praksa upravljanja se oslanja...
na integraciju i dobivanje podataka iz svih informacijskih sustava koje škola posjeduje. Razvoju digitalnih kompetencija odgojno-obrazovnih djelatnika i učenika se pristupa sustavno kroz kontinuirane programe usavršavanja za odgojno-obrazovne djelatnike te dodatne nastavne aktivnosti za učenike. Odgojno-obrazovni djelatnici koriste IKT za napredne načine poučavanja, razvijanje novih nastavnih sadržaja i vrednovanja znanja te davanje povratnih informacija učenicima. Odgojno-obrazovni djelatnici i učenici redovito štite autorskim pravom svoje digitalne sadržaje, a mogu koristiti i zajednički repozitorij sadržaja. Pristup IKT resursima koje škola samostalno planira i nabavlja je osiguran u svim prostorijama škole. U cijeloj školi je razvijena mrežna infrastruktura, sustav informacijske sigurnosti te se sustavno provodi kontrola i planira licenciranje digitalnih sadržaja, a mogu koristiti i sustava škole.

III. INSTRUMENT ZA PROCJENU DIGITALNE ZRELOSTI

Mjerni instrument korišten za procjenu digitalne zrelosti škola jest rubrika koja ima 38 redova koji odgovaraju elementima Okvira digitalne zrelosti te pet stupaca koji označavaju razine zrelosti: digitalno neosposobljeno, digitalno početnica, digitalno osposobljeno, digitalno napredno i digitalno zrelo. Za svaki od tih redaka (elementa) bilo je potrebno identificirati jednu od pet razina zrelosti (stupaca) na kojoj se škola nalazi po pitanju postojećeg stanja vezano uz taj element zrelosti. Metrika koja je odabrana za izračun razine digitalne zrelosti škola je tzv. taxicab metrika koja se uobičajeno koristi kada je odabrani mjerni instrument rubrika. Kako su opisnici svih elemenata prema razinama zrelosti dosta kompleksni, pa je i sama rubrika dosta kompleksna, odlučeno je da se mjerni instrument pojednostavi. Iz tog razloga je razvijen upitnik čiji odgovori su definirani na način da jasno pozicioniraju školu na određenu razinu digitalne zrelosti pojedinog elementa rubrike. Dakle, kombinacijom nekoliko jednostavnijih pitanja i odgovora iz upitnika dobila se pozicija na razini zrelosti svakog elementa rubrike. Samim time je rubrika za krajnjeg korisnika postala "nevidljiva", a jedini mjerni instrument koji je bio prikazan krajnjem korisniku je upitnik. No, svaka daljnja analiza zrelosti škole je rađena temeljem stanja rubrike u koju su preslikani svi korisnički odgovori iz upitnika.

IV. REZULTATI PROCJENE DIGITALNE ZRELOSTI

Na temelju Okvira za digitalnu zrelost škola i primjenom razvijenog instrumenta za procjenu digitalne zrelosti škola, provedena je samoprocjena i vanjska procjena 151 osnovne i srednje škole u Hrvatskoj.

Cilj provođenja samoprocjene i vanjske procjene bio je identificirati prostore za poboljšanja odnosno dobiti informaciju kako i gdje projekt eŠkole i slični projekti kao i kompletni sustav moraju pomoći u podizanju razine zrelosti škola u Hrvatskoj.

A. Samoprocjena

Samoprocjena škola je provedena u 6. i 7. mjesecu 2016. primjenom razvijenog sustava, a procjenitelji su bili unutarnji: ravnatelji i profesori. Instrument koji se koristio u samoprocjeni i u vanjskoj procjeni je upitnik čiji su se rezultati automatski preslikali u rubriku, s time da se samoprocjena od vanjske procjene razlikovala u procesnjiteljima, načinu pripreme i samoj provedbi. Za uspješnu samoprocjenu uvijek je važna dobra priprema ispitanika o načinu provedbe samoprocjene te cilju provedbe samoprocjene kako bi procjenitelji, u ovom slučaju ravnatelji škola, odgovarajući na pitanja anketnog upitnika dali stvarnu procjenu stanja digitalne zrelosti njihove škole. Nažalost, rezultati samoprocjene pokazali su da razina svijesti o provedbi i ciljevima samoprocjene u Hrvatskoj još nije zadovoljavajuća te da nisu dobiveni rezultati koji su odraz postojećeg stanja. Neka od ograničenja samoprocjene koja su uočena u samoprocjeni odabranih škola jesu nedostatak objektivnosti, samokritičnosti, osjećaj da se škole evaluira (ocjenjuje) i žele biti što bolje, nejasno pojašnjenje naime, ono na pitanja anketnog upitnika koji se uobičajeno koristi kada je odabrani mjerni instrument rubrika. Kako su opisnici svih elemenata prema razinama zrelosti dosta kompleksni, pa je i sama rubrika dosta kompleksna, odlučeno je da se mjerni instrument pojednostavi. Iz tog razloga je razvijen upitnik čiji odgovori su definirani na način da jasno pozicioniraju školu na određenu razinu digitalne zrelosti pojedinog elementa rubrike. Dakle, kombinacijom nekoliko jednostavnijih pitanja i odgovora iz upitnika dobila se pozicija na razini zrelosti svakog elementa rubrike. Samim time je rubrika za krajnjeg korisnika postala "nevidljiva", a jedini mjerni instrument koji je bio prikazan krajnjem korisniku je upitnik. No, svaka daljnja analiza zrelosti škole je rađena temeljem stanja rubrike u koju su preslikani svi korisnički odgovori iz upitnika.

B. Vanjska procjena

Vanjska procjena je provedena u 151 školi u 10. mjesecu 2016. od strane vanjskih procjenitelja, a vanjski
procjenitelji bili su stručnjaci FOI-ja i CARNeta. Rezultati vanjske procjene uzeti su kao mjerodavni i objektivni u okviru projekta e-Škole. Naime, vanjska procjena je bila potrebna zbog kompleksnosti samog instrumenta, ali i objektivnog pristupa te provedbe procjene od strane procjenitelja na temelju dokaza i realne procjene „na terenu“, te je kao takva dala objektivne rezultate procjene digitalne zrelosti škola.

U nastavku su prikazani rezultati vanjske procjene provedene na uzorku od 151 škole u Hrvatskoj definiranom u okviru projekta e-Škole.

Rezultati vanjske procjene (N=151) pokazuju da vanjski procjenitelji nisu niti jednu školu procijenili digitalno naprednom ili digitalno zrelom (razina 4 i 5), 27 škola procijenjeno je digitalno osposobljenima (razina 3), 124 škole procijenjene su kao digitalne početnice i niti jedna škola digitalno neosviještenom (Slika 3.).

Rezultati vanjske procjene razina digitalne zrelosti u području Planiranje, upravljanje i vodstvo pokazuju da je najveći broj škola ukupno 103 škole na razini digitalnih početnica (razina 2), 33 škole su na razini 1 - digitalno neosviještene škole, a 15 škola je na razini 3 – digitalno osposobljene škole. Nema škola koja su u ovom području procijenjene digitalno naprednim ili digitalno zrelim. Najveći broj škola (70 škola) je na razini digitalno osposobljenih škola (razina 3), čak 38 škola na razini 4 – digitalno napredne, a sedam škola je na visokoj razini 5 – digitalno zrele škole. Na razini 2 digitalnih početnica je samo 36 škola. Nema digitalno neosviještenih škola.

Rezultati vanjske procjene razina digitalne zrelosti u području IKT infrastruktura pokazuju da je 114 škola na razini digitalnih početnica (razina 2), 34 škole su na razini 3 - digitalno osposobljene, a samo tri škole su na razini 4 – digitalno napredne škole. Nema škola procijenjena kao digitalno neosviještenih, niti kao digitalno zrelih. Razine digitalne zrelosti po područjima prikazane su na Slici 5.

Rezultati vanjske procjene razina digitalne zrelosti u području IKT kultura pokazuju da je 118 škola na razini digitalnih početnica (razina 2), 27 škole su na razini 3 - digitalno osposobljene škole, a samo šest škola je na razini 1 – digitalno neosviještene škole. Također ni u ovom području nema škola koje su procijenjene digitalno naprednim ili digitalno zrelima.

Rezultati vanjske procjene razina digitalne zrelosti u području Razvoj digitalnih kompetencija pokazuju da je 118 škola na razini digitalnih početnica (razina 2), 27 škola na razini 3 - digitalno osposobljene škole, a samo šest škola je na razini 1 – digitalno neosviještene škole. Također ni u ovom području nema škola koje su procijenjene digitalno naprednim ili digitalno zrelima.

Kada se promatraju odstupanja u procesu samoprocjene i vanjske procjene prema promatranim područjima uočljivo je da je do većih odstupanja došlo u području Planiranje, upravljanje i vodstvo. Rezultati vanjske procjene razina digitalne zrelosti u području Planiranje, upravljanje, vodstvo pokazuju da je najveći broj škola ukupno 103 škole na razini digitalnih početnica (razina 2), 33 škole su na razini 1 - digitalno neosviještene škole, a 15 škola je na razini 3 – digitalno osposobljene škole. Nema škola koje su u ovom području procijenjene digitalno naprednim ili digitalno zrelima. Upravo kroz prilagodbu svojih strateških dokumenata, te nadogradnju postojećih dokumenata sa IKT strategijom, škole uveliko mogu djelovati na razinu postojeće zrelosti.

Rezultati vanjske procjene razina digitalne zrelosti u području IKT kulture što je bilo i za očekivati s obzirom da djelatnici škola kroz svoju organizacijsku kulturu podržavaju komunikaciju i suradnju. Rezultati vanjske procjene razina digitalne zrelosti u području IKT kultura su najbolji uspostavljajući razine u svim područjima. Najveći broj škola (70 škola) je na razini digitalno osposobljenih škola (razina 3), čak 38 škola na razini 4 – digitalno napredne, a sedam škola je na visokoj razini 5 – digitalno zrele škole. Na razini 2 digitalnih početnica je samo 36 škola. Nema digitalno neosviještenih škola.

Rezultati vanjske procjene razina digitalne zrelosti u području IKT infrastruktura pokazuju da je 114 škola na razini digitalnih početnica (razina 2), 34 škole su na razini 3 - digitalno osposobljene škole, a samo tri škole su na razini 4 – digitalno napredne škole. Nema škola procijenjena kao digitalno neosviještenih, niti kao digitalno zrelih. Razine digitalne zrelosti po područjima prikazane su na Slici 5.

Rezultati samoprocjene i vanjske procjene za sve škole dostupni su ravnateljima e-škola i voditeljima školskih timova u okviru sustava koji je razvijen za provedbu procjene te prikaza i analize rezultata (https://digitalna-zrelost.carnet.hr/). Mogućnosti prikaza i analize rezultata u sustavu prikazane su na slikama 6 i 7.
V. ZAKLJUČAK

Okvir digitalne zrelosti i instrument za procjenu digitalne zrelosti škola razvijeni u okviru projekta e-Škole predstavljaju prvi takav cjelovit koncept u čijem razvoju je korišćena znanstvena metodologija koja je obuhvatila niz metoda primijenjenih u pojedinim fazama razvoja. Iako su razvijeni za potrebe hrvatskog sustava obrazovanja, razvijeni okvir i instrument se zahvaljuju svojim generičkim karakteristikama mogu uz manje prilagodbe primijeniti i u drugim zemljama.

Okvir služi identificiranju područja i elemenata koji doprinose digitalnoj zrelosti škola te definiranju i planiranju mogućeg napretka u integraciji i efikasnom korišćenju digitalnih tehnologija, dok instrument služi za procjenu razine digitalne zrelosti škola, te za prepoznavanje područja za poboljšanja u kontekstu okvira digitalne zrelosti škola i podizanja razine zrelosti po područjima i elementima digitalne zrelosti.

Okvir i instrument su validirani su u postupku samoprocjene i vanjske procjene na uzorku od 151 škole. Rezultati koje su mjerodavni pokazuju stvarno stanje digitalne zrelosti školja, te su prepoznavanje područja za poboljšanja u kontekstu okvira digitalne zrelosti škola i podizanja razine zrelosti po područjima i elementima digitalne zrelosti.

Rezultati pokazuju da je od ukupno 151 škole koje su sudjelovale u procjeni čak 124 škola na razini digitalnih početnica. Iz tog razloga je u Hrvatskoj nužno podići razinu zrelosti škola provedbom niza mjera i aktivnosti koje su trebaju initiroti unutar sustava.

Prvu skupinu mjera provodi CARNet, a globalno su usmjerene podizanju svijesti o važnosti i mogućnostima upotrebe IKT-a u učenju i poučavanju prvenstveno kod menadžmenta škole i nastavnika, upravljanju IKT-om u školama i školskim procesima, podizanju razine digitalnih kompetencija nastavnika, te osvremenjavanju i jačanju postojeće IKT infrastrukture. Tako su osigurane brojne edukacije i podrška nastavnicima kako bi se podigla razina digitalnih kompetencija nastavnika, predlošci dokumenata za strateško planiranje uvođenja i korišćenja IKT-a kao podrška menadžmentu škole, uvodi se adekvatna IKT infrastruktura u škole, planirane su brojne e-usluge za nastavne procese, izrađuju se digitalni obrazovni sadržaji, scenariji poučavanja, analitika učenja itd.

Druga skupina mjera provedena je kroz samu online programsku potporu i dio je povratne informacije koju dobiva svaka škola. Naime, uz detaljni uvid u stanje svakog od 38 elemenata na razini digitalne zrelosti, škola dobiva i smjernice za poboljšanje. Na taj način se preko online sustava školi ukazuje na elemente koje je potrebno poboljšati kako bi škola planirala svoj put prema digitalno zreloj školji. Od svih ponuđenih elemenata za poboljšanje, škola može odabrati minimalni broj elemenata izračunate od strane sustava koje će poboljšati kako bi podigla svoju razinu zrelosti.

In modern education, the automatic generation of test items out of texts becomes increasingly important. We have recently presented an enhanced automatic question creator (EAQC) that is able to extract the most relevant concepts out of a text and to create test items based on these concepts. Furthermore, from eye-movement research it is known that learners fixate potentially relevant information longer and more often. In the present study, we investigated whether the measurement of (individual) relevance of EAQC-concepts is related to the frequency and duration of fixations from learners when they read a text, learn it or manually extract concepts out of it. Overall, results showed a non-significant tendency that participants needed more fixations when learning the text as compared to when reading it or extracting concepts. Saccade lengths were reliably longer when participants extracted concepts than when they read them; no other differences were found. How long and how often a concept was fixated did not vary with the subjective relevance of the concept according to participant’s ratings. Future research is therefore necessary to investigate a possible relationship between eye movement behavior and automated concept extraction.

I. INTRODUCTION

According to [1], personal computers as well as the internet have led to substantial changes in our community, whereas educational methods have changed little. Moreover, in [1] it is also argued that e-learning will change all sorts of learning and education in the 21st century and those who are seriously seeking to improve learning and teaching cannot ignore it.

One increasingly important part of modern education is the usage of automated question creation: There is a bunch of research on how question items can be created automatically from a given learning content, bringing together experts from technology, (cognitive) psychology, education and linguistics. For example, [2] used automatically generated questions to assess vocabulary. They reported that the vocabulary skills assessed with automatically created questions correlated significantly with vocabulary skills tested with human-written questions and standardized vocabulary tests. Furthermore, in [3] it was pointed out that automatic question generation can also support people with other mother tongues than English because non-native speakers often lack grammatical knowledge and foreign language vocabulary in order to prepare efficient questions.

We have recently developed an enhanced automatic question creator (EAQC) [4, 5, 6] that aims to generate individualized test items easily with small effort. It extracts concepts (i.e., the most relevant information such as key words and key phrases) out of a given text, by combining part-of-speech tagging, word statistics and semantic analysis. With these concepts, four types of questions can be created, namely open-ended items, completion exercises, true or false items, and multiple-choice items. The validity of the created items was already assessed in previous evaluation studies, demonstrating that the quality of the automatically extracted concepts and created questions is comparable to those generated by humans [4, 7]. Interestingly, and important for the current study, this was not only true for test items that were generated fully automatically (i.e., concepts and test items were created by the EAQC) but also for test items that were created semi-automatically (i.e., the EAQC generated questions based on concepts extracted manually from a text, e.g. by learners, [8]).

Creating test items semi-automatically ensures that the resulting test items address the needs of the learners, because the concepts extracted by the EAQC might not always be of high relevance for the learners. For instance, although a comparison of the concepts extracted manually by participants with the concepts automatically extracted by the EAQC showed a large overlap of concepts, there were also manually created concepts that had not been considered by the EAQC and vice versa [8]. This suggests that the individual relevance of a concept for a learner might not always correspond to the “generalized” relevance of a concept as computed by a tool such as the EAQC (not to mention that there are also individual differences between learners with regard to the
perceived relevance of a concept and contextual background).

To sum up, the (individual) relevance of the underlying concepts for a learner seems to be one crucial factor for successful automated question generation and should be emphasized in future research. As a starting point, we investigated in the current study whether the measured individual relevance of a concept is reflected in the eye movement behavior of a learner. More precisely, one might assume that the more relevant a concept is, the more often and longer it will be fixated while a learner studies a text. If there is such a relationship, analyzing the eye movements during reading and/or learning a text would allow us to determine which concepts are individually relevant for a learner (and which not). In turn, these concepts might then be used to feed the EAQC for the generation of questions that are consequently even more adjusted to the learner’s need.

The aim of the present study was therefore to investigate, in a first step, whether the relevance of a concept might be reflected in how long and often a concept is fixated by a learner. In other words, we were interested in whether eye tracking measurements provide a valid indicator for the relevance of key concepts.

One important variable when measuring eye movement behavior using eye tracking is the fixation duration. How long a word is fixated depends on several factors: For instance, it is well known that we fixate a word for about 225-250 ms [9, 10] during the reading process, i.e. our eyes keep on fixating a word for this period of time in order to process the information it provides. Such fixation durations can increase to about 260-330 ms when we view a scene and decrease to about 180-275 ms when we search for something in the environment. Within reading, previous research has also shown that infrequent words are fixated longer than frequent words (word-frequency effect; e.g., [11]) and that fixation durations also vary with the difficulty of the text (e.g., longer fixation durations were reported for Biology texts or Physics texts than for newspapers; [12]).

Another variable that is typically analyzed when eye movements are measured is the saccade length (i.e., the angular distance the eye gaze travels during the movement from one to another fixation). Saccade lengths do not only vary with the task (e.g. about 4° visual angle for scene viewing, 3° for visual search and 2° for reading [13]), but again also with text difficulty (e.g. shorter saccade lengths were observed when reading Biology texts or Physics texts and longer when reading newspapers; [12]). Crucial for our current research question is that there are some experiments showing that also syntactic language categories can be predicted from reading behavior. For example, we know that not all words are fixated when reading a text: While content words are fixated 85 % of the time, function words are only fixated about 35 % of the time [9, see also 14].

So far, we have shown that eye movement measurements (i.e. fixation duration and saccade lengths) vary with the task and correlate with the meanings of a text and the types of words in the text. Based on this, we were interested in whether some of these measurements might also be useful when defining the relevance of a concept. To our best knowledge, this has not been investigated yet. In the present study we therefore had participants read a text first and then learn it in preparation for a knowledge test. Furthermore, they were required to extract the main concepts (key words) out of the text. During all of these activities we recorded their eye movements. This allowed us not only to investigate whether the fixation durations and saccade lengths differ with the task but also how long and often they fixated each word/concept (as provided by the EAQC) during the various tasks. Using this information, we were able to investigate whether there is a relationship between these eye movement variables and the relevance of EAQC-extracted concepts (rated by the participants). In particular, we expected longer fixation durations and a higher number of fixations for those concepts extracted by the EAQC that are evaluated as more relevant by the learner.

II. METHODS

A. Design

In the current study participants were required to perform several tasks on a given text. These tasks required reading the text (Phase 1), learning it in preparation for a knowledge test (Phase 2) and extracting the main concepts out of it (Phase 3). Furthermore, participants were required to rank the self-extracted concepts with regard to their importance (Phase 4) as well as to assess the relevance of concepts which were extracted by the EAQC out of the same text (Phase 5). Additionally, in Phase 5 participants answered a short knowledge test about the learned text and some general questions about the experiment. Note that for the purpose of the present paper, only Phases 1-3 and the relevance assessment of Phase 5 are taken into consideration although we will present some overall findings also for Phase 4. In the first three phases the eye movements of the participants were recorded in order to analyze how long and how often each EAQC-based concept was fixated. These measures were then correlated with the ratings of the concepts extracted by the EAQC.

B. Participants

Nine female participants (students of Psychology) took part in the study (mean age: 22.6 years). They had normal or corrected-to-normal (contact lenses) vision and German was their native language. However all of them had English as a second language.
C. Stimuli and Procedure

The text we used for the tasks was a selection of an English research article about eye tracking, written by [15]. The selected parts contained four different aspects of eye tracking: general introduction about eye tracking (1), coarse overview on eye tracking’s physiological background (2), most important methods of analysis (3) and the usage of eye tracking for usability research (4). We slightly simplified some of the sentences to make them better understandable for the (German-speaking) readers. During the first three phases (i.e., reading, learning, concept extraction) participants were seated in a dimmed and soundproof booth while their eye movements were monitored with an Eyelink 1000 eye tracker (SR Research, Canada). Data were collected from the dominant eye with a sampling rate of 1000 Hz.

The text was presented on four successive slides using Experiment Builder (SR Research, Canada). Each slide consisted of 149.5 words on average. The text was written in black Arial font (22 px) on white background, the line spacing was 1.5.

At the beginning of a trial participants were asked to read the text (i.e. all four slides) carefully (Phase 1). Each of the four slides were then presented for maximally two minutes, but participants were able to proceed to the next slide once they had finished reading the slide by pressing a button. After this reading phase, participants were told that they should learn the text for an upcoming knowledge test (Phase 2). During this learning phase each slide was presented again consecutively for maximally two minutes. When participants completed the learning of all slides they had the opportunity to go through all slides for one more time in order to allow better learning. During the learning phase the participants were informed regularly by the experimenter about how much time was left until the next slide was presented.

After the learning phase, participants were given a break of several minutes. Then, they were asked to extract the, in their opinion, 1 to 5 most important concepts separately for each slide while their eye movements were tracked (Phase 3). To this end, the four slides were presented again consecutively (2 minutes per slide). Participants were required to speak out the concepts loudly, without moving their head, while the experimenter took them down separately on a lab sheet.

After the extraction phase, the participants were seated into another quiet room (as eye tracking was no longer required for the following tasks) and asked to rank the previously extracted concepts regarding their relevance (Phase 4). Finally, in Phase 5 participants were asked to fill in a questionnaire created with LimeSurvey (www.limesurvey.org). This questionnaire consisted of two parts: Part 1 included knowledge questions on the text (16 questions; 8 questions created by the EAQC, 8 questions created by the experimenter), as well as an assessment of participant’s general attitude and experiences during the task. Part 2 consisted of a rating of relevance (1 [not relevant] – 5 [very relevant]) for the 11 concepts which had been extracted by the EAQC before the experiment started. These 11 concepts were web pages, thinking aloud, the natural situation, gaze plot, eye tracking, computer monitor, fixations and saccades, area of interest analysis, hot spot, information, and mental model of system (for an overview of the procedure of this experiment, see Figure 1).

III. RESULTS

For the first three phases (reading, learning, concept extraction), eye movement data was analyzed separately for each of the four slides from the start of each slide until the button press (or time-out). As described above, during the learning phase, participants had the possibility to go through the slides once again; seven out of nine participants took this opportunity. However, for a better comparability across the participants we only analyzed the first run of the learning phase.

A. General eye-movement measures (Phases 1-3)

We first analyzed the eye movement data of the first three phases with regard to “traditional” measurements in order to be able to integrate the findings in the general literature. Pooled across all four slides, participants made on average 728.3 fixations ($SD = 77.4$) during the reading phase, $1,316.6$ fixations ($SD = 467.2$) during the first learning phase and $973.7$ fixations ($SD = 214.6$) during the extraction phase.

Per each slide, participants made $182.1$ fixations ($SD = 19.9$) during the reading phase, $329.1$ fixations ($SD = 158.2$) during the first learning phase and $243.4$ fixations ($SD = 65.5$) during the extraction phase. A one-way repeated ANOVA calculated over the number of fixations made per slide did not reveal a significant difference between the three phases, $F (1.13, 9.01) = 3.63, p = .09$. There was, however, a tendency ($p = .09$) showing that more fixations were made during the learning phase than during the reading or the extraction phase, whereas no difference was observed between the latter two ($p > .05$).

![Figure 1. Procedure of the experiment (Phases 1-5).](image-url)
Mean saccade lengths were 4.03 (SD = .39) for the reading phase, 4.46 (SD = .61) for the learning phase and 5.05 (SD = .55) for the extraction phase. A one-way repeated-measures ANOVA showed a significant effect of task, $F(2, 16) = 12.81, p < .001, \eta^2_p = .62$. Posttests (with Bonferroni-corrected alphas) revealed that saccadic lengths were reliably longer when participants extracted concepts than when reading or learning the concepts. No difference was found between the other tasks ($p > .05$).

**B. Participant’s concept extraction**

Participants extracted 65 concepts in total and 1.8 concepts (SD = 0.5) per slide on average. The most popular concepts regarding the number of extractions were “thinking aloud” (8 times), “hot spot (maps/visualizations)” (7 times), “fixations and saccades” (4 times) and “scan path” (4 times). The concepts extracted by the participants were consistent with some of the concepts extracted by the EAQC (see above), but there were also other manually extracted concepts that were not extracted by the EAQC, which is consistent with prior literature [8].

**C. Concept evaluation of EAQC concepts (Phase 5)**

Participants had to rate the relevance of concepts extracted by the EAQC using a 5-point Likert scale (1 = not relevant, 5 = very relevant). One participant’s data had to be excluded due to a computer error, so finally the data of eight participants were taken into account.

The results showed that the concepts “eye tracking” ($M = 4.8, SD = 0.4$), “fixations and saccades” ($M = 4.1, SD = 0.8$) and “hot spot” ($M = 3.9, SD = 0.8$) received the highest ratings. The lowest ratings were addressed to the concepts “web pages” ($M = 2.4, SD = 0.9$) and “information” ($M = 2.6, SD = 1.1$). All other concepts were rated from 3.0 to 3.6, not differing substantially from each other.

**D. Correlations between EAQC concepts and eye tracking measures**

In order to investigate a possible relationship between the relevance of the EAQC concepts and participants eye movements we correlated the participants’ rating for each of the 11 EAQC-extracted concepts in Phase 5 with two cognitive measures from the eye tracking data. These two measures were (1) how long the participants fixated a concept on average when they fixated it for the first time (average duration of first fixation, ADOFF) and (2) how often they fixated the concept during each phase (average fixation count, AFC).

Figure 2 provides the main findings of this analysis. In the reading phase, both the correlation between the concept ratings and ADOFF and between the concept ratings and the AFC were not significant (all $p$s > .05). This suggests that there is no relationship between the relevance of a concept and how long it was fixated. However, not depicted in Figure 2, the correlation between ADOFF and AFC was at the threshold to statistical significance ($r = .601, p = .05$). This would suggest that the longer a concept is fixated when looking at it for the first time during the reading phase, the more often it is fixated during the same phase.

Furthermore, for the learning phase and the concept extraction phase, the correlations between ADOFF and concept rating, as well as between AFC and concept rating did not reach statistical significance (all $p$s > .05; see Figure 2). However, in both the learning phase and the extracting phase, we found again a significant correlation between ADOFF and the AFC (learning phase: $r = .630, p = .038$; concept extraction phase: $r = .783, p = .004$), revealing that the longer a concept is fixated when looking at it for the first time, the more often it is fixated.

**IV. CONCLUSION**

In the current study we wanted to investigate whether eye movement measures might be useful in determining the perceived relevance of concepts out of a given text. To this end, participants read a text, learned it in preparation for a knowledge test and finally extracted concepts out of it while we were recording their eye movements.
Overall, the experiment showed that, as expected, different tasks lead to different eye movement’s behavior on the same text [12]: A tendency of a higher number of fixations arose during the learning phase as compared to the reading and extraction phase, while saccade lengths were the longest during the extraction phase as compared to the other two phases. However, with regard to our main research question, the correlation of eye tracking measurements with the participants’ ratings did not provide a clear picture, urging for future research. The correlations between the average fixation duration of a concept and the individual ratings for the EAQC-extracted concepts were not significant, neither were the correlations between the average number of fixations on a concept and its rating. These findings suggest that there is no reliable connection between the participants’ eye movements towards certain concepts and the subjective importance of these concepts. Only the correlation between the average fixation duration and the average number of fixations on a concept showed the expected significance.

There are a number of reasons that might have led to the current results and might be in this way also a starting point for future research. First, our sample size was rather small. Although such small sample sizes are very common within standard eye tracking research (given the large number of eye tracking data from each participant), future research on the validation of automated question creators with physiological eye measurements should include a larger sample size in order to receive distinct results.

Second, the text used in this experiment was a scientific text about eye tracking. Probably, a more general topic would result in a broader and more concise image of eye movements during the different exercises. Moreover, the text we used was written in English, whereas the mother tongue of all participants in our experiment was German (although all participants reported a sound knowledge of English). It would be nevertheless interesting in future research to investigate whether results differ for mother-tongue texts.

Finally, prior experiments as well as our experiment showed that participants’ perception towards what is relevant and what is not, is very widespread. This fact has to be further investigated as well in future research, perhaps by trying to find a relationship between the eye-movement measures and those concepts that were extracted by the participants themselves. This analysis was however out of the scope of the current study.

In sum, our experiment opened a door to link the modern and upcoming field of automated question creation with the field of classical research on cognitive processes using eye tracking measurements, aiming to illuminate and allow a validation and enhancement of automated question creation. A broad body of future research is needed to further investigate this connection, whereas this experiment provides first steps and important lessons learned for future research.

Learning to program – does it matter where you sit in the lecture theatre?

*School of Electronics, Electrical Engineering and Computer Science, Queens’ University, Belfast, Northern Ireland. BT9 6AY Tel: +44 (0)28 9097 1185, Email: aidan.megowan@qub.ac.uk

ABSTRACT - Seating position in university lectures is commonly linked with student grade performance. Sitting at the front of lecture theatre is generally reported to have a positive effect on final grade. This study investigates and analyses the seating positions, course engagement, prior programming experiences and academic abilities of students throughout a 12 week Java programming university programme and relates these themes to the students’ final grade performances. Unlike other studies in this area it did not control the students’ seating arrangements. This required the development of a mobile and web based software tracking system which enabled a unique unrestricted study of the effects of lecture theatre seating on assessment performance. It finds that the best assessment results were achieved by the students in the front row and that assessment score degraded the further students sat from the front. While the most engaged were found to regularly sit at the front the same was not true for the most academically able or those with the greatest prior programming experience.

Computing; Attitudes; Assessment performance; Seating Lecture theatre;

I. INTRODUCTION

The performance effect of where students sit during university lectures has received some limited research attention [1]. Conventional teaching experience and most of the research in the area has suggested those students that regularly sit at the front of the lecture theatre tend to achieve higher grades than those that sit elsewhere ([2]; [3]; [4]). These studies have tended to conclude that higher grades are achieved by the regular front row students because the academically best able students tend to voluntarily position themselves there. Giles [5] found a direct relationship between test scores and seating distance from the front of class: students in the front, middle, and back rows of class scored 80.0%, 71.6%, and 68.1% respectively on course exams.

Decision to sit at front – attitudes and abilities

Other studies have sought to further identify why there appears to be a relationship between grades and seating distance from the lecturer. Some studies have sought to establish the causation factors in the decision making of students with regard to the decision of where to sit. These studies have included an analysis of the attitudes of the students including attendance [6], attention [7] and motivation [8]. Generally they suggest that those that sit at the front are indeed the best attenders, most attentive and motivated. Becker [9] even suggests that those students that opt to sit at the front have a more positive regard for the lecturer. These studies conclude that the best and most engaged students are to be found at the front.

However, the convention that the best students are found at the front and this group will achieve the highest grades was challenged by Perkins [10]. In their seating experiment they randomly allocated seats to the students thereby preventing any potential natural clustering of the academically better able and engaged students at the front of the lecture theatre. Nevertheless, the study concurs with the majority of other studies. The same pattern of degradation of final grade occurs the further back the students sat. While the authors failed to identify why sitting in the front led to better grades, their results would suggest that there are other factors affecting performance and seating than simply student ability or positive attitudes.

Better learning experience

Regardless of ability or engagement, perhaps the students that sit at the front may simply have a better learning experience and consequently end up with better grades. Part of this better experience may involve better note taking. Traditional lecturing involves the presenter speaking almost continuously for an extended period of time while the students’ job is to listen and take notes [11]. The importance of accurate notes is not lost on students with [12] and [13] reporting that the majority of test questions on college exams come from the lectures and that students who take better class notes get better course grades. This in turn places demands on students’ ability to listen carefully and take notes that are accurate and complete. Conventional wisdom would also suggest the note taking is better done at the front rather than the back of the lecture theatre due to better sight lines and being easier to hear the lecturer.

Participation

Marx [14] links active participation of students in a lecture with a more positive learning experience and resulting in a strong positive influence on attention and long-term memory storage. Students that sit up front are generally less inhibited in asking questions and are able to make better eye contact with the lecturer and are regularly the most participative [15]. The ability to interact [16] and participate [17] in the lecture are important factors influencing the learning experience during the lecture. Traditional lecturing would tend to offer better participation opportunities at the front. It would follow then that if active participation opportunities are extended beyond the traditional front rows of the lecture hall by using active learning approaches then this would negate the perceived advantage to
sitting up front. An analysis of these active teaching styles and seating effect was conducted by Perkins [18]. Nonetheless, the results displayed the same degradation of grade the further the students sat from the front. This would suggest that even with active learning styles there are still performance gains to be made by sitting at the front.

There are some other obvious logistical reasons a student may opt to sit at the front. These include where their friends are sitting or if the student were late to class and the front happens to be all that is available [19] or better visibility and improved ability to hear at the front [20].

Issues and gaps in the research

While most studies report a correlation between seating position and performance, a small number of studies including [21] and [22] suggest that seating position has no effect on student attainment. There are some areas that have received little or no research attention. The methodology employed in most of the seating studies involved students either self-selecting their seats or being allocated seats at the beginning of the course. The students were then restricted to the same seat for the remaining number of lectures. This is not the natural or the usual occurrence on university courses. It is arguable that this control restriction improperly influences the research outcomes. It also follows that any temporal factors that may influence a student to change seats could not be assessed or reported on in these studies. For instance if a student that normally sits towards the back receives a low in-term grade does this influence them to start sitting at the front? Other unanswerable questions from these restricted movement studies include analysis of natural migrations over time, for example do those that sit at the front at the start of the course remain there throughout? What would cause a student to move? Do students tend to move towards the front as exam or submission dates approach in the hope to glean exam hints from the lecturer? Additionally while almost all studies have concentrated on the effects of front versus back seating few have considered the possible effects of seating to the left or right of the lecturer.

II. RESEARCH OBJECTIVES

This research study was designed to use an unrestricted and accurate lecture theatre seat tracking system to enable an investigation and identification of possible patterns relating to academic performance of students in a university Java programming course.

The key research questions are:

1. Do the most academically able students regularly sit at the front of lecture theatres?
2. Do the most engaged students regularly sit at the front of lecture theatres?
3. Do students with prior programming experience regularly sit at the front of lecture theatres?
4. Is there a relationship between student performance and seating position?
5. Do the best assessment results come from the front row students?

The answers to these questions will gain insights in the effects of seating on student academic performance. This has possible consequences for teaching delivery styles, class sizes, lecture venues and the architectural design of lecture theatres.

III. METHODOLOGY

The study was conducted with a cohort of 91 postgraduate students taking a compulsory module in Java programming in semester one of a one year Masters course in Software Development. The demographics of the cohort are shown in Table 1. The mode of allocating seats for the vast majority of previous studies in this area was in the initial lecture to either allow the students to sit where they wish or allocate seating at random. The students were then compelled to sit in the same seat for the remaining weeks’ lectures. Other variants on this included reversing seating positions of the students at some module during the module or simply asking students, in a post course questionnaire, where they sat. In this research the students were allowed to sit wherever they wished and were free to move seats throughout the twelve week module. In order to record each session seating arrangements a mobile application (PinPoint) was developed by the researchers.

Table 1 – Demographics of students in the study

Student seating tracking – PinPoint

The students were encouraged to use PinPoint (Figure 1), a mobile and web app to register their selected seating zone at the start of each lecture. To ensure authenticity each student’s profile was initially registered and authenticated with the PinPoint system. Subsequently each student simply selected the zone they were sitting in during each lecture. It was not possible for the student to select a zone outside of the lecture time, nor was it possible to submit more than once per lecture. The zones were front, middle and back further subdivided into left, centre and right. The lecture rooms all had excellent Wi-Fi facilities and the mobile data strength in most reached 4G levels.
Other data collection areas

The assessment of other factors that may affect seating position was grouped into several thematic areas, namely; student performance, course engagement, academic ability and relevant programming experience. There were two summative assessment periods at the end of weeks six and twelve. A survey was completed by each student at the beginning of the course to capture individual data such as previous programming experience. In addition a weekly non-assessed quiz relating to the previous week’s taught content was made available for each student. The score from the quiz for each student and the date submitted was recorded. All course materials were placed online via the course VLE and the individual student access statistics were collected. A questionnaire with various questions relating to seating position choice was given to the students at the end of the course.

IV. RESULTS AND CONCLUSIONS

The use of PinPoint was on a voluntary basis and all the 91 students actively participated in its use throughout the course. While PinPoint exactly recorded the seating positions in nine zones the results presented here are accurately aggregated into front, middle and back rows. In addition to enable comparisons with other studies, in instances where previous research attention has been focused on front row versus other seating locations the results were further aggregated in front row and other rows (middle and back).

1. Do the most academically able students regularly sit at the front of lecture theatres?

The students on the course with previous First Class Honours (n=17) degrees were for the purposes of the research considered to be the most academically able. While the researchers acknowledged that the previous degree may not have been directly related to programming themes or even STEM (Science, technology, engineering, and mathematics) based, the previous degree standard was considered a mark achieved through a rigorous independent academic process and likely a better measure of academic performance than a pre-course assessment.

The tracking of seating positions, as illustrated in Figure 2, shows that of the First Class degree students (35.3%) regularly sat in the front rows. The remaining 47.1% sat in the middle rows with 17.6% regularly sitting on the back row seats. While significantly more of these students sat in the front than the back, the majority actually sat in the middle.

Contrasting the First Class honours degree students with the other degree classifications (Figure 3) shows that proportionally more students with a First Class degree regularly sat at the front. The majority of students within each classification sat in the middle rows. The students with Upper Second Class degrees (2.1) were proportionally evenly distributed with the majority in the middle and comparable numbers in the front and back. The Lower Second Class degree (2.2) students also mostly sat in the middle but tended to aggregated more at the back than the front.

Recalling that there are disproportionate numbers of previous degree classifications within the cohort (1st (17), 2.1 (48), 2.2 (26)) it is of interest to review the actual numeric breakdown by seating areas and degree classifications (Table 3).

Table 3 -Percentage and actual numbers within each degree classification and aggregated seating position during the 12 week course.
The percentage breakdown by classification would therefore suggest that if the intake of the course had even numbers in each classification then the makeup of the front row would generally consist of the higher performing students. In reality for most similar courses this is unlikely to be the case. Indeed it is worth noting that in this occasion from total students in the front row (n=22) the majority (n=16) held the lower degree classification. This is in contrast with much of the previous research that has suggested that the best final results will come from the front rows based on the assertion that the best students are there. In this case the majority of the top end academic performers (64.7%) were not located in the front rows.

2. Do the most engaged students regularly sit at the front of lecture theatres?

The measure of engagement (engagement factor) was based on a mapping scale of: 1) access hits for online course materials, 2) attendance and 3) voluntary engagement with the weekly formative tests. Scaling was from 5 (high engagement) to 0 (no engagement). Historically the course attracts students that are considered to be highly motivated with high attendance levels, high attainment and observed high engagement with course materials. As such it was not surprising that the engagement mappings placed the majority of students within the range 3 to 5. The breakdown of engagement factor showed that the front row on average contained the most engaged students (3.50) followed by the middle (3.35) row and then the back rows (2.98).

The trend line in Figure 4 suggests that engagement declines from front to back rows. It should be noted that there were a large number of highly engaged students (an engagement factor greater than 4.0) clustered in the middle rows but also a large number of low engaged (an engagement factor less than 2.5) which affects the overall average engagement for this zone. The back row contains none of the most engaged students and proportionally the highest number of the least engaged. Based on the averages achieved per zone it can therefore be concluded that the most engaged students voluntarily clustered at the front throughout the course.

**Figure 4 – Course engagement ranging from 5 (high engagement) to 0 (no engagement) plotted against seating zone. Each point represents a student in respect to their calculated engagement in the course and their average seating position throughout the course.**

3. Do students with prior programming experience regularly sit at the front of lecture theatres?

Historically the course attracts a number of students that have some programming experience but a larger proportion that have none. This is also a current and comparable theme experienced in first year undergraduate Computer Science courses worldwide. Whereas in the past the majority of students entering first year computing degree courses would have had little or no programming knowledge, more recently and largely due to the recent uptake of computing qualifications in Secondary Level education, universities have seen an increase in the prior programming experience of students.

In this study and perhaps not surprisingly, the average assessment scores of the students that had some prior programming experience (72%) was higher than achieved by those without any programming experience (68%).

Considering the mixture of previous programming experience (n=41) and none (n=50), it is of relevance to report on the seating positions of these groups and also the breakdown per seating zone to judge if the most experienced and best academic performers sat in the front rows.

![Table 4 - previous programming and no programming experience groups as shown by actual numbers per seating zone and percentage breakdown per group within each zone.](image)

4. Is there a relationship between student performance and seating position? & 5. Do the best assessment results come from the front row students?

There were two equally weighted assessment points in the course which made up the final assessment score. Both were closed book assessments taken under exam conditions consisting of theory and application of the taught course content. The distribution of the overall assessment percentage scores shows normal distribution (p=0.193, Kolmogorov-Smirnov Z=1.081). Table 6 illustrates that the front row students returned the higher assessment scores in comparison to the students sitting elsewhere in the lecture theatre.

</tr>
</tbody>
</table>

To test the statistical significance of the assessment scores from the students in the two seating zones groups (front and other) an analysis using an Independent-Samples T Test was conducted. It revealed that despite the small sample sizes involved that the difference between scores achieved by the front row students and the other students was approaching statistical significance (p=0.059, t=1.900, df=180).

A more detailed view is presented in Figure 5 illustrating each student’s overall assessment score and their average seating position during the course. It demonstrates that there was a general trend where the assessment score degraded the further a
student sat from the front. The majority of top grades come from those at the front but not exclusively, there were two students that sat at the back and scored over 90%. The numbers of students that sat at the front and back zones are comparable. Yet, examining the assessment scores highlights just one failing student at the front but four failing students at the back.

Figure 5 – Overall student assessment scores and average seating position and trend line illustrating degradation in assessment score from front to back.

It can therefore be concluded that in this case there is a relationship between the seating position and assessment performance, with a general degradation in scores from the front to the back rows. Furthermore the best assessment results were achieved by the front row students.

V. DISCUSSION AND FUTURE WORK

General conclusions

The results of this research confirm the findings of much of the previous study in the area that indeed the best assessment results did come from the students that regularly sat in the front rows. Additionally the assessment results tended to degrade from the front to the back of the lecture theatre. Conversely, unlike other studies it finds that the assessment score patterns in relation to seating are not necessarily due to the best academics or those with prior experience in programming sitting at the front. The study did however identify that the most engaged students repeatedly sat in the front rows.

This suggests that there is a benefit to sitting at the front regardless of academic ability or prior subject knowledge. It points to engagement being a potentially significant factor determining assessment outcome. It may also indicate that other untested factors may be at work in positively influencing the front row performances.

One such factor is the influence of the physical environment of the lecture theatre. All the lecture theatres used in the study utilised addition screens to aid vision of the projected screen for those at the back. All the theatres had excellent audio capabilities; the quality of the audio at the back was as good as the front. However responses from the seating choice questionnaire highlighted that a number of students stated the ability to see and hear better at the front as a determinant of sitting position. The influence of the entrance / exit points in a lecture theatre may also be a factor affecting seating decisions. There may well be a considerable difference in seating effect when contrasting a lecture theatre that has the entrances at the front compared to one with the entrances at the back. In the former a student turning up late may well be happy to avoid attention and sit at the lower assessment performing back rows whereas in the latter the student may be forced to sit up front with the top performers.

The influence of the lecturer is also a relatively untested factor in previous research in relation to seating position. The style of teaching came up as an influence in seating choice in the student survey, with some responding that they actively avoided the front rows to actively avoiding having to answer questions. The majority of the lectures in this study involved individual and student programming activities. Over 95% of the students brought and used their own laptops for these activities during the lecture. In that sense the learning experience should have been reasonably homogenised irrespective of seating position. Yet, the results point to a better performance at the front.

It is perhaps that sitting at the front promotes a better learning experience. The cognitive activity of those at the front may be higher than those sitting elsewhere. As acknowledged by many of the seating survey responses, being at the front appears to promote more potential cognitive activity, be that with peers or the lecturer. There is certainly more chance of eye contact with the lecturer, or opportunity to ask or be asked questions by sitting at the front.

Get more students to the front?

It would appear that having more students regularly sitting at the front may be of benefit to their assessment score. There are a number of lecture theatre architectures aimed at facilitating greater numbers of students at the front or closer to the position of lectern. While these structures are perhaps of reasonable consideration for new lecture theatres the adaption of existing shaped theatres to these designs is likely cost and logistically prohibitive.

A reduction in class size would enable more students to sit at the front. Decreasing class sizes would effectively increase the ability of the front rows to potentially seat more students. However a reduction in class sizes for university programming classes is unlikely to happen any time soon. The demand for graduate computing professionals has steadily increased over the past numbers of years with the IT sector regularly requiring 140,000 entrants each year in the UK [23]. However, according to the Higher Education Statistics Agency [24] there are only 16,000 computing graduates per annum, leaving a shortfall of 120,000. Consequently UK universities have responded by increasing their intake in computing degrees. While the demand remains it is reasonable to expect that class sizes will remain high.

Perhaps it may be as simple as the lecturer encouraging the students to sit at the front or if the benefits of sitting at the front were explained then they may choose to sit there. Although in this research it should be noted that even with the lecture theatre at half capacity the front row regularly had some empty seats. It would appear that given the option some students will still likely chose to sit elsewhere. In that regard the decision of where to sit is personal and generally consciously made. The student questionnaire on seating positions found that most of the front row students sat there because of better vision, being less distracted at the front and the perception of being forced to pay more attention if closer to the lecturer. Those that sat at the back did so mostly because they wished to listen and not have to be involved in the class activities, importantly there was evidence to indicate that this was a particularly strong influence for students with diagnosed anxiety issues. Some others at the back explained that arriving late meant they could get to a seat at the back with least disruption to others. Many students responded that they tended to sit wherever their friends sat.
Limitations and future work

As with many predominantly quantitative based studies the understanding of the responses would be further enhanced with a more comprehensive qualitative study. The ability to interview students, individually or in focus groups, or getting them to record their seating choice decision for each lecture using the PinPoint app would provide a greater understanding of the findings. Replication of the study using the same methodology would of course test the repeatability of the results. It would be of interest to re-examine this issue with a more traditional less interactive style lecture.

It would also be of interest to analyse the intra group assessment performance. Does the performance of students with similar standard academic ability, engagement and prior subject knowledge remain consistent regardless of seating position?

As is common in many programming modules in universities there were a limited number of females in the cohort. This inhibits the study of any potential gender influences other than to report in this instance that there was normal distribution of the females throughout the lecture theatre.

While the study concentrated on highlighting differences between front, middle and back rows there would be merit in a further analysis of the zonal areas to include the left, middle and right areas of the lecture theatre.

The cohort in this study were generally regarded to be highly motivated, it would be if interest to extend the study to a less motivated group.

Although there were some occurrences of movement between seating zones over the twelve weeks it would be of interest analyse if there were any significant changes in seating due to an occasion, such as an exam revision lecture.

While this study was with a cohort of programming students the authors feel that the accuracy of the data collection methods used could easily be transferrable to other subjects areas.

Knowledge and Skills: A Critical View

Mario Radovan
University of Rijeka, Department of informatics,
Rijeka, Croatia
mradovan@inf.uniri.hr

Abstract - The paper puts forward a critical view on knowledge and education in the present techno-economic culture. This culture stresses the importance of knowledge and education, but it promotes only the instrumental knowledge that the present techno-economy directly needs. Such practice displaces other dimensions of the human knowledge and cognitive abilities, which are needed for the progress of people and humanity. Business forces are raising the means to the level of the end, and shape education in the way that serves business aim, rather than the promotion of knowledge. Information technology has brought many excellent means and services to education, but it should not be used in the way that reduces people to automatons that perform prescribed procedures, without understanding or asking anything beyond that.

I. INTRODUCTION

Let us describe some of the concepts that we use in the paper. Contemporary economic activities strongly depend on technology, and the development of new technological systems is powered by economic aims. The concept of techno-economy points to the connection of technology and economy and to their mutual dependence. The way people work and live is determined by the socio-economic system, more than by technology itself. This system shapes the technology we use and the environment in which we live: it shapes the physical and mental space of our existence, and our understanding of existence [1].

In computer terminology, a precisely defined finite process is called algorithm. A computer program implements an algorithm; when active, the program performs the process defined by that algorithm. Knowledge and activities of contemporary people are getting more and more algorithmic or procedural. Knowledge is reduced to the ability of performing precise procedures, and human cognitive activity is reduced to a constant learning and performing of such procedures. We are surrounded with screens and buttons, and to do anything, from buying bananas to flying an airliner, we must perform appropriate procedures with those screens and buttons. People have always wished to possess the power to control and steer the world; technology brought them plenty of such power. However, the means that give people power, shape their cognitive abilities and their mental space. Technology creates immense opportunities, but it compels people to think and behave in ways that it requires and imposes.

The concept of instrumental reason refers to that dimension (capacity) of human cognitive system, which allows people to perform specific procedures with the aim to produce specific effects. In other words, instrumental reason is the human reason used as a means (instrument) for carrying out a specific task. People have always used reason in this way in their endeavours to satisfy their needs and achieve their ends. The intense use of technology in all spaces of human activity has led to the complete domination of instrumental thinking. Technological means compel people to constantly think and act in instrumental way: in this way, those means gradually reduce human cognitive abilities to the instrumental dimension. For the procedural (instrumental) people, to know means to know how: they learn and think with the aim to do something, not with the aim to enjoy the understanding. They acts in the framework of the paradigm with which they are steered, without questioning its values, aims and effects.

We can speak about four kinds of human reasoning or about four dimensions of human cognitive abilities: creative, instrumental, critical and integrative. Creative reason explores the space of values, aims and visions of the human life and activities. Instrumental reason deals with the means and methods of the realization of the chosen aims and visions. Critical reason examines and evaluates the wider effects of the activities of the former two dimensions. Finally, integrative reason aims to keep the previous three components in balance, because only their harmonious coexistence can allow people to achieve their best possibilities. Education as well as public discourse should promote all four dimensions of human cognitive abilities. The present-day education promotes only instrumental reasoning and abilities, and public discourse, reduced to stupefying infotainment, promotes none. This reduces people to servants of the techno-economic system, who do not think about its aims and effects in a critical way.

We assume that emotions are the moving force behind all human reasoning and activities, creative and destructive ones. Reason by itself has no ends: reason chooses and evaluates ends on the basis of emotions. We must not blame instrumental reason when our emotions and passions make it serve destructive aims. Instrumental reason serves all aims: the problem is that human feelings and passions can lead to the adoption of destructive aims.
II. THE QUESTION OF KNOWLEDGE

Techno-economic society calls itself the knowledge society, because knowledge is essential for production and consumption. However, this society promotes only instrumental knowledge and procedural (algorithmic) thinking, which are needed for the performance of technological processes and business activities, so that this society does not deserve to be called the knowledge society. A more modest name, such as the skill society, would be more appropriate for this society. A descriptive name, such as the society of specific skills and general ignorance would describe the present society even better [2]. For the development of complex technological systems, as well as for their control and use, an huge amount of instrumental knowledge is needed, but all this knowledge belongs to only one dimension of human mental abilities.

It is important to make difference between knowledge and skills. A culture that mistakes skills for wisdom, and measures its progress in terms of production and consumption instead of in terms of cooperation and compassion, is doomed to failure: such culture "condemns itself to death", says Chris Hedges [3] (p. 103). Such claims may seem too strong, but life in such a culture is one-dimensional and it seems empty. Knowledge is something more comprehensive and less operative than algorithmic thinking and instrumental skills are. To make the world better, it is necessary to promote understanding, not only instrumental thinking, and solidarity, not only competition and struggle. General ignorance is dangerous, because it lowers the level of public discourse and makes manipulation easier. This usually leads toward radical views and aggressive behaviour.

Ignorance is present in techno-economically leading countries more than we are aware of. Let me mention an example. Craig Venter, a famous geneticist, delivered a lecture on the role of science and the challenges of the present world, which was broadcast by BBC television. In that lecture, Venter put forward many interesting data, some of which regarded the education and ignorance in the present-day world. Among other things, he said that 25 percent of American citizens do not know that the earth revolves around the sun. This means one out of four citizens. Hedges [3] says that "nearly a third" of the American population is "illiterate or barely literate" (p. 44). Let me add to this that "in the secular United States", 66 percent of people "believe in the Devil" [4] (p. 77). I am not sure what this believing actually means, but it does not seem encouraging in terms of knowledge and education.

Mark Bauerlein [5] puts forward data which show that general knowledge and literacy have been in decline among young people. Bauerlein mentions various reasons for such a bad situation, but he blames primarily the young because they do not read books enough, and teachers because they do not do their job well enough. He criticizes "the custodians of culture, the people who serve as stewards of civilization and mentors to the next generation"; those custodians and mentors are primarily "teachers, professors, writers, journalists, intellectuals, editors, librarians, and curators", as well as the institutions for which they work (p. 161). Bauerlein concludes that "they have let down the society that entrusts them to sustain intelligence and wisdom and beauty" (p. 161). We argue that Bauerlein's criticism misses the source of the problem. In ruthless capitalism, teachers and journalists are pawns that are compelled to behave according to the rules set by the system. Bauerlein blames the young and teachers, but he says nothing about the socio-economic system that shapes their reality. Our education and our ignorance are shaped by the socio-economic system; teachers and similar "stewards of civilization" do not have the power to change this system.

Bauerlein says that the young read less and less, especially when it comes to more demanding books. The consequence of this is a decline in the knowledge of history, culture, art, and science. The knowledge about current events, at the local and global level, is also in decline. This is bad, but it is wrong to blame the young and the "stewards of civilization" for such a situation. The young read less and less books because the industry produced new means and methods of efficient recording and distribution of all kinds of information contents. The reason for the decline in general knowledge is not in the fact that the young do not read books, but in the fact that the means and contents that have displaced and replaced books are used in the ways that are not good from the educational point of view. The information industry makes everything fast, exciting and shallow. Anyway, the behaviour of the young is the product of the society in which they have been raised; hence, the causes of the weaknesses in their behaviour must be sought in the weaknesses of the society, which Bauerlein does not do.

Socio-economic system sets the values and determines the structure of power in society. With this, the socio-economic system shapes the behaviour of people, especially of the young. It makes no sense to blame the young for the fact that they behave in the way they do, because they behave in the way that the world created by the older encourages and requires them to behave. It makes no sense to blame teachers and journalists, because business values and principles shape the rules according to which we all must behave. Teachers, journalists, librarians and similar creatures do not have the power to change the rules and values that have been set by the ruling paradigm (ruthless capitalism and consumerism) and by power-holders who shape the structure of power and the relationships in society and in the world. Bauerlein blames pawns, but he neglects the rules of the game, as well as the masters who play the game.

Images have displaced written contents, and Homo online has displaced the old, conceptually oriented, Homo sapiens. These are very relevant changes, but the socio-economic system has a much larger impact on the life of people and society than the means by themselves have. The decline in general knowledge is a product of the socio-economic system that shapes education and public discourse. Every economic system shapes people and society in its own image, and so does the present techno-economic system. I studied and graduated computer science because I wished to learn how these machines work under the surface. My students are not curious about
such things; they are interested in what they can do and achieve with those machines. Procedural people know virtually nothing about the internal structure of the systems they use, and even less about the theoretical principles on the basis of which these systems have been constructed and work. And they do not show much curiosity about that. Procedural people are masters of procedures, and ignoramuses about nearly everything else.

Finally, people spend more and more time on the learning of how to use the means; frequent upgrading makes the situation even more difficult. Devices and systems are getting more and more complex; new versions are overloaded with "capacities" and "intelligence" that most people do not need, but they make the process of learning the system and its functions more demanding. Frequent upgrading of tools compels us to spend more and more time and energy on the learning of how to use new tools for doing the same things we were doing with the previous versions of those tools. New and better things are developed with time, so that it is normal that new and upgraded versions of tools are produced and released. However, upgrading and changes are often made primarily for business reasons: to compel people to buy new things and to make them more and more dependent on the industry and its knowledge of how to use those things. Upgrading is unavoidable and welcome to a certain extent, but it often produces a huge waste of time and energy, and do not bring much good.

III. THE ROLE OF HIGHER EDUCATION

The intense development of industry in the nineteenth and twentieth century created a need for specialized knowledge and research. Higher education was required to satisfy those needs, so that the main task of higher education became to supply society with the labour force that possesses the instrumental knowledge that techno-economy needed. The demands about the autonomy of higher education and about critical analysis and discourse were displaced by economic reasons, and they have fallen into oblivion. The present higher education produces instrumental knowledge that techno-economy and corporate business ask it to produce. It shapes its teaching programs and research activities in accordance with business principles and the demands of the market. The industry of higher education is large and growing; however, the education is not moved by the authentic human desire to know, but by business principles and market value of the instrumental knowledge it produces [6].

Corporate business and the ruling socio-economic system have compelled universities to behave like business companies. Instrumental knowledge has been in demand, and universities have been compelled to produce this kind of knowledge. Corporate business shapes education in the way that serves its needs and promotes its aims. Knowledge gets value on the market, and this value is determined by the market. Higher education has become an industry that produces instrumental knowledge that the techno-economy needs and for which there is a demand on the labour market. Such education is reduced to the training for a job, and it does not promote a critical thinking about the ruling paradigm, its values and practice.

Leaders of the best known universities warn that the material dependence of universities on corporate business may have negative effects on their research and teaching activities. A former president of Harvard university said that the "commercialization of universities" is the most severe threat that the contemporary higher education faces. The growing material dependence of the university activities on corporate money can seriously compromise those activities. Teaching contents and research results can become partial and biased in favour of those who pay for them [7] (p. 263-64).

Higher education has always served the socio-economic system, rather than questioned and criticized it; it has taught students how to find a comfortable place in the system, rather than how to change it. Universities have seldom been sites of intense social criticism, because they existentially depend on the ruling system and power-holders. If they criticize the system and power-holders (economic, political, cultural) they may be punished for that. Universities have sometimes been places of intellectual resistance to the ruling narrative, but they have usually been socially conservative and politically passive. They did nor participate much in large social movements and changes that took place in modern history. The struggle for the abolition of slavery, the workers' struggle for better working conditions, and the struggle for the liberation of colonies were not influenced much by academic institutions and activities [6] (p. 2). The academic world has followed historical changes, more than it created them.

At the present time, the social impact of the university seems even lower than in the past. Instead of being a space of free and critical enquiry about all socially relevant issues, universities have become corporations and servants of corporate business that they financially depend on. Universities have adopted values and practice of the corporations they serve [3] (p, 110). They have become part of the world shaped by the corporate mind, values and aims. Their aim has become the efficient production of marketable instrumental knowledge, not the promotion of a wide and deep understanding [8]. Students are given a narrow specialized knowledge, without the insight into social values, ethical principles, and common good. Such students are only capable of serving the existing practice and structure of power. Universities produce formally educated people who should be considered illiterate by traditional standards, says Hedges [3] (p. 96). Young people have not been taught about the structure of social power; they know very little about their own civilization, and they do not seem to be able to maintain and advance it.

In the present techno-economic society, knowledge about history, culture, art, and social issues is in decline. The complete domination of instrumental education diminishes the abilities and readiness of new generations to assess their socio-economic system and its practice in a critical way and to make them better. Society needs professional training, but education should promote
analytical and critical thinking about all narratives and systems, values and aims, because such thinking is necessary for the progress of people and humanity. Education must produce the instrumental knowledge that society needs, but it should not be reduced to this task: it should teach more than instrumental knowledge and operative skills. It should teach the rational and objective way of thinking; it should present major traditional and contemporary narratives and historical events that shape our reality, in an impartial way. Higher education and scientific institutions must promote the understanding and critical discourse about every narrative and power that shape our lives, society and the world, or has the ambition to do so. Science and education cannot assume political leadership in a society, but they must enquire and evaluate every power, politics and behaviour. In this way, science and education can contribute essentially to the development of a more reasonable and more just world, and of new visions of the peaceful progress of humanity. On the other hand, limited to the production of instrumental knowledge, science and education only serve the preservation of the existing paradigm and structure of power, with all their drawbacks and weaknesses.

Education has always shaped new generations according to the values and needs of the dominant narrative and practice. Enthusiasts say that education must free young people from the tyranny of the truths and values of their time. But education has always aimed to subdue new generations to the tyranny of the truths and values of their times, and it has taught them how to best serve that tyranny. The basic aim of education must be to reduce ignorance, superstition, and suffering, says Neil Postman [9]; the aim of the present-day education is to mould new generations in accordance with the needs of the techno-economic system (p. 70). Education must teach young people about the human creative aspirations and destructive inclinations, and promote understanding, goodness, and beauty. Education must promote universal values and principles, openness, social justice, and human dignity. In this way, education promotes constructive and cooperative behaviour of people and communities, and creates a sense of coherence of human endeavours. Such education would make a great contribution to the solution of many problems and to the creation of better people and a better world. All ages needed such an education, but they did not have it; the present age is not an exception in this regard.

IV. THE MEANS AND THE CONTENTS

Information technology gives students the access to an immense amount of information contents from which they can learn. But the quantity of textbooks and learning materials has not been the problem in recent decades, even before the appearance of the internet and its services. On the other hand, the quality has been the problem, and the proliferation of information technology has made this problem worse. A huge increase of the quantity of information contents of all kinds has been accompanied with the fall in the average quality of those contents. Books used to be written by those who really knew the subject they were writing about, and who had a passion for explaining things in a clear and inspiring way. The present-day learning materials aim to be "fun", but I seldom find a real understanding and good explanations in those materials. As a former passionate computer programmer and the author of a book on programming, I can say that the level of teaching and of student's knowledge of computer programming is notably lower today than it was forty years ago. Programming is a demanding activity that requires knowledge and cognitive effort. Various video materials (films and cartoons) do not help in a serious teaching of computer programming. The same probably holds for many other subjects of education.

The learning and understanding of demanding things, such as formal theories and complex systems, requires a high level of concentration and a serious mental effort. Screens do not help concentration nor do they encourage students to make a serious mental effort. I have been working with screens for decades, but the reading from screen, especially of larger and demanding texts, has remained different for me than the reading of printed matter. On screen, everything looks superficial and ephemeral. Printed matter makes contents more physically present and lasting than screens do. The medium is not the message, but the medium matters. Learning from the web seems even more problematic. Web stimulates superficiality rather than concentration and cognitive effort. Links lure students to press them and seek knowledge somewhere else.

The world is inundated with information contents and messages of all kinds, but the sense of quality has been lost. The internet offers students a huge amount of contents of dubious quality, and stimulates surfing instead of concentrated and engaged reading and thinking. The internet contains countless useful data and information, but the learning from the internet is superficial and it shapes students in its own image. Information technology facilitated the production and distribution of an immense amount of information contents; to survive in this noisy jungle, we must constantly select. But with the increase of the quantity of information contents an efficient selecting is getting more and more difficult.

Computers must be used in teaching those things that are done by means of computers. All sorts of computations and designs are done by means of computers and software tools: it is normal to teach students how to do such things by means of computers and software tools. However, we hold that technology does not help in learning the principles and laws on which computations and designs are based. A bridge can be designed by means of computer and a software tool. But for such a tool to exist, somebody must produce it. To produce such a tool, it is necessary to know the laws and principles on the basis of which bridges are constructed. To be able to produce tools, we must know more than how to use them: we must know laws and principles that are implemented by those tools. Finally, we the ones who must constantly evaluate the aims of our individual and collective endeavours. Information technology is the means (tool) that increases the efficiency of doing, but it may obstruct the process of learning and understanding the basic principles and aims. If education is reduced to
the art of handling the means, people will become ignorant about laws and principles, and unable to choose and evaluate their aims.

V. THE ART OF TEACHING

Techno-economy aims to eliminate direct (live) lectures held by professors, and to replace them by learning systems based on information technology. I consider this idea bad for several reasons. I admit that at least half of the professors I have known as a student or later, have not seemed good to me. But some professors are good, and that is what matters here. Direct encounters with such people who know, and who know how to present knowledge, leave a lasting impression on the young people who want to learn and understand, not only to get a degree. A good professor presents a relevant content in a clear way, and shows a way of thinking about the topic he or she speaks about. If such people are eliminated because of business reasons, new generations will lose the possibility to encounter such people and to learn essential things from them. A physical encounter and a direct discourse with a person are quite different from the encounter over the screen. It has been said that "the excellence in teaching remains an art that cannot be simulated by machines" [10] (p. 221). This is probably true, but even if this art can be replicated by machines to a notable extent, why should this be done? If young people will be educated only by machines, they will become like machines. They will not be able to explore the possibilities of human progress; they will think only about the advance of technology. To hand over education to machines may be good for business, but it is bad for people.

Automated education will transform people into machines that learn from machines how to handle machines, and who understand and ask nothing beyond that. This will bring about a complete domination of instrumental reasoning over creative and critical reasoning, which is bad, because this will narrow the space of human abilities and experience. The automation of education is based on the bad assumption that money is the supreme value and that every activity must be evaluated exclusively according to the economic criteria. Virtual universities, without professors and campuses, may cost less, but such systems of higher education will lack the best that traditional universities offer: direct encounters and interactions between people.

Universities are peculiar physical places because of their specific atmosphere, which cannot be replicated by means of the internet. In spite of all communication technology, physical encounters are important and they will remain important, as long as we are physical beings. If professors and lecturing are eliminated, the understanding of life and the attitudes of new generations will be shaped only by celebrities and politicians, which is not good. Finally, being a professor is not so bad, although it is not as good as it may seem. Being a classical student is the best job I have ever known. Why should these jobs be eliminated? With the aim to lower the costs and increase profitability, ruthless capitalism has been replacing good jobs with machines, so that only bad jobs remain for people. This is not something I consider a progress of people and humanity.

VI. CONCLUSION

It is necessary to be "contemporary" to a certain extent to be able to live, but those who uncritically accept the ruling narrative of their time often act in suboptimal way. We must constantly examine the world in which we live, its values, means and aims. Information technology facilitates many excellent things and offers many good services in the space of education. But we must not raise the means to the level of the end, and shape the education in the way that serves corporate business, but does not promote a wider knowledge and understanding.

By thinking and living only at the instrumental level, people diminish their experience of existence, and with this they diminish themselves. We do not advocate a spirituality here, but a reflective and poetical attitude towards the world in which we live and toward existence. Instrumental reason has achieved great things at the operative level, but those whose mind has been reduced to the instrumental dimension do usually not see other things, without which the efficient functioning at the operative level do not bring much good.

Education cannot solve all problems of this world, especially not if people and communities do not behave in the way that promotes cooperation, mutual respect and solidarity. However, if education cannot solve all the problems, ignorance makes them much more dangerous and harmful. It is difficult to change dominant paradigm and practice, but we must preserve the awareness that things can be different; otherwise, we will create and accept a totalitarian world, in spite of many nice slogans that we constantly produce.

Abstract - In the educational context, understanding the future is important for two reasons. First, we are educating people for future tasks, which need skills that are useful in the future. Secondly, educators have to be able to select the most promising tools and technologies to apply in their work. The problem is that there is no clear way to weigh the importance of the alternatives – what the real importance of a certain technology will be in the near future and especially in the long term. In our paper, we focus on analyzing selected technologies. Our approach applies the framework developed by the authors. The promising technologies are reviewed by a systematic literature study, focusing on and restricted to the information and communication technology (ICT) sector. The findings are classified according to their importance and the time span of their effectiveness. The question we answer is “What should every educator know about changes in technology?”

I. INTRODUCTION

Technological changes and progress in technology are enablers and accelerators for wider changes in our society and economy. Ultimately, the consequences are seen not only in products, but also in processes, business models, and common behavioral patterns. It is justified to say that now one of the biggest change factors is information and communication technology (ICT). We do not wish to underrate other fields of technology, but in everyday life, the changes made possible by ICT in particular can be perceived the clearest. Forecasting is the highest level of being prepared for the future – especially if the prognoses are accurate. Having forecasts provides us with the means to be proactive – prepared in advance for situations that happen, or also preactive – having the means to affect in advance the alternatives that may happen.

For educators, understanding the future is important because they are educating people for future tasks (the “product” we are producing), and because they have to be able to select the most promising tools and technologies to be applied in their work (the optimal process and environment to “produce our product”). Both of these aspects are changing just as fast as the surrounding society.

The aim of the paper is to build a synthesis – not complete (which is actually not possible at all) but a list of a variety of technological changes that are worth recognizing now. The research question handled by our paper is “What should every educator know about changes in technology?” Our approach applies the principles of the Technology Change Analysis and Categorization (TCAC) framework introduced by Jaakkola et al. in [1]. The material used in the analysis covers the publicly available technological forecasting sources that are the best-known and most referred to. In spite of the fact that the material covers a limited scope of sources, we consider the picture it gives to be relatively reliable.

We have approached this study topic with two papers (Figure 1). The principles of the analysis method are introduced in Paper I [1]. The aim of the present paper (Paper II in Fig. 1) is to apply the method in ICT-related technologies and to give a synthesis – a list of the technological changes that are worth recognizing now (ICT Change Analysis and Categorization – ICAC).

Figure 1. Structure of the problem solving – two interconnected papers.

The research question handled by our paper is “What should every educator know about changes in technology?” The time span of our analysis covers mainly the next five years, but related aspects with a longer time span are also discussed. We selected this split approach to separate method development and its application from each other and provide the means for a deeper discussion than only one paper allows. We urge the reader to study both of these papers.

Figure 2 introduces the principles of the TCAC framework. It also reflects the structure of our paper. The method is based on Paper I [1]; the details can be found there.
Figure 2. TCAC framework – summary of the components of the analysis.

The starting point is data collected on the study context (in our case ICT-related changes) – Step 1. Two methods are used to analyze the data: hype cycle based analysis of pre-embryonic technologies to understand the delay of their commercial appearance, and life cycle model based analysis to understand the life cycle and renewal power of the technology analyzed – Step 2. There is also an arrow between the hype cycle curve and life cycle curve. Since the hype cycle represents the pre-embryonic phases of the phenomena analyzed, it ultimately feeds the embryonic phase of the life cycle analysis; pre-embryonic becomes embryonic provided that the exit (not valid for mass and commercial use) has not been realized before it. Finally, the changes are classified according to their importance in four categories – Step 3. This phase also includes “fine-tuning” the interpretations of the importance and effectiveness classes, i.e., to give them exact semantics. The result is the classification of the selected technologies (Publishing – Step 4).

The paper is structured in the following way. Section 2 covers the first step of the analysis method – collecting the material for further analysis and classification according to the principles of the systematic literature review. The findings are organized in table format, having topic areas and publishers as the dimensions. Every topic area is handled in detail in Section 3, which is divided into subsections according to the topics. Section 4 covers a summary of the classification of the findings. The results are published and visualized in mind map format. This section also validates our analysis method in a practical situation. Section 5 reflects the findings in terms of the education sector and gives answer(s) to our original research question. Section 6 concludes the paper.

II. WHAT WILL OUR NEAR FUTURE BE LIKE?

The main purpose of writing this paper is to make a review of the ICT-related technological changes that are relevant today. We specified the research problem to be discussed as “What should every educator know about changes in technology?” Especially in higher education, we must be prepared for the assignments of the future. Every educator should be an innovator in the adopter categories, or at least an early adopter (see [1]; Paper I).

We have approached the answer to the research question following the steps of the framework introduced in Fig. 2.

1. Data Collection: We collected the “raw data” for our analysis from fourteen analyst sources (Business Insider, Frogdesign, CSC, Fjord, PWC, Quantumrun, Howstuffworks, WEF, Wired, Forbes, Gartner, Deloitte, Forrester, IDC) and sixteen reports. It is augmented by two additional analyses (Cisco Trends and Analysis [5; 6]; Gartner Emerging Technologies 2016 [15]). The reports were selected according to the principles of systematic literature search. The search was restricted to publicly available material, also accepting indirect (from reliable sources) analysis material (due to the difficult availability and high prices of the original reports). The relevance and the reliability of the sources were analyzed by the researchers (authors) based on their long-term experience in the study field (expert opinion). Additional material was also reviewed without any remarkable new findings (penetration rule of the systematic literature study was achieved).

2. Trend Analysis: The findings were organized in seven main groups covering 22 primary topics to merge the overlapping findings of the original sources for trend analysis. Table 1 summarizes our findings from the reports.

3. Importance analysis: Classification of the importance and effectiveness of the reported technology is based on the discussion in Section 3.

4. Publishing: The final result - ICT Change Analysis and Categorization (ICAC) - is published in Fig. 4.

The reports used in the analysis are listed in the references of this paper. To avoid complexity, we have not used positioned source references in the text; these can be found indirectly from the Table 1 column headings.

Most of the studies analyzed were focused on the current time: what are the leading technologies for 2017; long-term studies covered the period ten years ahead from now. When examining these, it is, of course, good to keep in mind that changes are usually slow. Today’s technology provides the basis for the following ten years. In principle, everything that will be new in ten years’ time is already known today; ultimately, even long-term predictions do not provide anything dramatically new. The only thing worth recognizing is the uncertainty built into the trends, especially the ability to separate the hype effect from the reality. In the following review, we satisfy ourselves with a superficial examination; details are available in the original material.

III. HELPFUL HINTS

A. General findings

A common finding in all the reports analyzed is the rising importance of artificial intelligence (AI) – either as it is but mainly embedded in a wide variety of products and processes (robotics, intelligent analysis, intelligent sensors, networks, etc.). Embedded intelligence is seen no longer as a support, but as an alternative for human work. AI beats human intelligence because of its ability to manage masses of information and repeat the same routines carefully time after time. AI also has an unlimited memory capacity that can be retrieved quickly in decision making, as well as the capability to store large masses of information either directly or by remote access.

B. Artificial Intelligence and its Applications

Cognitive computing provides the means for “human kind of thinking” and machine learning (deep learning) for “human kind of learning” and adaption in new situations. Virtual assistants (software based chatbots; conversational systems) are used in the role of service robots and advisors (Apple (Siri), Google (Now), Amazon (Alexa) and Microsoft (Cortana) are examples of such tools). The real electromechanical robots help or replace people in a variety (of simple) human tasks. Voice activated speakers (also called Smart Speaker Hubs, Voice Activated Speakers) are Internet connected virtual assistants that use conversational systems as a user interface to activate demanded services. Such speakers are available e.g. from Amazon (Echo), Google (Now), LG, Harman Kardon, Lenovo and Sonos. When the opportunity to use more versatile communication than before provided by the new user interfaces (speech, haptic control, augmented reality (AR)) is connected here, a robot (soft or hard) becomes a part of ordinary processes, both in business and in private life. In robotics, such sub-areas as wearable intelligence (intelligent materials), wearable robots (e.g., to support the disabled in their daily life), the use of avatars and surrogates to replace humans (digital twins; physical-digital integration) in certain situations, are recognized in the reviewed analysis. One of the special areas in robotics, which has a promising future, is microrobotics. This is based on nano particles (zero size intelligence) that are small in size and possible to use, e.g., in medical care, to provide (non-destructive) access to such parts of the human body that are unreachable in traditional human hand touch-based medicine. Appearance of artificial heart is also reported related to the field of medicine.

C. Data and Analysis

One key technology area of today is big data. Quantumrun reports on a study by IBM: Every single day human beings create 2.5 quintillion (10**18) bytes of data. Individual human-related data is produced in a variety of ways: cellphone signals, social media, on-line shopping, credit card usage, web usage, service usage, health wearables are all examples. The data may be open (providing open access) or closed (access restricted and controlled). Individual-related data has in principle a closed characteristic, but in increasing amounts is kept open by the agreements defined by the “data owners” (e.g., most of the social media services). Big data technologies are used to manage and handle large amounts of data, centralized and distributed, closed and open. An increasing amount of data is signal data (audio, video, mixed format) that provide an important source for data analytics – to an increasing extent in real time.

Several analysts have pointed out the importance of big data technologies to support medical care – a good example of this is the Watson medical diagnostics system. Their reports are also worried about data usage ethics and ownership of data. The terms digital ethics, digital cannibalism, digital feudalism, security attacks are found in the reports analyzed. All of these focus on questions of privacy and data security and the use of data (access permitted or not permitted). Adaptive security architectures (based on intelligent, scalable architectures or platforms) are seen as a solution. One specific area of data analysis was handled in the report of IEEE [18] – face recognition. This technology provides enormous opportunities for recognizing peoples face from raw data, both in live stream and especially in stored data. In turn it further increases privacy related problems; technology itself starts to be reasonable mature for mass use.

D. Work Landscape

“Robots and AI will take our jobs.” It is estimated that between 35 and 50 percent of jobs that exist today are at risk of being lost to automation. Repetitive, blue-collar type jobs might be first, but even professionals — including paralegals, diagnosticians, and customer service representatives — will be at risk. The problem is that the jobs that will remain will require high levels of education and creativity, and there will be fewer of them to go around. We need to start thinking about what kinds of jobs the rest of the population will be doing – those that are no longer employable in their traditional jobs. Life-long learning and transfer to new jobs is not an answer to this societal problem.

E. User Interfaces

One sector widely referred to in the reports relates to new user interfaces. Virtual Reality (VR), Augmented Reality (AR), and Mixed Reality (MR) are seen to be at the breakthrough point for the mass market and applications. Promising use of these is seen in entertainment, therapy, usage as a digital interface, integrated in a variety of daily life and business applications, teaching and training. Glassless AR – 3D imagery, based on the Magic Leap AR technology (https://www.magicleap.com/) is also reported to be close to the embryonic phase. The use of audio-based interaction and natural language are a rising trend. This covers audio control, conversational systems, and real-time speech-to-speech language translation. Fold-up flexible screens start to be available for display purposes. Gesture-based and open-air haptic interfaces are mentioned as new interfacing technologies, as well as the rising importance of digital streaming as a replacement for traditional media distribution. The term “neurohacking” describes the technologies that are used to pay attention to the technologies that are used to identify the “inner signals” of the object – e.g., the signals from a human brain; the signals are retrieved from the brain connected sensors or...
remotely by retrieving the electromagnetic signals produced by human body. It can be seen as a first step towards the computer – brain interface that can be found in the “innovation trigger” phase of the Gartner hype cycle (see details below in this paper).

F. Device Innovations

In the category of device innovations, the reports mention that autonomous interacting vehicles are close to being ready for mass use; these cover autonomous cars, robotaxis, and also fly robotics. Most of the reports also recognize the fast growth of electricity as the power source of cars. It is also expected that in ten years autonomous buses managing 3D driving will be reality – at least in restricted usage. 3D printing is seen as an ordinary, but fast improving application. Transfer towards application areas that are more versatile than at present is going on: printing of complete systems, bioprinting (printable bio materials), and printing of transforming objects (4D printing based on materials adapting in time and situation). The IoT (Internet of Things) is in its emerging phase and mature for early stage applications. Intelligent home and adapting space are based on improved (Wifi) networked sensors (as an application area of IoT) and the analytics of the data produced by them. However, it is seen to suffer from the lack of seamless solutions (standardized interfaces and commonly accepted development platforms). Drones (UAVs – Unmanned Aerial Vehicles) show a lot of promise. A wide variety of application areas cover assistance of human work, surveillance tasks, supervision tasks, distribution tasks, and a variety of commercial tasks. A new sector of flight traffic control is also needed to control and guide the drone traffic.

G. Key Technologies

The reports list several key technologies. The fast growth of the Internet – both its use and its transmission capacity – is maybe the most important of these. The trend towards mobilization (mobilization of the 4th billion of the world population) and wide coverage (Internet everywhere) relate to this issue. Fast transfer towards cloud architectures will continue; cloud-based ICT infrastructure is becoming mainstream in companies. Simplifying (standardized) cloud platforms are awaited. In the data management area, the transfer toward NoSQL (non-structured) data handling provides opportunities for new data-oriented applications, as well as block chain technology. In addition to digital currency, application areas related to the latter cover wide opportunities in distributed trust creation (smart contracts, distributed ledgers).

H. Process and Business Landscape

The benefit of technology innovation is ultimately achieved only if it is adopted in daily actions and in business processes. Many of the reports point out the important role of the user and consumer: Customer satisfaction, customer experience, fast time to market, on-demand based services, customization, digital services, and combining virtual and physical experience are the factors mentioned in the reports. People live in a hyperconnected world, in which social presence and experience sharing play an important role. The transition from face-to-face communication to the use of virtual communication channels is accelerating. New phenomena appear (AR-based games like Pokemon Go), new jobs are created (bloggers for example), and massive messaging - an increasing amount based on video - are an essential part of the current lifestyle. Everything can be shared almost in real time; nothing remains a secret (if so desired, sometimes even when that is not the case). Characteristics of business are changed by the opportunities provided by technology. New businesses are born and some exiting ones disappear. The IoT is seen as changing business processes. Future companies are a part of an intelligent digital mesh, which implements the idea of Connected Intelligence Everywhere. It applies data science technologies and allows the creation of intelligent physical and software-based systems that collaborate as a member of the digital mesh (a term introduced by Gartner). The use of AI in operations and big data in management increases productivity. The concept of product is changing: digitally enhanced products and services provide new experiences for customers, increasing their satisfaction and diversifying their experience.

I. Managing System Complexity

As business is to an increasing extent based on networking, even the systems used to support business implement the same idea. Instead of large monolithic information systems, the future is for solutions that provide open interfaces, modular structure, and versatile interoperability support; these can be called complex systems of systems. The role of widely accepted and applied frameworks – development platforms – is growing. These are used to structure and layer the complexity following generally accepted principles. They also guide development experts to use the right architectural components in system implementation. The practical implementation of system components partially remains the responsibility of end-users (casual programmers). Expert work focuses more on conceptualization and structuring (new skill profile).

J. Mobile Data and Internet Traffic

The future of the telecommunication landscape can be envisaged based on two reports by Cisco [5; 6]. These reports provide a wide detailed view of the progress during the next five years. In this paper we provide a very general synthesis and encourage the reader to study the reference reports in detail. There will be a rapid transfer from traditional (wired) Internet traffic to mobile.

Global mobile data traffic in 2015 reached 3.7 exabytes \((10^{15})\) per month; in 2020 it is expected to be 30.6 exabytes. The traffic has grown 4,000-fold over the past 10 years and almost 400-million-fold over the past 15 years. More than half a billion mobile devices were added in 2015; Smartphones accounted for most of that growth. The total number of smartphones will be nearly 50 percent of global mobile devices and connections by 2020 and will transmit four-fifths of mobile data traffic. Global mobile devices and connections in 2015 grew to 7.9 billion and are projected to grow to 11.6 billion by 2020 (exceeding the world’s projected population for that time of 7.8 billion). By 2020, aggregate smartphone traffic will be 8.8 times greater than
it is today, with a CAGR (Compound Annual Growth Rate) of 54 percent. Annual global IP traffic (wired and wireless) will surpass the 1 ZB (zetta, 10**21) threshold in 2016, and reach 2.3 ZB by 2020. Its CAGR is calculated to be 22 percent from 2015 to 2020. Smartphone traffic will exceed PC traffic by 2020. Smartphones will account for 30 percent of total IP traffic in 2020, up from 8 percent in 2015. In general, traffic from wireless and mobile devices will account for two-thirds of total IP traffic by 2020, wired devices 34 percent. There will be 3.4 networked devices per capita by 2020. Globally, IP video traffic will be 82 percent of all consumer Internet traffic by 2020. Virtual reality traffic in 2015 was 17.9 PB (10**15) per month; it will increase 61-fold between 2015 and 2020, a CAGR of 127 percent. The recent issue of IEEE Spectrum [18] reports a study of a daily usage profile of selected applications in one day period (July 11th, 2016): 33.4% Pokemon Go (AR), 22.1% Facebook, 18.1% Snapchat, 17.9% Twitter an average Iphone user spent; this confirms the fast growth of AR traffic also in real life.

Summarizing the numbers above indicates exponential growth both in total IP traffic and especially in mobile traffic. The transfer toward more intelligent and mobile devices is clear (mobilization), and the exponentially growing amount of users and increasing complexity of the data format (video, AR) is also clear. Network operators are responding to this by providing faster transmission technologies. The figures also confirm the findings discussed above in the forecast analysis part of this paper.

K. The Appearance and Speed of Changes

Gartner publishes an annual technology forecast in the form of “The Hype Cycle of Emerging Technologies.” It provides a good overview of the expected changes in the time span from two to over 10 years; innovations are classified in five categories according to the delay in reaching the “Plateau of Productivity.” The Hype Cycle 2016 is given in Fig. 3 [15].

Figure 3. Gartner Hype Cycle of Emerging Technologies 2016 [15].

The Hype Cycle distills insights from more than 2,000 technologies into a succinct set of must-know emerging technologies and trends that will have the single greatest impact on strategic planning. These technologies show promise in delivering a high degree of competitive advantage to organizations over the next five to 10 years. The technologies included in the hype cycle also summarize (partially) the earlier analysis given in this paper, and put some of the findings in the right position in the time span. Since the same analysis is published annually, comparisons between years also provide valuable information for the reader about the progress and changes identified. One good example of radical changes in the analysis relates to “big data,” which was located on the 2014 cycle in the “Trough of Disillusionment” with a time span of 5-10 years. In the 2015 Cycle, it had disappeared with the comment “Big Data is out, Machine Learning is in.” Instead of total disappearance, the phrase indicates the importance of AI as part of analytics, rather than the data itself, which is seen as an ordinary part of a variety of technologies.

The 2016 report indicates that technology will continue to become more human-centric. It will introduce transparency between people, businesses, and things. The evolution of technology is becoming more adaptive, contextual, and fluid within the workplace, at home, and interacting with businesses and other people. Critical technologies include 4D Printing, Brain-Computer Interface, Human Augmentation, Volumetric Displays, Affective Computing, Connected Home, Nanotube Electronics, Augmented Reality, Virtual Reality, and Gesture Control Devices. Smart machine technologies will be the most disruptive class of technologies over the next 10 years. Enablers for this progress are the radical growth of computational power, near-endless amounts of data, and unprecedented advances in deep neural networks. Smart machine technologies harness data in order to adapt to new situations and solve problems that no one has encountered previously. The following technologies are seen to play key roles: Smart Dust, Machine Learning, Virtual Personal Assistants, Cognitive Expert Advisors, Smart Data Discovery, Smart Workspace, Conversational User Interfaces, Smart Robots, Commercial UAVs (Drones), Autonomous Vehicles, Natural-Language Question Answering, Personal Analytics, Enterprise Taxonomy and Ontology Management, Data Broker PaaS (dbrPaaS), and Context Brokering. The shift from technical infrastructure to ecosystem-enabling platforms is laying the foundations for entirely new business models, which are forming the bridge between humans and technology. Organizations must proactively understand and redefine their strategy to create platform-based business models. The key platform-enabling technologies include Neuromorphic Hardware, Quantum Computing, Blockchain, IoT Platform, Software-Defined Security, and Software-Defined Anything (SDX).

The paragraph above explaining some details related to Fig. 3 is quoted from the original source with minor changes and modifications.

IV. SUMMARY OF CHANGES IN ICT

The purpose of TCAC framework Step 3 is to classify the changes analyzed in four categories: Incremental changes, Radical changes, Changes in technological systems, and Changes in paradigms (explained in Paper I; Jaakkola et al. 2017) to enable the publishing of the results (Step 4). Figure 4 summarizes the technology analysis discussion of this paper in the form of the ICT Change Analysis and Categorization (ICAC) framework.
The classification may cause criticism—we accept that. The approach is partially subjective. However, it reflects our experience-based findings. Our aim is first to provide an expert opinion for those that are interested in the topic. Secondly, we want to provide a tool for applied use for those who are ready to do this kind of.

How to benefit from the analysis? This is the subject discussed in the following section.

V. HOW DOES IT AFFECT THE EDUCATION SECTOR?

At the beginning of our paper we promised to answer the question “What should every educator know about changes in technology?” The answer can be divided into two parts—effects on the education process itself, and effects on the goals of education from the content point of view.

The education process part is the easier sub-question to answer. Every educator should recognize the current situation and be prepared to use tools and technologies that support the study goals in the best way and suit the selected pedagogical approach. An additional aspect that must be taken into account is the audience, i.e., students. Education must motivate them and take into consideration their built-in behavioral patterns. At the moment,

- students in higher education start to be members of generation Z (birth years that range from the mid-1990s to the early 2010s; coming of age today); for the details of the generation classification see e.g. [3; 2]. Note: in different sources the year limits are varying a bit.
- the majority to generation X (birth from the middle 1960s to the late 1970s; coming of age late 1980s to late 1990s) and
- the oldest to the generation known as baby boomers (birth from the late 1940s to the late 1960s).

Recognizing the age profiles is important. Every generation has its own attitudes and values, technical skills, attitude to work, goals in life, interests and basic (professional) skills inherited from their education and adopted through their life experience. The educational methods should follow the needs of generation Z, which can be characterized by the term “digital native.” They are used to the Internet, computers, mobile devices, network-based communication, etc. They are nomads (used to working independently of time and place) and the concept of time differs from that of the older generations. The ICT skills of non-generation Z are not native but learned and variance seems to be wide. Consequently, every educator—either digitally native or learned—should be aware of the opportunities that technology provides for education both now and in the future. Therefore, understanding technological changes is necessary. New media supported learning methods based on distance participation, the blended learning approach (mixture of videos, face-to-face classes, self learning), time independence, and the use of modern technology is worthy of consideration. Answers to the question “What and how to use?” can be supported by the findings of our analysis.

The content of education is a slightly more complicated aspect. The perspective in education is partially on today and partially on the future. The time span from studies to work varies between education levels. In vocational education the time span is close to today; the objective is to provide skills and readiness for immediate utilization. In contrast, in higher education, the utilization span is longer but forgetting the ability for short-term applicability is not
The problem with technological forecasting is that finally, when we have found a good solution for everything, something unexpected happens: everything is sensitive to radical changes in our environment – the climate, political situation, etc., belong to factors outside our sphere of influence. Forecasting the future is no easy task; there is also a saying that neither is the forecasting of the past (what would have happened if we had selected an alternative path from the past to today; what would be our today then). One thing at least is sure: computerization in all its forms is continuing rapidly. A lot of tasks are done better and faster by computers: mathematical tasks, data management, combining information chunks to form knowledge, management of detailed data, understanding foreign languages, etc. It has been predicted that the computer-brain interface will become reality in around 10 years (still in the hype phase, however). We already have trials to transfer brain signal data for analysis by computers and interpretation as human feelings. This would be the first step.

What will the kernel of human skills be in the future? Detail management and fast calculations are no longer so important. The world and systems are becoming more and more complex. We have to be able to manage the whole - modularization and interfacing the pieces to collaborate. It is good to finish the paper with the saying of Larry Page (CEO of Google): “The main reason why companies fail is that they missed the future”. So – be very worried!

Interdisciplinary utilization of IT

S. Neradová, S. Zitta
University of Pardubice, Faculty of Engineering and Informatics, Pardubice, Czech Republic
sona.neradova@upce.cz

Abstract - This article describes a project realized in laboratory seminars. The aim was to practically show students utilization of information technologies in a non-technical discipline. The project involved observing and monitoring breathing of chosen plants. Recorded data were subsequently analysed into several conclusions. The goal was to design and practically build a solution which would enable to record the collected data from the sensors. The designed system contained wireless module and sensors for measuring temperature, humidity and CO₂ concentration. The collected data were transferred to the web server ThingSpeak. Data values could be studied through an internet browser and also downloaded for further analysis. The major founding is that interdisciplinary skills led to successful creation of financially undemanding functional unit, which enabled automation of the data collection. The students were given the opportunity to design an IT platform, to implement and to analyse collected data. Individual components of the project required combination of the skills from informatics, physics, biology and mathematics.

I. INTRODUCTION

Generally, education programs and concepts of all schools should preparing students for the “real life”, for different tasks in different companies and organisations. Logically, the primary target of every school is to provide students the best education and knowledge of the studied disciplines. This is not an easy task, especially in such dynamic discipline like information technologies. Students have to learn many things, the education programs are focused on programming languages, networking, data security, hardware… The IT world is changing very fast, technologies, which were new when students started are often obsolete when they graduate. This is also very demanding for teachers, who should follow this rapid development and create and continuously update content of their lessons. Although teachers have to focus on the content of the study and how to overhand the knowledge to students, they shouldn’t forget that it is also very important to guide students, how they can practically use their knowledge and interconnect it with other, totally different disciplines, what tasks they will face after leaving the school. And, last but not least, an interesting project and its’ successful finishing can create some sort of “positive feedback loop”- motivate students for self-study of the given topic and thus deepen their knowledge.

As mentioned in the previous text, a part of the education program of any school with IT as a subject of the study should be a project, where students can prove their ability to practically use what they have learned. Students should be able:

- Understand and analyse the given problem.
- Design a solution (with possible variants) on a theoretical level.
- Choose the best variant with regard to the feasibility, delivery time and given budget.
- Practically realize the chosen variant.
- Evaluate the result, conclude what they have learned.

II. THE PROJECT

General description

The described project has been realized with students of the High school of electrical engineering (author is also teaching in this school). The aim was to show students an example, how the IT can be used in a real application for measuring and collecting non-electrical values. To demonstrate their ability to fulfill such task, students had to design a measuring system to ascertain and document development of plants in closed system of breathing gasses (oxygen and carbon dioxide) in natural light conditions with different leaf surfaces and in different stages of their development. An important part of the tasks’ definition was to work with very limited financial budget to motivate students to carefully consider the price / performance ratio as it is usually required in the commercial environment.

Further processing and evaluation of the collected data was not a part of this project. However, the collected data were used in another students’ project (students from another school).

- Monitoring CO₂ concentration, temperature and humidity in a closed environment with experimental plants (there were 4 plants to be observed).
- Storing the collected data for later analysis and evaluation (the evaluation of the collected data was not a part of the project for students of the electro technical school).
- Keeping the costs of the designed system as low as possible.

Analysis of the project task

At the beginning of the project, it was necessary to analyse the task and determine the particular steps. Initially, the following questions had to be answered:
• How will be the desired quantities measured?
• How long will be the interval between particular measurements?
• How will be the measured data transferred to the data storage?
• Where will be the collected data stored?
• How will be the technical layout designed?

Solution for the particular steps

Once the particular steps were defined, students could start with their realisation.

Measuring the desired quantities

Selecting the most suitable sensors was a crucial part of success of the project. Students had to consider several parameters – accuracy of the measurement, digital or analog output, separate or integrated sensors and obviously the price. As there wasn’t an absolute accuracy required (more important was to monitor temperature changes during day), there were sensors DHT11 and DHT22 chosen for their excellent performance vs price ratio. These sensors provide acceptable accuracy; integrate temperature and humidity measurement in one unit at low price. There were both types selected to get the opportunity to compare them in a real environment. The situation with CO₂ sensors was different: available sensors are mainly dedicated for industrial applications; their price was therefore too high for a student’s project. The only sensor acceptable for the project budget was the MQ135, although this sensor has some drawbacks that students had to overcome.

Determining the intervals of measurement

Students have to find the balance between the amount of collected data and reliability of the measurement. As compromise there was an interval of 10 minutes chosen: it doesn’t generate too large data but still provides enough data to compensate failures (caused by interferences, voltage drops etc.).

Data transfer to the data storage

There were two options considered, how to connect the sensors: wired and wireless. Students had to consider pros and cons of both solutions. Wired connection offers higher reliability, but there would be a dedicated computer (with additional interface) needed for connecting the sensors. For wireless connection, there were just Wi-Fi modules required. Potentially lower reliability of the connection could be easily compensated by certain redundancy of measured data and calculating the average. As the most suitable Wi-Fi module and interface for the sensors there was the ESP8266 chosen. Students considered also using Arduino or Raspberry, but they wouldn’t offer any advantage in this application compare to the ESP8266.

Storing the collected data

Also for this particular task, students had two options: storing the collected data on a local server or using one of the publicly available cloud services. Using a local server would require certain skills for programming web accessible database and require an additional HW.

Generally, it wouldn’t bring any advantage comparing to a public cloud, especially because the Thingspeak cloud provides services, which were specifically designed for collecting data using IoT. Using Thingspeak automatically solved tasks like programming a database and backup the collected data. The limits of the free of charge version of this service (which is available for non-commercial projects) weren’t affecting this project.

III. TECHNICAL LAYOUT

On the basis of the previously described analysis, technical documentation was created. The following table shows the required numbers and types of particular components.

TABLE I. TECHNICAL DOCUMENTATION

Wiring diagram is shown on the next picture.

Figure 1. Schematic wiring diagram

The experimental plants were planted into pots and covered with 0,7 litre clear glasses. Along with the plants,
sensors MQ135 [2] for measurement of CO₂ concentration and sensors DHT11 [3], DHT22 [4] for measurement of temperature and humidity were situated under the glasses. The sensors were connected to the module ESP8266 with short cables. The module provided reading of the entries from the sensors in 10 minute intervals. Relatively short interval of 10 minutes was chosen to enable elimination of drop-outs caused by random interference. The sensor MQ135 does not provide data of measured temperature but voltage equal to the temperature, therefore the module ESP8266 also performed the conversion. Analog input of the module ESP8266 was used to connect the sensor MQ135. Dependence of the module MQ135 on the temperature is not neutral, therefore correction constant for each of the sensors was established by measuring the voltage at 0°C and 20°C. The constant was afterwards used during the conversion. The module ESP8266 also dispatched the collected data about CO₂ concentration, temperature and humidity via local Wi-Fi network to server Thingspeak.com where the data were saved (including dates and times). After the experiment, the collected, saved data were downloaded from the server in csv format and subsequently evaluated in program MS Excel.

I. THE ESP8266 MODULE DESCRIPTION

![The ESP8266 module](image)

The module ESP8266 is an affordable module with control microprocessor, programmable GPIO, HSPI/UART/PWM/12C/12S interfaces and integrated Wi-Fi unit. The module exists in multiple variations which differ with number and type of inputs / outputs and with RAM. The variation ESP8266 ESP-12E Development Board with integrated USB interface and 4MB RAM was used in this experiment. The integrated USB interface facilitates programming of the module and it can be also used for power supply of the module. The firm Espressif Systems is the producer of the module. Detailed data and technical parameters about the module are accessible at the producer’s webpage [https://espressif.com](http://espressif.com).

Many programme libraries and even actual firmware for the module ESP8266 are accessible. Its programmes can be written in multiple programming languages. In this experiment, firmware NodeMCU 1.5.4.1 was uploaded to the module, and scripting language Lua was used for programming. Programmes in the language Lua can be written in any text editor. In this project, a specialized editor LuaEdit was used (free-downloadable e.g. at [http://luaedit.sourceforge.net](http://luaedit.sourceforge.net)) which provides expanded options for editing and tuning of programmes written in the Lua language [5]. The firmware and the actual service programme for communication with the sensors, the temperature calculation and the data dispatch were uploaded to the module via interface ESPIplorer (see [http://esp8266.ru](http://esp8266.ru)) which is also freely available, and is specially designed for the ESP8266 modules [6].

II. THE MQ135 MODULE DESCRIPTION

The module MQ135 is sensor-based module designed for measurement of gas concentration. The gas sensor, operative repeater LN393 for output amplification, analogue voltage output and digital output with TTL level are attached to the module. The voltage on the analogue output is directly proportional to the gas concentration. The conversional characteristics between the gas concentration / voltage and additional parameters are stated in the producer’s datasheet.

![The module MQ135](image)

The DHT11 and DHT22 modules description

The DHT11 and DHT22 modules are designed for temperature and humidity measurement. There is one data output accessible for the connection to the control microprocessor. Also, two power supply pins are present. The difference between the DHT11 and DHT22 types occurs in the range of measurement and the sensitivity. The DHT11 type measures temperature in the range 0 – 50 degrees Celsius with accuracy ±1 °C and humidity in the range 20 – 90 % with accuracy ±4 %. The advanced module DHT22 enables to measure the temperature in the range -40 to +80 degrees Celsius with accuracy ±0,5 °C and the air humidity in the range 0-100 % with accuracy ±2 %. Parameters of the modules are stated in the producer’s datasheet.

![The DHT11 and DHT22 modules for temperature and humidity measurement](image)

III. THE THINGSPEAK SERVER

In this project, the Thing speak.com server was used as the data storage. This server does not offer only the storage and basic data visualisation but also an analysis via MATLAB programme, warning dispatch, Twitter messages dispatch and other functions. Some of the functions are available only in the paid version,
nevertheless the server is for non-commercial use (with limited number of entries 3 million / year) free of charge.

To use the server, it is necessary to create a user account. After logging in to the account, it is possible to create so called channels where the data are saved. The channels or more precisely the saved data can be tagged and their development can be observed via charts. Data from 8 devices is the maximum which is possible to store in one channel. The saved data are downloadable in csv format at any time. It is also possible to upload data to the server (again in the csv format). The channels can be established as private, thereafter it is necessary to log in for the access to them. The second option is to establish the channel as public, thereafter the view of the channel is freely accessible. When creating a channel, a unique 16 digit alphanumeric chain, so called API-Key, is generated. This chain serves for identification of the channel and it is necessary to enter it when programming the log in procedure of the device connected to the Thingspeak.com server.

Extensive documentation, tutorials, examples of the programming code (including links to extern servers like GitHub or Instructables) and community forum, where it is possible to ask other users and search for solutions, are at disposal at the server.

Following pictures show the data, which were stored on the Thingspeak server.

![Figure 5. Output voltage](image)

![Figure 6. Calculated CO₂ concentration](image)

![Figure 7. Measured temperature](image)

![Figure 8. Measured humidity](image)

IV. CONCLUSION

The goal of the project was fulfilled. The students designed and tested solution, which enabled collecting data from the sensors. Students have learned how to analyse the given task, split it into particular steps and consider possible variants of the solution for each particular step. They have learned that the solution should be the best compromise between the technically ideal solution and the practically available resources.

The students were acquainted with settings of hardware, software installation and data storage at the Thingspeak server. During the project, the students learned how to connect the real word with the digital one. They tried the measuring of physical quantities via sensors in practise. The mutual cooperation between the students during solving the project leads to the cognition that interconnection between different disciplines is very important.

ACKNOWLEDGMENT

This work and contribution is supported by the project of the student grant competition of the University of Pardubice, Faculty of Electrical Engineering and Informatics "Usage of ambient intelligence in the area of information systems and their communication".

Maximizing Quality Class Time Using Computers for a Flipped Classroom Approach

C. P. Fulford, fulford@hawaii.edu and S. Paek, spaek@hawaii.edu
Learning Design and Technology, University of Hawaii at Manoa, Honolulu, Hawaii, USA

Abstract - This study presents a two-course sequence of graduate instructional design courses that were developed and implemented using a flipped classroom model for both online and face-to-face contexts. This model is an instructional strategy that reverses what is traditionally done at home and what is done at school, such as watching video lectures at home and working authentic problems in class. The presentation will 1) demonstrate how the two courses were designed and developed, 2) share findings from student responses on surveys regarding perceptions and satisfaction with the new model, and 3) discuss the successes and challenges of implementing these courses.

I. INTRODUCTION & PROBLEM

Computers in education have reached a new level of capability. With connectivity so widespread, teachers have new opportunities to utilize them in more creative ways. One way to use them strategically is through “flipping the classroom”. The idea behind flipped classrooms is that work traditionally completed as homework, such as problem solving, writing, and group work is better undertaken in class with the support and guidance of classmates and the instructor [1]. In contrast, activities such as listening to a lecture or watching videos are better accomplished at home [2]. Thus, a truly flipped classroom uses in-class time for active learning and problem solving on the part of students.

While the benefits and drawbacks of flipped classrooms have been explored elsewhere [1, 3, 4], Bishop and Verleger [5] explain that the flipped classroom model “represents a unique combination of learning theories once thought to be incompatible—active, problem-based learning activities founded upon a constructivist ideology and instructional lectures derived from direct instruction methods founded upon behaviorist principles” (para.1). Drawing on this powerful idea, the authors designed and developed a two-course sequence of instructional design courses in a graduate program in Hawaii.

Instructional design (ID) is a “construct that refers to the principles and procedures by which instructional materials, lessons, and whole systems can be developed in a consistent and reliable fashion” [6, p. 574]. It is the practice of creating “instructional experiences which make the acquisition of knowledge and skill more efficient, effective, and appealing.” [7, p. 2] Teaching students about the principles and procedures of ID requires an emphasis on both theory and practice.

Accordingly, many ID courses rely on project-based learning models, ones that organize learning around design and technology projects [8]. Although effective in many contexts [9,10], it can be difficult for students, particularly those starting a Master’s program in ID, to start working on a project in the beginning of their program, as they often have little to no background. This reality can be a challenge for instructors teaching introductory ID courses at the graduate level.

For example, how can an ID course be designed to balance theory, research, and practice? How can an ID course cover enough breath of content versus providing enough depth? How can an ID course provide authentic experiences while being able to use well thought out academic cases? Essentially, how can more content be included in already full courses?

With these challenges in mind, the authors, faculty members in a graduate program that emphasizes instructional design, developed two courses using a flipped classroom instructional model. What the instructors hoped to do was to create a studio course where students could work on ID projects while the instructor was available to assist. This purpose of this paper is to discuss how the courses were developed, and investigate how they changed over a two-year period.

II. LITERATURE REVIEW

A. Benefits of Flipped Classrooms

Flipping the classroom involves providing instructional resources for students to use outside of class so that class time is freed up for other instructional activities [11]. Literature shows that there are many benefits to flipped classrooms. For example, it encourages active and independent learning thereby increasing student engagement, strengthening team-based skills, personalizing student guidance, and focusing classroom discussion [1,12].

Flipped classrooms may also provide for better interaction and communication since it may allow teachers greater insight into students’ grasp of information and learning as a result of increased student to teacher interaction. When a flipped classroom is designed well, it can increase flexibility and provide nearly unlimited access to learning materials [4].

Flipped classroom pedagogy can also address situations in which students miss lectures due to illness or...
who are engaged in university-supported activities such as athletics. It allows students to move at their own pace, access instruction at any time, and obtain expertise from multiple people [4,13].

B. Concerns About Flipped Classrooms

Though, there are some concerns about flipped classrooms. First, teachers must ensure that students have connectivity and access to the materials being provided online [14]. And with a growing movement towards no homework, can teachers justify the increased time requirements outside of class without improved pedagogy in class?

Use of lectures to provide instruction may disregard individual student learning styles unless ample materials are used to overcome this deficit. Students experienced with the out-of-class instruction may not be as interactive as a lecturer who is able to directly answer students’ questions and engage them in discussions. The online prerecorded lectures don’t have the same ability to monitor comprehension and provide just-in-time information when needed [15].

Flipped classrooms do not work just by moving everything to home tasks. The lack of adapting the classroom environment to reflect the flipped classroom’s ability to support student-centered learning can hinder the methods effectiveness. This paired with the lack of accountability for students to complete the out-of-class instruction, can limit the desire of some teachers to try this new strategy. [16].

III. METHODOLOGY

A. Development

Winter [17] proposed that “Flipped learning is composed of two integral but inherently different learning spaces (p. 68)” . The “individual space” is now the place where students receive direct instruction, such as recorded lectures, web-based materials, and readings. The students themselves generally manage how they approach these materials.

The “group space” is in the classroom, which can provide a rich source of interaction and communications. Here they may work on assignments, engage in activities, and dialog with the teacher and other students. The instructors used this idea, and both behaviorist and constructivist theories and models in developing both group learning spaces and individual learning spaces for this project [17].

The first year was a heavy development period that progressed week by week, as the individual learning space was developed. The platform for the course was a university-based version of Sakai, a learning management system (LMS). Within this system, weekly modules were created that contained all of the materials.

Over the first year, online lectures of narrated slidshows were produced that were carefully recorded and edited to increase the production value and decrease the length of the videos. A YouTube channel was created for open access to these for other instructors of ID at

https://www.youtube.com/channel/UCPqBgPU11GL-xdN9Qhpuc0g.

Research literature, web resources, professional examples, and past exemplary student projects were found and posted. To ensure accountability for students were accessing and using the required materials, a discussion group was set up for students to post their weekly reflections on the material they had watched and read. Each student was required to post one reflection with a relevant question at the end and respond to two other students’ reflections and questions.

The group learning space was during the scheduled class time. The instructors made short presentations to follow-up on the week’s topic, answer questions, note interesting comments or questions from students’ reflections, and clarify the assignments for the next week. Then, activities were used to engage the students in active learning of the topic. Students were given time to work in their teams on their course projects, and then present progress on their projects and have it critiqued. Peer review sessions in both courses encouraged students to learn from each other and learn designer roles used in the workplace. They also made end of project presentations.

B. Setting

The courses chosen for redevelopment in this project were the first two ID courses that students take in the masters program for Learning Design and Technology. Both are core courses that prepare ID professionals. One is taken in the first semester, and the second in the next semester.

LTEC 600 - Theory and Practice in Educational Technology covers foundational processes, methods, theories, and strategies, and discusses how these are put into practice in the field. It uses academic case studies and teamwork. The products and outcomes of the course are: a front-end analysis developed using student’s new knowledge of systems theory, need assessment, change theory, task analysis; and a technology project using the new models and methods they have learned. They also develop their professional skills including teamwork, grant writing, and presentation skills.

LTEC 613 - Instructional Design and Development covers the complete process of ID and uses authentic projects and teamwork. The products and outcomes of the course are a technology-based individualized instructional module developed using the students’ practical application of design methods, processes, and strategies. They also develop test and survey instruments, apply visual design principles, and engage in a practical experience with formative evaluation. They continue to develop their team and presentation skills.

C. Participants

Participants were in LTEC 600 and 613, the two sequential courses for first year Master’s students. There was one section taught on campus and the other taught online. A full professor taught campus section and an assistant professor taught the online section. There was one teaching assistant shared with both sections each semester who made up the team. This team met once a
week for two years to develop the course and conduct the research.

Because of slightly different schedules in the first year, the online section could be mostly flipped one semester earlier than the campus section. Even now it is almost impossible to make the two sections exactly identical. Class activities due to the class time difference and the limited face-to-face interaction for online students are often modified.

These courses were for graduate students, and relied solely on a flipped classroom model for both online and face-to-face sections. Two sections of each course were offered in two different platforms over a two-year period. There were 25 students in the first year and 22 in the second year.

IV. PROCEDURES

This paper evaluates student perceptions regarding the design and use of the flipped classroom model particularly investigating differences between students in the first year of development and that of the second year.

A. Research Instrument

A questionnaire was distributed at the end of the 2nd year. There were 10 sections including instructions and demographics. In six of the sections, there were 48 Likert type questions with the “not” side equal to 1 and the “very” side equal to 5. In all cases except the section on “challenges” “not” signified negative and “very” signified positive.

There were 14 open-ended questions, typically one at the end of each section for additional comments on the topic and 4 in the final section for opinions, comments, and suggestions.

The response rate was very high at 77%. Of the 47 students in the courses, 36 responded. The sample consisted of 65% females and 35% males. Because this was a master’s degree and professional program, there were a relatively high percentage of older students.

B. Independent variables

There were two independent variables: year of the trial and delivery method. (Please note, data regarding comparisons of online versus campus will be reported in another paper. This paper compares only within group data.)

There were a total of 36 students in the sample. They were fairly evenly distributed. (See Table 1.)

C. Dependent variables

Dependent variables were drawn from the various sections of the questionnaire. Each had Likert style questions and an open-ended question. These were:
- Engagement – 8 questions,
- Effectiveness (compared to a traditional class) – 7 questions,
- Benefits – 8 questions,
- Individual space – 11 questions,
- Group space – 8 questions.

The individual space and group space questions targeted specific strategies that were used in the design of these particular courses.

V. RESULTS AND ANALYSIS

To examine if there were any differences between Year 1 and Year 2 in terms of how students perceived the flipped classroom model, the survey data was analyzed using independent samples t-tests. Results of this study are reported using a 2-tailed significance at the (p<.05) level.

A. Engagement & Effectiveness

There were no significant differences with engagement between the first and second year students with regard to engagement, though Year 2 was marginally higher. There were however, three significant findings with regard to engagement within campus students. Second year campus students reported significantly higher enjoyment, t(18)=2.22, p=.040, efficiency, t(18)=2.12, p=.045, and engagement, t(18)=2.821, p=.011, than the first year campus students. (See Table 2.)

</tbody>
</table>

* Significant at p<.05

When comparing the effectiveness of flipped classrooms to traditional ones, all Year 2 students perceived engagement compared to traditional classes was only marginally higher than all Year 1 students. Though within campus students, those in Year 2 reported the flipped classroom significantly higher, t(18)=2.30, p=.033 overall, especially with regard to it being more engaging, t(9.88)=2.712, p=.022 and efficient, t(18)=2.72, p=.014 and marginally more effective than a traditional class, t(11.18)=2.11, p=.058. (See Table 3.)
This quote shows the typical sentiment of some students.

At first I was quite resistant to the idea and it forced me to change my way of thinking and learning, but now that I can read backwards so to say it makes a lot of sense. Highly efficient and effective. For someone who has a full time job and going to school at night with limited amounts of energy, this method was a LOT more effective and conducive. Year 2, Campus Student

B. Benefits

There were no significant differences in benefits overall between Year 1 and Year 2, however there were differences within delivery methods for years in both the campus delivery and the online delivery. There were significant differences between the first and second year campus group with two questions regarding: having the ability to rewind and repeat the videos, \(t(9.72)=2.35, p=.041\), and not having to listen and follow the lecture in class \(t(18)=-2.76, p=.037\). (See Table 4.) There were also significant differences \(t(18)=-2.26, p=.036\) with higher average benefits for Year 2. Year 2 also showed marginally higher differences regarding: having materials in various formats and having more class time to work in groups.

TABLE 4. BENEFITS - YEAR COMPARISON CAMPUS DELIVERY

<td>4.45*</td>
<td>.934</td>
</tr>
</tbody>
</table>

* Significant at p<.05

Interestingly the opposite occurred in online sections. Students in Year 1 (\(M=5.00, SD=0.00\)) strongly agreed that having more class time to work in groups was beneficial, which was significantly higher, \(t(14)=2.53, p=.035\) than the responses from Year 2 students (\(M=4.56, SD=.53\)). Overall, students in Year 1 (\(M=4.80, SD=.307\)) valued benefits of flipped classroom higher than Year 2 students (\(M=4.41, SD=.315\)), and the difference was statistically significant, \(t(14)=2.44, p=.029\).

This student quote is an example of challenges compared to benefits.

The workload was a bit much especially in a flipped classroom setting, as it feels like there’s a lot more to stay on top of compared to a traditional classroom. Flipped classroom discussions are great in a sense that students will be able to provide better ideas after taking some time to come up with their own thoughts. Year 2, Campus Student

C. Challenges

Overall between the two years, students in different years found different things challenging. Sixteen student sin Year 1 (\(M=3.38, SD=957\)) reported significantly higher levels of challenge with recorded lectures that are less detailed, \(t(34)=2.170, p=.037\) than 20 students in Year 2 (\(M=2.60, SD=1.42\)). Though the students in Year 2 (\(M=3.40, SD=883\)) found the schedule significantly more challenging, \(t(34)=-2.14, p=.039\) than the Year 1 group. (\(M=2.75, SD=9.31\)).

Within the campus group, Year 1 students were significantly more challenged than the Year 2 group with regard to two survey items and the overall average challenge. The survey items were: Recorded lectures are less detailed than in class lectures, \(t(15.06)=2.84, p=.013\), and working in class in groups with the instructor watching, \(t(18)=2.88, p=.010\). The average of all survey items on challenge was also significant, \(t(18)=2.25, p=.037\). (See Table 5.)

<td>.694</td>
</tr>
</tbody>
</table>

* Significant at p<.05

Within the online group, Year 2 also reported marginally higher levels of challenge with the schedule. To highlight the results regarding challenges, here are three student quotes.

Recorded lectures allow you to work at your own pace, but allow you to ask questions in the next face-to-face meeting, this might work for some but might not for others. Year 1, Campus Student
Sometimes the schedule was confusing since not all classes are flipped and knowing what was due for what class was sometimes hard. Year 2, Campus Student

D. Individual Learning Space

With regard to strategies used in the individual learning space, there was one significant result at the p<.05 level. First-year trial students reported higher, t(34)=2.07, p=.046 usefulness for reflections discussions (M=3.81, SD=1.109) than second year students (M=3.00, SD=1.21). In the online group there were marginally higher scores for students in the first year with regard to reflections. Overall the students seemed happy with the individual learning space. Here are some typical quotes.

Recorded lectures are great since you can pause and rewatch as many times as needed, and do some research at the same time. I’ve learned a lot more watching recorded lectures than traditional lectures since it is hard to keep up with traditional lectures and is easier to lose focus. We can always ask questions by emailing or talking to the instructor in person in class, so that was never an issue. Year 2, Campus Student

I feel as though I might not have had access to so many resources and information had the class not been flipped. Year 1, Online Student

E. Group Learning Space

With regard to the group learning space there were no significant differences between Year 1 and 2, only marginal differences. First year students felt more strongly about the ability to share their work and have it critiqued, and second year students about the short instructor presentations to review content and preview the next week.

Within delivery methods there were three topics that were significantly different at the p<.05 level: in class group time, the ability to share and critique projects, and peer reviews.

First-year online students reported significantly higher usefulness for in-class group time to work on projects, t(8.00)=2.530, p=.035, group presentations to share and critique work, t(8.00)=3.162, p=.013 and peer reviews of projects, t(8.00)=2.350, p=.053, than second year students. Second year campus students reported significantly higher usefulness for in-class group time to work on projects than first year campus students, t(8.00)=3.50, p=.008. These students also marginally preferred the short instructor presentations, t(18)=1.743, p=.098. (See Table 6.)

Here are some thoughts from students.

Excellent vehicle to accommodate varying paces and skill level students. Makes more efficient use of class time assuming that all students have exposed themselves to the course content before it is talked about in class. Online Year 1

I think spending time in class actually working on group work and applying the information learned through videos and readings is a more efficient use of time than being lectured to. Year 2, Campus Student

VI. DISCUSSION

Some of the not so surprising differences occurred between the first and second year groups. There are particularly more significant differences between the campus students’ Year 1 and Year 2 particularly with regard to engagement, benefits, and challenges. Obviously there were some things that needed to be worked on, most especially expectations and understanding of how flipped classrooms work. Online students are generally expecting a lot of work online outside the classroom. Campus students don’t seem to have this expectation. Since online courses are already closer to the flipped model, it is not surprising that the campus students had a greater appreciation of its effectiveness compared to a traditional class once it was fully implemented. They appeared to see better engagement, more benefits and have fewer challenges the second year.

In an effort to improve issues of engagement and effectiveness, an orientation to flipped classrooms was added in the second year to create a better understanding of the process and to help set more positive expectations. In the future we will also use the results of this study to discuss the benefits and some of the challenges they will face in the flipped classroom.

In the study there appeared to be a clear lack of understanding of the course schedule using the flipped classroom model. In addition to being one of the challenges, this came up in the comments and in class in Year 2. As a result, the schedule has been reworked and more effort put into clarifying it in the short presentation each week at the beginning of each class. This seems to be working. The third year students will also be surveyed for continual improvement.

Within the campus group, the second year students perceived greater benefit from the ability to watch and rewind the videos than the first year students, most likely because they given the full lecture and then the video during much of the first semester. In the department’s
online courses, video recordings of the class proceeding are generally posted after class, so these students are more accustomed to having videos of lectures available.

Though it was not as clear from the data, the video lectures had a number of appreciative comments. This was gratifying as a lot of effort were put into making them as professional as possible. Producing the lecture videos is very time consuming, but is well worth the trouble. Student reflections often commented on their usefulness, as do others who view them through the YouTube.

Although the group space had higher significance in some areas in the first year online group, overall the group space means are high, particularly time to work on projects with teammates engaged in discussions and critiques and peer reviews has a positive response. Since online students are not physically together, and sometimes not even on the same island, it is understandable that having time for group interaction is essential. To provide even more group time, the presentation at the beginning of the group time is worth working together. A team approach is definitely worthwhile.

The biggest change that has occurred over time has been increasing the amount of student work time in class and providing instructor facilitation. It is really hard to give up the mindset and control one has in a traditional classroom. It is a little like trying to drive on the other side of the road. You have always prepared for class in a particular way and now your role is completely different. It took time evolve these courses into truly flipped classrooms. Although it does take substantial time and effort to develop everything needed, the model does appear to have considerable benefits as well as a few challenges.

ACKNOWLEDGMENT

We would like to thank our Learning Design and Technology students who were patient in the process of developing these courses, especially those that subsequently participated in the research. We would especially like to thank our teaching assistants Dainan M. Skeem, Kimberly Suwa, Elon Ng, and Bhonna Gaspar who served on our team and contributed their ideas during the development process.

Abstract – In this study is explored the changing path of e-Learning discipline since its appearance to nowadays. E-Learning has evolved in different ways in different sectors therefore it might have different implications in certain periods of time in certain sector. A small number of things have changed in the last half century as much as the way we learn. Consequently, a significant research is going on throughout these periods in identifying cases of success in the application of e-learning. In this context, the study presented in this paper is about the analysis of the evolution on research papers related to e-learning and any form of computer assisted education published in the last five decades. We show the methodology for gathering these papers from the DBLP database, including their authors and conferences where they are published. We present the results from this study showing how published work regarding e-Learning is distributed through years, which are the conferences where these papers show up mostly and what is the collaboration community in this framework.

I. INTRODUCTION

Defining e-Learning is a challenge having in view the fact that the common definitions are so extremely wide-ranging that almost any kind of learning that involves electronics seems to fit the definition. Although initially used in the business sectors for computer-based or online training, the term ‘e-Learning’ has increasingly been taken up within education. E-Learning generally refers to learning that is prepared, delivered, or managed using a variety of technologies which can be set out either locally or globally.

However, it is essential to note that e-Learning has evolved in different ways in different sectors therefore it might have different meanings in certain periods of time in certain sector. According to Paul Nicholson in his article about the History of e-Learning “The History of e-Learning across all sectors is best summed up as: ‘Opportunities multiply as they are seized.’ as for the past 40 years, educators and trainers at all levels of Education, Business, Training and the Military made use of computers in different ways to support and enhance teaching and learning” [12]. As a result, the contemporary use of the term ‘e-Learning’ has different meanings in different contexts and different periods of time. In other words, although the prefix ‘e’ in e-Learning gives us information that the course is digitized and can be stored in electronic form, it was the rise of Internet that brought the prefix ‘e’ into popular usage. To be more specific, almost in the same time with the increased usage of Internet we noticed the dawn of new disciplines such as e-commerce, e-business and e-government, what makes even more clear that it is the Internet that is really the defining technology in e-Learning. Actually, it is the online aspect that makes e-Learning different and if an institution is dealing with the essential concerns that e-Learning raises for education, it needs primarily to focus on the particular characteristics of the Internet. Learning from CD-ROMs has been in use for quite a long period but because the offline mode of delivery they carry out the same functionality as books and they do not tackle the issues that the Internet raises.

Hence, a more appropriate characterization presenting the current use of e-Learning would be as learning experience that utilizes Internet-related technologies to some degree. This definition highlights the Internet as the primary medium with regards to e-Learning but does not leave out combination with other media and approaches.

Teachers are using more and more technology and technological tools to improve their teaching practice aiming to enhance the learning process for their students. There are a lot of research papers which illustrate various aspects that describe tools and methodologies for improving the learning process, together with the obtained results after applying these approaches. On the other hand, although new century frameworks are thought to advocate new types of knowledge, little has changed and significant changes related to how technologies change all three types of knowledge - foundational, meta, and humanistic need to be conveyed [8]. For example, it has been investigated how digital games would benefit from a systematic program of experimental work, examining in detail which game features are most effective in promoting engagement and supporting learning [9]. It has been shown also that playground (hole-in-the-wall) computer kiosk, made freely available to children, without supervision, indicate uniform improvement in the computing skills of the children who used these kiosks [11]. Many projects explore a wide choice of innovative instructional strategies, such as integrating technology into teaching and differentiating learning for students with special needs [5]. Researchers in [6] discuss the characteristics of Web 2.0 that differentiate it from the Web of the 1990s, describe the contextual conditions in which students use the Web today, and examine how Web 2.0’s unique capabilities and youth’s proclivities in using it influence learning and teaching. e-Learning can also support the learning principles of problem-based learning, in groups working either face-to-face or online [10].

In this article, we will describe the methodology used to extract papers that have content related to the e-Learning, using a specific list of keywords. This database
of gained articles, has information about paper titles, authors, years of publication and conference/journal where they appear. A quantitative analysis of this database is made based on the different used keywords. Despite this it has been examined how the e-learning research is distributed through years, conferences, and authors, showing when the first e-learning articles started to show up, when their number started to increase rapidly, which are the main e-learning conferences and who are the authors with the largest numbers of papers and collaborators in the e-Learning community.

II. EXTRACTING DBLP DATA

For the purposes of this research we have used DBLP Computer Science Bibliography, downloading the entire DBLP dataset and then converting this dataset, which is in XML format, to a relational schema, which has the following three main relations:

- authors, with information about name and paper(id), for example:
  Chris Rizos (name), conf/3dgis/ArsanaRS06 (paper id)

- papers, with information about paper id, title, year of publication, conference, for example:
  conf/aaai/MichalowskiBN11 (paper id), Bayesian Learning of Generalized Board Positions for Improved Move Prediction in Computer Go (title), 2011 (year), AAAI (conference name)

- conferences, with information about name and description, for example:
  AAAI (conference name), Proceedings of the Twenty-Fifth AAAI Conference on Artificial Intelligence, AAAI 2011, San Francisco, California, USA (description)

III. EXTRACTING DATA OF INTEREST

The power of e-Learning is too vast and enthusiastic to be used only locally, thus currently we are facing a strong and successful intersection with a variety of other areas as well. One could draw a Venn diagram with e-Learning overlying with other topics in education, such as lifelong learning, education in developing countries, assessment approaches, learning institutions’ role, intellectual property, flexibility in education, etc.

However, since we were interested only on the papers that concern computer assisted learning, we extracted these data using keywords, which are the most intuitive to our perception about computer assisted learning.

All our keywords contain two or just one word. Keywords that we used are shown in Table 1, together with the number of paper titles that contain these keywords.

As it can be seen, the most used keyword is e-learning (2895 titles), followed by the keyword computer learning (1068 titles).

For the keyword google classroom we have only 2 papers (one in 2014, and the other one in 2015).

Similar is the situation with flipping classroom and e-books learning, which is not surprising since all of them are concepts and methodologies that started to show up recently.

In this way in total we extracted 8786 papers. These new dataset is used for further analysis on the papers regarding tendencies in the era of e-learning.

From these relations, we have created views on researchers that are authors of our extracted papers, associating to each of them an ‘id’ that will be used later for easier processing. Also, we have created a list of authors and papers, which is a subset of the authors relation. This list is much easier for further processing compare to the initial authors relation, which has even 5303478 entities.

1 This number is not equal to the sum of papers gained for different keywords, since more keywords can appear in a same paper.
IV. ANALYSING RESULTS

As part of the research we have done different investigations on different aspects that concern computer assisted learning. The first matter of interest understandably is about the timing – when did computers started to assist in learning and how the research regarding this issue distributed through years. Fig. 1 shows this distribution for almost a half century:

A paper entitled “Analog & hybrid computers in education: a panel session” was published in early 1967, marking so the beginning of a new era where machines will be used to assist in teaching math concepts: “Since the analog computer is ideally suited to solving differential equations, its use in teaching that subject is well established. With the advent of inexpensive, reliable, and accurate function generators and multipliers the analog computer can also be effectively used to teach other topics in mathematics” [1].

Following five papers in the next year, none of which is gained as false positive (containing provided keywords, but not linked to the concepts of e-Learning). Until the early 90’s, there are continual publications in each year, but there is no substantial increase in terms of total published papers.

Exception is the year 1974, when even 14 papers regarding computer-based learning were published. In the late 90’s the number of published papers started to increase considerably, having the peak in 2008, when 688 papers were published.

Another aspect that is of interest is related to the conferences that hosted this type of papers. The top conference is IACL'T conference (IEEE International Conference on Advanced Learning Technologies) which hosted 599 papers, followed by SIGCSE (283 papers), ITiCSE (191) and WebNet (171 papers).

Seven conferences hosted over 100 papers, other fifteen hosted over than 50 papers, twenty conferences hosted more than 30 papers, 113 conference hosted more than 10 papers and the other 1430 conferences hosted less than 10 papers in total.

V. COAUTHORSHIP NETWORK IN E-LEARNING CONTEXT

The main idea behind specialized networks created for specific category of experts and researchers is to group them around a topic which could be of help to each other. In such a network, professionals can communicate with each other and share their achievements [7]. They can follow different experts in their field of interest and subfields in that area, can upload papers or make/answer questions. This is all about knowledge sharing.

A lot of work has been done at analyzing scientific collaboration networks. From the time of the pioneering article of Price [13] and Beaver & Rosen [2][3][4], a considerable amount of research articles has put emphasis on different ways and functions of scientific collaboration in particular scientific areas.
In the context of our research, we analyzed the coauthorship network of authors engaged in e-learning research. The extracted data from the DBLP database, regarding has no direct information for the coauthorship network, but we have the list of papers (identified by their paper key) and a list of authors, each of them having information about published papers. The second list is the total list of all DBLP authors. In this way, from these two lists we extracted only authors that published papers from the list gained with the keywords explained in Table 1.

In this way, we have identified 18196 authors, which form in total 34154 one-to-one coauthorship relationships. From these relationships, 27445 are unique, which means that these authors have only one common paper. The “strongest” relationship have Ivan Ganchev and Mairtin O‘Droma, which have 51 common papers.

The highest number of coauthors has Kinshuk, who in total has 63 coauthors in context of this research. Fig. 2 shows a subgraph of the overall graph of the coauthorship network, where this researcher is denoted with red color. The subgraph is only for authors with more than 30 coauthors, that is way not all the authors are shown in this figure. The same researcher has the largest number of paper which is 25. He is followed by Toshio Okamoto, who has 24 papers and 29 different coauthors in our (extracted) paper titles.

VI. CONCLUSION AND FUTURE WORK
Although e-Learning is present for pretty long period and is making significant progress, even if we take these results into account, more study, research and application work is compulsory in order to produce more cases of success and to generalize e-Learning in training and education.

In this paper is presented the investigation that was made through the evolution of e-Learning research community, bringing here the main actors of this community such as conferences and authors.

We plan to further extend this research with exploration of paper content. Using different natural language processing algorithms, we can observe how concepts and topics have evolved through past decades in this community.

Abstract - We live in a world of accelerating changes, where technology plays an important role as an enabler. Looking ahead means being prepared for these changes. Preparedness may be reactive – reacting to the situation at the moment something happens; proactive – being prepared in advance for a situation that may happen; or preactive – being able in advance to affect something that may happen in the future and how it happens. Forecasting the future helps us to be prepared for new situations. It is based on making predictions that are derived from understanding past and present data. Known data is organized in the form of trends and further extrapolated to cover the future. From the technical point of view, there are a variety of approaches for forecasting: algorithmic, simulation, statistical analysis etc. The methods used may be quantitative (future data is seen as a function of past data) or qualitative (subjective, based on the opinion or judgment of the target group used in the analysis).

Technology is an essential part of education, both in supporting effective learning and as a content of teaching itself. As a result, every educator needs skills to analyze the future of relevant technologies. In this paper, we introduce a framework that can be used in analysis of the importance of technological changes in education and as a part of curricula. The approach is based on trend analysis and classification of the relevant technologies to take into account the time span of their effects in society. The question we answer in this paper is “How can an educator analyze the consequences of technological changes in their work?”. The educators’ telescope to the future of technology

I. INTRODUCTION

Technological forecasting deals with the characteristics of technology. It is also used to survive in the future, in the long term and from the strategic point of view (being preactive, or at least proactive; to recognize the opportunities and risks; to recognize the weaknesses and to be able to benefit from the strengths). The forecasts provide insight into future opportunities and the processes applying them. The methods of technological forecasting are commonly known and available for all that are interested in them. The approaches may be quantitative (exact) or qualitative (heuristic); the methods cover a wide variety of alternatives representing algorithmic, simulation based, statistical analysis based techniques, or systematic ways to collect data to represent the opinion or judgment of the target group. Making one’s own (usually focused) forecasts is done in a closed manner (by companies, organizations, individuals) but a lot of such knowledge is publicly available from open sources. The latter are in most cases freely available and applicable for different purposes.

Although technological changes seem to be problematic, there is a lot of regularity built into the changes. In the short term, changes base on the innovations known today. Even in the middle to long term, the changes base on the expected evolution of the currently known innovations. Forecasts rarely reach further than 15-20 years ahead.

The study methods used in technological forecasting are usually based on known trends of the past and their continuum to the future. The aim of this paper is to provide a framework that helps educators to analyze the technological changes surrounding them and to help them to be prepared in the future changes, in their course contents, curricula structure and relevance, learning methods and the tools used. The framework is based on commonly known models that are integrated to provide several viewpoints to the phenomena related to changes in the technology landscape. The key elements of our framework cover the principles of the innovation process and technology adoption, the concept of technology life cycles, and the importance of the technologies in the society, including the expected adoption delay of them.

![Figure 1. Structure of the problem solving – two interconnected papers](image)

We approach this study topic with two papers (Figure 1). We selected this split approach to separate method development and its application from each other. This
approach provides a means for a slightly deeper discussion on the study method than only one paper allows, and more space to the discussion on the technological changes and their importance. In spite of this “paired characteristic”, both are also self-standing research papers.

The research question handled in this paper (Paper 1 in Fig. 1) is “How can an educator analyze the consequences of technological changes in their work?” To answer this question we will introduce our analysis framework. In Paper II (Fig. 1; [10]), the framework is applied for analyzing the changes caused by Information and Communication Technology (ICT) related innovations.

This paper is structured in the following way. Section 2 links the paper to the theoretical foundations of it and in our earlier studies. In Section 3 we discuss the analysis tools on a general level. Sections 4-6 cover the components of our model: importance and effectiveness classification (4), life cycle model (5), and hype cycle (6). Section 7 integrates the model components in the form of the Technology Change Analysis and Categorization (TCAC) Framework and its application process. Section 8 summarizes the paper.

II. BACKGROUND OF THE STUDY AND RELATED STUDIES

In this paper we will focus on the life cycle of an innovation. In technology research, there is an analogy between life cycle models and the diffusion models that describe the adoption of a new technology. [11; 12; 4] Whereas a life cycle model focuses on the maturity of a technology, the diffusion approach is focused on its adoption among potential users. In both cases the distribution curve follows the same S-shaped figure.

The life cycle model analysis presented in this paper has its roots in the early 1990s in [4]. The concept of the “Heuristic Diffusion Model” as a technology analysis method approaches the problems of technological changes from the aspect of phenomena understanding rather than exact mathematical modeling. Since that, the authors have published several research papers having different focus in this topic. The recent years, studies have focused on the analysis of technology driven changes in society and the business environment, the papers related to this work are the basis of the current pair of papers. The first step in this “foundation building” is the paper [5] which introduced the main principles of trend based analysis and interpretation of the trends. The paper ends with a discussion covering a wide variety of trend analyses (based on public data sources), without any synthesis.

The focus of the paper [6] was on the use of Open Data and the role of open ecosystems in the current society. It also handled open ecosystem related trends, culminating in the first (very preliminary) version of the Technological TCAC Framework; we call it the “ICT Change Analysis and Categorization (ICAC)” framework; Paper II [10]. It applies the theory of Freeman & Perez [1] to the findings of ICT related change factors. The same theme was continued in papers [6; 7] focusing on open data related changes in society, and further in the paper [8] focusing on data driven ecosystems, the role of social networking, security related problems, and scalable business models (hyperscalability). Both of these papers cover new improved versions of the ICAC.

One more version, still based on minor iterative and incremental changes to the earlier version, was published in a conference presentation [9]; the topic was related to the value of data and its privacy / ownership. An interesting observation arose when preparing the talk – the trend discontinuity of some major trends, i.e. the fact that the importance level of some phenomena may change fast, something that seems to be an important driver of future changes suddenly takes on the role of embedded and indirect technology driver. The crystallized analysis method used in the analysis, TCAC, is introduced in this paper, and its application in ICT related changes, the final ICAC version, is presented in Paper II [10].

Technological forecasting is a topic of long term and wide research interest. It covers both innovation related topic areas and modelling of diffusion. One of the “bibles” related to forecasting methods is the book of J.P. Martino [13]. His work in advances in technological forecasting is available in his paper [14]. In the area of diffusion models and innovation adoption remarkable work is done by Rogers (adoption) and Majahan (adoption of innovations, innovation life cycles) [11; 12]. Because our aim is to introduce our analysis framework, we have excluded wider systematic review of earlier studies. However, most relevant references are listed in the following sections of this paper embedded in each topic context. The topics cover classification of the importance of innovations [1], trends, diffusion and adoption [11; 12; 4; 5] and Gartners Hype Cycle of embryonic technologies [2].

III. COMPONENTS OF THE ANALYSIS FRAMEWORK

Forecasting helps us to be prepared in the future. In most cases, predictions are based on analyzing past and present data and extrapolating the existing trend to the future. However, there is a problem and a paradox: in spite of understanding the past, the future does not follow the trend. The time span is also important. It is not so difficult to see into the near future, but seeing far ahead is no easy task. As a result, published analyses usually cover “important trends of the next year” as near future analysis. These are usually based on the reviews of expert opinions more than on the use of systematic fact-based analysis approaches. Consequently, the results are not uniform, and look at the same phenomenon from different viewpoints. The fact is, however, that when one makes technology prognoses, nothing radical can happen in the next ten years if the analysis environment remains stable, especially in the technology context. All we apply in ten years from now has more or less already been invented.

Why then make these predictions? The answer is: most of us can neither see the near future, nor recognize the importance of the technologies already in our use. Something that we feel important (from our subjective point of view) may be of very little importance on the global scale, and vice versa. The technology analysis makes us focus our thinking on the right things – it answers the question “What kind of progress should we take into account?”
An additional question is “What is the importance of each technology?” There is no clear way to weigh the real importance and effectiveness of a certain technology neither in the near future and especially not in the long term. Our TCAC framework gives at least a partial answer to this question. The following sections contain some “tools” – ways to analyze future changes, to help the reader in the analysis. It covers the following viewpoints: (1) classification of the innovation importance (Section 4), (2) trend and life cycle model principles – the S-shape (Section 5), and (3) the hype cycle of pre-embryonic technologies (Section 6). The final framework (Section 7) is built of these components.

IV. CLASSIFICATION OF INNOVATIONS

The classification of innovations answers the question “What is the importance of each technology?” Our work applies the idea presented by Freeman & Perez [1]. According to them,

- Incremental changes appear continuously in existing products and services (continuing the existing trend);
- Radical changes appear when new research findings are applied in products to transfer their properties or performance to a new step or cycle (movement to a new trend);
- Changes in technological systems are caused by combinations of several incremental and radical innovations in societal and organizational systems;
- Changes in paradigms are revolutionary and lead to pervasive effects throughout the target system under discussion (in our case the information society).

The external importance and effectiveness of technologies grows from top to bottom.

![Figure 2. Technology category analysis illustrated](image)

Classifying the importance of technologies according to this classification is not easy. We follow the principles introduced by Freeman and Perez in [1] and in more detailed by Jaakkola in [4]:

- Incremental changes accelerate the existing change on the existing trend;
- In the case of radical changes the trend continues, but at a certain moment there is an upward shift (break in the trend) caused by the innovation.
- Changes in technological systems are combinations of several technological innovations providing means for changes in societal systems, daily ways of operating and business models; the key aspect is increasing competitiveness and fast growth of productivity for early adopters.

- Changes in paradigms indicate permanent changes in societal systems, daily ways of operating and business models replacing the old ones.

There are several ways to illustrate the categorization. In our framework we have selected a mind map (Fig. 2) to illustrate the categorization and to group the topic areas belonging to each category. The arrows between the categories indicate the transfer of technologies from categories of lower importance to ones of higher importance.

V. TRENDS, LIFE CYCLE ANALYSIS AND DIFFUSION

A trend shows the changes in the target phenomenon as a function of time. In technology analysis the trend represents the life cycle of an innovation from embryonic phase towards maturation. It follows the S-shape curve, illustrating simultaneously both the maturity and the adoption of the technology. Fig. 3 represents the generalized life cycle / diffusion model.

The analogy between life cycles and the adoption process can be explained by the human decision-making process. According to Rogers [12], the adoption (diffusion) of a product (technology) among potential adopters can be divided into four classes: innovators (2.5%), early adopters (13.5%), early majority (34%), late majority (34%), and laggards (16%); see lower text box in Fig. 3. The cumulative adoption curve follows logistic distribution, most commonly analyzed by the mathematical model developed by Bass (Bass’s diffusion model, see e.g. the paper [11]). The adoption decision is based on the uncertainty related to the technology: the more mature it is, the more experience-based information is available of it; this accelerates the (imitation based) adoption of it towards the full penetration (full user potential reached). Because of that the use of technology indicates its maturity (depth of the use, importance to the users; only a mature technology is widely spread among the potential users).

![Figure 3. Technology life cycle / diffusion model](image)

When we look at the same phenomenon from the technology maturity (life cycle) point of view, its stability increases along the life cycle. The life cycle can be divided into four phases (upper text box in Fig. 3): Embryonic (not stabilized), (accelerated) growing, mature (slowing
growth), and aging (old technology). Finally, it is followed by the decline phase, in which the technology is replaced by a new one or by a new generation of the existing one. Analysts can use the life cycle model to support their decision making with two questions: What is the right time to adopt it? What is the right time to replace it? The embryonic phase is usually a period of uncertainty—we do not yet exactly know its future and the technology is not yet fully stabilized; several competing alternatives exist. This part is described usually by a hype cycle (discussed below), providing the means for more detailed analysis covering the transfer from the pre-embryonic (hype) to embryonic phase.

In life cycle analysis, the curve can also be interpreted as a consumption curve of the innovation power of a technology. The innovation potential is consumed along the life cycle and fully used at the end of the aging phase. It also describes the existence of competitive edge and productivity benefits to its users: the innovation power (ability to provide competitive edge to its users) will be big at the beginning of the lifespan, but also the uncertainty level and the risk of the failure are high.

VI. HYPER CYCLE

The hype cycle (also called hype slope) is an illustration of technology promises. It was introduced by Gartner Group, which is one of the best-known long-term actors in the area of technology studies and analysis. It illustrates the very first part of the life cycle of a technology (pre-embryonic phase in Figure 3) and answers the questions: When do new technologies make bold promises? How do you discern the hype from what's commercially viable? When will such claims pay off, if at all? Gartner annually publishes a variety of hype cycles in different technology sectors. These provide an insight into managing the decision to deploy selected technologies to meet specific business goals.

Gartner introduces the hype cycle as a research methodology for pre-embryonic technologies [2]. The structure is illustrated in Figure 4.

![Figure 4. The hype cycle – interpreting technology hype](image)

Each Hype Cycle drills down into the five key phases of a technology's life cycle (following the definitions of Gartner [2]):

- **Technology Trigger:** A potential technology breakthrough kicks things off. Early proof-of-concept stories and media interest trigger significant publicity. Often no usable products exist and commercial viability is unproven.
- **Peak of Inflated Expectations:** Early publicity produces a number of success stories—often accompanied by scores of failures. Some companies take action; many do not.
- **Trough of Disillusionment:** Interest wanes as experiments and implementations fail to deliver. Producers of the technology shake out or fail. Investments continue only if the surviving providers improve their products to the satisfaction of early adopters.
- **Slope of Enlightenment:** More instances of how the technology can benefit the enterprise start to crystallize and become more widely understood. Second- and third-generation products appear from technology providers. More enterprises fund pilots; conservative companies remain cautious.
- **Plateau of Productivity:** Mainstream adoption starts to take off. Criteria for assessing provider viability are more clearly defined. The technology's broad market applicability and relevance are clearly paying off.
- **Exit** (added to the original source by the authors) occurs if ultimately the technology has not been able to prove its validity for commercial and mass use—to be ready to transfer towards the embryonic phase of the life cycle.

The Gartner Hype Cycle illustrates the maturity and adoption of technologies and applications in graphical form. It also shows how they are potentially relevant to solving real business problems and exploiting new opportunities. For decision makers, it is an analysis tool about the promise of an emerging technology; for risk takers, it opens the door to the frontier of new technologies, and for the decision-maker who appreciates safety, it will lead to a decision not to use the possibilities of the technology at this stage. It also supports preparedness for the appearance of new technology—being proactive and preparing the organization for future changes (being preemptive).

VII. FROM COMPONENTS TO THE MODEL

Figure 5 summarizes the components of our approach and provides a process model to produce the TCAC. The final result of the analysis process introduced in Fig. 5 is the classification structure of the relevant factors of the analysis context. In our pair of papers, the context is ICT-related technological changes (ICAC). The analysis steps are the following:

1. The starting point is data collected on the study context (in our case ICT-related technological changes; Paper II). Everything is based on the data collected from valid and relevant sources; these depend on the study topic. In validating the data sources, our recommendation is to apply the principles of systematic literature review to guarantee that all
important sources are found and that new ones no longer provide the kind of new information that should be taken into account.

2. Two methods are used to analyze the data. Hype cycle based embryonic analysis (Section 6) is used to find pre-embryonic technologies to understand the delay of their commercial appearance. Life cycle model based analysis (Section 5) is used to understand the life cycle and renewal power of the technology analyzed. There is also an arrow between the hype cycle curve and life cycle analysis; pre-embryonic becomes embryonic, unless the exit (not valid for mass and commercial use) is realized before it.

3. The changes are classified according to their importance by using the four categories of Perez and Freeman (Section 4).

4. The last part of the analysis is publishing. Based on the analyst’s best knowledge as an expert in the topic area, the result phenomena (in our case ICT related technologies) are published in visually informative form. We have selected a mind map.

![Systematic Data Collection](image)

**Figure 5. Technological Change Analysis and Categorization (TCAC) Framework – summary of the components of the analysis**

As part of the publishing – because in any case the analysis remains the subjective opinion of the analyst (group) – it is good to implicitly define the interpretations of the four importance classes.

VIII. CONCLUSION

The paper introduces a framework that provides a systematic approach for analyzing real world phenomena from their life cycle point of view. It is the pair of another paper published in the same forum as this one (Paper II; [10]), in which we have applied the TCAC framework to analyze ICT-related technological changes. However – the model is context-free, and it can be used for a variety of analysis contexts and topic areas. The paper introduces the background of the work, its components, and its use – without real application in this paper.

As the model represents an artifact, the method used to develop the model follows the principles of design science. Hevner et al. [3] state that in design science research the novel knowledge and understanding come from the design process of an artifact. Hevner et al. give very clear guidelines for the design science research process, defining seven steps. The steps both provide a design path for the researcher and provide the means to validate the work. We have included both aspects in the following list of design science guidelines:

1. **Design as an artifact.** The artifact is a model.
2. **Problem relevance:** The model handles a relevant problem in a society, e.g. in the education sector.
3. **Design evaluation:** The design is evaluated by several earlier pilot models. The final model is an iteration of these, taking into account the weaknesses and strengths of the earlier versions, and finally synthesized into the process introduced in this paper.
4. **Research contributions:** The model provides a practical tool for analysts in different (life cycle) analysis tasks.
5. **Research rigor:** The model is rigorously validated by the developers.
6. **Design as a search process:** During the research process the authors have, in addition to a lot of fun in collaboration, increased their understanding both of the innovation diffusion process and the phenomenon analyzed.
7. **Communication of research:** The earlier versions of the work are communicated in several earlier publications in order to get feedback. The feedback and the developers’ own critical findings are taken into account in the result model.

Finally, our model will be validated in a practical case in Paper II in a real analysis environment. This proves its usefulness and also its use in creating new knowledge related to the ICT-related technological changes in the education environment.

Abstract – Around the World and particularly in the Europe the conservation of the habitats becomes more important. For that reason, the project of connecting nature and people in Europe promotes the European Green Belt that stretch across 12,000 km. A part of ICT rich environments is also the three state nature park (Goričko-Raab-Őrség) spanning Slovenia, Austria and Hungary.

Inhabitants the Goričko nature park are important factor for the park’s the long time survival and preservation. But living in the park also presents multiple limitations and young people see them as hampering constraints of their life. Therefore, the activities for constant promotion and value of the park needs to become the daily routine. The old fashion promotional activities are not effective for the youngsters, which are accustomed to the fast life style and daily use of ICT. The study was made how to incorporate ICT into the promotion and daily life of the nature park and empower the activities to create visitors own footprint in the park and park's cyber space. The promotional activities, educational activities and competition between youngsters are covered in the article. The ICT is the backbone for the teamwork; individual's curiosity; and professionals.

I. INTRODUCTION

ICT gadgets have become a part of our daily life. If the older generations see them as necessary evil, the young see them as extension/upgrade of their bodies. The use of cell phones, tablets and computers have changed the perspective on time, motivation, and learning. Traditional methods of studying; though effective; are seem boring to the young generations of students and regretfully they make them less inquisitive about their surroundings. "Going out" and playing in the backyards, forests, meadows, climbing trees, seems very odd to them. The term digital natives denotes generations born into the ICT reach environment, and should be distinguished from digital immigrants – generations born before ICT rich environments [1]. It is generally accepted that digital natives possess knowledge and skills to safely navigate in digital worlds, but there are signs that this assumption is only wishful thinking [2]. We want to teach digital natives to respect and protect the nature and all its biodiversity.

Sadly, people often seems to care less for things that seems granted to them. Therefore, the inhabitants of the nature parks see them more as the limitations than the wonders of the nature that needs to be protected for the posterity. Nature parks "health" depends on their inhabitants and these were sufficient reasons to do the research and uncover the coupling between the nature park Goričko (the Park), schools, and professionals employed for nature park conservation. In the year 2016, the research about the Educational potential of landscape park Goričko (see Figure 1) was prepared and presented to the public [1].

The research used online survey among teachers in the area of the park and the results are presented in this article. The objectives of our study were to show multiple aspects of cooperation and complementarity between educational institutions and park administration [1].

![Figure 1: Tree-stare part Goričko-Őrség-Raab](image)

II. EDUCATIONAL BACKGROUND

The Slovenian educational system have defined quality of education; educational processes; and educational goals in the White paper on education in Republic of Slovenia [2]. Slovenian view is in-line with descriptors of the quality of knowledge defined by different authors [3] [4] [5]. However, in practice the quality of knowledge could be the mash between educational strategies with non-cognitive, emotionally motivational and value components [6].

Outdoor education in natural and landscape parks often combines teaching of the schoolteachers and professionals from the park. While teachers are trained for teaching contents according to the curricular goals, this is not always true for employees of the park, who are not always trained educators. For them teaching in the real environment is always only a part of their regular work. Because of their limited pedagogical content knowledge [9] their teaching is usually confined to lower cognitive levels, which they consider as high quality. But for the retention of the knowledge, real world education should consider also
higher cognitive processes, as they are described in the revised Bloom taxonomy (Figure 2). Learning by doing [7] is still considered as one of the most effective principle for learning of skills in the combination with the factual knowledge. The highest levels achievements occurs in the context of goals and objectives that are relevant, meaningful, and attract the students. The motivation is the essential ingredient that allow full utilization of the real world experiences. The motivation of the students have changed in the course of the years and what was once motivational today is considered boring for the “touch screen” generations. Traditional ICT skills are in decline [8] and we need to find another paradigm to activate the students.

The educational activities in the Park are summoned in the educational worksheets where different questions and educational assignments guide students in the park. Analysis of the worksheets, using revised Bloom taxonomy (Figure 2) [9], shows that in most cases the questions and the assignments are on the lower order thinking skills. Rarely the assignment require higher order thinking (cognitive processes) and metacognitive knowledge dimensions. It is somehow understandable that this is the case because park’s administration do not have a clear understanding of students' previous knowledge and higher order of thinking cannot be achieved without the solid ground understanding. Therefore, for better quality work assignment the cooperation between schools and the Park's professionals is almost mandatory. But it is not that bad as it may have seen because it is possible to upgrade the current worksheets into new form with fairly simple procedures known from the past [10].

Objective of the research were:

- Acquire the current state of the cooperation between the Park's professionals and the teachers of local schools.
- Discover the ways to enhance the cooperation between the Park's professionals and the teachers of local schools.
- Provide blueprint principles to activate the digital natives to participate in the nature protection.

Some questions were optional and connected with answers from previous questions [1]. The survey questions covers four main topic of the research and the gathered data provide us valuable feedback [1]:

- about the knowledge of teachers about educational activities of the park officials;
- motivation of the teachers to cooperate with the park officials in the design and in the production of learning topics;
- obstacles to visit the Nature park Goričko; and
- teachers' position to the educational activities in the park.

In the course of the research, the semi-structured interview was used on three members of the Park professionals who were assigned for the cooperation with the schools. The details of the interviews are not part of this article but can be find the other article [14].

We have received the responses from 11 schools but six (6) responses about the teachers' affiliation were missing, therefore it is possible that we have answers from all schools in the area of the Park. Total number of responses was 59. Most of the teachers were familiar with the activities (73.7 %) that were prepared for the education by the park administration. Half of the remaining teachers (~13 % of all responses) were unaware that the park has its own web page with all relevant data available. Acquired responses also shows that the most effective way to disseminate the educational activities are web site and recommendations of colleagues (55.6 %).

Table 1: Information acquisition

If we add to the score the scheduled professional associations and e-mail we cover the 83.9 % of the interested teachers population. Traditional dissemination channels (radio, TV, press) are waste of time and resources. Because the Ministry of Education use the electronic communication only for a decade now, we expected such results. The only not entirely expected result was the proportion of teachers that would like to have regular monthly e-mail update (81.4 %). We thought that this proportion would be even higher because school usually cannot react quickly to unscheduled activities.

Most of the teachers (96.4 %) would like to cooperate with the park administration in their educational activities. Only around a third (34.6 %) would like to cooperate in the preparation of learning materials. The rest, 61.8 % have not thought about this possibility.

Despite good intentions of the teachers, the reality is somehow different. Professionals from the Park expressed, in the interviews, that their effort in the preparation of

III. SURVEY

In the course of 2014 the teachers of natural sciences from primary schools in the area of the Nature Park Goričko were surveyed [1]. The invitation to participate in online survey was send to the addresses of twelve (12) primary schools situated in the area of the Park. The survey had 24 questions. Most of them were closed type questions; some were also five (5) level Likert type questions; and some were open type questions.
educational activities is not always recognized by schools and much more educational activities could be scheduled in the park [1]. However, teachers and park's professionals agree that the biggest obstacle is the low budget of the educational institutions. Optimal educational activities are between 1 and 2 hours long for elementary education (6 to 10 year) and 2 and 4 hours for primary schools education (11 to 14 year) [1].

The factors of the highest importance for the educational activities in the Park would be [1]:

- Real examples from domestic environment.
- Direct contact with the real world.
- The development of a responsible attitude towards the environment.
- Increased motivation for learning.

In general, teachers have good experiences with the Park's professionals. Amazingly, 91.9 % of those who have already been in the Park, with their students, grade the learning activities as good or very good and no negative grade was issued by any teacher [1].

IV. MOTIVATING ACTIVITIES

For the design of the contemporary education, the key competences [11] and the generic competences [10] need to be considered. Learning activities should cover all competence spectrum. The generic competences in our case are [1][10]:

- the ability to collect information,
- the ability of analysis and organization of information,
- the ability to interpret,
- the ability to synthesize conclusions,
- the ability to learn and solve problems,
- transfer theory into practice,
- application of mathematical ideas and techniques,
- adaptation to the new realities,
- quality awareness,
- the ability to work independently and participate in the teamwork,
- organizing and planning work,
- verbal and written communication,
- interpersonal interaction, and
- safety at work.

Therefore, the revised Bloom taxonomy and the competences provide the suitable framework for tailoring the content of learning. However, we need to find the motivation for the students inside the same framework. The ability to motivate is like an art of applied psychology because it differentiates substantially between individuals and between cultures [12] [13]. What motivates the students in one country generally does not apply to the students in the others [14].

The students in questions are primary school kids living in the Park. They having access to or possess all contemporary home ICT equipment. Like most modern world youngster, they often consider old educational principles obsolete because it provides information too slow and often in strictly predefined schedule [15] [16]. They do not consider learning by heart as the mean to train their brain and expand their brains capacities and capabilities; but as unnecessary, old school, obsolete, nonsense, stupid, time-consuming activity because everything is available on Google in just a few seconds.

A. Application of ICT in the work assignment

There are numerous occasions where ICT can be used in the education. Lately many educational specialists strive to use it just where it is most appropriate. The appropriateness of the use of ICT does not depend only on teachers' skills and feeling but also the students. Contemporary students have different demands for the learning materials and the educational principles. Even the best topics that are appropriate for their age and attracts them become boring if they are not presented properly. The previous knowledge of the students is also important in the educational processes. The right assignment for the right students is much more motivating and challenging [6].

Traditionally the assignments are delivered in the paper formats (worksheets). Such worksheets have many benefits and also some limitations. The paper never run out of electricity and can be used for extended duration of the learning in the park. Paper can be copied and distributed to all participants and even if some papers fall to the ground, into the mud or water, no harm is done. Obvious benefits of the paper is overwhelming and it is wise to use it. Despite papers' benefits there are also some drawbacks of the paper. Paper is passive and cannot provide the feedback. However, the questions (quiz type) on the paper can be easily transformed to the digital form and their use on the portable electronic devices (phone, tablet or laptop) could provide instant feedback. The quiz's results are immediately stored and no additional effort is needed to achieve them. The paper can present text and images but not the sound and video. For the identification of the natural wildlife in the park sometimes even the optimal printed image is not enough for unexperienced users. However, the video with the sound (e.g. bird's song) or even interactive 3D model of the specimens would enables young students to achieve much better results.

The important part of learning is also preparing the sketches of the wildlife. Today's children and even older students perceive such assignments are total waste of time because they could use their phone to make a photo almost in an instance. Even the sensors on the portable devices could be used for measurements (temperature, atmospheric pressure, humidity, altitude, light intensity ...). Why don't we use the phones and tablets if they are so great? The problems arose with their diversity. For the educational purposes, each student should have adequate (standard) user experience. The screen resolution, processing power, storage capacity, sensory array, operating system ... makes the effective use of students' devices a logistic nightmare. The effective use of ICT depends not only on technology but also on communication infrastructure. The sufficient cheap and reliable bandwidth is mandatory.

BYOD (Bring your own device) [17] works only occasionally therefore a combination of both, paper and portable devices, are still a wise decision.
B. The digital library

The Park is important biodiversity environment. The cataloguing processes of all wildlife and plants could take years. It would be wise to encourage visitors to participate in this enterprise. Especially this could be motivating for the students who live in the Park and could provide images and videos all year round. A geotagging of the data could be used for different analysis and distribution of the acquired data to the individual visitors who want to explore the Park. For the ease of use of portable devices with cameras, the QR codes could be used since they were already tested in the education [18] [19] [20] [21]. Throughout the park, a weather resisting QR code could be posted (see Figure 4). Visitors and students could read them with their devices with the camera and get the online data. Since the Park is located in the three states (see Figure 1) the information could be translated into different languages further improving the experience of the students and enhance their key competence – communication in the foreign language.

![QR code sample](image3.png)

Figure 3: QR code sample

Throughout the park, a weather resisting QR code could be posted (see Figure 4). Visitors and students could read them with their devices with the camera and get the online data. Since the Park is located in the three states (see Figure 1) the information could be translated into different languages further improving the experience of the students and enhance their key competence – communication in the foreign language.

![A place where QR codes could be used.](image4.png)

Figure 4: A place where QR codes could be used.

Most mobile devices have web browsers and are able to display text and images. The interactive elements processed on the devices (using script languages) are not so reliable and other multimedia elements can be even more problematic. If design require multimedia element to be displayed in the context of the web page but the device play multimedia stream in full screen the intended user experience is lost [22]. Despite obvious observed shortcoming this is just temporary fault that will fade out with the new devices.

![The digital content available to the visitors](image5.png)

Figure 5: The digital content available to the visitors

C. The multimedia library

A subsection of a digital library is a multimedia library. In general, it all seems the same but the technical characteristics are different. Images takes much less disk space and even moderate web server could serve hundreds of users. However, the multimedia library with audio and video materials is much more storage demanding and requires huge bandwidth for pleasant user experience. Video can be stored in various bitrates or on the fly transcoded to the user's specific bandwidth or devices' capabilities. Both principles are possible and both require a reliable funding for the system operation.

The multimedia library could be used everywhere and particularly in the classroom education. Multimedia can act as a learning material or promotion. Logistics for students that wants to visit the Park becomes more complex with the distance therefore better motivation is needed for the decision "to go". Multimedia can provide the overview of the Park's educational activities and influence teachers and headmasters to schedule the educational activities there. However, the use of multimedia in the park on the portable devices a necessary ICT infrastructure must be constructed and maintained. Internet access and powering stations should be available upon major routes and points of interest.
D. Competitions

One of the motivation factors for the students to visit the Park and learn there could be the competitions between their peers. The value system to encourage the learning should be established and the best should be promoted on different levels.

There are different possibilities for the competitions:
- individuals knowledge,
- schools competition (teamwork),
- scoring the products (picture, video, presentation, …).

Good cooperation between countries could culminate even in the financial support for the international competition. Governments of three countries could apply their professionals to prepare the EU funded project even lowering their costs.

E. Proposed improvements

The research gives us the better understanding of the present situation of the educational activities in the Park. Based on the analysis in this topic we can summarize the proposed improvements and we suggest:
- Cooperation of the Parks professionals and teachers should become operational.
- Use of revised Bloom's taxonomy and competences framework for the design of the work assignments.
- Design of the learning materials for dual purpose (paper and electronic).
- Prepare activities where students would actively participate and their results would be available online using Web 2.0 paradigm.
- Build the infrastructure and user interface for the digital/multimedia library.

The assignments for students could be modified to encourage their active cooperation and stimulate their creativity and innovation. The findings can be applied in different situations of outdoor educational activities and seemingly embed the ICT into the existing and future information infrastructure of the (nature) parks, educational trails or other similar installations.

V. Conclusion

The nature protected environments and especially Nature Park Gorčko live and flourish with its inhabitants. The awareness of the importance of biodiversity should start with the kids and continue through their life. Therefore, this never-ending project requires dedicated professionals, motivated teachers, and their cooperation. The legislative representatives should provide sufficient funding and benefits to the park’s inhabitants who should not consider living in the park as constraints.

The Park's professionals spent considerable effort to enhance educational activities in the Park and cooperate with the public educational institutions. Our analysis have shown that ICT could be used to promote the Park even more.

The modern educational paradigm demands students’ active participation in the learning processes. This could be achieved with establishment of digital library that works as public domain. Additional financial investment could be recovered in a short time. More visitors and students could boost the local economy and further provide the benefits to the conservation of the nature. There are also additional benefits of use of social media for promotion and education, but this requires additional human resources because social media are much more vibrant and requires quick responses and regular updates not to be considered “dead”.

Experiences in Using Educational Recommender System ELARS to Support E-Learning

Martina Holenko Dlab
Department of Informatics, University of Rijeka, Rijeka, Croatia
mholenko@inf.uniri.hr

Abstract – Educational recommender systems have the potential to support e-learning by personalizing learning process to the individual characteristics of students. To achieve this, such systems can recommend e-courses, learning materials, learning paths, collaborators and similar. This paper describes experiences in using educational recommender system ELARS for the e-course “Hypermedia Supported Education”. The system provides personalization in the context of e-learning activities (e-tivities) by recommending optional e-tivities, possible collaborators, Web 2.0 tools and by offering advice. Analysis of students’ academic achievements and results of conducted questionnaire are presented together with teacher’s observations and guidelines for further development of the ELARS system.

I. INTRODUCTION

One of the trends in web personalization is to provide a tailored user experience using recommender systems [1], [2], [3]. Web personalization presumes the presentation of a content to match a specific user's preferences. The use of recommender systems expands the possibilities for web personalization by providing navigation support in order to help users to find appropriate items (e.g. web pages, books, restaurants, music videos, etc.) [4]. Personalization, as key element of recommender systems, can be applied to support education process as well [5].

The recommendation process is based on data regarding target users (to whom is recommended), data regarding items (what is recommended), and recommendation techniques (how is recommended). The following techniques are in use: content-based recommendations, collaborative filtering, and knowledge-based recommendations. In most cases, these techniques are combined and hybrid recommenders are developed [6]. Personalization techniques and items that are recommended vary depending on whether e-learning is moderated or non-moderated. Moderated e-learning refers to e-learning through a set of structured course activities defined by a teacher, usually performed with the help of learning management systems – LMSs. On the other hand, non-moderated e-learning is self-regulated so the students decide where, how and when they want to learn [7].

The development of learning environments that support e-learning is influenced by so-called Web 2.0 and e-learning 2.0 [8] and e-learning 2.0 [9]. E-learning 2.0 promotes interaction between students that can be accomplished during collaborative e-learning activities, called e-tivities [10]. E-tivities are usually performed with the help of Web 2.0 tools (e.g. collaborative writing in Wikispaces, blogging in Blogger, mental mapping in MindMeister). The changes driven by the development of Web 2.0 bring new possibilities for personalization that will ensure the achievement of learning outcomes in so-called “2.0” environments [11]. All the above mentioned motivated the development of the educational recommender system ELARS (E-Learning Activities Recommender System) [12]. ELARS was developed during the research project “E-Learning Recommender System” in order to enable personalization of e-tivities in “2.0” learning environment. During the project, didactical models for different types of moderated e-courses were developed [13]. All developed models promote acquiring knowledge in line with the constructivist theory of learning and advantages of Web 2.0 technologies for e-learning.

This paper presents experiences from several years of using educational recommender system ELARS for the e-course “Hypermedia Supported Education”. Results of analysis of students’ academic achievements and conducted questionnaire are presented as well as teacher's observations and guidelines for further development of the system. The paper is organized as follows: Section II presents review of the related work. Section III presents means of personalization in the ELARS recommender system. Section IV describes experiences from the e-course “Hypermedia Supported Education” and the results of course evaluation while section V brings conclusions.

II. STATE OF THE ART

Among existing educational recommender systems, systems that recommend learning objects (e.g. additional teaching materials) prevail. Recommended learning objects can be published on the Web or available in a learning management system [14], [15]. Similarly, the recommendations can support access to appropriate learning materials within learning objects repositories, as is the case with the system DELPHOS [16] and the MERLOT repository [17]. Recommending learning objects may also include determining personalized learning paths [18], [19] and recommendations of university courses. Examples are CourseRank system, used at the Stanford University [20], and smart e-course recommender [21]. Instead of recommending learning objects, fewer systems recommend activities that accompany the process of e-learning [5], for example, during learning of programming. For example, the system WeHelp warns on the most common mistakes Part of available types of recommendations covered by the domain independent approach, TORMES methodology, are intended to support e-tivities (e.g. it is recommended which blog posts target student should comment) [23].
Development of systems that are not restricted to recommending learning objects is especially important in the context of e-learning 2.0 where the emphasis is not on the reproduction of the learning content. Students should create their own versions of subject matter through collaboration with colleagues, which can be achieved by organizing collaborative e-tivities. Additionally, for supporting collaborative learning, it is necessary to develop approaches to recommend collaborators of peers for learning activities. Example is the approach presented in [24] which proposes a model for recommendation of peers to communicate and/or collaborate with based on students’ preferences about some important features of the learning process. Authors in [25] describe a model for recommending collaborators to work in pairs. Collaborators are recommended to target student in respect with information that include knowledge, social and technical aspect of potential collaborator. When used in the context of non-modernized or self-directed e-learning, recommendation techniques have the potential to support creation of personal learning environments (PLE) or mash-up applications that combine several data sources in one Web service. For example, in the system ReMashed [26] users can combine content from different Web 2.0 services based on the received recommendations.

Existing educational recommender systems take into account that recommendations in the educational domain cannot be determined solely based on interests and preferences. Therefore, together with these characteristics [27], data regarding student’s knowledge [1], communication skills [23], and learning styles [1], [15] are used in the recommendation process. Regarding the used techniques, the most of the systems rely on hybrid techniques so, for example, combine content-based recommendations with collaborative filtering. An exception are systems for self-directed learning within social networks where usually only collaborative filtering is used [5].

III. PERSONALIZATION IN THE ELARS SYSTEM

To foster personalization within moderated e-learning scenarios in ELARS system, educational recommendation strategy was implemented [28]. It takes into account that e-learning is an active process which includes interaction not only between a student and prepared learning content, but also between students themselves. The strategy relies on learning design specification which describes the sequence of e-course activities and on data representing characteristics of target users and items.

A. Learning design

Learning design represent a workflow of course activities that are classified into six categories (Table I) and grouped into learning modules. The most important categories for the recommendation process are e-tivity using Web 2.0 tool and decision activity. E-tivities can be optional (i.e. teachers can plan several e-tivities among which student will choose one). Recommendations are presented to students within decision activities. For that reason, this type includes recommendation criterion that should be set in the process of defining learning design (i.e. select user’s characteristics that will be used in the recommendation process) [13]. For example, optional e-tivities can be recommended depending on the activity level reached for preceding e-tivity and/or preferences of tools offered for its realization.

B. Target users

In order to achieve personalization and enable recommendations of various items, four groups of characteristics are used to represent students and groups: preferences of learning styles according to VARK model (visual, read/write, aural, kinesthetic) [29], preferences of Web 2.0 tools, knowledge levels, and activity levels. All characteristics (Fig. 1) are represented as continuous variables with values ranging from -1 to 1 and used in the recommendation system. Data regarding students’ preferences towards Web 2.0 tools are identified using questionnaire available in the ELARS system. To collect data regarding VARK learning styles preferences, students are asked to solve online questionnaire [30] and enter the results in the ELARS system. Knowledge and activity level are automatically determined based on student's results for testing activities and e-tivities. Activity level represents quantitative aspects of students’ engagement in e-tivities. Calculation of activity level is based on automatically collected activity data from Web 2.0 tools using APIs [31]. Collected data is analyzed in order to determine quantity and continuity of contributions. Activity level is calculated for each formed group, as well. Other characteristics are not determined for the group as a whole. If needed for the recommendation process, data representing group members are aggregated.

C. Items

ELARS enables four types of recommendations to personalize collaborative learning: optional e-tivities, Web 2.0 tools, collaborators, and advice [31].

<table>

</tbody>
</table>
E-tivities are recommended if they are optional. List of characteristics that represent an e-tivity includes Web 2.0 tool(s) that is/are offered for its realization, learning styles for which its task is appropriate for, teacher’s expectations regarding quantitative aspects of participation in terms of expected quantity of contributions. Web 2.0 tools are recommended if more than one tool is offered for carrying out an e-tivity. Characteristics included in the representation include possible categories of contributions (updates, comments, tagging, sharing), appropriateness for VARK learning styles and similar. Collaborators are recommended in case an e-tivity is defined as group-based. Potential collaborators are those students who participate in the e-tivity and not have been grouped yet. Potential collaborators are at the same time the users (students) and are represented with a set of characteristics specified in the previous subsection. Advice is used to encourage students and groups regarding four different aspects of active participation. Each piece of the advice is accompanied with the appropriate symbol indicating whether the recommendation is based on (un)satisfactory activity level or it recommends encouraging participation of collaborators. The text includes explanation that contains variable parts (e.g. due dates, names of active collaborators) and recommended action (Table II). Besides, students can see their activity level and activity levels for their collaborators and other groups.

D. Recommendation techniques

Recommendation techniques used are adapted to the educational domain and to the chosen set of items. Based on the data about items and/or target users, offered e-tivities, Web 2.0 tools and collaborators are ranked and appropriate advice is displayed [28].

Optional e-tivities and collaborators recommendations are determined using content-based (attribute-based) recommendations during which student’s characteristics and matching characteristics of e-tivity or potential collaborator are compared (Fig. 2) and similarity measure is calculated. So for example, an optional e-tivity that has characteristics the most similar the target student's characteristics will be at the top of the list of recommended e-tivities. Web 2.0 tools recommendations are determined using hybrid approach that combines content-based (attribute-based) recommendations and collaborative filtering. For providing advice, knowledge-based (constraint-based) recommendation technique with "if...then..." rules is used.

IV. EXPERIENCES IN USING ELARS FOR E-COURSE “HYPERMEDIA IN EDUCATION”

ELARS was developed to foster achievement of learning outcomes and increase the level of user's motivation and participation during moderated e-courses. On completion of each course, evaluation is carried out to determine the extent to which students are satisfied with the course and with the ELARS system. Students’ feedback and teachers’ experiences are used to improve the course and the system. The course “Hypermedia in Education” was one of the first e-courses enhanced by the ELARS system. It is a blended learning course designed for students in the graduate program in Computer Science major at the Department of Informatics, University of Rijeka, Croatia.

</tr>
</tbody>
</table>
A. E-learning environment

The course “Hypermedia in Education” is managed by two teachers. Besides ELARS, teachers and students use MudRi LMS and a set of Web 2.0 tools that are not integrated in the LMS, but available online [31]: Blogger, Diigo, Google Drive, MindMeister, SlideShare, Wikispaces, and YouTube. Using the LMS, teachers prepare learning materials, conduct online assessments and communicate with students. They also perform preparatory tasks in Web 2.0 tools. In the ELARS, teachers define course activities and their workflow, customize recommendation rules, and monitor students’ activity levels after a certain e-ivity starts. Students, on the other hand, study learning content, read instructions, solve online tests, and communicate with teachers in the LMS. Students carry out planned e-tivities using Web 2.0 tools. They use ELARS before e-tivities to select among recommended items and during e-tivities to read advice.

B. Course content and learning design

The overall course objective is that students acquire fundamental theoretical knowledge about e-learning and the usage of hypermedia learning materials. The students are trained to implement information and communications technologies (ICT) in traditional (f2f) education as well as to use contemporary e-learning approaches. The course is organized in the following modules: ICT and hypermedia in education, E-learning and distance learning, Web 2.0 and collaborative e-tivities, and Final test. To enable students to achieve learning outcomes of the course, the first three aforementioned learning modules contain learning materials, self-assessment tests, and e-tivities. During the module Final test, one testing activity in the classroom is planned. Students are supposed to solve an online test with multiple-choice questions in the LMS. Initially, the course learning design included the following personalized (collaborative) e-tivities [31]:

1. Seminar 1 – students are expected to write analysis of potential use of ICT in Education (individually)
2. Mind mapping – students are expected to draw mind map which shows the key concepts of the assigned topic (groups with 4 or 5 members)
3. Wiki – students are expected to create wiki document with analysis of selected distance learning courses (groups with 4 or 5 members)
4. Optional e-ivity 1 – students are expected to summarize subject matter in the middle of the course (groups with 4 or 5 members)
5. Seminar 2 – students are expected to write a seminar with description of assigned Web 2.0 tool and identify its potential use in education and create and publish presentation (in pairs)
6. Optional e-ivity 2 – students are expected to summarize subject matter at the end of the course (individually)

After the first year of the execution of the course, learning design was slightly changed. Based on teachers’ observations and feedback received from students, e-tivities Mind mapping and Optional e-ivity 1 were left out in order to reduce the total number of e-tivities. In addition, students suggested that user interface of the ELARS system should be changed since they were not able to browse through recommendations on different hand-held devices like tablets and smartphones, but just on laptops and desktop computers. Therefore, user interface was redesigned using Bootstrap framework for developing responsive Web applications.

C. Evaluation method and participants

The purpose of presented research was to determine is there any significant difference in students’ course results and attitudes after the changes in the course learning design. In addition, the aim was to gather additional experiences and comments from the students that will encourage further improvements of the course or the ELARS system. The first group of participants consisted of students who participated in the course during the academic year 2013/2014 (N=21). Those students participated in six e-tivities. The second group consisted of students who participated in the course after the changes in the learning design, during the academic years 2014/2015 and 2016/2017 (N=26). Those students participated in four e-tivities and were expected to engage to a greater extent and during longer period of time than students from the first group.

A comparison of the course results for students from the first and the second group was carried out. Points from final test were compared using the t-test for parametric independent samples. Final course points were compared using the Mann-Whitney U test for nonparametric
independent samples. In both cases, D'Agostino-Pearson test was used prior comparison to accept or reject normality of data. Furthermore, students’ attitudes towards applied learning model and the use of Web 2.0 tools and the ELARS system for e-tivities were tested using a questionnaire. Students expressed their attitudes towards statements shown in Table III using the Likert scale (1 – Strongly Disagree, 5 – Strongly Agree). A couple of open-ended questions for students’ comments and suggestions regarding the course and the ELARS system were also included in the questionnaire.

D. Results and discussion

Comparison of students’ academic achievements (points) showed that there is no statistically significant differences in the results on final test ($p=0.12$) nor in the final course results ($p=0.91$). In the first group, average result on final test was 84% and final course result was 82% while in the second group, average result on final test was 85% and final course result was 86%. These numbers indicate that students from both groups achieved course learning outcomes (regardless the changes in the learning design) and that they were motivated to acquire knowledge through planned e-tivities.

Table III shows average results with standard deviations for the most important statements from the questionnaire. Values are approximately the same, which suggests that performed changes in the course learning design did not affect students’ attitudes. Students from both groups have a positive attitude towards the implemented learning model. They consider it effective for their learning, especially regarding freedom to choose optional e-tivities, collaborators and tools for e-tivities. These results were expected since different students have different needs and preferences, which imply the necessity for flexibility in the learning design.

Students’ attitudes about the usefulness of Web 2.0 tools were positive, which is important, considering that all e-tivities were performed using Web 2.0 tools. In general, students did not have problems with using tools, but it should be noted that students who are not studying computer science could have difficulties and require additional instructions. Students also expressed affirmative attitude regarding usefulness of the ELARS system for e-tivities. The most of them believe that the system positively influenced on their motivation and engagement level. It was observed that some students are well aware of the benefits of personalization while others are not. In their comments, some students stated that they would prefer to receive more recommendations of optional e-tivities, which indicates that they perceive the advantages of personalization. Recommendations of optional e-tivities include a high level of personalization because the task of each offered e-tivity is tailored to a particular learning style. For example, student can revise subject matter at the end of the course by drawing a mind map (visual LS) or writing a summary (read/write LS).

When asked about the criterion for generating recommendations, the most of the students were neutral regarding the fact that items are recommended based on criterion defined by the teacher. It is not surprising that students would like to receive recommendations based only on their preferences. This is especially the case with collaborators recommendation when most of the students know each other well and have no doubt about who they want to collaborate with. In the future, implementation of new recommendation rules that will include student’s preferences towards their colleagues should be considered. Additionally, is necessary to improve the presentation of recommendations, to make the used recommendation criterion more clear. Some students stated that it would be more convenient if the system would be integrated within the LMS. This suggestion will be also considered during the further development of the system.

V. Conclusions

Implementation of educational recommender system in the e-learning should presume ongoing evaluation regarding system’s effectiveness, in term of determining the influence of the system on students’ academic achievements, as well as students’ satisfaction with the system and received recommendations. Evaluation results for the course “Hypermedia in Education” showed that e-tivities included in the learning design enable students to gain knowledge through collaboration with their colleagues. Despite minor changes, the students from both groups achieved high results and expressed positive attitudes regarding the e-course and the ELARS system.

Several years of experience on this e-course showed that, although the ELARS support moderated e-learning, to some extent non-moderated or self-directed e-learning is supported as well. By reading recommendations, students received potentially useful information, applicable outside the context of e-tivities included in this

e-course. This refers to colleagues they would like to collaborate with in the future and on Web 2.0 tools or e-tivities and they found useful (for example, for revision of subject matter).

Students’ comments indicate that the future work should focus on improvements of collaborators recommendations. These recommendations are perceived as least useful, so implementation of new algorithms that will be used for dividing students to groups based on their characteristics and the criteria defined by the teacher is planned. Thus, the possibilities for personalization of e-tivities in the ELARS systems will be extended by offering recommendations to teachers. After receiving the recommendation, the teacher will have the opportunity to accept formed groups or to revise the grouping criterion and restart the process. Further ELARS development will also include changes in the user interface in order to enable new functionalities and support teachers while forming groups with the help of the system.

ACKNOWLEDGMENT
The research has been conducted under the project “E-learning Recommender System” (reference number 1313.1.3.05) supported by University of Rijeka (Croatia).

Abstract - Regular discussion in the LLI. (Life Long Learning) courses for the teachers in primary and secondary education gives us insight into their opinion. We discovered that teachers of primary and secondary education in our country believe that the highest retention of knowledge and understanding of mechanics can be achieved in the real world environment (in lab and outdoor) observing the natural physics phenomena and repeating the experiments that led to the physics laws. We know that this is just partially true. It is our belief that simulations using as supplement to real laboratory experiments increase students' understanding of mechanics. Physical processes are often beyond the capability of humans to observe them in schools. Teaching students we have seen that adequate understanding using lab experiments is difficult even in the simplest mechanic phenomena (ball rolling on the slope). Students were unable to comprehend the full concept of the physics phenomena from the experiment unless we teach them theory first. In this article, we explain how we used simulations that allow students to adjust the experiments to their comprehension abilities. We compared the accuracy of three different freeware simulations to the highly accurate proprietary one. We have also analyzed the observed simulation software to be customized to the accurate transformation of 3D world experiment to the 2D simulated presentation (e.g. the sphere and the cylinder cross-section look equal in 2D screen but the physics background is different).

1. INTRODUCTION

The use of computers in physics has brought many new opportunities for demonstration of physical phenomena. Computers are able to present static objects and dynamic phenomena in different ways depending on the required complexity. Presentation can be from simple 2D images on the transparencies (PPT), to the videos or simulations of 3D interactive models. Computers can control the experiments and/or acquire measurements. When the experiment of specific physical phenomena can not be done in the lab or we wish to enhance its clarity we can use computer's simulations. Simulations allow us to change parameters and observe their interactive physics response. On the internet, there are numerous simulations, which are ready for use in the classroom [1]. Each of them is ready to treat specific physical phenomena, or their part. However, the described simulations can not be used to treat all physical phenomena [2][3]. In the teaching of physics the observation of the real physical phenomena is of great importance, but in some cases this is not possible (it’s time consuming, not repeatable etc.). In such situations the physics teacher prepare school experiments, where he or she demonstrate the physics phenomena to the students in order to analyze the influences of specific factors on the experiment dynamic. The experiment should not be substituted but supplemented with ICT tools, e.g. simulations [4]. In frame of Didactics of Physics we teach the university students that by following the strategy of introducing the simulation into the teaching of physics they need first to execute the real experiment and secondly they have to show the same physics experiment in the simulation environment and compare the results. The students can perhaps observe the differences which arising therfrom measurement errors or inaccuracy of simulations. If the difference is too great, the trust of students in simulation can not be achieved. If the results match, the trust in simulation is present and we can use the simulation in new physics situations that we can not access with real experiment. The accuracy of the simulation is obviously crucial.

In this paper we have limit ourselves to the free accessible simulation software: Algodoo [5], Step [6] and Physon [7]. They all allow a virtual space where we are free to move and insert arbitrary objects. Movement and interaction(s) between objects obey the physical laws. Such software is called Physics sandbox. Physical engine of the simulations assure accurate objects’ interactions based on mathematical modeled of physical laws. The virtual space where the objects are inserted is named the interactive simulation environment. A common feature of all simulation environments is a transformation between 3D space into the 2D projection (on screen). Simulation environments are build by inserting objects (blocks, circuits, any polygonal wire, springs, and other building blocks), which can be combined to the complex structures, such as a trolley with the engine.

The software simulations can be used in teaching physics on different occasions and educational topics, both in elementary school (primary school), [8] and high school (secondary school). [9] The potential user can use our experience of the three public available software simulation and use them in the classroom.
A. Application of the computer in the physics education

The experimental observation of the phenomenon can not be replaced by any other method, because it enables the control of conditions for the observation of the physical phenomenon [4] [10] [11]. Various reasons lead to the fact that the experimental observations in practice are not always possible. Some of the reasons are listed below [2] [12]:

- Research subject is too big or too small,
- The observed process is too fast for human,
- Financial expenses are too high,
- Experiments are dangerous,
- The school experimental environment is typically limited to specific place or area properties, (we cannot test the experiment on other planets/moons with different gravitational constant).

B. Strategy of the simulation

Three main factors occurred in the treatment of the concept of strategy of the simulation: real system, model, and simulation. The real system or part of the real world is what we want to present in a graphic way. The model is a theoretical description of the real system, which must be precise enough to explain the crucial behavior of the real system. The model can be used to test the theory too. Modeling is the process of adequate describing the relationship between the model and the real system. Simulation can be defined as an abstract model, which is implemented as a computer program. Simulation is a demonstrational computer model in which the phenomena dynamics is calculated and presented in time steps (the certain time increments) [10].

One of the main advantages of using simulations in teaching of physics is that students can freely change the parameters of the simulation. Setting the value of the simulation's parameters the entire course of the simulation changes and that enables verification of the various hypotheses. The simulation strategy in education is particularly suitable for analysing the functional interaction(s) between the parts of the complex system. In the physics teaching the experiment is indispensable, but is does not allow us to control all the environmental or inter-object influences. Therefore, it is wise to add the simulations to the experiment for better students' understanding of underlaying concepts of physics phenomena. Simulations in the education allows the teacher can overcome some real world constraints and explain the behaviour of physics phenomena in the artificially changed environments. The simulation is not suitable for everything therefore should be logically included to the educational processes. The teacher should be trained in the use of simulation strategy and should encourage the discussion during the use of simulation. The students could use the simulations for understanding the background of the physics phenomena and understand why some differences between simulation and real world phenomena can occur [2] [10].

C. Possibilities of the application of simulation in the education

We estimated that the teaching methods where simulation environments can be used are as following [4] [10]:

- Demonstration,
- Method of written and graphic work,
- Practical work – laboratory work.

Simulation can be used in all phases of education, from introductory demonstrations, to introducing the new concepts at new content teaching, and to verify acquired knowledge.

D. Execution of the experiment is followed by the preparation of the simulation

We chose to show a simple experiment: the calibration of the spring [13]. Accessories that are needed in the experiment: a spring, a ruler, and a variety of weights. Students hung a ruler next spring (for measuring the distance). With the addition of the weights (10 g) to the spring, they record the extension of the spring. Acquired data are later used to draw a graph and the graph can be used to see the relationship between weight (or even better, the force) and elongation for any given weight (Figure 1). Expected is linear dependency, if we not exceed the limit elastic values. The result of the calibration is the determination of the spring constant in N/m.

Figure 1: Simple test for calibration of the spring in Step.

II. OVERVIEW OF INTERACTIVE SIMULATION ENVIRONMENTS

In this section, we present the details of the specific simulation software and Simulation environment. We also introduce the basic characteristics of the physical engine.

A. Algodoo

Simulation environment allows adding the basic objects to the simulated world: blocks, rings, ropes, and springs. From individual basic objects, we built complex (composite) structures, e.g. a trolley with the engine. Various physical properties can be modified for any individual building part; we also can change the properties
of the environment. When the simulation is ready to run, we can observe a static or dynamic behavior of each object, influenced by other objects in its vicinity and surrounding.

Algodoo simulate mechanical systems defined by Newton's equations. This does not begin with a form of Newton's laws, from which to get associated differential equations that could be used for discreet method of calculation. The equations are written in the Lagrange formulation of mechanics. Lagrange's formulation uses a discrete time and position format. Lagrange's formulae enables us to use the differences in intervals to walk through the system of equations. This approach has been used to describe particles' system, a system of rigid bodies with the extremities and motors, collisions, contacts, dry friction, viscous incompressible fluids, and elastic-plastic materials. To stabilize the extreme edge, control, and physical engine, the calculations used framework SPOOK [14]. At each timeframe, simulation environment calculates a large system of equations, which is comparable in size to the number of extreme edge and contacts of bodies.

The constraints of the software simulation are the following:

- The simulation runs at the time interval of 1/60 sec (60 Hz). It is not possible to model the events that are happening in a shorter time interval. It is therefore not advisable to generate simulations for the bodies that are less than a centimeter wide.

- When the simulation is running, it calculates a large system of equations using a numerical method. In order to ensure smooth interactive simulation events the fast approximations are used. Unfortunately, this can lead to the differences between simulated results and the physics theory.

- We must be aware that the simulation software is complex and may contain bugs or faults in the program.

- Algodoo authors' claim that they are trying to make the simulation software to conduct physical simulations at a high level, but legally there is no assurance for this.

B. Step

Simulation software is available under GNU GPLv2 open access license [15]. The design of the simulations was done in the following steps: we add the body and the force of gravity to the simulated model. By pressing the button "Simulate" the simulation started and bodies started to move according to the calculated physical laws. Bodies and forces attributes can be changed even during the simulation and they are immediately used in the calculations.

Simulation software Step uses software library StepCore for physical engine. This engine is used inside the simulation environment for all simulation calculations (even the complex one) but can also be used in our own software for which necessary programming skills are required. The design of the library, which can be disseminated and adjusted, has enabled us to implement precise simulations. Capabilities of the physical engine and the simulation environment are:

- Particles, spring damping, various forces, gravitational force, gravitational and Coulomb force can be added to the simulated model.
- Rigid bodies can be added.
- Collision of the bodies can be detected.
- Soft bodies, which can deform and consist of particles - connected with springs, can be created.
- Molecular dynamics is based on the Lennard-Jones potential. This allows simulations of gas and liquid, condensation and evaporation, and the calculation of macroscopic liquids.
- Measurement errors (i.e. 1.2 ± 0.3) for any property can be specified. Calculations of all values are done using statistical formulas.
- There are many differential solvers which user can choose. Solver component in the simulation environment allows stepwise calculation. Most of them are based on GSL-library [16].
- Errors of calculation component solver are added to those made by the user.

C. Physion

An online community maintains the project. Therefore, a number of examples, tutorials and videos can be found in the forum or in the YouTube. Physionet offers the possibility of inserting program code in JavaScript.

Physionet uses many open-source technologies and is based on a physical engine Box2D library [17]. Physical engines that are designed primarily for use in computer games are focus on fast and fluid calculations. That means heavy use of fast approximations that can generate significant differences between physics theory and real world. Our hypotesis is that these approximations will not significantly influence the results for the school's educational use. Based on the capabilities of the library physical engine we discovered that we can simulate in Physion similar simulation as in the previous two simulation environments.

III. COMPARISON OF THE SIMULATIONS

We know that the tests we have performed (more our tests are available in [18]) are not suitable for a general review but we are trying to make at least elementary impartial review, presented in the following table (Table 1).

<table>
<thead>
<tr>
<th>Accurate modeling of the objects</th>

Table 1: Conclusion and comparison of experiences in the modeling and simulations' use.
For all force oscillations of the spring (Figure 2), the oscillation is damped with a force $F_d = -bv$, where $b$ is the damping coefficient and the $v$ is the velocity of movement of the block. The block was operated by a force of the spring $F_{sx} = -kx$ (the $x$ denotes the extension of the spring) and the force of gravity $F_g$. We omit the influence of the $F_g$ on the movement because it had no effect on the oscillations (only define the stable-equilibrium position).

For all forces acting on the block, we wrote:

$$ma = -bv - kx. \tag{1}$$

We rewrite the (1) by replacing the velocity $v$ with $dx/dt$ and acceleration $a$ with $d^2x/dt^2$ and get

$$m \frac{d^2x}{dt^2} = -b \frac{dx}{dt} - kx. \tag{2}$$

The solution of the equation is the following

$$x(t) = x_m e^{-bt/2m} \cos(\omega' t + \varphi), \tag{3}$$

where $x_m$ is the starting amplitude and $\omega'$ angular frequency of damped oscillation. The angular frequency is defined with the following equation:

$$\omega' = \sqrt{\frac{k}{m} - \frac{b^2}{4m^2}}. \tag{4}$$

Equation (3) implies that because of the dampening coefficient $b$ the amplitude $x_m$ exponentially decrease with time $t$. The angular frequency $\omega'$ also decrease because of (4). The physical unit for the $b$ is [Ns/m] or [kg/s].

### C. Preparation of the simulations

We can compare the data if we create the similar conditions for all three models and simulations. All three simulations work on the numeric step-by-step calculations. For comparison, we set the time step 0.02 (or 50 Hz or 50 calculations per second) to calculate the value for the numeric step calculations. For comparison, we set the time step 0.02 (or 50 Hz or 50 calculations per second) to calculate the values. With this setup, we obtained the same number of data from each simulations. In the design of the model we use the block with the mass $m = 1$ kg, the spring coefficient $k = 35$ N/m and springs own damping coefficient $b = 0.5$ kg/s. We tried to standardize the maximum amplitude $x_m$ as much as possible. The duration of the simulation was 10 seconds.

### D. Preparation of the simulations – Algodoo

We prepared the simulation in Algodoo as seen in the Figure 3. We delete the lower surface and added a new one to forms a ceiling. We secure the spring to the block and on the ceiling. The block size was set on 0.4 m on all sides, and its weight to 0.5 kg. Block was placed (hanged) at a distance of 1 m from the ceiling. The spring constant was set on 35 N/m. In Algodoo we had some problems by defining the $b$ directly, so we defined the damping ratio $\zeta$, which we calculated for given data $b=0.5$ Ns/m, $m=0.5$ kg and $k=35$ N/m with [19]:

$$\zeta = \frac{b}{2\sqrt{mk}}. \tag{5}$$

### A. Testing the quantitative credibility of the simulation environments

In high school physics, a significant increase of the need for quantitative use of simulations emerges. It is therefore important that the measured results from the experiments and calculated results from the simulations are comparable. For the quantitative credibility test of simulation environments, we prepared the same simulation in all three simulation environments and compared the results with the model that we have created with the reference software Berkeley Madonna.

For each simulation environment, we prepare the equal model and start the simulation with the same parameters. We have used a damped oscillation model for the test. In the simulations, we allow the plotting of graphs (position / time). Calculated data from each simulation were compared with the data we have obtained by use of the reference software Berkeley Madonna.

### B. Physics background of damped oscillation

The oscillation is damped, when another body (e.g. surrounding media), which inhibits dampening (presence of the frictional force, proportional to the velocity), influences the body that is swinging [19]. The block with mass $m$ were fixed with a spring coefficient $k$ and the own damping coefficient $b$ (Figure 2). We observe the damped oscillations due to springs own damping coefficient. Potential energy (consequently the kinetic energy) of the spring oscillation transmutes to the internal energy of the spring.

Figure 2: The model used for the damped oscillation.
We set simulation to run for 10 seconds. Data were displayed on the graph and there are built-in function to export the data in CSV (comma separated value) text file.

E. Preparation of the simulations – Step

The modeling in the Step started with the position of the block 1 m from the center of the coordinate system – origin (which represent the ceiling) (Figure 4). We set the coordinates for the block (0, 1) m (first number present x and second y coordinate). We secure the block on both ends to the simulation background with the object Pin. In the coordinate center (0, 0) m we set the block with size (0.4, 0.4) m and set its weight to the 0.5 kg. We attached the spring to both blocks (the upper one was fixed, the lower one can oscillate). In the attributes of the spring we set localPosition1/2 on both ends to ensure that spring is connected to the center axes of the blocks. With the object WeightForce we add the force of gravity.

Again, we set the simulation to run for 10 seconds, before we save the calculated data.

F. Preparation of the simulations – Physion

When we opened the software Physion there were a initial new environment with three blocks that have been deleted. First, we create a ceiling (Figure 5), which was made up of the block size (10.0, 0.2) m at a height of 1 m from the coordinate center (0, 0) m. We added the block size (0.5, 0.5) m (the size 0.4 was changed to 0.5 because we could define the mass of the block only by changing the blocks density). We add the mass of the block by setting its density to 2 (which equals to 0.5 kg). We connect both blocks with the spring for which we set k and b (equal to models in other simulations). We need to set gravitational force to 9.81 m/s² and frequency of the calculation to 50 Hz.

<td>b = 0,05</td>
</tr>
</tbody>
</table>

G. Preparation of the simulations – Berkeley Madonna

Berkeley Madonna is a software package for mathematical modeling [20] developed by the University of California at Berkeley. With this software, it is possible to numerically solve the differential equation [20]. The software is used in many fields of science for research and learning. Calculations were performed with Runge-Kutta 4th order (RK4). In frame of measurement errors, the Berkeley Madonna simulation results perfectly match with experimental results. Consequently, we used this software as the reference.

To create a mathematical model, we need an equation in differential form. We transformed (1) for dampening oscillation by setting instead of a the dv/dt, and thus we get

$$\frac{dv}{dt} = \frac{-b v}{m} - \frac{k x}{m}$$  (6)

Equation (6) was therefore in a form ready for use in the software. In (6) are two variables v and x, therefore, we have yet to define v = dx/dt. Into the program we inserted the settings; the equations; and the initial value (see Table 2). For the initial values, we used the same values as were used in the other three simulations. In the simulation we used the calculation method RK4.
After running the simulation for 10 s we get the graph (Figure 6) of displacement (position) and velocity of the oscillating block as function of time. We have saved the data to the CSV file. We used the data for the analysis of the position of the block in time.

Figure 6: Graphs from Berkeley Madonna: position (black), velocity (red).

IV. COMPARISON OF THE RESULTS OF THE SIMULATIONS

We tested the accuracy of three free accessible simulation environments with the reference simulation. The data of the damped oscillation collected from each simulation environment and in addition the Berkeley Madonna data as reference, were combined in a single graph (Figure 7). From the graph, we conclude that all the simulation environments successfully passed our accuracy test. Simulated results form the damped oscillations models in Algodoo, Step, and Physion and mathematical model in Berkeley Madonna were comparable, since the peaks of the individual cycles were well matched. The matching of results is satisfactory for displacement axis (small differences only for results of Step), but even more for the time axis (excellent matching). All three simulation environments (Algodoo, Step and Physion) prove to be quantitatively credible and consequently adequate for use in classroom. We are aware that this is just one example, but it was planned carefully as possible. This took into account some specific physics and computer knowledge and skills. The results of our credibility test were positive and confirms the appropriateness of the simulation environments.

Figure 7: Cumulative graph from all simulations: Algodoo (blue), Step (green), Physion (black), and Berkeley Madonna (red). The overlapping of curves is excellent.

V. CONCLUSION

In support of operating systems, we found that most of desktop operating systems supports Algodoo, because it could be installed on Windows operating systems, Mac OS X and GNU / Linux using Wine program. Step can be installed only by users of GNU / Linux operating system. For Physion, it was possible to install it on Windows and GNU / Linux using Wine software. As we can see the users of GNU / Linux could install all three simulation environments which is very favourable for the free software.

Physical content coverage analysis showed that the three reviewed simulation environments mostly overlap. It is possible to create models to simulate numerous physical phenomena in mechanics. In addition, the Algodoo enables simulations in content of light, buoyancy and swimming. The Step enables simulations in content relating to electrical charge. Physion and Algodoo are the most comparable, but in modeling of simulations using Algodoo we can add also the effect of air resistance.

In our analysis, we find out that the three reviewed public available simulation environments (Algodoo, Step, Physion) provide the necessary software supplement to the experimental work at physics teaching. The quantitative testing of the credibility of the simulation environments, based on the analyzing the almost perfectly overlapping of the time dependency of the displacement of the dumped oscillators, proves the adequacy of them. They cover most of the typical content in primary and secondary schools; they may be also adequate for university level education of physics. In the future, we can expect the development of even more advanced simulation software for teaching physics and for other disciplines in school. The accuracy of the analyzed simulation environments is appropriate, consequently all three simulation environments are adequate for using them in the teaching of physics in elementary and high schools.

Abstract - The paper is devoted to a competence-oriented model of representation of educational content. The model is based on the requirements to results of educational programs in higher education and illustrates the approach to developing e-learning courses as structured sets of didactical units containing evaluation funds. Didactical units of training material are the content elements of e-learning encyclopedias. Evaluation funds of didactical units allow determining the level of graduates’ competence. The multivariant presentation of the training material helps to build individual learning trajectories for persons with disabilities, for students with different backgrounds and with different individual characteristics of personal and cognitive spheres.

II. REQUIREMENTS OF FEDERAL STATE EDUCATIONAL STANDARD OF HIGHER EDUCATION TO THE LEVEL OF LEARNING OUTCOMES OF GRADUATES

The founding document of the higher education in the Russian Federation is a federal state educational standard of higher education (FSES HE). The Ministry of Education and Science of Russian Federation defines the enlarged groups of specialties, each of them contains the definite sub-fields. The Ministry calls such sub-fields “directions”. The examples of the enlarged groups of specialties are “Mathematics and Mechanics”, “Computer and Information Sciences”, “Physics and Astronomy”, etc. The examples of directions within the enlarged group “Computer and Information Sciences” are “Fundamental Informatics and Computer Sciences”, “Mathematics and Computer Sciences”, “Mathematical Software and Administration of Information Systems”, etc. For each direction, the Ministry approves a separate FSES HE. This standard contains requirements for the learning outcomes of the graduates.

These requirements are a list of competencies that each graduate must achieve. The standard defines three types of competencies: the general cultural, the general professional and the professional competencies. There are several groups of the professional competencies according to the activities, towards which the educational program is oriented: research activities, design and production activities, management activities, methodical activities, and others. The university choose all or several activities for each educational program and provide only those competences, which belong to the chosen activities. It leads to a significant variety of bachelor and master’s programs depending on the profile of the university. For example, the educational program in the pedagogical university differs significantly from the program in the same direction in a classical or a technical university.

Thus, the bachelor educational direction “Computer Science” in South Ural State University (National Research University) [5] presents two bachelor programs: “Calculative Machines, Complexes, Systems and Networks” and “Information and Analytical Support of Management in Social and Economic Systems”. The master educational direction “Fundamental Informatics and Information Technologies” includes two programs: “Technology of high load systems” and “Database Technologies”.

For each educational program, the university develops the model of a graduate meeting the requirements of FSES, the needs of the regional labor market and its own
scientific and educational interests. The model specifies definite competences for each subject in a curriculum.

The teacher decides which learning materials he will use to achieve the given set of the competences for his subject. Therefore, the learning materials of the same subject can vary greatly among teachers. These learning materials form the educational content of the whole educational program.

Thus, the university has the actual problem of verification of compliance of the learning materials developed by a teacher with the model of a graduate.

III. VERIFICATION OF COMPLIANCE OF EDUCATIONAL CONTENT WITH THE REQUIREMENTS OF FSES HE

Traditionally teachers divide the learning materials into several sections and sub-sections (topics). A didactical unit is a minimum indivisible unit of the learning material, e.g., a definition, an example, an exercise. We understand a topic as a nonempty relatively independent set of didactical units combined by semantic logical relations.

For each didactical unit the teacher can prepare the evaluation fund of its achievement. An evaluation fund is a set of questions, assignments, exercises and other tasks for student, which allow checking his knowledge. It can include different types of control tools: quiz questions, practical tasks for independent or group implementation, case studies, essay topics, reports, etc. One control tool can check the achievement of several didactical units; several control tools can check one didactical unit.

According to the interpretations of the concept of a competence [6], any competence can be implemented at various levels: knowledge, understanding, and skills. To determine the minimum required level of achievement of the competence the university needs first to establish the compliance of the evaluation fund of all subjects with the competences. The teacher must specify such compliance for all didactical units within his course.

If you have a general bank of didactical units, which can overlap or reenter in different courses, the incomplete comprehension by the student of all didactical units will not constitute the incomplete or insufficient mastery of the competencies defined in the model of the graduate. A graduate can master all competencies, even missing some material. Indeed, not all students master all the learning material at the highest level.

The aim of the university is to find the decision of two problems:

1) Define a minimum required level of mastering the competencies by a graduate;

2) Prepare the curriculum that would achieve and exceed this minimum level.

It is impossible to formalize the process of solution of both problems. However, there are the opportunities for the partial automation, at least at the stage of compliance of the existing curriculum with the requirements of FSES HE. We can compare FSES requirements with the entire set of evaluation funds of all courses of the curriculum.

IV. ELEMENTS OF EDUCATION CONTENT REPRESENTATION

In terms of the compliance of the curriculum with the requirements of FSES, we operate the specific concepts: the module of the education content and the component of this module.

The module of the education content is a set of logically interconnected concepts that form a holistic unit of information. The closest concept to the module in terms of a course is a topic.

Each module contains a set of related components. A didactical unit is the closest term to a component. A component represents an item of the module too, but, in contrast to the didactical unit, it may contain a set of elements, equivalent by content but different by the form of representation. For example, a definition may be given in the form of a text, a diagram, an audio or a video file. Different forms of representation of information will allow each student choosing the most convenient method of obtaining the learning material according to his leading psychological type of perception (auditory, visual, kinesthetic), which will undoubtedly have a beneficial effect on the learning outcomes [7].

The frequently used component types are:

- theory – a detailed theoretical description of the concept;
- summary – a brief theoretical description of the concept, the definition or the formula;
- example – an example to illustrate the concept;
- solution – an example of the typical task solution;
- exercise – an practical assignment for the theoretical material;
- bibliography – a bibliography on a given topic.

For each component, the teacher prepares the evaluation fund containing the tasks for checking the competencies.

The most frequently used types of tasks in the evaluation fund are:

- questions – a list of open-type questions;
- test – a list of closed-type questions;
- assignment – a task to check the practical skills and abilities.

It seems appropriate to combine modules into a thematic set according to their content. We call it an e-learning encyclopedia (ELE). A teacher can use the e-learning encyclopedias to develop a new course.

V. MODEL OF REPRESENTATION OF EDUCATIONAL CONTENT

To develop a new course, a teacher needs to specify both a list of modules, and their chronological sequence. An e-learning course (ELC) is a directed graph, whose nodes are modules, and arcs specify the sequence of the study of two connected modules. A teacher chooses
modules which he wants to include into his course. It provides a variability of the course content created by different teachers.

Fig. 1 shows a fragment of the ELC “Basics of Programming”. Each node in the graph corresponds to a module chosen by a teacher from the e-learning encyclopedia.

The traditional representation of the sequence of learning materials in the form of a tree graph has many disadvantages [9], the main of which, in our opinion, is the inability to build an individual learning path for a student. If a teacher wants his students to study several algorithms of the internal sorting, it is no matter which algorithm they will study first, as well as the order of all other algorithms. Therefore, the e-learning course should provide various trajectories for the module.

Fig. 2 presents a fragment of the graph illustrating the different trajectories of achievement the module C: A – B – C; A – D – C; A – B – E – C. Here modules in a double border mean the mandatory modules required from a student. Modules A and C are mandatory in this figure. A background shows modules, which the student did not pass yet. In fig. 2 they are modules E, C and D.

The comparison of the paths B – C and B – E – C is interesting. Indeed, after the study of module B, a student may transfer directly to the module C, but may first meet the modules B, which will not be mandatory to achieve the module C.

A basic trajectory for his course is for those students who are ready to pass only the minimum amount of topics. Those who want to study the course deep can pass the additional modules. The students will have the ability to choose that trajectory which seems to him the most appropriate. The reasons to miss some modules may be different: the student already knows some of the modules, he is not interested in all of them, the modules are too difficult for him, or he does not have time for the full course.

When forming the graph a teacher can specify the property of necessity of each module. An attribute “Necessity” of a module means that this module is required for the successful completion of the course. Since each module has evaluation tasks, we get the whole evaluation fund for the course.

Additionally, a system can control the property “Available” for each module. It will change the status for the modules after the student passed the income module.

The general scheme of the competence-oriented model of educational content is presented in fig. 3. “M” means “module”, “CMN” means “component” and “CMT” means “competence” here. According to the model, the curriculum consists of e-learning courses. An e-learning course is associated with a number of modules. One module can be included in many ELC. The modules can

---

**Figure 1.** Fragment of ELC “Basics of programming”

**Figure 2.** A fragment of the graph with different trajectories of module C achievement

**Figure 3.** Competence-oriented model of representation of educational content
be grouped into an e-learning encyclopedia (ELE). One module can belong to several ELEs. Each module is a nonempty set of components associated with the set of evaluation tasks. All evaluation tasks together create a total evaluation fund of the curriculum. FSSEH and the university provide a list of competencies, which graduates must achieve. Now the verification of the competencies achievement is possible through the evaluation fund of all courses.

The presented model is a basis for specifying requirements to the software for verification of the compliance of the curriculum with the requirements of FSSEH.

VI. DEFINITION OF REQUIREMENTS FOR A SOFTWARE IMPLEMENTING A COMPETENCE-ORIENTED MODEL OF REPRESENTATION OF EDUCATIONAL CONTENT

Let us describe the requirements to the software implementing a competence-oriented model of representation of educational content.

The basic software functionality is the following:
1) To create and modify an e-learning course;
2) To create an e-learning course based on an existing one;
3) To create and modify an e-learning encyclopedia;
4) To create a new type of a module component;
5) To create a new module component;
6) To create a new module;
7) To build the trajectories of the e-learning course;
8) To search components by keywords.

Interesting features of the designed software are the following.
1) Automatic generation of documentation by selection of types of components included in the ELC. For example, the system will form a guide for performing the practical assignments (by selecting the components of the type solution), or a glossary (by selecting the components of the type summary), etc.

2) Verification of compliance of the curriculum to the requirements of FSSEH.
3) Verification of learning outcomes of graduates to the competencies.
4) Construction of the individual study trajectory.

We see the possible ways for the further development of the model by introducing the following functions into the system:
1) Development of the algorithm of analysis of the competencies in FSSEH.
2) Development of a fuzzy algorithm of the complexity evaluation of the course by its information content, hierarchal structure, and heterogeneity [10, 11].

VII. CONCLUSIONS

The proposed model of representation of educational content shows the possibility of verifying the students’ learning outcomes to the requirements for graduates of a definite educational direction. This verification is possible due to a logical connection of the competencies, which a graduate must achieve, and the content of learning materials.

All e-learning courses in our model consist of the modules. Modules, in turn, consist of the components of the learning material each of which has a set of evaluation tasks. The connection between the content of learning materials and the competencies through the evaluation fund provides a variation of possible courses in a curriculum. Thus, the presented model could become a means to check whether the content of the e-learning courses meets the requirements to a graduate of the university.

Using CODESYS as a Tool for Programming and Simulation in Applied Education at University

D. Lukac
*Rheinische Fachhochschule Köln gGmbH,
University of Applied Sciences, Köln, Germany
dusko.lukac@rfh-koeln.de

Abstract - The software platform CODESYS, is an application for the industrial automatic control engineering, which becomes more and more a competition product, to the similar systems currently used in Europe. For this reason it is increasingly utilized in the school and university lessons as an education tool. In this article, with the help of a practical example, it is shown how the called platform can be used for the programming according IEC 61131-3, as well as, for the visualization purposes in industrial automatic control engineering. The example in this paper is presented, by using of freely available version of the software platform, which is accessible to all students and lecturers.

Keywords — CODESYS, PLC, Visualization, Simulation, Education, University, Practice, IEC 61131-3

I. INTRODUCTION

There are numerous software platforms for the programming according to IEC 61131-3 standard [1]. While the last years the platforms of manufacturers like Siemens or Schneider Electric in Europe or Allen-Bradley as Rockwell Automation from the USA have been used at universities and schools, in the meantime, there are many alternatives. Some have market-technically positioned themselves very well and become a true contention to the “big manufacturers”. One of such alternatives is the company 3S-Smart-Smart Software Solutions GmbH, which have developed the software platform CODESYS. CODESYS (early known as “CoDeSys”) is a developing environment for Programmable Logic Controllers (PLC) which is working according to the IEC 61131-3 standard for the application development in the industrial automation. The base of the platform, is the programming tool „CODESYS Development System“. It offers comprehensive integrated solutions for the comfortable project engineering of automation applications to users – with the objective to support them practically by the realization of its tasks [2].

II. WHY TO USE CODESYS IN EDUCATIONAL PRACTICE?

One, for the education practice an important criterion is, that the software can be used for free, and possibly without any special functional restrictions. CODESYS is after registration on the web page of the manufacturer with all functions, including visualization option, a free tool. With CODESYS, users create successfully easy and demanding automation applications for industrial controls aimed for the application in factories, mobile machines, energy and building automation systems and many other ranges. Many aspects and properties of the system help them in it. In one single Human Machine Interface (HMI), various functions of the system are available. It concerns an entire program system according to the IEC 61131-3 – from the classical PLC programming up to the object-oriented control programming. The platform offers comprehensive properties to the comfortable project engineering and introduction of automation applications, as for example data monitoring, search of application errors (debugging), update of application in the company (online change) [3]. Optional additional modules for the methodical application development are also available as e.g. UML, version administration, static code analysis, profiling and test automation as well as configuration and introduction of the most important industrial field bus systems and I/O systems. Following figure shows the working environment of the tool:

Figure 1. CODESYS Integrated add-on components [4, p.2]

The system also offers seamless integration of optional additional components for the project engineering like visualization, inflexion control / CNC / robotics, safety
modules and this above only by one face working environment [4]. Therefore it has positive impact on the minimization of the engineering expenditure means [5].

III. A PRACTICAL EXAMPLE OF CODESYS-APPLICATION AT UNIVERSITY

In form of project example [6] in this part is introduced, how like CODESYS can be practically used at universities. It concerns a programming and simulation of a system existing in reality at the Rheinischen Fachhochschule, University of Applied Sciences in Cologne, Germany. The automation system exists of two robots (KUKA and Manutec robots), a conveyer belt with a video camera and reed sensors as well as a turntable. On this system a work piece is transported, taken up and placed again by robot. The whole system communicates over a head computer, a control PLC, which exchanges sensor signals. The whole system is presented in the following figure.

![Figure 2. Automation arrangement in Robotics Lab of the RFH University](image)

From the interpretation of the conceptual formulation following basic conditions have been fixed:

1. In the whole attachment only one work piece exists, therefore, it is renounced a query of the work piece sensors before startup procedure.
2. In the first parallel implementation, the roundtable for work piece is to be aligned and at the same time the conveyer is to be brought in the position BT_1, if the carriage is loaded.
3. The second parallel implementation lets the roundtable with the work piece rotate to the place BDTKU and provides return for a carriage.

Interpretation of the conceptual procedure is necessary for programmers in order to define the conditions for programming. The programming has been carried out by the automatic sequence control method. Therefore it is necessary to subdivide the whole task in a subtasks, which, step by step, after fulfilling the so called transition condition, can be set in function, resetting in the meantime the step before. The detailed program procedure can be taken from the Grafcet in the following figure:

![Figure 3. Grafcet sequential presentation of the program](image)

In the step 0 the system should be initialized. If the sensor BT_5 is active, or in addition still KUKA_A1 is on (X6), the initialization step goes parallel in the steps 11 and 21.

In step 11 the turntable is switched on so long, until the position BDT_MU is reached and afterwards in step 12 it is switched off. Parallel in addition the transport carriage engine is activated in step 21 and it is driven in the legal run up to the sensor BT_1. Step 22 serves as a waiting step for the detection of turntable finished position.

The whole procedure continues according to the described principle.

IV. IMPLEMENTATION WITH CODESYS

Within the scope of the project, three different programming languages: Sequential Function Chart (SFC), Instruction List (IS) and Function Block Diagram (FBD) are introduced. The procedure of programming in CODESYS and the programming in detail, is to be taken from the following paragraphs. In the following text, because of the realization of the problem is in German
language, therefore the German terms for programming languages are used. These are AS for Sequential Function Chart, AWL for Instruction List and FUP for Function Block Diagram.

A. Input of the global variables

The input of the so-called global variable list can occur through two different possibilities, as a source program input or by the system available table. An extract is presented in the following figure:

![Figure 4: Source program input](image)

Besides, the variables are entered directly as a source code according to the schema:

- Variable name: Data type;
- Example: BT_1: BOOL;

Nevertheless, this input is laborious and takes up a relatively lot of time. Alternatively the possibility of the tabular input, which exists, can be used. This is an extract presented in the following figure:

![Figure 5: Source program input](image)

On this occasion, merely the name and the data types must be entered by hand. It is much easier in the practical sense, concerning the working load.

B. Representation of the program code as an SFC object

After the SFC object has been created, a start element is initialized by the programme CODESYS automatically. This is also characterized as “Init step” and serves for the case that the program should be transmitted on a PLC hardware, to check by starting procedure of the PLC whether all other steps of the SFC are put on zero (in logical low state). If this is not the case, a message would be displayed and the attachment launched anew.

As an example of the SFC programming, the steps 42, 52 and 6 of the program are used as presented in the figure below. If the program has arrived in the steps 42 and 52, the crossing in Step6 is only possible, if both conditions for steps are fulfilled on top and the transition KU with them. If this is the case, then the exit signal KUKA_E1 would be set on logical TRUE state. One can recognize that the principle is the same in the whole program.

![Figure 6: Example of the SFC object](image)

C. Representation of the program code as an IL object

The instruction list (IL) is a programming language similar to assembler and exists of a sequence of instructions. Also it is described under the IEC norm 61131-3. Every instruction is based primarily on the loading of values in the battery (LD instruction). This is presented in following as an extract of the IL program code:

![Figure 7: Example of the IL object](image)

In the so called execution part of the IL object in the figure above, LD and AND load the operand data from the battery and check by means of a one AND logic gate whether the step X6, the variable BT_5 and KUKA_A1...
are logically in TRUE state. If this is the case, the actual step X6 must be unset. Because here no step query is necessary, it can be directly begun with the steps X11 and X21 anew.

D. Representation of the program code as an FBD object

The FBD representation is presented by activation of the Manutec robot in the program. After the work piece with the conveyor belt was driven to the final position and the roundtable has aligned itself, the control unit is activated. It allows that Manutec robot lays the work piece on roundtable. This is presented in following figure as an extract of the FBD program code:

![Figure 8. Example of the FBD object](image)

E. Visualization

The Codesys platform also permits visualization of the implementations. With the help of the following figure, the graphics were copied for the visualization. Therefore all invisible objects graphics are switched on to visible in the course of the online procedure or they can be, according to necessity, switched off. According to this procedure, the visualization with CODESYS is actually the alternating change of the picture colors. It is quite simple model of visualization and by best perception of the author, it can be only used for very simple visualization tasks. This kind of visualization is only in 2D available and does not allow measurement of the true time speeded for one simulation process. Nevertheless it is sufficient for most of the control tasks which needs to be solved in the daily educational business. For any other visualization purposes we refer to explanations in [7].

![Figure 9. Graphics for visualization](image)

Consequently the visualization of the different steps can be released. With the help of the figure for color declaration for BT_4, it is briefly explained how like the sensor BT_4 for a color envelope is set.

![Figure 10. Setting the colors for visualization of BT_4](image)
Under the window properties for the selected rectangle the desired color is selected in the subitem “colors” for the normal state and state of alert, which then, by the state of the color variable (here signal: BT_4) changes between normal state and state of alert.

V. CONCLUSION

The objective of the present work was to briefly present the software platform CODESYS and to show how a simulation of the PLC program as well as a visualization for educational purposes can be created with the platform. For those purposes, the different PLC programming languages were used including the different way of the task solution. Extract of the realized program codes have been presented. It can be stated that, compared with the programming task according to IEC 61131-3, the realization of the visualization is considerable and complex one, and expects more additional program capacity. At this stage can be argued that the software platform is very recommendable for the use in the educational practice, but that the visualization part should be improved by software developers.

Developing curiosity and multimedia skills with programming experiments

Abstract Browsers have become the most common communication channel. We spend hours using them to get news and communicate with friends, far more time than communicating face-to-face. WWW-based communication and content-creation for www will be the most common job in future work life for students specializing in software engineering.

We expect our screens to be colorful and animated, thus students should understand technologies, which are used for e.g. for painting jumping Mario to screen. But massive flow of new software engineering ideas, technologies and frameworks which appear in all-increasing temp tend to make students passive receivers of descriptions of new menus and commands without giving them any possibility to investigate and understand, what is behind these menus and commands, killing their natural curiosity. There should be time to experiment, compare formats, technologies and investigate their relations. In the presentation are described experiments used for investigating, how different formats for describing animation in HTML5 document influence animation rendering speed.

I. INTRODUCTION

Curiosity, active interest, desire to know more about something is a precondition for brain for learning [1]. Curiosity makes us consider, ponder different aspects of new and this is needed to understand it. But constant, all the time accelerating flow of new information, new tools and technologies what we are supposed to introduce to our students is effectively making the whole teaching process a mechanical dumping of new facts, procedures, technologies without leaving students time for investigation, discovering the real nature of new technologies or tools.

Especially rapid is the flow of updates, new technologies, new tools in the field of Software Engineering (SE). This creates constant pressure for SE students, who are in danger to drown in constant flow of new menus and commands without time to investigate, what is behind these new menus. And half of this what they learn now becomes in two-three years already obsolete [2].

More important than just teaching menus and commands of new frameworks is developing analytical, inquiring attitudes, ability to seek to understand how new technologies work, what is in them really new and what – just a marketing noise, how different technologies are intervened, support each other (or not) and why they so quickly replace old ones.

Especially intense is this problem in SE new fields: mobile, web and cloud programming. Here a programmer is working with minimal resources for understanding inner workings, debugging, but at the same the code should not only work, but should be memory-efficient and work quickly. Even small delays in page loading does seriously reduce website’s user experience and can mean turning customers away [3].

Current SE students should understand the technical side of this media, this will essential part of their future work.

II. DIGITAL COMMUNICATION

Communication, the base of the advancement of mankind, is rapidly moving online. Online communication is visual, colorful and animated, e.g. Microsoft replaced in Windows 8 and Windows 10 the old start menu with start screen with animated live tiles. Games, game news and game discussion are a permanent section in all social media channels, but also in many old 'solid' news channels.

The major mechanism for presenting common digital content on screen is browser. Only very specialized programs (Photoshop, Excel) or big games still use their own windowing systems but even those have already many browser-based analogues. Browser is the first program what we usually open when we start computer and browsers are already considered as the basis of a whole Operating System (OS) [4].

A browser-based interactive media is essentially an frame-based video. Processor calculates next frame content and accompanying sounds, from these bits is then rendered text/images on screen and played sounds/music. For best results developers want maximal color depth (bpp – Bits Per Pixel, determines color quality) and framerate (fps – Frames Per Second), which determines animation smoothness and game responsiveness. But both these features increase processor load, memory use and decrease speed, thus may make animation jumpy or sound disrupted.

Development of browser content is based on use of the HTML language. With HTML are strongly tied several other languages – JavaScript, CSS (current version – CSS3), SVG (Scalable Vector Graphics, a graphics vector language), Flash, WebGL (for 3D graphics). Due to history and current situation with of development of these technologies their interplay is not transparent, it is often
difficult to select one of several possible development strategies.

III. BROWSERS, HTML5, CSS3

Human society and culture is based on communication. For long time all communication was based on natural languages. But in the second half of the last century appeared programming languages as means to communicate with 'tools for intelligence' – computers and other devices. With development of techno- and info-sphere communication is more and more moving into Internet and the widely used method is browser-based communication using the HTML language, which allows to use all traditional communication modes – text, images, sound, video, but has added a new feature – it is interactive, messages receiver can actively participate in forming received content.

HTML was not designed as a programming language – the original 18 tags permitted only most-basic text layout options for distributing research reports of scientists working in the Nuclear Research Center in Cern. But it contained one important new tag - the hyperlink; this was the revolutionary concept that created the current-day Internet. And when Netscape invented new programming language JavaScript, which transformed until then passive www-pages into dynamic, interactive media, the web development and use exploded. JavaScript is used by 94.4% of all the websites [5] and is the programming language with highest ranking [6].

Modern web browsers have become a complicated multichannel translators. They accept input from several channels – HTML/XML/SVG text with links to other sources, images, video, sound tags, keyboard and mouse or/and touch input; input may be provided from several files – the HTML-document itself and data from linked external sources, e.g. external CSS (Cascading Style Sheets) and JavaScript files, images, sound/video files (see Figure 1). With these different types of inputs browsers compile complex output for computer/mobile screen, create voice and play sound and video.

![Image](57x213 to 289x314)

Figure 1. Inputs-outputs of common web browser.

Thus in principle browser works like a programming language's translator – it transforms information presented in format/syntax of input channels into format/syntax required by output channels/devices. But its task is essentially more complex – the information presented in inputs is interlinked, depends on each other, e.g. 3D-placement on screen of a paragraph of text depends on size/placement of text/pictures before this paragraph (the CSS box model) and all CSS-formatting rules, which could be introduced in several different places - the 'cascading' feature of CSS.

New features are added to browsers and its input languages in frantic temp. All major browsers – Google Chrome, Microsoft Internet Explorer (IE), Mozilla’s Firefox (FF), Opera - publish several major updates per year, minor updates appear in every 6-8 weeks [7] and most of them are already ‘evergreen’ - they automatically update themselves. In recent years have appeared also several new browsers: Microsoft Edge (for Windows 10 only) [8], Vivaldi [9], Brave [10], Yandex browser [11], Maxton cloud browser [12].

With such a frantic temp of development it is difficult to maintain overall balance and consonance of all parts of HTML-documents - DOM (Domain Object Model [13], all elements of a HTML document) tree, JavaScript, CSS, add-on's) and new features, which are developed by different parties.

Quite illustrative is development of Cascading Style Sheets (CSS) language. This was simple and natural format to describe styling of web pages, when it was introduced 20 years ago. But innovators found, that "CSS is primitive and incomplete" [14] if we could not have borders with rounded corners, thus should be improved and so appeared frameworks - layers of code re-organizing use of CSS features. First was introduced an extension of CSS - Sass (Syntactically Awesome Style Sheets [15]), where are introduced variables, nested rules, inline imports and other features and which has two syntax options. However, to use it you should first know CSS quite well and also have the programming language Ruby compiler installed in your computer, since the extension is a Ruby program. Then Sass was extended with simple scripting language SassScript. But for some people Sass still is not good enough so we get open-source CSS authoring framework Compass [16]. Now writing style rules - something what could be done with any text editor, Notepad or (for highly technical persons) Notepad++ and which few would call programming requires two interdependent frameworks, compiler for the Ruby language and several Ruby Gems to output CSS. And to see the result this should be uploaded to server.

CSS frameworks may be useful for professional developers of big web sites, but even there their use is questionable [17]. For students they are an overkill.

CSS3 introduced several methods for animating elements of HTML document. For instance, CSS property transform manipulates the size, shape, and position of a CSS box and its contents through rotating, skewing, scaling and translating. CSS3 animations allows animation of most HTML elements without using JavaScript or Flash [18], but this is a rather restricted type of animation – CSS3 does not allow variables, thus everything should be fixed before, animation cannot be changed on run-time. CSS3 is introducing also several other very advanced features, e.g. media queries, which allow to apply CSS rules depending on properties of device (e.g. screen width) which is used to present the content. Most of these features already work in many browsers; however, currently (Jan 2017) CSS3 is not yet implemented in
Microsoft browsers IE 11 and Edge, these browsers 'know' only CSS2.

IV. TOO MUCH IS CONFUSING

Animation, movement is the major way to make WWW documents more attractive, thus most of developers want to use this feature. For a long time the only technologies allowing to show movement in WWW were video and Flash. Video is a non-interactive media, thus the main technology for developing interactive, dynamic web content, games and portals was Flash. When Steve Jobs declared in 2010 Flash a 'persona-non-grata' on Apple devices, its popularity decreased also on other platforms. But because of its (very) good performance it is still widely used, so rumors about its death seem to be strongly over-accelerated [19]. Microsoft even included Flash player in its new browser Microsoft Edge - and dropped its own inventions, the ActiveX components and Silverlight. Thus ActiveX and Silverlight become another dying-out stars in quickly changing landscape of web technologies.

The major technology platform for developing interactive web content - games, communication and business portals is currently latest version of HTML – the HTML5. HTML5 introduced a new element – canvas – an area in HTML-document where JavaScript commands can draw and thus create animations.

HTML5 allows to implement animations using several formats and technologies:

- showing animated .gif images either as a part of HTML-document (i.e. with HTML-code) or drawing with JavaScript on canvas; this old image format contains series of frames for storing short animations, is restricted to 8 bpp (bits per pixel) color resolution (i.e. image can have max 256 colors) and animation speed cannot be controlled by browser, it has to be pre-set when creating the .gif animation file, but animation (image) is easy to scale (make smaller, making it bigger destroys quality);

- animation on HTML5 canvas with JavaScript: showing/moving images, possibly clipping them to some figure;

- procedural texture – merging texture images changing their opacity [32]; here this was used to produce Sun's lava texture from only one image;

- CSS3 allows to create frame-based spritesheet animation without using JavaScript [20];

- SVG; SVG elements can be manipulated like HTML elements using transform functions, but many commands and attributes do not work the same way on SVG elements as they do on HTML elements, JavaScript feature detection fails, the local coordinate system of an element works differently for HTML elements and SVG elements, the CSS properties of SVG elements have different names, e.g. instead of background-color should be used fill etc.

When HTML5, CSS and JavaScript arrived, several browsers, especially Microsoft Internet Explorer (IE) browser versions 6..10 did not follow standards, thus web content developers had insert into their code special checks for browser version, e.g. in HTML:

```html
<defs>
  <linearGradient id="SunGradient" x1="0" y1="0" x2="100%" y2="100%">
    <stop offset="0%" stop-color="#feeeb1"/>
    <stop offset="100%" stop-color="#0099ff"/>
  </linearGradient>
</defs>
```

In order to unify development and eliminate browsers incompatibilities was in 2006 introduced a cross-browser JavaScript library jQuery, which provided a consistent interface that works across different browsers, i.e. also in Microsoft's browsers. With time jQuery has included many properties, e.g. fade ins and fade outs (a 'visual sugar') and animations by manipulating CSS properties. Since JavaScript libraries are a non-transparent layer of code (it is very difficult to check what went wrong is an error occurs in a used library – they act like a compiled module), libraries should be introduced only after students have acquired solid JavaScript skills. But since jQuery is currently very popular, we considered also animation created with jQuery.

V. WHAT TO USE?

Browser input consists of several parts – the HTML-document (HTML code), CSS stylesheets, JavaScript file(s) (there may be several), image, sound, video files. These are handled by different browser's sub-programs – the browser's layout engine with CSS interpreter and the JavaScript engine. All major browsers use their own, independently developed engines:

<table>
<thead>
<tr>
<th>Browser</th>
<th>Layout Engine</th>
<th>JavaScript interpreter</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firefox</td>
<td>Gecko</td>
<td>SpiderMonkey</td>
</tr>
<tr>
<td>Chrome</td>
<td>Blink</td>
<td>V8</td>
</tr>
<tr>
<td>Internet Explorer</td>
<td>Trident</td>
<td>Chakra</td>
</tr>
<tr>
<td>Microsoft Edge</td>
<td>EdgeHTML</td>
<td>Chakra</td>
</tr>
<tr>
<td>Opera</td>
<td>WebKit</td>
<td>V8</td>
</tr>
<tr>
<td>Safari</td>
<td>WebKit</td>
<td>JavaScriptCore</td>
</tr>
</tbody>
</table>

They all interpret HTML+CSS+JavaScript code a bit differently and the 'inner working' even of major browser engines are mystery, explanations cover only one particular browser [21], [22], [23] and are presented in rather general terms. There is not yet 'browser theory', which were comparable to IT subject 'Translator theory' [24], developed for classical programming languages. This creates many questions. Performance of some components - JavaScript engines, CSS layout calculation, screen renders etc. may be rather different [25]. How this influences the overall performance, in which order are applied CSS rules, if determining DOM tree element attributes is better from HTML-text or from JavaScript, levelling browser's build-in defaults (e.g. different default margins) – these practical issues are unexplained.

For instance, when developing a Christmas game "Santa in Wild Forest" we wanted to introduce a light effect – torch/moonlight moving together with Santa, see Figure 1. It turned out, that the effect can be implemented using different technologies/formats, but they all had some problems (image on mobile screen look a bit dirty) and some solutions worked in different browsers differently.
Thus instead of following intense flow of marketing shouts: "Use jQuery!" [26], "Use Angular!" [27], "Use TypeScript!" [28], "Use Facebook's React Native!" [29], "Use Intel SDK!" [30] we decided first to test with a practical application the real value, first of all – speed – of different animation technologies. Implementing test applications and performing tests give students much better understanding of value of different technologies then just implementing something in one (usually rather randomly selected) format.

VI. THE TEST APPLICATIONS

For comparing different animation formats we implemented a scheme of Lunar Eclipse (actually happened during the course on 20.03.2015), which contained several animated and/or half-opaque elements, see Figure 3.

To investigate influence of different animation formats and opacity change technologies on animation speed and memory requirements we prepared tests T1..T9 [31], which all are versions of this animation.

![Figure 2. A screenshot from mobile game "Santa in Wild Forest", developed as a part of the course, captured from mobile phone screen in original mobile screen resolution – 768x1220px; - Santa Clause has to collect all parcels, which Krampus throw into dark forest; we investigated possibilities to add torch/moonlight effect, i.e. create a half-transparent circle covering Santa and moving together with Santa.](image)

![Figure 3. The test application (captured from mobile browser) and its animated objects: Sun (upper left corner with animated lava texture), Earth (lower right corner, rotating), Moon (small grey circle close to Earth), Moon shadow (larger half-transparent grey circle on Earth surface), Earth atmosphere (light half-transparent halo surrounding Earth).](image)

<table>
<thead>
<tr>
<th>Test file</th>
<th>Animation description</th>
</tr>
</thead>
<tbody>
<tr>
<td>T1: eclipse1.htm</td>
<td>The whole screen is covered with canvas with contents as the CSS-defined background image; Earth is animated with JavaScript (texture is constantly moved behind a clipping circle, drawn on canvas by JavaScript); all other objects are images in HTML document placed using CSS attribute z-order over the canvas; the canvas: Sun is animated .gif image (32 frames) with transparent background, Moon, Moon shadow, Earth atmosphere – images, transparency is 'built-in' to images with Photoshop (is not adjusted in the HTML-document); placement of images is defined with CSS using position attribute value 'fixed'.</td>
</tr>
<tr>
<td>T2: eclipse2.htm</td>
<td>The whole screen is covered with canvas with contents as the CSS-defined background image; Earth is animated with JavaScript (texture is constantly moved left-to-right behind a clipping circle, drawn using JavaScript using the 2D-graphics context of canvas); all other objects are images in HTML document placed using CSS attribute z-order over the canvas; Sun is animated .gif image (32 frames) with transparent background, Moon, Moon shadow and Earth atmosphere images is defined with CSS rules</td>
</tr>
<tr>
<td>T3: eclipse3.htm</td>
<td>The whole screen is a DIV with cosmos as the CSS-defined background image; Sun is animated .gif image, minimal canvas is used only behind Earth, which is animated with JavaScript (texture is constantly moved behind a clipping circle drawn by JavaScript using the 2D-graphics context of canvas); all other objects are images in HTML document placed using CSS attribute z-order over the canvas, 50% transparency of Moon shadow and Earth atmosphere images is defined in Photoshop</td>
</tr>
<tr>
<td>T4: eclipse4.htm</td>
<td>As previous, but 50% transparency of Moon shadow and Earth atmosphere images is defined with CSS rules</td>
</tr>
<tr>
<td>T5: eclipse5.htm</td>
<td>The whole screen is a series of DIV-s (no canvas); the main DIV with cosmos as the CSS-defined background image covers the whole screen, smaller DIV-s for Earth, Moon, Moon shadow and Earth atmosphere images are placed over it using the CSS position, width/height and z-order attributes; Sun is animated with CSS3 rules (the 32 frames of the sprite sheet were obtained from the animated .gif image), Earth is also animated with CSS (texture is constantly moved behind a CSS clipping circle); transparency of Moon shadow and Earth atmosphere images is defined in Photoshop</td>
</tr>
<tr>
<td>T6: eclipse6.htm</td>
<td>The whole screen is a series of DIV-s (no canvas); the main DIV with cosmos as the CSS-defined background image covers the whole screen, smaller DIV-s for Earth, Moon, Moon shadow and Earth atmosphere images are placed over it using the CSS position, width/height and z-order attributes; Sun is video in WebM format, the video is clipped by CSS clipping circle (works correctly only in Firefox; Chrome has its own proprietary format for alpha transparency in WebM-video); Earth is animated with CSS (texture is constantly moved behind a CSS clipping circle); transparency of Moon shadow and Earth atmosphere images is created in Photoshop</td>
</tr>
<tr>
<td>T7: eclipse7.htm</td>
<td>Sun texture is procedurally generated by JavaScript and jQuery on minimal canvas using two additional canvases (the idea from [32]); all other elements are as in previous example</td>
</tr>
<tr>

<td>As in previous but jQuery library (253 kb) was removed and replaced with JavaScript</td>
</tr>
<tr>
<td>T9: eclipse9.htm</td>
<td>Texture of Sun is procedurally generated (without jQuery), Earth is JavaScript animation on a separate canvas, thus together there are 4 canvases</td>
</tr>
</tbody>
</table>
VII. RESULTS

All test animations eclipse1.htm..eclipse9.htm were HTML5-documents looking similar on screen, but since implemented using different technologies/formats they also produced different results: time needed for constant number of animations (10 rotations of Earth) and RAM memory used by browser. They all had a small JavaScript script, which measured the time was used to run 10 rotations of the Earth; the results were shown on screen in a separate small DIV and stored using the HTML5 local storage feature. For memory performance there is not yet a separate small DIV and stored using the HTML5 local storage feature. For memory performance there is not yet general standards; in Chrome is available a proprietary method performance.memory [33], but this can be used only if Chrome is started with specific switch and in our tests Chrome reported always the same values. IE allows to see some memory statistics with the UI Responsiveness tool [34]:

<table>

We performed similar tests also with a mobile phone browsers in an android mobile (LG E975a, Android 4.4.2 'KitKat'); here were used the phone OS built-in browser, Chrome and UC cloud browser (made in China), which currently is a ‘rising star’ in the landscape of mobile browsers [36]. In the following table are presented the raw results (test times in milliseconds) and results after normalizing using Chrome as the etalon.

Although mobile browsers show more differences both between browsers and between tests, the general tendencies were rather similar.

VIII. CONCLUSIONS FROM TESTS

These results allowed students to draw several conclusions:

- there are no essential differences in speed between major browsers, but Microsoft browsers do not (yet) implement CSS3 (only CSS2)
- HTML5 canvas+JavaScript allows to create complicated animations, but reduces animation speed ca three times (tests T5, T6, T7 did not use canvas). This result was for students surprising, since canvas is commonly considered the main element in all graphics-intense web applications (games, portals etc.) but it becomes understandable if one thinks what actually is loaded as the
canvas 2D context – this is an interpreter 2D graphics commands, which builds its own name table etc.

- using several canvases does not make application slower (test T9);
- changing opacity of bitmaps with JavaScript does not make application slower and allows better to control result (tests T2, T4)
- CSS3 animations and CSS3 clipping (with circle) are quick, but quite difficult to scale (changing size of frame-based CSS animation is very error prone) and did not work in Microsoft browsers
- video in webM format with transparent background (test T6) can be achieved (using CSS3 clipping) only in Firefox (Chrome has for this a proprietary extension [37]);
- results of tests T7, T8, T9 indicate, that jQuery was officious – big, especially for mobile applications (current version 3.1.1 – 261 kB) and did not have any advantages. The jQuery library was introduced to make Microsoft browsers IE6..IE10 to understand standards, but currently Microsoft has also started to follow them, so jQuery is (mostly) not needed. But jQuery introduces rather difficult to understand cryptic syntax (what has to be learned) and is changing custom semantics, e.g. cryptic jQuery command to get canvas object:-

```
var $canvas = $('\#canvas');
```

returns array (#canvas suggests, that there are several canvas objects having the same id?!); equivalent to this, but more understandable plain JavaScript command

```
var $canvas = document.getElementById('canvas');
```

returns 'flat' variable, thus all uses of these variables also require different syntax. Use of jQuery also increased memory requirements (as measured in IE 11). It was relatively easy to remove all dependencies of jQuery - we actually had to change only 8 lines to convert the script into 'clean' JavaScript, where jQuery was not used.

Students discovered even more, e.g. the speed of canvas animation depends essentially on size of animated objects – scaling page down decreased rendering time.

IX. CONCLUSIONS FROM THE PROJECT

The main benefit of the project was not discovery of dubious properties of use of canvas or other technical results – this may change with the next updates of browsers. The main benefit of the project for students was in making them think and explore, showing exploratory attitude for use of software technologies instead of following blindly the next marketing hype and learning dumby commands of some commercial framework (e.g. Intel XDK – 643 MB, 35800 files, development for Android phones requires also Android SDK – 27.2 GB, 154999 files). Browsers are the most important communication channel of future and students should understand well the browser technology and for this they should experiment and investigate.

Informetrics: the Development, Conditions and Perspectives

A. Papić

 Faculty of social sciences and humanities/Department of information sciences, Osijek, Croatia
apapic@ffos.hr

Abstract - The paper gives an insight into the development of informetrics from its beginnings. Informetrics is a part of information sciences dedicated to measuring of information phenomenon. Informetrics can be defined as the discipline which studies quantitative aspects of information in any form not only within scientific community but also within any other social community. The term informetrics is an umbrella term for several similar but different disciplines such as bibliometrics, scientometrics, webometrics, altmetrics etc. Therefor the paper firstly explains the terminological issues related to different metric disciplines. Also, the paper aims to explore global and local conditions of informetrics and its position across other disciplines. According to the obtained research results the possible directions for the development of informetrics in Croatia are suggested.

I. INTRODUCTION

Nowadays a great attention is given to different kinds of metrics such as journal level metrics, article level metrics, author level metrics, university level metrics etc. in purpose to rank and evaluate those entities. Today many players exist at the market regarding measuring different metrics indicators and there is a quite terminological chaos dealing similar but different terms of metrics such as informetrics, bibliometrics, scientometrics, webometrics, altmetrics etc. The oldest terms were bibliometrics and scientometrics. The historical development of those two disciplines was almost synchronous. The first equivalent of term bibliometrics so called bibliometrie was firstly mentioned by Otlet in his work Traite de documentacion in 1934 year. In 1969 year Pritchard has introduced the English term bibliometrics defined as application of mathematical and statistical methods to books and other communication media [5]. In the same year two Russians Nalinov and Mulchenko have firstly coined the term naukometrya which was equivalent for scientometrics [4]. The term scientometrics became very popular from 1978 year when Tibor Braun in Hungary established the journal called Scientometrics. According to Wilson scientometrics studies quantitative aspects of science about science, scientific communication and science policy [2]. The newest term introduced by Björneborn and Ingwersen is webometrics which main purpose is to analyze WWW with bibliometrics and informetrics approaches [8]. Altmetrics is the latest metrics term and encompasses different kinds of alternative ways of article level metrics such as views, downloads, tweets, likes etc. In 1979 year almost at the same time Nacke [3] and Blackert & Siegel [1] introduced the German term informetrie as equivalent of the term informetrics. The term informetrics is the widest term and tends to encompass all other metrics. According to Tague-Sutcliffe the informetrics studies quantitative aspects of information in any kind and within any social community not only scientific community [7]. The literature review conducted within this paper also starts from this very point of view. This paper aims to explore global and local conditions of informetrics and its position across other disciplines thus the research questions raised in this paper are the following:

(1) How much informetric disciplines correlate to other traditional disciplines?
(2) In which geographical regions and universities are informetric disciplines mostly employed?
(3) Which are the most authoritative authors and journals within informetric disciplines?

After the second section which deals with explanation of the method used in this paper, the paper is structured in a way that each of the following sections are in fact answers to the raised research questions. Namely, the third section explains correlation of informetrics to other traditional disciplines, the fourth section describes informetrics across geographical regions and the fifth section highlights the most authoritative authors and journals within informetric disciplines. Concluding remarks are summarized at the end of the paper.

II. METHOD

Scopus is bibliographic and citation database which indexes journals, book series and conference proceedings from all scientific areas. Scopus includes sources from all scientific areas and within Scopus database more than 130 Croatian journals are indexed. Citation data within Scopus database are available from 1996 year till today. Scopus contains more than 40 million records and even 70 percent of them have an abstract. Scopus is a product of Elsevier corporation. The method used in this paper is bibliometric analysis of literature within Scopus database according to following search strategy:

TITLE-ABS-KEY (informetrics ) OR TITLE-ABS-KEY ( bibliometrics ) OR TITLE-ABS-KEY ( webometrics ) OR TITLE-ABS-KEY ( altmetrics ) OR TITLE-ABS-KEY ( scientometrics ) AND ( EXCLUDE ( PUBYEAR,
Total of 11,051 documents according to this search strategy were found in time period from 1974 year till 2016 year (without 2017 year) and analyzed for the purpose of answering to the research questions.

III. INFORMETRICS ACROSS DISCIPLINES

According to data available through the Scopus database informetrics correlates mostly with Medicine (49.2%), Social sciences (26.5%) and Computer science (22.1%). Some of the other disciplines which correlate with informetrics in smaller extent are Biochemistry, Genetics and Molecular biology (5.3%), Decision sciences (4.9%), Mathematics (4.1%), Engineering (3.7%) etc. Fig. 1. shows intensive raise of informetrics in scientific communication from the year 2000 till today. It can be seen at the Fig. 1. that the peak in number of published units dealing with informetric disciplines mostly in methodological sense was in the year 2014.

IV. INFORMETRICS ACROSS REGIONS

Distribution of documents regarding informetric disciplines across different countries at Fig. 2. shows that the most documents were published in United States (2342), United Kingdom (972), Spain (846), China (775), Brazil (526), Germany (526), Canada (507), Australia (376), Netherlands (374) and India (357).
Fig. 3. shows the most productive universities in the world regarding informetric disciplines. At the first place is Universidade de Sao Paulo (114), Indiana University (98), KU Leuven (98), Universidad de Granada (93), Universitat de Valencia (89), University of Wolverhampton (84), Administrative Headquarters of the Max Planck Society (83), Wuhan University (83), Universiteit Antwerpen (80) and University of Toronto (79).

![Figure 3. Distribution of documents regarding different informetric disciplines by author affiliation [6]](image)

V. AUTHORITIES IN INFORMETRICS

Fig. 4. shows the most prestigious journals in the world which publish content regarding different informetric disciplines. The most prestigious journals are Scientometrics (808), Nature (216), Journal of Informetrics (182), Journal of the Association for Information Science and Technology (117) and Plos One (113).

![Figure 4. The most prestigious journals regarding different informetric disciplines [6]](image)
Scientometrics is an international journal for all quantitative aspects of the science of science, communication in science and science policy produced by Springer. The journal Scientometrics is concerned with the quantitative features and characteristics of science and scientific research. The scope of the journal Scientometrics encompasses investigations about the development and mechanism of science studied by statistical mathematical methods. Nature is the weekly, international and interdisciplinary journal of science. Nature is a weekly international journal publishing the peer-reviewed research in all fields of science and technology on the basis of its originality, importance, interdisciplinary interest, timeliness, accessibility, elegance and surprising conclusions. The journal Nature provides rapid and authoritative news and interpretation of trends affecting science and scientists. Journal of Informetrics is produced by Elsevier. Journal of Informetrics publishes high-quality research on quantitative aspects of information science. The scope of the journal encompasses topics in bibliometrics, scientometrics, webometrics, and altmetrics as well as contributions studying informetric problems using methods from other quantitative fields, such as mathematics, statistics, computer science, economics and econometrics, operations research, and network science. Journal of the Association for Information Science and Technology (JASIST) is a fully refereed scholarly and technical periodical and has been published continuously since 1950. JASIST publishes reports of research and development in a wide range of subjects and applications in information science and technology. Plos One is the world’s first multidisciplinary Open Access journal. Plos One provides a platform to publish primary research, including interdisciplinary and replication studies. Plos One facilitates the discovery of connections between research whether within or between disciplines.

Fig. 5. shows the most influential authors which publish content regarding different informetric disciplines. The most influential authors are Bornmann, L. (92), Thelwall, M. (78), Abramo, G. (76), D’Angelo, C. A. (75), Aleixandre-Benavent, R. (61), Glänzel, W. (57), Egghe, L. (52), Leydesdorff, L. (52), Ho, Y. S. (46) and Rousseau, R. (45). The great authorities who should be accentuated within this field are certainly authors such as Glänzel, Thelwall, Leidesdorff and Bornmann. Wolfgang Glänzel is full professor based at KU Leuven, Belgium where he is Director of the Centre for R&D Monitoring, one of the leading research centres in bibliometrics. Professor Glänzel is amongst the most prolific and highly cited researchers in his area. He was awarded the Derek de Solla Price Medal in recognition of his contributions. Among many other roles, Professor Glänzel serves as editor-in-chief of Scientometrics. He is also affiliated with the Institute for Research Organisation of the Hungarian Academy of Sciences and holds doctorates in both mathematics and social science. Michael Thelwall is professor of Information Science and leader of the Statistical Cybermetrics Research Group at the University of Wolverhampton, which he joined in 1989. He is also Docent at the Department of Information Studies at Åbo Akademi University, and a research associate at the Oxford Internet Institute. His PhD was in Pure Mathematics from the University of Lancaster. His current research field includes identifying and analysing web phenomena using quantitative-led research methods, including altmetrics and sentiment analysis, and has pioneered an information science approach to link analysis. He is an associate editor of the Journal of the Association for Information Science and Technology. Loet Leidesdorff holds Ph.D. in Sociology, M.A. in Philosophy and M.Sc. in Biochemistry. He is professor in the Dynamics of Scientific Communication and Technological Innovation at the Amsterdam School of Communications Research of the University of Amsterdam.
Leydesdorff has published extensively in systems theory, social network analysis and scientometrics. He received the Derek de Solla Price Award for Scientometrics and Informetrics in 2003. Bornmann Lutz works as a sociologist of science at the Division for Science and Innovation Studies in the Administrative Headquarters of the Max Planck Society in Munich, Germany. His current research interests include research evaluation, bibliometrics and altmetrics. He is a member of the editorial board of *Journal of Informetrics* (Elsevier), *PLOS ONE*, *Scientometrics* (Springer), and *Journal of the American Society for Information Science and Technology* (Wiley).

VI. CONCLUSION

Informetrics is very young discipline but lately became very popular and employed in scientific communication. The main purpose of informetric disciplines is to inform other traditional and well established disciplines such as Medicine, disciplines within Social sciences such as library and information sciences, sociology of science and history of science mostly with scientometric and bibliometric approaches, disciplines within Computer science mostly with webometric and altmetric approaches. Although informetric disciplines are popular at the global scene the position of Croatia at that scene is almost invisible. This paper highlights the importance of positioning Croatian authors and Croatian journals at the local and global scene regarding informetrics trends.

For example first step toward better visibility of Croatian authors in terms of informetrics indicators could be integration of bibliometric and altmetric indicators such as h-index of authors, altmetric score and other article level metric indicators within CROSBI-Croatian Scientific Bibliography. Researches supported by different informetric disciplines could have great benefits for decision makers and creators of science policy and national educational policy in general.

Structuring E-Learning Multi-Criteria Decision Making Problems

Nikola Kadoić, Nina Begićević Redep, Blaženka Divjak
Faculty of Organization and Informatics, Varaždin, Croatia
{nkadoic, nbegicev, bdivjak}@foi.hr

Abstract - Problem structuring is one of the most critical phases of decision making process. A well-posed problem has direct impact on effective decision making, especially when we use the multi-criteria decision making methods. There are different decision making methods that have been used for decision making on e-learning issues in higher education, but the most suitable method for this kind of problems is the Analytic Network Process (ANP). ANP meets all the theoretical requirements of decision making in higher education, but policy makers use it very rarely in practice because of its implementation weaknesses. One of the weaknesses is a lack of support in structuring problem in the form of a network. This paper brings an overview of several problem structuring methods and approaches, such as simple top-down and bottom-up approaches, the PrOACT approach, ISM (Interpretative Structural Modelling), DEMATEL (Decision Making Trial and Evaluation Laboratory) and the PAPRIKA structuring method. It also brings analysis of how those structuring methods and approaches help overcome some of the ANP weaknesses. Finally, we provide some recommendations of how to design a new problem structuring method that fits the ANP needs.

I. INTRODUCTION

The following quote “A good solution to a well-posed problem is almost always a smarter choice than an excellent solution to a poorly posed one.” [1] is a very popular quote in decision making field. It highlights the importance of good decision making problem analysis before making any strategic decision. When we make decisions on different strategic e-learning issues and challenges, a real problem analysis before decision making is also requested in the e-learning field.

There are different approaches that we can use for decision making problem structuring. Depending on characteristics of the field in which we make decisions, different problem structuring method(s) are appropriate. E-learning belongs to the field of education in general, but here it will be related to the higher education (HE) field. To identify the most suitable method for decision making on e-learning issues, we follow the next steps:

1. Firstly, we analyse characteristics of decision making in e-learning and HE,
2. secondly, we analyse the characteristics of decision making methods to be applicable in e-learning and HE field, and
3. finally, we analyse decision making methods that shall apply in HE and e-learning field to identify their demands regarding structuring of decision making problem.

Some of those steps are already partly investigated. In [2] author identified characteristics of decision making in e-learning and HE. In [3], [4] authors identified characteristics of decision making methods which would be applicable in the area of HE and e-learning. These features are: problem structuring when multiple perspectives and levels of decision making have to be involved, modelling influences between decision making elements, supporting both – qualitative and quantitative scales (criteria), supporting group decision making, enabling sensitivity analysis including risk, opportunities, benefits and costs. The only method that fits all the demands and characteristics is the Analytic Network Process (ANP) [3], [5].

ANP is a multi-criteria decision making method introduced by Saaty [6] as a generalisation of the Analytic Hierarchical Process (AHP). AHP method is one of the most widely exploited multi criteria decision-making methods in cases when the decision (the selection of given alternatives and their prioritising) is based on several tangible and intangible criteria (sub-criteria). The process of complex decision problem solving is based on the problem decomposition into a hierarchy structure which consists of the goal, the criteria, the sub-criteria and the alternatives. In ANP, decision making problems are structured in the form of a network. The basic structure of ANP is an influence network of clusters and nodes (criteria) contained within the clusters [7]. A network has clusters of elements, with the elements in one cluster being connected to elements in the other cluster (outer dependence) or the same cluster (inner dependence). In outer influence one compares the influence of elements in a cluster on elements in the other cluster with respect to a control criterion; and in inner influence one compares the influence of elements in a group on each other.

Priorities in a network are established in the same way as in AHP using pairwise comparisons and judgments based on the Fundamental Scale (1 to 9 scale of absolute numbers) [6] and deriving priorities as the eigenvector of the judgment matrices. The outline of the ANP steps can be found in [7].

II. KEY FEATURES OF PROBLEM STRUCTURING METHODS TO FIT THE ANP NEEDS

Even though in the ANP general directions are given of how to structure decision making problem, in practice
policy makers often experience some issues related to problem structuring as well as applying other ANP steps. According to the literature and authors’ experience in the ANP implementation, some of those issues are:

- Structuring decision making problem into optimal number of clusters and elements in clusters is a challenge,
- Problem structuring procedures in the ANP do not include identifying the weights of influences between criteria which makes criteria pairwise comparisons difficult, sometimes not even understandable for decision makers,
- Similarly, on cluster level, the cluster pairwise comparisons are also difficult, especially in the situations when policy makers have to pairwise compare same clusters with respect to several different clusters [8], [9],
- Problem structuring can result with clusters which are strongly inter-connected (many influences between criteria of various clusters), but weakly intra-connected (small number of influences between criteria in the same cluster). That makes cluster comparison more confusable (see Figure 1: pairwise comparison of clusters 1-2-3-4-5 and A-B-C is more confusable in the second example than in the first),
- Decision making problem structuring can result with clusters which contain criteria that belong to different fields of expertise. Policy makers cannot make accurate pairwise comparisons and judgements if they are not experts in all needed fields of expertise, e.g. it is difficult to compare ICT and accounting criteria for expert in the ICT field. So, we would like for clusters to contain same-profession criteria, like in the paper [10],
- Finally, decision making problem structure has a direct influence on the number of pairwise comparisons [11].

To conclude, we identified several key features of problem structuring features to fit the ANP needs. These features are:

1. Identifying criteria (nodes in clusters);
2. Modelling influences between criteria (causality);
3. Identifying weights of influences between criteria;
4. Forming network structure;
5. Forming clusters;
6. Forming clusters with strong inter-connection and weak intra-connection; and
7. Forming same-profession clusters.

Some of the examples of the ANP problem structures can be found in [12] (case: strategic planning and decision making on e-learning implementation on the institutional level), [13] (case: evaluating e-Learning platform) and [14] (case: ODL system selection). The above mentioned decision making problem structures are created based on the literature analysis and brainstorming. Details about that approaches will be given in III.-A.

In next section of the paper, we will present several structuring methods and approaches, describe how to use them and analyse them regarding the ANP needs. In section 4 we will summarise results of analyses from section 3 in table form. Finally, in section 5 we will give some recommendations of possible structuring method which will combine advantages of the existing structuring methods.

III. ANALYSIS OF DIFFERENT PROBLEM STRUCTURING APPROACHES AND METHODS

Problem structuring methods that we will analyse in this paper are (1) general top-down and bottom-up approach, (2) the PrOACT approach, (3) the Interpretive structural modelling (ISM), (4) the Decision making trial and evaluation laboratory (DEMATEL) and (5) the PAPRIKA structuring method.

A. General top-down and bottom-up approaches

Top-down and bottom-up are basic and the simplest approaches of decision making problem structuring:

- By using a top-down approach, first, we identify the decision making goal. Then, we choose networks that will be analysed. Decision making problems can be analysed from a position of four merits: benefits (B), opportunities (O), costs (C) and risks (R); and depending on the problem we can analyse one or more networks. Then we identify control criteria for each merit (and sub-criteria, if applicable), clusters for each control (sub-) criterion and finally identify criteria for each cluster [7].
• Opposite approach, bottom-up approach means doing all steps like in top-down approach, but in reverse order, starting from criteria, through clusters, control (sub-)criteria and merits to goal.

Decision makers often combine those two approaches and structure problem in both directions simultaneously. Structuring procedure finishes when results from applying both approaches “meet each other”. Depending on e-learning problem complexity, some levels of problem structure will or will not be present. More complex problems might have all mentioned levels, but less complex problems might not contain e.g. control criteria (or sub-criteria).

When we analyse BOCR aspects of decision making problem, some of those aspects can be modelled as networks and some as hierarchies. For example, benefits (B) can be modelled as a network, and costs can be modelled as a hierarchy, like in [15]. Of course, the ANP method will be applied to network models and the AHP to hierarchy models.

Regarding fitting the ANP needs, we can conclude that top-down, bottom-up or combined approaches fit some of the ANP needs. Firstly, we can identify decision making criteria, but we cannot be sure that we covered all the important criteria. Secondly, we can model influences between criteria, but not determine the weights of those influences. Criteria are formed into clusters by the decision maker. There are no procedures that will ensure an appropriate number of criteria per cluster, consider influences between criteria when forming clusters or group same-profession criteria in the same cluster. All of this depends on the decision maker and his/her e-learning problem knowledge, analytics capabilities and how much knowledge (s)he has on the ANP method.

B. The PrOACT approach

The PrOACT approach (also known as a proactive approach) represents decomposition of decision making problem on several main elements [1]:

1. Pr (Problem). Problem is an entity which poses a barrier for a particular group of people in certain time and place;
2. O (Objectives). Objectives are goals that we want to achieve by solving the problem. Objectives can be created by using top-down or bottom-up approaches. Also, a method called problem tree can be used in a way that for the defined problem (Pr) we identify problem-sources and problem-consequences. When we get the whole list of problems, then we can define objectives which we will respond to problems. Finally, after objectives are defined, the criteria such as measures of objectives and their scales are determined.
3. A (Alternatives). Alternatives are possible decisions, choices and between them, we want to choose the best one. Some decision making problems have clear alternatives, and in some cases, we must analyse the problem and goal deeply to make the right definition. Methods that can be helpful in the phase of creating alternatives are: brainstorming/brainwriting, case studies, focus groups, nominal group technique, DELPHI, morphological analysis, Theory of Solving Inventive Problems (Russian: Theoria Resheneyva Isobretatelskehuh Zadach, TRIZ).
4. C (Consequences). Consequences are values that alternatives achieve per each criterion. Usually, multi-criteria decision making problem structures are described in a table form (decision making matrix or table of values).
5. T (Trade-offs). Trade-offs mean expressing the values of a certain criterion in terms of another criterion. Trade-offs are mainly used in Even Swaps method [1].

The PrOACT approach has been introduced by authors of Even Swaps method, and it has been designed for purposes of Even Swaps method [1]. However, this approach can be used with other methods which require decision making table as their input. For example, Electre, Topsis, Promethee and some other methods can benefit from applying PrOACT in the problem structuring phase. Still, most of them would also need some additional data that is not already provided in the table of values that was formed as a result of applying the PrOACT approach.

The PrOACT approach can be used for identifying criteria, and similarly to top-down, bottom-up and combined approaches. However, we cannot be sure that we covered all the criteria. Regarding fitting of the ANP needs, the PrOACT approach is not very useful, especially not for complex decision making problems such as strategic e-learning decision making problems. Namely, the PrOACT approach is a one-level approach: there are no procedures that will guide us to define merits, control criteria, clusters, and criteria. Also, the PrOACT approach does not model influences between criteria which means that the resulted model is not the network. All generated criteria form one cluster.

C. Interpretative Structural Modelling (ISM)

The ISM method is almost always combined with Delphi method. Therefore, Delphi can be considered as the first step in the ISM process. The role of Delphi in the ISM process is to ensure a complete list of criteria that describe strategic e-learning decision making problem [16]. Conducting the ISM includes active involvement of decision making problem experts and literature review.

The ISM is useful for analyzing the complex socioeconomic systems. It also helps to impose order and direction on the complexity of relationships among elements of a system. The ISM has two components [16]:

1. Building the hierarchical relationship – modelling influences between elements by using basics of graph theory.
2. Analysis using the MICMAC matrix (fra. Matriced’ Impacts Croise’s Multiplication Appliqué a UN Classement) which consists of ties between elements (criteria). It is used to analyse the driving power and dependence power.
of elements (criteria). It further helps to find the key criteria that are driving the whole process. MICMAC provides valuable insights about the relative importance and interdependencies among the criteria.

Steps of ISM (shortened according to [16], [17], [18]):
1. Identification of decision making elements – conducting Delphi method with experts and literature review to get a full list of criteria.
2. The creation of Reachability Matrix - this is a quadrate matrix of criteria with influences between them. In the matrix, on the address (x, y) can be 0 or 1. If there is 1, it means that criterion x has an influence on criterion y, and if there is 0, it means that x has no influence on x. Also, the concept of transitivity is applied.
3. Partitioning the Reachability Matrix - Reachability Matrix is partitioning into levels (clusters) to get a hierarchy of relationships between criteria.
4. MICMAC analysis: for each criterion, we should calculate driving power (summing rows) and dependence power (summing columns in Reachability Matrix).
5. Building ISM model – a hierarchy of relationships in decision making problem is built.

The main advantages of the ISM are [19]: systematic procedure; efficiency (when the ISM is software-supported); the ISM results and the model are understandable to users; it focuses users to think about only one aspect of the problem at the time. Disadvantages are: in the case of a vast number of elements, the process can be very tiring; experts from decision making problem domain are mandatory.

ISM becomes very desirable regarding fitting the ANP needs, but does it fit all the needs? Surely, it identifies the criteria, and here users are advised to conduct Delphi and literature review to be sure that they covered all decision making problem aspects (criteria). Also, systematically we can identify influences between criteria, but the weights of those influences are still missing. On the other hand, the ISM model is not a network structure with a cluster that is required in the ANP. However, the partitioning procedure can be interesting regarding creating clusters with strong inter-connection and weak intra-connection. However, to achieve that, a further adaption of the method is needed. Finally, the process of partitioning of Reachability Matrix does not consider the field of expertise (profession) of criteria when levels are created; so, it is not ensured that levels contain same-profession criteria.

D. The Decision Making Trial and Evaluation Laboratory (DEMATEL)

There are some similarities between ISM and DEMATEL [20]. The main goals of DEMATEL method are similar to the purpose of ISM. There are two main results of DEMATEL:
1. Casual diagram (also known as impact-relation map, [21]) - diagram of only significant influences between elements (criteria in decision making problem), which shows only influences that are over threshold value [22].
2. Relation Matrix – describes influences between criteria. Weights of influences are included now. In most often cases, five-scale 0-4 is used: 0, 1, 2, and 3 represent ‘No influence’, ‘Low influence’, ‘High influence’, and ‘Very high influence’ respectively [23].

Like ISM, DEMATEL has also been already applied in combination with ANP. DEMATEL and ISM provide a systematic, logical reasoning process to determine causality. They clearly delineate the relationships of the complex elements at the system level, direction and impact [20]. DEMATEL can propose the most important criteria which affect other criteria. DEMATEL can reduce the number of criteria [24].

Regarding fitting the ANP needs, by applying DEMATEL, we can model influences between criteria, as well as calculate weights of influences between criteria. Like in top-down, bottom-up and combined approaches, as well as in the PrOACT, we cannot be sure if we covered all the relevant criteria. The result of DEMATEL, impact-relational map (IRM), has a network structure, but this structure is not usable for ANP. However, network structure that would come as a result of drawing relation matrix would be very interesting regarding ANP. On the other hand, the procedure of how input data for IRM are calculated might be helpful in creating a cluster with strong inter-connection and weak intra-connection relationships because in IRM we draw only the strongest relationships. Other procedures for forming cluster are not available, and neither are procedures for creating same-profession clusters.

E. The PAPRIKA method

1000Minds applies patented PAPRIKA method – an acronym for Potentially All Pairwise RanKings of all possible Alternatives [25]. This method requires special decision making problem structure, so we will explain it here and later analyse in related to ANP. 1000Minds is an online suite of tools and processes to help individuals and groups make decisions, and also to understand other people’s choices. 1000Minds has tools for decision-making, prioritisation and discovering stakeholders’ preferences via conjoint analysis [25]. Depending on the application, 1000Minds can also help the user to think about the value for money of alternatives and allocate budgets or other scarce resources.

To be able to apply PAPRIKA method, structuring of a decision making problem consists of several steps:
1. identifying all criteria for decision making,
2. identifying all values that some alternative can achieve per certain criterion,
3. making pairwise comparisons of all possible pair combinations of possible alternatives’ values (e.g. what do you prefer: a hypothetical alternative with values x on criterion 1 and y on criterion 2 OR a hypothetical alternative with
values $z$ on criterion 1 and $v$ on criterion 2) to get criteria weights and alternative priorities.

This decision making problem structuring reminds on modelling in Dex method. DEX is a qualitative multi-criteria method, in which all criteria are represented by qualitative (symbolic, verbal) attributes. The attributes are structured into a hierarchy, and the evaluation of alternatives is governed by decision rules [26].

This problem structuring method has many weaknesses regarding fitting the ANP needs. First of all, just like the PrOACT method, criteria are identified in one-level approach. Then, there are no hierarchical or network levels. Finally, this method does not fit most of the ANP demands, and the features of the method do not contribute to the ANP needs.

IV. RESULTS: HOW DIFFERENT PROBLEM STRUCTURING METHODS FIT THE ANP NEEDS

In Table II we have summarised how different problem structuring methods and approaches fit the ANP needs.

<table>

</tr>
</tbody>
</table>

If we simply count number of fits, we can say that the method that best fits the ANP needs is DEMATEL. Also, if the top-down or bottom-up approach is implemented by experts in both, decision making problem field and ANP method, the results might be even better than in DEMATEL - if experts pay attention to (1) profession of criteria (create same-profession clusters) and (2) connections between criteria when forming clusters (strong inter- and weak intra-connection). On the other hand, there is room for improvement of the structuring method.

V. RECOMMENDATIONS FOR UPGRADED PROBLEM STRUCTURING METHOD

In this section, we give some recommendations for upgraded problem structuring method which will combine good sides of the presented model structuring approaches and upgrade them with some additional features:

1. The starting point of the upgraded method is Delphi and literature review. Those methods ensure a list of all criteria that are relevant for certain e-learning problem.
2. All identified criteria will be grouped by experts or Q-sorting into several groups that are related according to four merits: B, O, C and R, and further analysis goes separately for each merit.
3. To all identified criteria, we join a profession (field of expertise). A profession will be considered in step 5 as a factor for creating same-profession clusters.
4. Now, in each merit, we identify influences between criteria and calculate their weights (as in DEMATEL).
5. This step requires the development of clustering procedure that will separate weighted network of criteria into clusters. Those clusters will consist of same-profession criteria (as a feature with the highest priority) and will have weak inter- and strong intra- connection between criteria. Cluster size should be between 5 to 9 (number of criteria in the cluster) in most of the clusters. To develop that procedure, algorithms that resulted in ISM model and IRM model can be analysed and possibly reused, as well as different cluster algorithms, such as algorithms in the Pajek [27], an algorithm for affinity analysis [28] and others.

After developing the method, it should be evaluated by using qualitative and quantitative analysis, including software implementation which will simplify new structuring method applications. The proposed method will fit the best into ANP needs, but it requires considerable resources in expertize (use of experts), time and professional guidance.

VI. CONCLUSION

Dealing with different e-learning challenges systematically requires making the proper strategic decisions related to those challenges. Prerequisite for making a right decision requires a good structure of decision making problem. The method that meets the most characteristics of decision making in HE is the ANP method.

In this paper, we presented several problems structuring approaches and described how they fit the ANP needs. We conclude that the most suitable structuring method regarding the ANP needs is the DEMATEL. However, the DEMATEL still has weaknesses, so we gave some recommendations for upgraded problem structuring method that will be based on the DEMATEL.

Abstract - Research on educational e-courses that contain only a series of motivating elements of computer games but do not include playing computer games has intensified since 2010 [1][6]. This field of research is called gamification and represents the use of game elements (mechanics, dynamics and aesthetics) in a field (education, marketing etc.) that is not a computer game. A review of literature related to the field of teaching with online courses in information technology (e.g. programming, software engineering) shows that the topic of gamification has so far been inadequately explored, with the lack of theoretical and empirical research that would involve gamification methodology. Previous studies have shown that gamification can have a positive impact on the pedagogical and psychological aspects of e-learning. In this paper empirical research is presented regarding the use of gamification in online teaching of programming. A gamified e-course was designed for the lectures in programming, and a possible positive effect was examined on the usage of learning materials in an experimental group of students who will use a gamified e-course (online system).

I. INTRODUCTION

The idea of using an e-learning system with the attributes of a computer game, but without game playing, has been a rapidly growing trend since 2010 [2][5][6]. Recent research on a similar topic of serious games confirms a positive attitude of subjects (learners) who used interactive dynamic systems (with an emphasis on learning) like computer simulations (economic, political, military etc.) where a student plays according to a predefined scenario and monitors the outcomes of his/her decisions on goal realization and learning outcomes. For this purpose commercial games can be used, as well as specialized educational games designed for specific fields of study.

The term "gamification" represents the use of elements (mechanics, dynamics and aesthetics) of computer games in the field that is not a computer game [2][5][6]. Gamification as a rising trend has been recognized by many researchers and institutions like Gartner Research [8][14][19][24][25].

In 2013 gamification was positioned as a technological innovation whose development should be followed with the exceptional importance (see: [4][9][15]). Previous studies have focused on proving that this approach gives positive results in various fields like business, marketing and education [12][17][20]. A simple search using the scientific literature search engine Google Scholar (http://scholar.google.com; February 2017) reveals that in the documents related to the year 2010 the term “gamification” appears only 173 times, while in those for the year 2013 and 2016 it appears 3,780 times and 8,410 times, respectively.

About a decade ago it was demonstrated that the use of elements of computer games can have a positive impact on the psychological characteristics of students and learning behavior (for instance, see: [22]). A review of literature related to the field of teaching information technology (e.g. programming, software engineering) revealed that, until recently, there have been very few empirical studies related to gamification of respective online courses. Also, it has not been clearly defined what all the elements of computer games are that should be specifically taken into account when designing online courses, as well as how they can be effectively implemented in the (re)design of existing online learning systems.

In our study experimental research methodology will be used. A traditional (for the control group) and gamified (for the experimental group) online course will be designed to investigate the influence of the use of elements of computer games on learning outcomes in an online environment.

When creating a gamified online course, according to Iosup and Epema [11], teachers, designers and/or administrators of gamified online courses are expected to ensure at least one week for the consideration of the computer game elements which are included in the e-course, and at least one day for creating educational content. Furthermore, Iosup and Epema [11] state that it is necessary to set aside at least two hours to analyze questions for each teaching unit as well as two days for entering the results of each knowledge assessment. Finally, it is important to ensure one week for analysis of the transition to gamification.

II. RESEARCH BACKGROUND

With today’s pervasive use of technology in everyday life, there is a growing need for technological advancement in the use of online education that would be based on pedagogical and psychological processes which positively influence the student's perception of the teaching content and their motivation for active participation, research and cooperation [1][6][7]. An earlier example is the use of 3D virtual worlds in online learning where Second Life was the most commonly used product.

Second Life enables online connectivity and teaching/training in 3D virtual space with the use of
ed
educational methods/metaphors that can be used in many other technological forms in the future.

A turning point for the use of gamification was the “GSummit 2014” conference held in San Francisco with numerous speakers, investors and members of the world’s leading companies presenting and seeking gamified solutions for their products and systems [7]. Another conference entitled “Gamification World Conference 2016” was held in Madrid, Spain, with the presence of the most famous researchers of gamification methodology and technology in the world, such as [3], [13], [16], [26], [29].

According to Souza-Concilio and Pacheco [23], the implementation of elements of computer games is getting more visible in various fields including education, health and fitness, task management, environmental sustainability, science, user generated content and others. About 40 years ago Malone et al. [15] emphasized the need to make learning more interesting. As a confirmation of their claim, it must be noted the value of gamification market had risen to 513 million dollars by 2013, with its value increasing to 980 million dollars in 2014, amounting to as much as 2.8 billion dollars in 2016 [19][27][28].

The importance of gamification can also be illustrated by the recent EU project call in the Horizon 2020 funding scheme (ICT-21-2014) for research of gamification technologies with funding opportunity of eight million euros in total. A more recent call was launched in 2016 for proposals that could be funded with up to one million euros (ICT-24-2016) [10].

The previously presented market value and research funding opportunities indicate the relevance of gamification research. In this paper the authors will focus on the context of online education, especially in the field of informatics and software engineering. Therefore related theoretical and empirical analyses are presented as well as a proposal for standardization of elements of computer games that might come into consideration for implementation with the learning management system (LMS) Moodle.

According to Nielson [18] and Schonfeld [21], the following 24 types of gamification mechanisms that are currently recognized and accepted in practice have been most frequently cited in the literature (see Table 1).

### TABLE 1. MECHANICS AND AESTHETICS IN A GAMIFICATION SYSTEM

Each element in Table 1 can be categorized according to three attributes: (1) the mechanics of a game, (2) benefits and (3) personality. Mechanics of the game can be divided into behaviour, feedback and promotion. According to the categorization by Bartle [3], personality can be divided into winner, wordsmith, collector and researcher subtypes, all of which represent basic types of users or players in a game. The components of computer games (i.e. mechanics) shown in Table 1 are not new. It is the use of information and communication technology to support a more effective and visually attractive creation/application of a game that represents today’s novel modality for gamification. In that respect, it should be noted that not all of the elements of computer games are appropriate for all types of players. However, most of those elements can find some application in business or education systems.

### III. RESEARCH HYPOTHESIS

For this research paper only one directional hypothesis is defined:

- **H1:** An online course which is pedagogically designed with the application of the elements of computer games (i.e. gamified) will have a greater effect on the amount of use of online teaching materials in comparison with a course with the same educational content, but without the presence of elements of computer games.

To confirm the hypothesis H1, first a research of literature was conducted focusing on the topic of motivation of the participants in gamified online courses and other related positive effects. The focus was also placed on online courses related to information and communication technologies in higher education institutions. In the empirical phase of our research an investigation was performed of the influence of gamification on the use of e-learning materials. In the analysis of empirical data the log report of participants’ activities in the Moodle LMS was used for both the experimental and the control group of subjects.

### IV. CURRENT STATE OF THE USE OF ELEMENTS OF COMPUTER GAMES IN E-LEARNING

The research that is presented in this paper began by collecting the views of teachers in two higher education institutions (HEI) from two Central European universities. A total of 43 correctly completed survey forms were collected from the HEI teachers. All of the subjects/respondents used the Moodle LMS in their academic teaching. Their courses were mostly delivered in the second or third year of an undergraduate study.

It must be noted that our survey respondents were not using the customization functionality of the Moodle LMS and their answer to the question “Do you use a special custom graphics template?” was “No” or "We have no choice". Also, most of the respondents (53%) were not familiar with the learning systems of Khan Academy, Duolingo or similar learning systems. This was not a positive indicator of how broad their knowledge of e-learning was since the aforementioned systems had received prestigious awards as well as introduced some innovative approaches to knowledge transfer via e-learning. Furthermore, in their response to the survey question regarding the use of external links (plugins/functionality)
that can be added into the Moodle LMS system (Facebook, Twitter, Yahoo, YouTube, Gmail, G-search, Wiki) as many as 58% of respondents chose the response "none of the above".

Other questions in our survey among academic teachers were related to the mode of presentation of learning materials in an online course. Our survey revealed that the majority of respondents preferred traditional (offline) teaching materials, but in their online course material they also frequently used static text that is accompanied with a PowerPoint presentation or a PDF document/article. In the Moodle LMS system the most widely used functionalities by our respondents were the following:

1. Forum (86%)
2. Achieved current points (67%)
3. Questionnaires (65%)
4. Multimedia (58%)
5. Bonus teaching materials (49%)
6. Editing of profile & avatar (28%)

According to the surveyed teachers, the most frequent activities that their students performed in the LMS environment were:

1. Use of quizzes and assignments (53%)
2. Feedback from students to the professor (53%)
3. Student cooperation on problem solving tasks (26%)
4. Individual voluntary casual tasks (26%)
5. Personalization of user interface (14%)

Most of the teachers agreed that story and motivational elements visible in computer games can have a positive impact on the interest of students regarding the teaching subject. Also, a considerable percent of respondents (49%) stated that they were not familiar with the flow theory, which is important in interpretation of gamification of e-learning, while only 37% of them replied that they were partially informed about flow theory.

Our survey of teachers at two academic institutions in Croatia revealed that the variety of their implementation of pedagogical elements related to computer games in their e-learning courses was, on average, rather low. As it is previously listed, the most widely used pedagogical features were discussion forums, questionnaires, quizzes, assignments, multimedia, bonus teaching materials, as well as feedback from the instructor to students, and vice versa. The surveyed teachers were not familiar with e-learning systems and products for e-learning like Khan Academy or Duolingo. It would be of great value to the teachers to be included into an online course covering the possibilities of e-learning and digital networking tools which are more game-oriented.

In the continuation of this paper the authors will try to demonstrate that the use of elements of computer games (i.e. gamification) can positively affect the use of teaching and non-teaching material that is available to students within an e-learning system like Moodle.

V. PROCEDURE AND SUBJECTS

For the purpose of our study a new installation of Moodle 2.7. LMS was used with additional gamification components. The gamification elements were added in form of plugins because they were not available in the initial version of Moodle 2.7 system. A conceptual model with potentially useful gamification elements was created on the basis of a survey of academic teachers who used e-learning, available plugins for Moodle 2.7 system, and Octalysis Gamification Framework [http://yukaichou.com/gamification-examples/octalysis-complete-gamification-framework/]. For the experimental group of students a gamified e-learning course for teaching computer programming (on the topic “Batch and Stack”) was designed in Moodle with the use of selected elements of computer games. Conversely, for the control group of students, a traditional non-gamified online course was developed in parallel and with equal content in the Moodle system that was located on a separate physical server. The traditional non-gamified course had only three elements that were set besides the educational materials: profile and avatar area, use of forums, and nonlinear access to educational materials.

To complete the development of both e-learning courses (gamified and traditional), the teaching content and teaching materials of all the basic teaching material that was adapted for this research was standardized (made equal) for both e-learning courses and reduced to HTML text accompanied by pictures or videos. In other words, identical basic educational content and materials were placed in both e-learning systems. Also, the teaching materials and topics that were used online in both e-learning courses were not used for lecturing in traditional classroom face-to-face environments, including exercises in computer laboratories. Students were instructed to use online teaching materials in the gamified and non-gamified course completely alone, without any intervention from the teacher in the physical environment. In this manner, the subjective influence of teachers on students in both the experimental and the control group was considerably reduced, increasing the credibility and reliability of the experimental procedure. It must especially be noted that the teaching materials used in the course did not differ in its content or in the order in which they were listed the Moodle system. After the two weeks during which the students were involved with the online course materials their log entries were analysed to draw conclusion regarding hypothesis H1.

The subjects in this study were students of an informatics college in the Republic of Croatia. All of the students attended the course "Programming 2" at the undergraduate level of study of informatics in the winter semester of the academic year 2015/2016. The total number of subjects who were voluntary participants in the study was 201. The subjects were divided into two groups: the experimental group and the control group. Of the total number of subjects, 44 (or 21.9%) were female and 157 (or 87.1%) were of male gender. Their average age was 20 years. Information on our convenience sample of subjects is presented in more detail in Figure 1. The permission for students’ participation in the study was requested and obtained by the relevant higher education institution authorities.

VI. RESULTS AND DISCUSSION

The analysis of the initial written test of prior knowledge (pre-test) in Table 2 provides insight into the distribution of the subjects/respondents in the control and experimental group. The data presented in Table 2 indicate that there was
no statistically significant difference between the experimental (G_ex) and the control (G_con) group regarding the results of prior knowledge testing (pretest). The value of the t-test was 0.57, with p>0.56. Also, there was only a slight difference between the mean results of the two groups (about 5% of the standard deviation). It can be concluded that the two groups were suitable for performing the subsequent experimental research procedure.

In the continuation of this paper a report is presented on student activities that was generated based on the log entries from the Moodle system. This represents the final part of our data analysis which will enable the confirmation or rejection of our research hypothesis H1.

Table 3 provides a list of activities that were accessed by students within the gamified and non-gamified online course. For the experimental group of students, the average number of 9.07 access attempts was registered in log entries for all of the activities listed in Table 3, while for the students in the control group the average number of registered instances of access was only 1.03. The results in Table 3 indicate a significant difference in favor of the experimental group. It can be concluded that the experimental group showed a much greater average interest in the available activities in the online course such as "Forum" (5.6 times greater), “Learning outcomes” (9.7 times greater) and "List of terms" (43.3 times greater).

Table 4 shows the access frequency / number of instances of access to course materials by respondents in the experimental and the control group with regard to core learning content and bonus materials. The experimental group of respondents used both the basic teaching materials and bonus materials which were added to the course to motivate students for additional learning and to access content more frequently. It can be seen in Table 4 that the experimental group of respondents accessed the teaching and bonus materials on 34.92 occasions on average, while the same kind of materials were accessed by the control group only on 9.46 occasions on average. Therefore, it can be calculated that regarding the data in Table 4 the summative indicators of frequency of access to all of the listed learning activities and bonus materials

In the central empirical part of our study it was confirmed that the e-learning course which is designed by applying elements of computer games (i.e. gamified) can have a positive effect resulting in greater frequency of use of teaching materials compared to the course with the same educational content, but without the presence of elements of computer games.

In the central empirical part of our study it was confirmed that the e-learning course which is designed by applying elements of computer games (i.e. gamified) can have a positive effect resulting in greater frequency of use of teaching materials compared to the course with the same educational content, but without the presence of elements of computer games. Therefore, the hypotheses H1 was confirmed. This is clearly evident in the graphical analysis of objective indicators of online activity of experimental and control group of subjects regarding their frequency of access...
to learning materials placed in the Moodle system (see Figure 2).

The main contribution of this paper is related to the verification of the hypothesis that gamification can lead to greater usage of the gamified e-course educational materials measured by objective indicators that are present within the Moodle system in terms of participants’ activity logs.

LIMITATIONS

The main limitations of our study are related to the following:

• **Students’ obligations.** Our research was conducted during regular classes at the higher education institution. In addition to having to use the experimental e-learning system, students had obligations in other courses. It is important to emphasize that participation was voluntary. Conducting the experiment was planned at a time when students did not have a mid-term or final exam. Individual tasks and obligations at the level of the study program could not be included in the analysis of each student workload, but it is highly possible that students had other obligations related to other courses during the use of the experimental system.

• **Time period of the use of online courses.** Research activities for each course were planned with particular regard to the academic syllabus and other educational assignments. It was decided that the measurement should be carried out in a short time-period during the two to three weeks after the students had gained access to learning materials in the online courses that were designed for the experiment.

Abstract – When employed in educational settings, cloud computing applications enable users to create, store, organize, and share divergent artefacts with their peers. As an outcome, they have a large number of users worldwide which makes them vulnerable to a variety of security and privacy related threats. With an aim to examine the extent of the perceived security and privacy in the context of cloud computing applications that are most commonly used for educational purposes, an empirical study was carried out. Participants in the study were students from two Croatian higher education institutions. Data was gathered by means of the post-use questionnaire. Study findings uncovered pros and cons of examined cloud computing applications with respect to the manner they are addressing security and privacy concerns of their users.

I. INTRODUCTION

The introduction of Cloud Computing technologies in higher education institutions improves the efficiency of existing resources usage, as well as the reliability and scalability of software tools and applications, enabling users to create, store, organize, and share divergent artefacts with their peers.

According to the National Institute of Standards and Technology (NIST) definition, “the cloud computing is a model for enabling convenient, resource pooling, ubiquitous, on-demand access which can be easily delivered with different types of service provider interaction” [1]. The cloud computing follows simple “pay as you go” (PAYG) model, where you pay for the services you’ve used [2].

Cloud computing is an emerging new computing environment for delivering computing services which can be categorized regarding its basic components, deployment models and service delivery models. An overview of Cloud computing components is presented in Figure 1. [3].

The demand for cloud computing applications in educational ecosystem builds on the promises of free to low-cost alternatives to expensive tools. Cloud computing applications are especially suitable for educational institutions lacking technical expertise [4] to support their own IT infrastructure. According to [5] and [6], students and higher education institutions benefited from the advantages and effectiveness that cloud computing applications provided them.

While cloud computing applications present a great opportunity for educational institutions, its usage raises concern about a variety of security and privacy threats, by placing a very large amount of student, teacher and institution data into the hands of a third-party service providers [7].

The objective of this paper is to examine the degree of perceived security and perceived privacy of cloud computing applications commonly used in educational settings.

The remainder of the paper is structured as follows. Brief theoretical foundation of our study is provided in next section. Findings of an empirical study are presented and discussed in third section. Concluding remarks, study limitations, and future work plans are offered in last section.

II. BACKGROUND TO THE RESEARCH

Most cloud computing applications used in the educational ecosystem today are SaaS cloud services that operate in the “public” cloud. These applications include productivity suites like Microsoft Office 365 and Google Apps along with data storage services such as Microsoft OneDrive and Google Drive.

One of the most significant barriers to cloud computing adoption are security and privacy [8], that relate to risk areas such as external data storage, dependency on the “public” internet, lack of control, multi-tenancy and integration with internal security.
Among the main privacy challenges for cloud computing are complexity of risk assessment in a cloud environment, emergence of new business models and their implications for consumer privacy and achieving regulatory compliance.

The concept of trust is elaborated by [11], with numerous trust objects and measures that can operationalize the impact of trust on the adoption of technological innovations. They identified the following items as appropriate for the operationalization of the security & trust factor in the context of cloud computing: data security, trustfulness of the cloud service provider, contractual agreements and geographical location where data is stored and processed. According to [11], security is viewed as a composite notion, namely “the combination of confidentiality, the prevention of the unauthorized disclosure of information, integrity, the prevention of the unauthorized amendment or deletion of information, and availability, the prevention of the unauthorized withholding of information”.

A mapping of cloud service and security requirements was carried out by [12], while [13] composed a list and description of cloud computing threats, compromised attributes and related studies.

Topic areas in information privacy research include among others, information privacy concerns, information privacy attitudes, trust and information privacy and information privacy practices [13].

Examining the individuals’ security and privacy concerns with their intention to use mobile applications, [14] developed a research model from the principal tenets of the theory of planned behaviour (TPB) and protection motivation theory (PMT). The study by [15] has provided early empirical support for a model that explains the formation of privacy concerns from the CPM theory perspective. The authors state that the globalization of economies and information technology and the ubiquitous distributed storage and sharing of data puts the issue of privacy on the forefront of social policies and practices. Drawing on the CPM theory, [15] developed a model suggesting that privacy concerns form because of an individual’s disposition to value privacy, or situational cues that enable one person to assess the consequences of information disclosure.

III. EMPIRICAL STUDY

A. Procedure

The study was conducted during the winter semester of the academic year 2016/17. in controlled lab conditions and was composed of two main parts: (1) scenario-based interaction with two cloud computing application for managing artefacts and (2) evaluation of their perceived security and privacy by means of the post-use questionnaire. Upon arriving to the lab, the participants were welcomed and briefly acquainted with the study. At the beginning of the scenario performance session, each participant received the form containing a list of 12 representative steps of interaction. Participants were asked to carry out all scenario steps twice – first with Google Drive and thereafter by means of Microsoft OneDrive (both shown in Figure 2). Upon finishing all the scenario steps with both cloud based applications, the participants were asked to complete the post-use questionnaire. At the end of the study, respondents were debriefed, and thanked for their participation. The duration of the study was 40 minutes.

B. Apparatus

The post-use questionnaire was administrated online by means of the KwikSurveys questionnaire builder. The questionnaire comprised 16 items related to participants’ demography and 35 items meant for measuring facets of perceived security and privacy. Items on perceived security and perceived privacy were adopted from Cheung and Lee [16], Flavián and Guinalíu [17], Janda et al. [18], O’Cass and Fenech [19], and Ranganathan and Ganapathy [20]. Responses to the post-use questionnaire items were modulated on a five point Likert scale (1 - strongly agree, 5 – strongly disagree). The psychometric features of the
measuring instrument were examined with respect to the construct validity and reliability [21]. Convergent and discriminant validity, as indicators of construct validity, were explored by means of a principal component analysis (PCA) with equamax rotation and Keiser normalization. With an aim to verify that the requirements for factor extraction were met, the Kaiser-Meyer-Olkin test of sampling adequacy and Bartlett's test of sphericity were evaluated. As a criterion for identifying the number of factors, an eigenvalue greater than one was employed. Only items with loadings above .40 and cross-loadings below .40 were retained [22]. Reliability in terms of the internal consistency of extracted factors was measured with Cronbach's Alpha coefficient.

C. Participants

A total of 318 subjects took part in the study. They ranged in age from 18 to 48 years (M = 21.03, SD = 4.197). The sample was composed of 67.30% male and 32.70% female students. At the time study took place, majority of them (50.31%) were students at Juraj Dobrila University of Pula, Department of Information and Communication Technologies while remaining 49.69% studied at Polytechnic of Rijeka. Most of the study participants (80.50%) were full-time students. When the computer literacy is considered, respondents are proficient users of both computers and the Internet. More specifically, they have between 2 and 29 years (M = 11.82, SD = 3.559) of experience in employing computers and between 2 and 20 years (M = 9.76, SD = 3.092) of experience in using the Internet. In addition, 74.21% and 82.08% of participants believe that their computer skills and Internet skills, respectively, are at least very good. When the frequency of using the Internet for different purposes is taken into account, 69.50% of respondents is employing it for communication at least 11 hours per week, 60.06% of students is using the Internet for educational purposes between 4 and 20 hours per week, 71.07% of participants is using the Internet for fun more than 11 hours per week, and 41.82% of students is using the Internet for business purposes at least one hour per week. Study participants had also been loyal users of popular social Web applications. Namely, 65.55% respondents have been socializing on Facebook for more than 6 years, 52.86% of them have been podcasting on YouTube for more than 7 years, whereas 67.96% of students have been sharing their moments with a community for less than 2 years. Regarding the length of using Google Drive and Microsoft OneDrive, 49.16% of participants have been using them for more than one year, while 12.04% have not used aforementioned cloud computing applications prior to this study.

D. Findings

The Kaiser-Meyer-Olkin measure of sampling adequacy (KMO = .936, KMO = .944) and Bartlett’s test of sphericity (χ2 = 7638.851, p = .000; χ2 = 8026.838, p = .000) confirmed that the data in the case of both Google Drive and Microsoft OneDrive, respectively, have met the requirements for conducting the principal component analysis (PCA). During the purification procedure, eight items (SCR6, SCR7, SCR8, SCR11, SCR14, SCR15, PRV10, and PRV11) were dropped. As presented in Table 1 and Table 2 (see Appendix), the final iteration of PCA uncovered two dimensions of perceived security and four dimensions of perceived privacy, respectively. They accounted for 69.137% and 66.021% of the sample variance in the case of Google Drive and Microsoft OneDrive, respectively. Values of the Cronbach's Alpha coefficient were in range from .787 (in the case of measuring the Confidentiality of Google Drive) to .934 (in the context of evaluating Integrity of Microsoft OneDrive) thus indicating that reliability of scales was deemed adequate. Items marked with asterisk are reverse coded.

Results of data analysis indicate that 66.67% and 57.55% of study subjects believe that Google Drive and Microsoft OneDrive, respectively, have built-in high-quality mechanisms that protect users’ artefacts from unauthorized use (SCR1). It was also found that 63.84% and 58.49% of students reported that Google Drive and Microsoft OneDrive, respectively, have integrated good security measures that protect their personal information (SCR2). In addition, 61.64% and 53.77% of study participants stated that Google Drive and Microsoft OneDrive, respectively, protect the security of all activities carried out by their employment (SCR3). The collected data also imply that 61.01% and 53.14% of students perceive that Google Drive and Microsoft OneDrive, respectively, have good protection mechanisms that prevent the theft of their identity by a third party (SCR4). Moreover, it was discovered that only 38.99% and 34.91% of respondents believe that Google Drive and Microsoft OneDrive, respectively, are protected to the extent that no third party cannot falsely introduce oneself to their users (SCR5).

Results of data analysis also indicate that 69.50% and 62.58% of subjects believe that Google Drive and Microsoft OneDrive, respectively, have built-in mechanisms that prevent unauthorized changes to information about the user (SCR9). Furthermore, 68.24% and 61.95% of students agree that Google Drive and Microsoft OneDrive, respectively, have built-in mechanisms that prevent unauthorized modification of stored documents (SCR10). Similarly, 75.47% and 71.70% of subjects is convinced that Google Drive and Microsoft OneDrive, respectively, verify user's identity before granting access to personal data and documents (SCR12).

The data gathered from study participants revealed that 76.73% and 71.07% of them believe that Google Drive and Microsoft OneDrive, respectively, is taking care of the protection of personal data and documents that are stored on it (SCR13). In addition, results of data analysis imply that 69.81% and 60.38% of students think that Google Drive and Microsoft OneDrive, respectively, are secure cloud computing applications (SCR16). Finally, according to data presented in Table 1, 63.52% and 57.23% of study subjects believe that Google Drive and Microsoft OneDrive, respectively, have implemented all the required security mechanisms (SCR17).

Data displayed in Table 2 imply that 32.30% and 33.65% of study participants is concerned that Google Drive and Microsoft OneDrive, respectively, will use their personal data for other purposes without their permission (PRV1). Furthermore, the findings of the pilot study imply that 39.94% and 36.48% of respondents think that Google Drive and Microsoft OneDrive, respectively, collect too...
much information about their users (PRV2). It was also discovered that 31.45% and 32.70% of study subjects is concerned about the privacy of their personal information when using Google Drive and Microsoft OneDrive, respectively (PRV3). In addition, 32.08% and 31.45% of students is concerned that Google Drive and Microsoft OneDrive, respectively, will give their personal information to third parties without their permission (PRV4). The collected data also indicate that 65.09% and 58.18% of study participants think that Google Drive and Microsoft OneDrive, respectively, will take care of the privacy of their users (PRV5). Moreover, it was found that 52.52% and 46.86% of respondents feel that their privacy is protected when storing their personal information and documents on the Google Drive and Microsoft OneDrive, respectively (PRV6).

According to the results of data analysis, 70.13% and 65.72% of study subjects think that Google Drive and Microsoft OneDrive, respectively, comply with the laws and regulations on the protection of users’ personal data (PRV7). In addition, 48.43% and 47.80% of students agree that Google Drive and Microsoft OneDrive, respectively, collect only the information about users that is necessary for their use (PRV8). Data gathered from students revealed that 63.84% and 61.01% of them think that while collecting data about users, Google Drive and Microsoft OneDrive, respectively, respect their rights (PRV9). Students responses are also implying that 38.68% and 37.74% of them is afraid to provide Google Drive and Microsoft OneDrive, respectively, with their personal information because they do not know what these cloud computing applications could do with them (PRV12).

Considering the results of data analysis, 43.40% and 41.51% of students think is risky to provide Google Drive and Microsoft OneDrive, respectively, with their personal information (PRV13). It was also discovered that equal number of students (25.47%) believe that if they provide Google Drive or Microsoft OneDrive with their personal information, they could be faced with unexpected problems (PRV14). Moreover, 25.47% and 23.59% of respondents think that Google Drive and Microsoft OneDrive, respectively, could use their personal information in an inappropriate fashion (PRV15). Results of the data analysis also indicate that 34.59% and 35.54% of study participants think there is a very strong correlation between the potential loss of privacy and disclosure of personal information to Google Drive and Microsoft OneDrive, respectively (PRV16). Moreover, 43.71% and 39.31% of students believe that they have control over who has the access to their personal data collected by Google Drive and Microsoft OneDrive, respectively (PRV17), Finally, as can be observed from students’ responses, 40.25% and 36.48% of them think they have control over how Google Drive and Microsoft OneDrive, respectively, are using their personal information (PRV18).

IV. CONCLUSION

The aim of this paper was to examine the perceived security and perceived privacy of cloud computing applications. For that purpose, an empirical study was carried out. Based on the data collected from study participants, psychometric features of measuring instrument were evaluated. Construct validity was tested with the use of a principal component analysis whereas Cronbach's Alpha coefficient was employed for assessing the construct reliability. As an outcome, data analysis uncovered two dimensions of perceived security (Integrity and Confidentiality) and four facets of perceived privacy (Privacy Concerns, Privacy Protection, Privacy Risks, and Privacy Control).

As with all empirical studies, some limitations which require further examination have to be acknowledged. The first one deals with the homogeneity of participants. Although students in our study are a representative sample of cloud-based applications users, perceived security and perceived privacy might vary if it would be evaluated by more heterogeneous group of users. The second limitation is that the findings cannot be generalized to all types of cloud computing applications except to the ones involved in the study. Keeping the set forth limitations in mind, study outcomes should be interpreted with caution.

Takin into account that this study is a part of an ongoing work, our future work efforts will be focused on exploring the extent to which identified aspects of perceived security and perceived privacy contribute to users’ behavioural intentions regarding the employment of cloud computing applications.

Abstract - The study presented in this paper aims to explore students’ characteristics and to determine student groups based on their previous education and socio-demographic characteristics. Descriptive data mining method, cluster analysis, is applied in the analysis process. Data used in the research is collected among first, second and third year IT students. Research results indicate profile of successful IT student. As such, research results provide useful insight into both micro and macro level aspects of educational process, which can benefit both students and academic institutions. Data mining has shown promising results in educational domain and a substantial potential to serve as a tool for improvement of quality in education.

Keywords - educational data mining, academic performance, cluster analysis, educational strategy

I. INTRODUCTION

The goal of higher education institutions is to provide a quality education process to all enrolled students. One way to achieve this goal is by discovering knowledge about students’ performance and students’ characteristics. This knowledge can in many cases be extracted from different data sets by using various data mining techniques. In this paper a research that includes evaluation of cluster analysis, a data mining approach, for the purpose of IT student’s performance description is presented and elaborated. Thus, in this paper specific educational setting is used – 217 university undergraduates in computer science. Presented research is focused on the students’ socio-demographic characteristics and high school grades. Although some authors argue that high school grades are unreliable variable for prediction because there are no common grading standards across schools or across courses in the same school [1], others have proven that previous grades are the most important factor of academic performance [2]. Furthermore, Petersen, Louw and Dumont indicated transition period from high school and adjustment to the university environment as an important factor in predicting university outcomes [3]. Hillman found differences in academic performance among students from different types of high schools [4]. The aim of this paper is to understand the profile of IT students in order to build students learning strategies and to enhance institutional policy making.

II. RESEARCH METHODOLOGY

Based on the results of the previous studies, the research presented in this paper is constructed around main hypothesis which states: “Type of high school and higher grades in high school are associated with higher university grades”.

This chapter describes in detail methodology applied in order to test the hypothesis and gives an overview of the data collection.

A. Cluster analysis

Data mining is one of the fastest growing fields in ICT sector. Educational data mining, as a subfield of data mining, is an emerging interdisciplinary research area that develops methods for data exploration in educational domain [5]. Its main objective is to analyze educational data sets in order to resolve educational research issues [6]. There are two main tasks of educational data mining: descriptive and predictive modelling. Whereas predictive modelling methods seek to predict or classify data according to the target variable, descriptive modelling methods are not dependent on any driving objective function and their aim is to explain and describe data. Cluster analysis is the most common technique used for descriptive modelling [7]. It is applicable in the wide range of domains, including social science, like: education [8; 9; 10; 11; 12; 13], strategic management and economics [14; 15; 16], natural sciences like medicine [17], and genetics [18], or technical science in the domain of environment protection [19].

Clustering performs grouping of cases into classes of similar objects. As a result, clusters are obtained. Cluster refers to a collection of records that are similar to one another and dissimilar to records in other clusters [20]. Clustering algorithms are classified into one of two groups: hierarchical or nonhierarchical clustering. Hereinafter, nonhierarchical algorithm, k-means clustering, is applied, since it is more frequently used in analytics industry [21].

B. Data description

The data were collected via a questionnaire among first, second and third year students of the undergraduate study programme Information and Business Systems at the Faculty of Organization and Informatics, University of Zagreb. Questionnaire comprised of 11 attributes (see Table 2). Questionnaire was paper-based and 217 questionnaires were collected from a stratified proportional data sample. Data sample was representative considering the total number of students enrolled in each year of the study programme as shown in Table I. The attribute upon which the population is stratified (Year of
the study) is statistically significantly correlated with the dependent attribute, grade point average (GPA). This relationship justifies selection of the attribute for stratification.

### Table I. Representative Data Sample Details

</tbody>
</table>

Most of the respondents were male, more than 80%. This distribution is in line with Faculty of Organization and Informatics distribution. Almost half of respondents came from gymnasiums (either general or mathematical programme). One third of respondents came from technical or electrotechnical high schools (see Table II).

<td>No grade = 18,43%, 2 = 42,86%, 3 = 32,72%, 4 = 5,07%, 5 = 0,92%</td>
</tr>
<tr>
<td>English 1 faculty grade</td>
<td>2 = 21,66%, 3 = 35,48%, 4 = 32,72%, 5 = 10,14%</td>
</tr>
<tr>
<td>GPA</td>
<td>Mean = 3,1; St. Dev. = 0,6</td>
</tr>
</tbody>
</table>

The lowest high school grades were from the Math course (less than a third of respondents had 5), whereas the highest high school grades were from the Informatics course (85% of the students had grades 4 or 5). Some of the first year students still did not pass Informatics 1 course (11,52%), Mathematics 1 (6,91%) or Programming 1 (18,43%). The highest faculty grades that students have achieved were the grades from English 1 course.

### III. Research Results

In order to test the stated hypothesis, first clustering was performed based on the following attributes: Gender, Year of study, High school, Mathematics high school grade, Informatics high school grade and English high school grade. Different number of clusters was varied and finally number 8 was selected as the optimal number of clusters. Number of students in each cluster is represented in Table III.

### Table III. Number of Instances in Clusters

<table>
<thead>
<tr>
<th>Cluster</th>
<th>Number of instances</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>18</td>
</tr>
<tr>
<td>2</td>

<td>15</td>
</tr>
<tr>
<td>7</td>
<td>15</td>
</tr>
<tr>
<td>8</td>
<td>23</td>
</tr>
</tbody>
</table>

Clusters 5 and 2 are the largest, whereas clusters 6 and 7 are the smallest. In addition, the characteristics of students in each cluster have been examined and relationships of clusters with performance of the students have been investigated.

Since “grades are often seen as the gold standard measure of success in education, and determining the factors that affect academic achievement has been a common endeavor by educational researchers” [21], attributes regarding high school grades are in the center of this research.

### Table IV. Cluster One Characteristics

<table>
<thead>
<tr>
<th>Cluster</th>
<th>Gender</th>

<th>Informatics HSG</th>
<th>English HSG</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Male</td>
<td>Second</td>
<td>Technical</td>
<td>5</td>
<td>5</td>
<td>5</td>
</tr>
</tbody>
</table>

Cluster 1 consists of second year male students which achieved excellent grades from all courses at the high school, as shown in Table IV.
Cluster 2 consists of the students whose faculties GPA is the lowest. Their characteristics are shown in Table V.

Cluster 6 includes first year male students from technical high schools (see Table IX).

Students from the cluster 7 come from the economic high schools and their characteristic is lower English and Mathematics grade and high Informatics grade (Table X).

Cluster 8 (see Table XI) consists of male students from general gymnasiums with low Mathematics background.

The clustering procedure serves as a good starting point for students’ performance observation. The presented findings identify subgroups of students with different academic success. GPA has been used as a measure of success of IT students (students with GPA 4 and above were considered as successful). Finally, to test hypothesis regression analysis was performed. Results indicated statistically significant relationship between type of high school and high school grades with faculties GPA. The magnitude of the prediction was found to be higher than the one with socio-demographic characteristics. When the relationship between academic success and characteristic of specific subgroups was examined, high
school programme was found to be a significant predictor of academic success. The magnitude of the prediction was found to be higher than the one with socio-demographic characteristics. The greater predictive ability of type of the programme for university achievement may be the result of more diversity in curriculum in the high school sample. Such results are compatible with the results of the McKenzie and Schweitzer who have identified that previous academic performance is the most significant predictor of the university performance [2]. In this paper, significant relationship between high school programme and academic performance has been identified: general gymnasium provides a good starting point for IT students.

This research tackles another significant issue: gender based performance differences in information and communication technologies. Research results refute hypothesis that “Hi-tech = guy-tech” [23]. Exactly the opposite, cluster with the highest GPA consists of female students. These results are in line with previous research results that have confirmed woman success in the STEM field [24; 25; 26]. Results of this study did not confirm the pattern observed in the literature [27] which states that women underperform on difficult (Mathematics and Informatics) courses.

IV. CONCLUSION

The research presented in this paper deals with developed student clusters, based on students’ previous education, which provide a basis for IT students’ success prediction. Interpretation and employment of the obtained results can be very useful for instructors to predict the performance of new students and to make decisions about helping students. Findings of this research consist of the following:

- Research results have practical implications for advising students and support in institutional strategy definition,
- “One size fits all” model cannot be effectively applied to all students and the solution is to segment students and perform different approach for each group.

Presented study has several limitations, mostly concerning the nature of the sample and the attributes included in the questionnaire. The research tackles only one, very specific type of students, IT students. Guidelines for further research are to perform comprehensive researches on bigger data set, several years in duration, with different students of different study programmes.

Comparison of Game Engines for Serious Games

Sanja Pavkov, Ivona Franković, Nataša Hoić-Božić
Department of Informatics, University of Rijeka, Rijeka, Croatia
spavkov@student.uniri.hr
ifarankovic@inf.uniri.hr
natasah@inf.uniri.hr

Abstract — Serious educational games are specially designed computer games which are used in an educational setting, in other words, they are interactive competitive lessons with defined learning outcomes which allow students to have fun during learning. The importance of serious games in contemporary educational practice is increasing. Applying serious games in teaching, students facilitate the learning process, adopt new skills and abilities, show more interest in learning, are more focused and more active in a class, and better understand and apply lessons learned. The complexity of serious games requires large efforts for their development. For the development of serious games teachers mostly use commercial game engines. One of the important parts of game development is a selection of appropriate development tool. Due to the range of available tools the choice of platforms for serious games is a challenge, whose selection often has considerably different goals and technical requirements depending on context and usage. The aim of this paper is to propose criteria which should be considered before selecting a game engine for serious games and shows results of a comparison of evaluated most popular game engines. Some recommendations for teachers about choosing the most suitable game engines for serious games development are also presented.

Keywords: serious games, game engine, developing serious games

I. INTRODUCTION

The 21st century is marked by the use of information technology like Internet, computers, laptops, tablets, and other smart devices to almost all areas of human activity. We are surrounded by technology from all sides, from the jobs, government and public administration, schools, universities, hospitals, banks, through to our homes. Since the computer has become an indispensable part of our everyday life, its use in education is increasing and more important. Evaluation and monitoring of the impact of computer-assisted learning have shown that the combination of learning the traditional way and learning using computers is good and useful and provides a better understanding and memorized material. As a consequence, the need arose for developing new skills to prepare students for new jobs and technologies [1]. According to Prensky technology is important to live, survive and thrive in the 21st century. He points out that youth today communicate, search information and socialize differently than their predecessors [2]. Kids of the digital age are generations of students who are familiar with digital technology and using digital devices from an early age. Information and communication technology (ICT) has almost become a native language to them or a language with which they communicate, express themselves, understand, and perceive the world around them.

Today is necessary to have a new set of skills to succeed in learning, working and living. Those competencies are beyond ICT literacy and include communication, collaboration, social and cultural skills, creativity, critical thinking, problem-solving, productivity, flexibility, risk-taking, conflict management, and a sense of initiative. They should be developed by everyone, from primary school to lifelong students. For the acquisition of those skills, the effectiveness of adopting active learning methodologies is widely acknowledged; they involve activities that accentuate the development of learner skills. Active learning enhances students engagement in learning tasks and enables them to deal with new challenges, solve problems, and adapt to changes in technology and knowledge [3].

Serious games are becoming more and more popular form of active learning. Serious games are specially designed computer games which are used in an educational setting. They enable the learner to have some control of the game activity and engage in interaction [4]. The complexity of serious games requires large efforts for their development and needs a lot of planning. One of the important parts of game development is a selection of appropriate development tool or game engine. Teachers mostly use a commercial engine for serious games design and it should be chosen to provide developing the game with all necessary education goals set for students.

This paper proposes criteria which should be considered before selecting a game engine for serious games. The second part introduces the serious games, while the third part is about game engine. The fourth part describes criteria and provides comparison results of evaluated game engines. In the last, fifth part we draw the conclusion.

II. SERIOUS GAMES

Serious games in teaching and education encourage students to participate in the learning process. It is important that these games are stimulating and motivating and that they develop students’ creativity [4]. The game in education can be used in all stages of the teaching process, from the introductory part as a motivation for students to the evaluation and formative or summative assessment of students. Serious games allow students to complete tasks, acquire knowledge and reasoning of certain principles while having fun. They represent a simulation that includes the challenge of solving a particular task important for students [5]. Important elements that contribute to the educational values of the game are stimuli, fantasy, challenge, and curiosity.

Games in general can be classified into seven
categories: adventure, role-playing games, shooting games, simulation, puzzles, strategy and sports games [3]. Games in education are: quiz games, word games, puzzle games with branching scenarios, various simulations with the tasks, simulation environments, simulations that require personal answers toy and game playing role [5].

Serious Games are primarily used for learning and adopting the learning content in a fun way aiming to increase student interest and motivation. During the development of the game, it is necessary to pay attention that all the learning outcomes are fulfilled. Every serious game has to have well-defined learning objectives and promote the development of important skills in order to increase cognitive and intellectual abilities of students.

The process of serious games creation is based on the methodology SADDIE which include Specification of the game, Analysis, Design, Development, Implementation, and Evaluation [3]. Creating a didactic computer game requires choosing an appropriate tool or game engine during the analysis phase. There are a number of different types of programming tools and several different alternative systems for creating computer games, such as programming languages, multimedia development environments, environments designed specifically for game development, development tools for e-learning software and the modding environment (some gaming environments come with an additional creation engine that allows the development of extensions to the game such as new storylines known as "modding") [6].

III. GAME ENGINES

Today there are many types of software tools for developing computer games, so it is a challenging task to choose the appropriate game engine for educational games. There are many dilemmas which tool to choose because they all have strengths as well as problems. Some of them are fast for development, some may have performance issues, some require a programming skills, and some come with a developer-friendly interface [7].

For the purposes of this study, we evaluated five different game engines, these are respectively: Adventure Game Studio, Construct 2, e-Adventure, GameMaker: Studio, Phaser Editor. Each of these tools is downloadable, installed on the computer and used for game development in order to choose those engines in which 2D adventure game can be realized. Below is an overview of the examined tools for creating computer games with general information and a brief description of each of them.

A. Adventure Game Studio

Adventure Game Studio (AGS) engine is a Windows-based integrated development environment (IDE 2) which allows users to create 2D "point and click" adventure games. It primary target group is not educators, although can potentially be used to create educational games. Among the biggest disadvantages to the development of educational games using this engine are: his games cannot easily be integrated with Learning Management Systems (LMS) or inserted in a SCORM package and does not have educational features to allow assessment of student performance [8] [9]. On the other hand, Adventure Game Studio supports high-resolution graphics, has a fully integrated audio and video. Games created with it can be run on multiple operating systems, supports the use of thousands of sprite's (sprite is a two-dimensional bitmap graphic that is integrated into a larger scene, it can either be a static image or an animated graphic that plays a specific role), creating hundreds of rooms, an unlimited number of characters, dialogue, GUI and other interface elements [10].

B. Construct 2

Programming tool Construct 2 is HTML5 tool designed specifically for 2D games and provides game development without coding to all users regardless of previous knowledge of programming. Currently is available installation on a Windows platform only but games created with it can run on a very large number of different platforms which is a big advantage of this tool. It offers a simple Drag-and-Drop (DnD) interface, is easy and intuitive to use, and it is intended primarily for people who have no prior experience with programming [11].

C. e-Adventure

The e-Adventure engine has emerged within the research project at the University of Madrid (Universidad Complutense de Madrid) in Spain with an aim to facilitating the integration of educational and simulation games in the educational [12]. The tool is specially designed to create a Point & Click adventure type of educational games [13]. The three main objectives of development e-Adventure tool are: reducing the development cost for serious games, the inclusion of educational specific features in a game engine and games integration with existing educational materials in virtual learning environments.

The platform is composed of two applications - a game authoring editor (for creating the educational games) and a game engine (for execution of the games). The editor is completely instructor oriented, it does not require any technical background or programming skills to be used [14]. Through a simple and intuitive graphical interface tool, it enables the creation of games by creating scenes, objects, characters, dialogue and conditions that define the logic of the action in the game. The e-Adventure supports the creation of two different types of adventure games: third-person and first-person games [13].

Using this engine, teachers can create their own educational video games or adapt some existing popular games to add educational value. According to that, e-Adventure provides educational features that other popular game engines usually don't. The two most important educational features of this tool are the assessment reports and the integration with popular LMS (e.g. Moodle) [15].

As an example of an application in education, the e-Adventure platform is using for making educational computer games at the Faculty of Education, University of Ljubljana [3] and at the Department of Informatics, University of Rijeka.

D. GameMaker: Studio

GameMaker: Studio is a development tool for creating a 2D video game. It is also possible to develop 3D video games, but the documentation notifies about the possibility of having several problems with depths, views and other attributes [16]. This engine is used by teachers in several schools to create digital games that suit their curriculum or to improve pupils' programming skills. This engine enables development of games without programming skills. It offers an intuitive and easy Drag-and-Drop (DnD) interface action icon that provides a very quick start development of its own games. Actions are used to define...
how, when and where we want to something happened during the game. It is possible to load and create images, sounds and other graphical elements, and to add them to the objects in the scene. While creating actions, GameMaker: Studio in the background creates code of those actions which this tools make appropriate for users with and without programming experience [17]. GameMaker: Studio allows to create games for various platforms, including Windows, MAC OS, Web, Android and iOS [18]. The feature of this engine includes a sprite editor, timelines, paths, room editor, a custom programming language GameMaker Language (GML) and connection with external databases [19].

E. Phaser editor

Phaser Editor is an integrated development environment for creating HTML5 2D games. For a development of games in this tool, it is necessary to know programming. It offers a lot of examples, different Physics libraries and some plugins [20]. Programming is not required only for adding objects to the scene since it is done using a simple drag-and-drop option. However, everything else must be programmed by a user therefore knowledge of JavaScript programming language is required. [21].

The compared data of selected engines, the least system is required for installation and some properties related to hardware. Examination shows that most of the benchmarked engines, only e-Adventure programming tool has multi-language support and, support for SCROM 1.2 (Sharable Content Object Reference Model – a collection of standards and specifications for web-based e-learning) reference model and the possibility of integration with the LMS systems. Also, is the only tool among compared that is tailored to work with people with special needs.

According to the criterion of interoperability, all compared engines support the ASCII character set, while UTF-8 character set only Adventure Game Studio does not support. Regarding the criterion of usability, e-Adventure, GameMaker: Studio and Construct 2 enable creating games without programming. GameMaker: Studio has an advanced option that enabled programming in a way that allows users can create more game options. Adventure Game Studio requires programming scripts that define certain actions in the game.

C. Engine system requirements and installation

Engine system requirements include which operating system is required for installation and some properties related to hardware. Examination shows that most of the comparison tool requires minimum Windows XP, Windows Vista or newer operating system. Considering the compared data of selected engines, the least system requirements for installation has Adventure Game Studio. Installation criterion describes how easy engine installation is, and testing has shown that all engines are simple to install and have appropriate installation instructions.
D. Functionality and the ability to export

Functionality analysis the features that are specific for game development, while ability to export lists possible ways of exporting games for different platforms. The comparison of selected engines based on the functionality criteria are given in Table 3.3 After the comparison according to the criteria of functionality, we found out that all tools support the development of 2D computer games quite good. eAdventure allows making first-person games where the main character is not present, and third-person where the game is playing with the main character (avatar), Adventure Game Studio allows creating games in the third person, while other engines do not have limited modes for games creation. In the Adventure Game Studio and eAdventure navigation through the game is with the mouse pointer, and in other tools keyboard controls can also be used. Construct 2 and GameMaker: Studio have built-in Box2D Simulator Editor by which elements like friction and gravity are define. Adventure Game Studio and eAdventure engines have built-in dialogue editors, while GameMaker: Studio has a separate external editor that saves dialogues which are implemented in the project in .txt files. In the eAdventure dialogue can be displayed normally, as a whisper or as a thought, and dialogue text can be converted to speech. It provides the ability to change the main character, NPC (a non-player character/non-person character/non-playable character is any character that is not controlled by a player) or items appearance in scenes. These changes are flags conditioned. It has a built-in book subject that facilitates the information entry or giving instructions to a player. Built-in item inventory has Adventure Game Studio and eAdventure, while in others are necessary to program the inventory. In Adventure Game Studio and eAdventure are necessary to set up the main character to every scene, regardless of whether it is needed there or not. Out of all tools, only eAdventure offers game statistics view. Assessment and evaluation through a various question can be made in eAdventure offers game statistics view. Assessment and whether it is needed there or not. Out of all tools, only

Ranging the ability to export the game the most options for exporting offers Construct 2, and at least Phaser Editor engine, but we should consider that it's created in 2015 and is still in development phase. All engines can export games for Windows and Linux platforms. eAdventure and Phaser Editor can't export for Android, iOS nor consoles’ platforms and Phaser can't export for Mac OS X. Only eAdventure offers the ability to export g games as learning object where the project is saved as educational content.

E. Multimedia support and working environment

Criterion multimedia support is related to which multimedia elements engine supports, while engines working environment analyzes if an engine is user-friendly. After the comparison according to multimedia criterion, it seems that all compared engines allow the inclusion of multimedia elements like images, sound, video and animation. Compared engines mainly support common formats for image, sound, video and animation, while GameMaker: Studio supports vector graphics. The e-Adventure can create animations of the main characters and NPC only for standing, talking, walking and the use of objects, while other tools can create animations on request. Considering the category of engine working environment all compared engines have an intuitive graphical interface with Drag-and-Drop options that can be adjusted if necessary. Also, all of them allow testing of the project as well as the detection of errors that occur when creating games.

F. Review of work with selected software tools for comparison

The research involved five engines for creating computer games which are primarily designed for making 2D games. For this study, we have developed our criteria and according to them compared all selected engines. In every engine, we made a basic version of the game, while in GameMaker: Studio a full version of the game was developed. For each compared tool we've created a new project in order to examine the functionality and features of the engine. We adapted designed game scenario to the possibilities of particular engine while some elements could not be realized in each of them. Further, in GameMaker: Studio, Construct 2 and Phaser Editor free engine versions was not possible to use.

all the features and functionalities. After the comparison, GameMaker: Studio was chosen for the development of the full game "Explore the solar system", since it met all the required criteria. We decided to use it because it's a free engine for developing 2D adventures games for PCs. It has an intuitive graphical interface and complete engine, and it's relatively easy to create game with this engine. It has very good user community, offers various examples, tutorials, manuals, forums, developers personal experience.

The serious game "Explore the solar system" is intended for 5th grade students and is associated with teaching unit Earth in space in Geography course. The game can be used at the beginning of the lesson as an introduction in order to provide students' motivation for learning. Also, it can provide the repetition about the Solar system in a funnier and more interesting way for students. The game type that we developed is a 2D point and click adventure.

V. CONCLUSION

One aspect of using ICT in the education is game-based learning and using serious computer games. Implementing games encourage students to participate and develop their creativity. They are primarily used for successful material completion in a more interesting and fun way. Serious games represent an opportunity for enhancing education from primary school through to lifelong learning.

The creation of a serious game is a complex project, and one of the most challenging task is to choose the appropriate game engine. Within this study, we examined five tools for game development. The comparison showed that each tool has certain advantages and disadvantages. Customers choose development platform based on engine characteristics, the experience they have in game development and their needs. This paper proposed criteria that will allow the developer to select the engine based on these characteristics.

For game development, we chose GameMaker: Studio since it met all the criteria set. It's a very affordable engine with intuitive graphical interface and simple mode which facilitate game development.

GameMaker: Studio is suitable for beginners in game development, or for those who do not have much programming experience because in a very short period they can make a simple game.

University of Zagreb, Faculty of Organization and Informatics, Varaždin, Croatia
vvidacek@foi.hr

Abstract: The rapid development of digital technology and the constantly increasing number of online information sources have meant that students’ skills related to information seeking are crucial for academic success. This Paper presents the selected findings of a case study with an emphasis on identifying differences and similarities between international and Croatian students’ information seeking skills in an online environment. Internet search engines, E-books, online databases and research networks are the online resources which were analysed in this study in order to discover information on the literacy of two groups of students. Quantitative research was conducted in March of 2015 via an online survey and the sample consisted of 70 international and 69 Croatian students. The following research fields were identified in line with the literature review and the expected research outcomes: (1) discover similarities and differences in usage of online information for academic purposes between international and Croatian students, (2) compare the frequency of usage of different online sources between international and Croatian students, and (3) describe the most common online sources of information used by the two groups of students. The results of the study could be used to raise awareness of the need to develop students’ online information skills and to improve courses within the Croatian higher education system by harmonizing them with those from European Union.

Key words: Online Resources, Information Seeking, Students

I. INTRODUCTION

Rapid technology development, the Internet era and ever-increasing amounts of available information in the on-line environment within and academic context require that students develop skills connected to information literacy. Generally, information literacy is defined by the American Library Association as the abilities that enable people to ‘recognize when information is needed and have the ability to locate, evaluate and effectively use information’[1]. Information literacy skills are closely connected to technological innovations and the Internet so student competencies should be oriented on the successful navigation through on-line resources, knowledge production and collaboration with colleagues [2].

Nowadays students often tend to accept information without checking its accuracy[3], and therefore it is important to develop their research skills. In an on-line environment, on-line search engines are a primary step in seeking information, and when resources such as E-books, on-line library databases and research networks for scientists are used, time and skills are demanded in an academic context. Even students who feel confident searching for information on-line have an overdependence on trivial information sources from search engines, and this can be problematic in information diffusion in an on-line context. The results of research that focused on identifying E-resources such as E-books, journals, databases, articles, search engines and websites show that students often cannot identify resources correctly or at least not on a level that is academically acceptable [4]. In order that student on-line information search processes for academic purposes could be better understood, the SCOOP research tool was developed to identify crucial information related to students on-line search behaviour and the problems they came across while searching for information on-line [5]. Students not only just consume on-line information, they also generate information through their academic work, and the use of on-line sources that are suitable within an academic context is crucial for developing a learning society on an international level.

Research in Croatia was conducted which connected the use and perceptions of on-line academic databases among university teachers and researchers. These results show that use of this on-line source of information is not satisfactory, especially in cases of younger academic staff, such as teaching assistants at university, who need instructions and trainings how to use on-line databases to retrieve information adequately [6]. These results also show that even those working in academic society who teach students have insufficient information literacy skills, so it can be assumed that students’ skills for on-line information
sources are not sufficiently developed. The manner in which students search for and use information is a part of their academic skillset and research competences. Different student strategies for using information resources have different benefits for student academic achievement and they depend on the actual needs of the user’s understanding. Improving access methods can produce better information query efficacy and help students to gather information and attain academically in general [7]. The nonlinear model of information-seeking behaviour among academics includes three core processes (which are linked to opening, orientation and consolidation) and three levels of contextual interaction. Contextual interactions within the nonlinear model are linked to external and internal context and depends on a cognitive approach. Information seeking processes within the nonlinear model are similar to the processes on an artist’s palette, which means that their preparation and starting and finishing points are not fixed. All information-seeking processes are nonlinear, dynamic, holistic, and flowing [8]. The elements of this model are connected to the development of information literacy curricula.

Research results [9] show that seeking scientific information is a complex process for which only few students have sufficient knowledge. The search process includes library competences. Researchers [9] divided respondents into three groups, according to their different levels of competences for scientific information searches: novice, intermediate and expert users. According to the results for all three groups, collaboration between faculty and librarians is necessary in order to help students to gather information for their learning outcomes. Research conducted among postgraduate engineering students shows that there is a linear relationship between a user’s cognitive style and information seeking. Different user profiles depend on the differences in a user’s information seeking skills [10]. Database experts and students that attend the college information management course, in which they gather trend transition skills, have better learning performances in comparison with users of other databases. A comparison of students who use conventional search engines with database experts shows that the latter can easier target the issue [11]. International students and students from different cultures, such as Chinese students, mostly use two search engines: Baidu and Google. Baidu is more popular because students are familiar with their interface and the Chinese resources. Google is used more often for global information seeking and information provided in English language, whereas BAIrDU is used for everyday communication and networking [12].

II. METHODOLOGY

Research was conducted amongst international and Croatian students in March of 2015 via an on-line survey. Students were asked to answer anonymously and on a voluntary basis.

A. Respondents

The Research’s core sample (N=139) consisted of two independent samples: 69 international students and 70 Croatian students. Details on the distribution of respondents according to gender, age and type of study is shown in Table 1.

TABLE 1. DISTRIBUTION OF RESPONDENTS ACCORDING TO GENDER, AGE AND TYPE OF STUDY

Some meaningful differences between the two student groups will be mentioned in following paragraph. From data shown in Table 1, it can be stated that most of the international respondents were from the following countries: the United Kingdom, Netherlands, Germany, Norway, Switzerland, Portugal, Greece, France, Spain, Romania, Latvia, Italy, Ukraine, Austria, Macedonia and Poland. 16.55% were 27 years or older and 28.06% were undergraduate students. In case of Croatian students, 30.22% of respondents belonged to age group from 21 to 23 and 30.94% of them were graduates.

B. Questionnaire

The questionnaire was created in English and Croatian and contained 31 items. Results of both questionnaires were summarised and one data set was used for answer analysis.

The first part of the questionnaire consisted of questions about the respondent’S socio-demographic characteristics: gender, age, type of study and home country (for European students) or university (for Croatian respondents). The second part included 27 items about on-line information resources and student attitudes about their use for academic purposes. A 5 point Likert scale was used to measure student attitudes or opinions by level of agreement or disagreement with a particular item. The Cronbach alpha coefficient was
The Main limitations of this study relate to its sample size (N=139), and a larger and differently structured sample size would ensure a more representative distribution of the population. For example, respondents in the Croatian student sample were mostly from the University of Zagreb’s Faculty of Organization and Informatics, and students from other universities were not included. One limitation of this study’s result is also the effect of pseudorandom sample (N=139) that it is not representative for whole faculty population. Still, the selected sample includes students from all levels of study (undergraduate, graduate and postgraduate levels) and amounts to approximately 5% of the core sample which includes 3,000 students from the Faculty. In the case of international students, respondents were from different countries and universities (19 various home countries were listed in the responses). A better approach would have been to compare student attitudes to on-line information searches from just from one foreign country. Furthermore, the data was collected in 2015, so student opinions could have changed in the interim. To find further differences in usage of different on-line scientific resources for academic purposes, more detailed questions should have been included in the questionnaire.

III. RESULTS AND INTERPRETATION

Three research questions were determined to identify similarities and differences between international and Croatian students’ information seeking skills within an on-line environment.

A. Similarities and Differences between International and Croatian Students Regarding On-line Information Usage

In order to compare whether there are differences in on-line information usage habits between international and Croatian students for academic purposes, two types of analyses were performed for the following types of on-line information sources: a) Internet search engines (Google, Yahoo and Bing), b) On-line scientific databases (EBSCO, Science Direct, ProQuest and Wiley On-line Library), c) E-books (Google books, Scribd, Intechopen) and d) social networking sites for scientists and researchers (ResearchGate, Academia.edu).

Levene’s Test for Equality of Variances was first used to determine if the two groups had about the same or different variability between scores. The results are shown in Figure 1. Since the Sig. value in the four analysed resources in Levene’s Test is > 0.05, it can be concluded that variability in two observed groups of students is not significantly different.

An independent samples t-test was used to compare the means determine the differences in habits of on-line information source usage between two unrelated groups of students (Croatian and international students) for academic purposes. The results of t-test show that there is a statistically significant difference between international and Croatian students regarding usage habits of on-line scientific databases (t=2.39, df=137, p<0.05). It can be concluded that international students use databases more than Croatian students for academic purposes (Mint=3.36, sdint = 1.18, mix=2.89, sdx= 1.17).

The t-test for results of another three analysed sources of on-line information shows that there is not a statistically significant difference between international and Croatian students regarding Internet search engine usage habits (t=0.17, df=137, p=0.05), E-books (t=0.547, df=137, p>0.05) and social networking sites for scientists and researchers (t=0.11, df=137, p>0.05). When comparing the means for each on-line source, it can be concluded that Croatian students are slightly more likely to use Internet search engines (MCR=4.76, sdcro= 0.711, MINT=4.74, SDINT = 0.50) and E-books (MCR=3.10, sdcro= 1.14, MINT=2.84, sdx= 1.08) than international students, but the differences are not statistically significant. On the other side, international students have a habit to use research social networks for researchers and scientists slightly more that Croatian students, but the differences are not statistically different (MINT=2.51, sdx= 1.12, MCR=2.23, sdx= 1.29).

The results show there is need to improving the skills required to use scientific databases among Croatian students because currently they have a habit of using simple, non-scientific sources of on-line

| Table: HABITS OF USAGE THE ON-LINE INFORMATION AMONG INTERNATIONAL AND CROATIAN STUDENTS |
|------------------------------------------|-----|-----|-----|-----|
| On-line database                        |     |    |    |    |
| CRO                                      | 70  | 2.89| 1.17| 0.14|
| INT                                      | 69  | 3.36| 1.18| 0.14|
| Internet search engines                  |     |    |    |    |
| RH                                       | 70  | 4.76| .71 | 0.09|
| EU                                       | 69  | 4.74| .50 | 0.06|
| E-books                                  |     |    |    |    |
| RH                                       | 70  | 3.10| 1.14| 0.14|
| EU                                       | 69  | 2.84| 1.08| 0.13|
| Research networks                        |     |    |    |    |
| RH                                       | 70  | 2.23| 1.29| 0.15|
| EU                                       | 69  | 2.51| 1.12| 0.14|

Legend: CRO = Croatian Students, INT = International Students
information rather than those which are more complex and better suited for academic purposes. The reasons for such results could be following: Croatian students are not familiar enough with this kind of information and their importance in producing higher quality student papers and researchers as they consider them more skill and time intensive, and another issue could be that there is no access to relevant scientific databases for academics at a national level or that the prices for specific articles is relatively high.

Other results in general show no differences in habits of Internet search engine, E-books and social networking sites usage for scientists and researchers. The main reasons for such on-line seeking behaviour could be that these are sources students use in everyday life, they consider them appropriate enough for academic purposes, they are intuitive to use and do not demand special information literacy skills and they are also free and easy to access.

B. Comparative Frequency of Usage of Different On-line Sources by International and Croatian Students

In order to determine comparative frequency of usage of different on-line sources by international and Croatian students, two types of analyses were performed for the following types of on-line information sources: a) Internet search engines (Google, Yahoo and Bing), b) On-line scientific databases (EBSCO, Science Direct, ProQuest and Wiley On-line Library), c) E-books (Google books, Scribd, Intechopen) and d) social networking sites for scientists and researchers (ResearchGate, Academia.edu). A 5 scale Likert scale was used to determine the frequency of usage of these four on-line resources and the possible answers were: 1 – Never used, 2 – Used once 2, 3 – Using 2 or 3 times a month, 4 - Using every week, 5 – Using every day.

</table>

Likewise for the first research question, Levene’s Test for Equality of Variances was used to determine if the two groups had about the same or different amounts of variability between scores. Since the Sig. value in the four analysed resources in Levene’s test is > 0.05, it can be concluded that variability in two observed groups of students is not significantly different.

The t-test results of another three analysed sources of on-line information show that there is not a statistically significant difference between international and Croatian students regarding to frequency of use of Internet search engines (t=0.53, df=137, p>0.05), E-books (t=0.73, df=137, p>0.05) and social networking sites for scientists and researchers (t=0.53, df=137, p>0.05). When comparing the means for each on-line source, it can be concluded that Croatian students use Internet search engines (MCRO=4.10, sdCRO= 0.09, MINT=4.03, sdINT = 0.10) and E-books (MCRO=3.33 sdCRO= 1.00, MINT=3.26, sdINT = 0.98) more often than international students. International students more often find information for their academic purposes on research networks than Croatian students (MINT=3.09, sdINT = 0.10 M CRO=2.97, sdCRO= 1.15). An independent sample t-test was used to compare the means and find differences in frequency of usage of on-line information sources between international and Croatian students. The results of this t-test show that there is a statistically significant difference between international and Croatian students regarding to frequency of use of on-line scientific databases (t=3.50, df=137, p<0.05). It can be concluded that international students use databases more frequently than Croatian students for academic purposes (MINT=3.88, sdINT = 1.13, MCRO=3.17, sdCRO= 1.26). The t-test results of another three analysed sources of on-line information show that there is no statistically significant difference between international and Croatian students regarding frequency of Internet search engine usage (t=0.53, df=137, p>0.05), E-books (t=0.73, df=137, p>0.05) and social networking sites for scientists and researchers (t=0.53, df=137, p>0.05).

When comparing the means for each on-line source, it can be concluded that Croatian students use Internet search engines (MCRO=4.10, sdCRO= 0.09, MINT=4.03, sdINT = 0.10) and E-books (MCRO=3.33 sdCRO= 1.00, MINT=3.26, sdINT = 0.98) more often than international students. International students find information for their academic purposes slightly more often than Croatian students on research networks, but there is not a statistical difference (MINT=3.09, sdINT = 0.10 M CRO=2.97, sdCRO= 1.15).

The results of second research question are similar to the first and show that international students have a preference for using scientific resources (on-line scientific databases and on-line networks for researchers) for information more often than Croatian students do. The key reason for such a difference could be that European counties have more developed practices at a national or institutional level than Croatia, and these measures improve awareness of the
importance of using scientific on-line sources and developing need skills in an academic context.

C. On-line Sources of Information Used by International and Croatian Students – Knowledge and Skills

A third research question was used to determine how students evaluate their knowledge and skills in usage of the most common on-line sources of information. Possible answers ranged from 1, which indicated a low level of knowledge and skills, and 5, which indicated a very high level of usage of some information source for academic purposes. Results are shown in Figure 2.

![Figure 1](image.png)

**FIGURE 1: KNOWLEDGE AND SKILLS LINKED TO THE ON-LINE SOURCES OF INFORMATION BETWEEN INTERNATIONAL AND CROATIA STUDENTS**

Legend: Access x: Type of On-line Sources; Access y: Answers on the Likert Scale (1-5)

From the data represented on this graph, Croatian students from this sample evaluated their skills and knowledge more positively in cases of Internet search engines, and E-books and international students consider themselves more skillful in using on-line scientific databases and on-line networks for researchers and scientists. It can be concluded that both group of students have highly developed skills for Internet search engine usage, but there is room for improvement regarding other on-line sources, especially in case of the Croatian group of students who have lower scores than international students.

IV. CONCLUSION

The results of this study show that students from Croatia and international students use similar sources to gather information for academic purposes. Those sources are mostly linked to Internet search engines, E-books (such as Google books, Scribd, Intechopen…), on-line scientific databases (such as EBSCO, Science Direct, ProQuest, Wiley On-line Library…) and on-line networks (such as Research Gate, Academia.edu…).

There is the slightly more frequent usage of databases by international students in comparison with Croatian students. Reasons for this could include possible access to data bases and different research skills. Further education in the field of attaining academic skills and the development of information seeking behaviour could be improved with specific courses and training. Closer collaboration between librarians, staff and students is a necessary prerequisite for using academic sources of information for research purposes. In general, higher education should include information literacy in curricula and focus more on developing requisite research skills so that student can use appropriate on-line information sources for academic tasks. Further research could include more students from other universities so that this core sample could be more relevant.

V. REFERENCES

Recursions and how to teach them

Predrag Brođanac
V. gimnazija, Zagreb
predrag.brodanac@skole.hr

Summary – Learning programming is difficult. This refers to primary and secondary school students, but to university student beginners at programming too. These particular reasons stand as a challenge to teachers, as well. Most of the authors agree that recursion presents one of the most difficult concepts at programming, whereas some authors think it is the most difficult concept in programming. On the other hand, it is no longer only an important mathematical concept, but a programming technique, a way of algorithm thinking, and a tool to problem solving. There have been many attempts how to teach recursions. Hereinafter, one can find certain approaches for which authors claim to bring a better understanding of this important concept.

Key words: recursion, learning models, learning styles.

I. INTRODUCTION

Recursion is a technique within which a program function, a procedure or a method calls itself; and a recursive algorithm is the one self-referencing [1] If a function continuously calls itself, the process would never stop, therefore a recursive function should meet three of the following conditions [2]:

- recursive calling termination condition,
- recursive relation,
- consecutive recursive calling should be converged according to the recursive calling termination condition.

The basic example of a recursive function is the function for product of first \( n \) positive integers, known as the factorials. In the Python programming language function is as follows:

```python
def fact(n):
    if n == 1: #1
        return 1
    else:
        return n * fact(n - 1) #2
```

Command (#1) has a defined recursion termination condition. The issue here is a basic case with a trivial problem solution. In the upper example, a basic case is the one in which one should multiply the first 1 positive integer and that product is 1. Should the basic case not be the situation here, the function performance is done recursively (#2). Namely, the product of the first \( n \) positive integers can be attained in the manner that the product of the first \( n-1 \) positive integers is multiplied by \( n \). This statement is evident, for example, at multiplication of the first 5 positive integers:

\[
fact(5) = 1 \cdot 2 \cdot 3 \cdot 4 \cdot 5 = \frac{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5}{fact(4)} = fact(4) \cdot 5
\]

Command (#2) has, therefore, defined the recursive relation. Since the value, used to call the function, constantly decreases, it stands clearly that recursive calling converges to the basic case, i.e. \( n = 1 \).

Recursion is a special case of the Divide-Conquer-Glue technique [3], where the problem addressed is divided into smaller problems, which later are solved independently, and, finally, by „gluing“ the solutions we come to the initial problem solution. Recursion here is specific in the way that smaller problems solved here are the same as the initial problem, only they differ in „size“, which we also call the instance, i.e. dimension. For example, \( fact(5) \) and \( fact(4) \) are two instances of the problem of multiplication of the first \( n \) positive integers, wherein \( fact(5) \) instance represents the product of the first 5 positive integers, whereas \( fact(4) \) instance represents the product of the first 4 positive integers.

At the same time, we can observe recursion as a loop generalization [4]. A loop consists of a set of commands that repeat. The most common loops used in programming languages are the for and while loops. Commonly, the loop has one of the following two shapes:

```python
command-1
command-2
... command-n  (decision on repeated performance)
```

or

```python
command (decision on one-time execution)
command-1
command-2
... command-n (decision on repeated execution)
```

One can easily notice that decision on executing of a block shall be made at the end or at the beginning of the block of commands. Recursion can be observed as a case where a decision on repeated execution of a block of commands can be made at any point within the block:

```python
block-1
command
... Jump to block-1 (condition satisfied)
... command
end of the block
```

During executing of the block-1, the execution comes to a stop and the commands of the same block are called again. This repeated call may cause another call, etc. After the commands of one block have been executed fully, we return to the following command of the block that has called the block execution, wherein the executed block's results may be used in the future for executing of the block.
that called the block executed. It is important to mention that while calling the new block, the status of the block that called it should be filed, and then later on loaded, and continue to execute. It is realized by runtime stack [5]. Each time a recursive subprogram has been called, variables, parameters, return address and other required data are stored on the stack. At the moment when a subprogram is returning the control over to the subprogram which called it, the related data are popped from the stack.

A large number of programs, that are usually solved recursively, are possible to be solved by using loops, as well. For example, such is the program for multiplication of the first $n$ positive integers. Its non-recursive solution in the Python has the following form:

```python
def fact(n):
    t=1
    for i in range(2, n + 1):
        t *= i
    return t
```

There are recursive problems which cannot be solved by loops or the loop-based solution is much more complex, and this may serve as motivation for recursions [6]. Sometimes, instead of the recursive, one can implement a problem solution which, using the stack, simulates recursion, e.g. for Fibonacci number computation. Similar to the loops, usage of the stack may be upgraded in the way that recursive solution of the $n$th Fibonacci number is the sum of the two preceding:

```python
def b_z(n):
    if n < 3:
        return 1
    else:
        return b_z(n-1) + b_z(n-2)
```

![Picture 1: Recursive computing of the 5th Fibonacci number](image)

As one can see, certain recursive calls, e.g. $b_z(2)$, occur on several occasions, which shall result in slower function performance than the following non-recursive solution:

```python
def b_z(n):
    a = b = 1
    for i in range(3, n + 1):
        a, b = b, a + b
    return b
```

One should mention that recursive solution of the $n$th Fibonacci number computation may be upgraded in the way that the already calculated problem solutions be stored in the data structure, therefore avoiding the multiple computing types:

The appropriate recursive solution in the Python would be:

```python
def b_z(n):
    if n < 3:
        return 1
    else:
        return b_z(n-1) + b_z(n-2)
```

```
+---------------------
| b_z(5)              |
+---------------------
|                   +
| b_z(4)             |
|                   +
| b_z(3)             |
|                   +
| b_z(2)             |
|                   +
| b_z(1)             |
```

There is another division of the recursive programs defined by [16]. He addresses three types of recursions:

- **structural** – at recursive call, the arguments, by which the recursion is called, are either unchanged or closer to the basic case. If the parameter of the recursive function be, for example, data structure, the recursive call will happen over the real subgroup of that structure. That way, when binary tree traverse, one recursive call traverses only one tree branch,

- **generative** – the arguments used to call the recursive function are computed each time over again and there is no guarantee that a change of parameters leads to the basic case. Examples to such recursions is the Collatz Problem$^3$ and Euclidean algorithm for $\gcd(m, n)

$$ A(m, n) = \begin{cases} 
  n + 1 & m = 0 \\
  A(m - 1, n) & m > 0 ; n = 0 \\
  A(m - 1, A(m, n - 1)) & m > 0 ; n > 0 
\end{cases} $$

$^3$ The first and second Fibonacci number are 1, and each number is the sum of the two preceding.

II. CLASSIFICATION OF RECURSIONS

Recursive algorithms can be classified on multiple grounds. One of such categorizations has been stated by [15]:

- **linear** – has only one recursive call. A typical example of such a recursion is computing factorials. A special type of linear recursion is tail recursion. This recursion has recursive call as the last command within the function.

- **Multiple or exponential** – doesn't have only one recursive call, but it can have more of them. An example of such a recursion is generating all permutations of the set from $n$ various elements.

- **nested** – recursive call is one of its arguments. Ackermann’s function$^2$ is an example of such a recursion,

- **mutual** – this one doesn't call only itself, but another function, which then calls the first function again. We can have more than two functions. An example of such a recursion is a slightly different point of view on computing the $n$th element of the Fibonacci sequence [15]

- **linear** – has only one recursive call. A typical example of such a recursion is computing factorials. A special type of linear recursion is tail recursion. This recursion has recursive call as the last command within the function.

- **Multiple or exponential** – doesn't have only one recursive call, but it can have more of them. An example of such a recursion is generating all permutations of the set from $n$ various elements.

There is another division of the recursive programs defined by [16]. He addresses three types of recursions:

- **structural** – at recursive call, the arguments, by which the recursion is called, are either unchanged or closer to the basic case. If the parameter of the recursive function be, for example, data structure, the recursive call will happen over the real subgroup of that structure. That way, when binary tree traverse, one recursive call traverses only one tree branch,
calculating the largest common divisor of two positive integers,

- accumulative – in these recursions, among the parameters of recursions, there is one more or several additional parameters containing partial solutions of problems.

III. ARE RECURSIONS TRULY THAT DIFFICULT?

Almost every author writing about recursions, already in their introductions claims that it is one of the most difficult concepts for programming beginners. Even [17] and [18] agree with the fact that it is the most difficult concept. According to the research described in [18], including 559 students and 34 teachers at 6 European universities, the most difficult concepts for the students were: recursions, pointers, abstract data types, etc.

Having finished learning the recursions, students will be using them seldom for any other further problem solution, except if it has been explicitly demanded from them to do so [19], and even in situations when they have an offered solution to the same problem by the loop, i.d. by recursion, they will get a better understanding of the solution implemented by the loop [20].

Recursion problem is linked to constructivism [1], is argued by the fact that making references to the already existing knowledge is really important for gaining new knowledge, whereas recursions have nothing to refer to on account of them being so specific.

IV. CONCEPTUAL MODELS FOR TEACHING RECURSIONS

Many an author has made an attempt to make the recursions more appealing to beginner programmers. Some authors think that suitable preparatory actions, such as playing specially designed games, can help in later understanding of recursions. Whereas, others are of the opinion that analogies to problems that students are familiar with are of much importance; and there are some who think that visualization of the recursion flow is essential, while there are those whose opinion is that following the flow is not necessarily connected to development of recursive thinking, but they regulate a line of steps how to develop a recursive way of thinking.

Mental model defines a certain way of understanding abstract concepts or certain real systems [21]. It determines our way of thinking and acting, as well. Conceptual model stands for a manner of presenting new contents by an individual. Understanding of the content can be described as possessing a mental model on the content. Conceptual model represents an important tool for understanding of and teaching new contents. One of the teacher's tasks is to build a conceptual model enabling students develop a suitable mental model. According to the Structural Mapping Theory an important factor in adopting new content are analogies. Analogies represent a connection between a known (base) and unknown (target) domain. The conceptual model, within that context, would represent the base we take the analogies from for the unknown domain (target). Considering the area which we take the analogies from, we can talk about

- abstract conceptual model – its base is abstract, for example the mathematical model,
- concrete conceptual model – its base is concrete, for example a concrete object.

There is a set of models for teaching recursions, [21] bring 5 models:

- Russian Dolls – the Russian doll can contain a smaller doll within itself, which contains a smaller one, etc. (recursion),
- Process Tracing – tracing recursive calls. It describes the functioning of recursion,
- Stack Simulation – recursion mechanism is simulated from the computer perspective, where each recursive call creates a new record on the runtime stack,
- Mathematical Induction – recursions from the formal, mathematical aspect,
- Structure Template – explains recursions based on the example of recursive programs, describing therefore the basic case and recursive relation. The template for solving recursive problem comes down to: searching for recursive relation and defining the basic case.

In their work, the authors refer to learning styles, making reference to the Kolb's definition of learning styles, according to which a manner of information processing is one of the basic factors having influence on mental model design. Combination of manners, in which we perceive information and in which we process them, defines our learning style. Speaking of Kolb’s learning styles we can observe them through two dimensions:

1. way of adopting knowledge: concrete experience and abstract conceptualization
2. way of experience transformation: reflexive observation and active experimenting

School students and university students with different learning styles will have a different reaction to various teaching methods, therefore teaching methods should be suitable to students' learning style. The authors have performed a research showing that students with abstract learning style are more successful at learning recursions than students with concrete learning style. No research has shown that the abstract type has a better understanding of recursions if they have been explained by abstract model, nor that the concrete type has a better understanding of recursions if they have been explained by a concrete model. Two mental models for teaching recursion describe [7]:

- The Little People model – there is a large number of little people in the computer, each of them being an expert for a specific task (function) performance. When there is a certain problem, it is to be divided into smaller pieces and the little people hired to solve these smaller pieces. An example of such a model from perspective of a manager and a worker has been described even in [3].
- „Top-Down Frames” model – enables tracing recursive calls on paper. A new window is created for each recursive call that is within the window which has called it. Within the window there is recursive function program code with concrete parameters values, whereas at the bottom of the window there is a value that the appropriate recursive call returns.

\textsuperscript{3} For the positive integer \( n \) we define transformations in the following manner: if the number is even, it becomes \( \frac{n}{2} \), otherwise it becomes \( 3 \times n + 1 \). The question is how many of transformations, such as this one, over the \( n \) is to be performed in order to reach number 1.
The author [5] addresses the following recursion teaching models in his work:

- **Induction** – recursion is explained as a function that calls itself. The Fibonacci numbers are set as an example. It is an important approach, however it lacks a deeper understanding of how recursions function.

- **Runtime stack** – a simulation runtime stack is created in computer, which stack is an occurrence in recursive calls. The shortfall of this manner of tracing occurrences in the runtime stack is it being done on paper.

- **Function performance tracing** – each time there is a recursive call, a line is written with the name of the subprogram being called, and with suitable parameters. The same thing happens at returning from the recursive call. At output, one has to take care of the indents in order to visualize recursive calling. Tracing can be realized on paper, as well, and it makes a runtime stack simplification. Presenting recursive functions that call themselves iteratively may not be the perfect solution, e.g. functions for computing the Fibonacci numbers, i.e. Ackermann's function.

- **Recursion tree** – tree whose nodes represent the momentary surrounding, encompassing the parameters and local variables. At that point, the nodes are identified with recursive calls, and a node's children are recursive calls occurring in a suitable surrounding. Some of the shortfalls of the recursive tree are: (1) it does not contain the value returned by the recursive call; (2) it is not easy to draw a tree in case when we have more than two recursive calls within a function.

- **Activation tree** – a combination of the runtime stack and recursive tree. Each node contains, besides the name of the function and parameters, the function's return value. The author is of the opinion that this manner has no shortfalls.

### Table 1: Activation Tree Node

**A. Preliminary work that improves recursion learning**

One of the ways that contributes to a better understanding of recursions later on, is playing a well thought computer game that will develop the recursive way of thinking. Authors [22] and [2] describe one of these games, called Cargo-Bot, showing that it helps in recursion learning.

**B. Concrete Teaching Model Examples**

The largest number of authors has been studying some of the learning models.

[23] provides 3 examples that can serve as introductory examples, of which each may have its drama version:

- **Opening of presents** (closed brackets problem) – a friend has given you a watch, however, in order to keep the suspense going, the watch had been placed inside a box, inside another box, etc. The objective is to describe the gift opening algorithm in one's own words.

- **Chain design** (factorials) – there are \( N \) links with springs defined, which are to make a chain together. The idea of recursive solutions is to give one’s friend to make a chain of \( N-1 \) length, and then add one more link at the end of the chain.

- **Eating chocolate** (searching for elements on the list) – at our disposal we have a bar of hazelnut chocolate. We are to eat only those squares containing the hazelnuts.

The authors of the [24] have an interesting way to describe how to adopt the recursion concept. It is their opinion that in times of object-oriented programming one should change their approach to teaching recursion, as well. They, also, think that recursion learning should be implemented over data structures. This is illustrated by an abstract data structure list OurList in the Python, whose every instance had two properties: head – preserves the element value, and rest – all the remaining list elements. The authors have been able to explain this kind of a structure to the students, and, through role playing, the students were to come up with certain basic operations over the lists: counting how many time does a certain element appear on the list, verifying whether or not the defined element exists on the list, adding an element at the end of the list, and so on. Each student represents an instance of the list and the teacher has established which student represents the whole list. Only the students sitting next to each other are allowed to speak to each other.

The authors [25] provide an example to recursion teaching of children at the age of 11 to 14. Recursions are described on examples not directly connected to programming. The following problems are stated as examples:

- **Genome sorting** – the students were handed envelopes containing integers (from 1 to 14) and were to line up the numbers without opening the envelopes. They were using only one student, comparator. He was the only one able to open the envelopes and say which envelope contains the larger number. The comparator's service costs one monetary unit for each comparison. The objective is to sort the envelopes the way to spend as little money as possible.

- **Visual recursion** – a picture containing the same picture in one of its parts, etc. Students were given several pictures and they were to determine which of these pictures contained recursions, and to provide their opinions through discussion.

- **Sierpinski Carpet** – one of the students is drawing, and the other one is describing. The one describing was given the picture of the Sierpinski Carpet and is to describe, to the one who is drawing, how to draw the picture.

- **Line Up** – students are lined up, as in a queue, and their eyes have been blind-folded. They are to determine how many students are there in front of them in the queue, without ever leaving the line.

Parallel car parking principle, along the road can also be a good introductory example to illustrate recursions [26]. For example, there is a street 10 units long and we would like to know how many cars can fit into these 10 units. After a car has been parked in a random space, it occupies a single unit and it „divides“ the street into two parts. The total number of cars parked is going to be: the number of cars that can be parked in front of the parked car, the number of cars that can be parked behind the car parked, increased by one parked car.
The author [27] describes an interesting example of introducing the recursion through examples from the computer world. Recursions have been described on the example of:

- Computer system of files and folders - going through the tree like structure of files and folders by using the Python os module.
- Web searching – using urllib.parse module, by which we can reach each all the URLs on a single page and then recursively visit all those URLs.

Recursions are not natural in imperative languages [28], [29] whereas functional languages are stated to be the alternative.

Numerous works ([13], [30], [31]) deal with models of stack simulation, i.e. with visualisation of recursion tracing. To be able to understand recursions it is key to understand the principal of a subprogram execution termination, and transfer of the execution flow onto another subprogram [13]. In this context it is the moments that are important when a subprogram calls another subprogram, i.e. itself in a case of recursion. The author calls this moment active transfer of the execution flow. The moment the called subprogram has been executed till the end, the execution control returns to the subprogram that called it – execution flow passive transfer. These, but many other procedures have been visualised in the EROSI system (Explicit Representor Of Subprogram Invocations). These authors’ work demonstrates that usage of this program improves understanding, and writing of recursive programs, as well.

Besides a computer, recursion mechanism visualisation is possible on paper, too. [31] speaks of the recursion graph notation – RGraph. The idea for this kind of an approach has come to life as a reaction to the recursive tree, which, according to its author, doesn’t have an accentuated passive transfer and value return at the end of the recursive call; which is solved in RGraph. Square nodes in the graph represent recursion call, while oval nodes represent preliminary actions for recursion call, i.e. actions after recursion call. Moreover, there are two types of edges: dashed line and full line. The dashed ones are those that go from the higher level onto the lower level, whereas the full lines represent the edges among the nods on the same level.

C. Abstract Model Examples

Concrete model of recursion teaching is not enough for a deeper understanding of recursions [10], [32], [33]. Recursion execution tracing is the basic mechanism that is going to help the recursions-inexperienced students to be successful at computing the recursive function value, however that does not mean that they will be able to understand the recursion fully, and especially the passive transfer of execution control that is happening at the moment of our exiting the function’s recursive call.

Programming represents a specific way of thinking and addresses problem solving [10], where the focus is placed on figuring out algorithms, and not on the programming language syntax.

Algorithm to approach the recursive problem solving has been described by [10] and [11]. According to [10], the basic steps are:

1. **Finding the basic case** – the smallest instance of the problem with a basic solution,
2. **Rules simplification** – manner to reduce the size of a problem,
3. **Natural recursion** – link between a simplified and an actual solution to the problem,
4. **Finish** – merging of the previous steps into a single recursive function.

V. LOOPS BEFORE RECURSIONS OR VICE VERSA?

There is also a debate on when to teach recursions. Several authors think that they should be taught after loops, while another group thinks that it is better to show the recursions before the loops.

The research according to which it is better to learn loops first, and then recursions, has been presented in [34]. On the other hand, [35] and [36] propose learning recursions before iterations. The authors [35] state several arguments to their hypothesis: recursion makes a special case of Divide-Conquer-Glue method; to understand recursions, it is enough to know functions and branching, whereas, to understand loops, one needs to understand a brand new context; the basic reason for not understanding recursions arises due to the created mental model of the loop.

VI. CONCLUSION

Most researchers will agree with the statement that, on one hand, recursions make an extremely important concept in computing, and an exceptionally complex one for beginners, on the other hand. There are various methodologies for teaching recursions, which can generally be divided into concrete and abstract. One group of researchers point out that concrete methods are better, whereas another group states that one should use abstract methodology in order to understand recursions fully. The truth is, surely, somewhere in the middle. One should use various concrete methods, their visualisations, etc., to be able to understand the recursion mechanisms. However, this is not the way the students will develop a recursive manner of thinking. They will develop it only if they have a deep knowledge of recursions, if they will be using them in various situations during their education, if the teacher has the habit of leading them into thinking could the problem on the table be solved recursively, and so on.

**Picture 3: Visualisation of Execution of the 4th Element of the Fibonacci Sequence Recursive Computing by the RGraph**

Hybrid visualisation model is the one trying to unify more conceptual teaching models. One of such has been described by [12]. Their idea was to unify the conceptual model of stack simulation and structure templates. The result of it is creation of a system for helping students learning recursions, called ChiQua-Tutor. Stack simulation model is based on the graphic variant of the RGraph. The system offers a few standard problems that enable studying of recursions (factorials, palindrome, etc.), and provides recursions tracing, complementing of recursive algorithms, creating the RGraph for a set recursive code, animating of recursion execution, etc. After using this tool, a significant leverage in solving recursive problems has been observed.

Abstract - Learning management systems such as Schoology and Edmodo promote a learning environment that leads to achieving the expected learning outcomes through encouraging student participation. Although most teachers use learning management systems as a part of implementing the Flipped Classroom, these tools can also be used as a platform for student-teacher communication and provide an online environment for engaging in interactive classroom activities and sharing various learning materials. This paper will explore the advantages and disadvantages of Schoology and Edmodo platforms.

I. INTRODUCTION

A learning management system is a software application for the administration, documentation, tracking, reporting and delivery of electronic educational technology (also called e-learning) courses or training programs.[1] Learning management systems promote a learning environment that leads to achieving the expected learning outcomes through encouraging student participation.

There are many learning management systems available on the market; platforms offer a wide range of features for diverse users. The most popular LMS services among teachers are Edmodo, Moodle and Schoology.

Although most teachers use learning management systems as a part of implementing the Flipped Classroom, these tools can also be used as a platform for student-teacher communication and provide an online environment for engaging in interactive classroom activities and sharing various learning materials. Moreover, such platforms can help teachers to easily collaborate with other educators in the community.

Currently, we are using Edmodo and Schoology for class discussions, placing and viewing students’ assignments, sharing digital learning materials, creating e-learning course materials and tracking progress for ninety-three students from 13 to 18 years of age.

This paper will explore the advantages and disadvantages of Schoology and Edmodo platforms.

II. LITERATURE REVIEW

A. EDMODO

Edmodo[2] is an easy-to-use learning management system similar to Facebook, designed for teachers, students and parents. Through Edmodo teachers can share content, educational applications and important information. Students can connect to the classroom, access homework, learning materials and submit assignments even after the school day is over. Edmodo’s collaboration features enable teachers to easily communicate with other teachers in the country.

In order to observe their child’s progress or to discuss with his/her teachers, parents can access the Edmodo website either under their child’s username or they may create their own account. Parents can also receive alerts from teachers about school events, missed assignments and other important messages.

After creating an Edmodo account, classes for students can be created. Also, when using Edmodo, the teacher is able to create smaller student groups within a class (Schoology lacks this particular feature).

We are using the Edmodo portal for the following activities:

Edmodo is very suitable for sharing various course materials such as different files and links. This platform is extremely useful in subjects that teach students different programming languages such as SQL and Java by using specific software such as MySQL and NetBeans, because the teacher has an option to upload videos that explain how to install a program, software features, as well as explanations for certain assignments.

As teachers, when creating quizzes and tests, we prefer the Schoology portal because we can customize a wide array of settings for each test/quiz. The following settings
can be adjusted: Instructions, Submissions (e.g. Enable until, Enable from…Until), Time Limit, Attempt Limit (e.g. Attempt Limit: 3 times, Grade by: Highest Score), Randomize the Order of the Questions, Resumable, Paging, Question Review, View Submissions, Hide Point Value, and other features[4].

B. Schoology

Schoology[5] is a learning management system (LMS) that provides a number of various collaboration tools and enables teachers to share e-learning courses, administrate classes, keep gradebooks and communicate with other teachers and students.

We are using the Schoology portal for the following activities:

Because we are using Schoology to create quizzes/tests, we are also using this portal for tracking student progress via Gradebook[6].

Schoology offers the possibility to create course media albums in order to organize photos, videos and/or audio files for different courses. Teachers can allow comments on each item within an album. Students can have an option to upload and tag media[7].

By using Schoology teachers can create an interactive discussion for students. Students can respond to any post by another student. The students’ comments can be moderated, which requires a teacher to approve each post before it is published [8].

III. Pilot Study

Edmodo and Schoology have several common features, such as a familiar interface (similar to Facebook interface), comprehensive products such as discussion panels, announcements, schedules and grading; both platforms are generally available free of charge.

A short overview of Edmodo and Schoology features is shown in Table I.

Our research was conducted on Edmodo and Schoology learning managements systems on ninety-three students from 13 to 18 years of age for specific subjects from vocational education such as Java programming, Embedded Systems, Databases and Server operating systems.

IV. Findings

The majority of students stated that shared course materials can be easily accessed using both Edmodo and Schoology as shown in Figure 1.

![Figure 1](Image)

**Figure 1.** Question for students: “Do you find that both Edmodo and Schoology provide easy access to course materials?”

Our research has shown that the majority of students have noticed the difference between quizzes and tests made in Edmodo and Schoology as shown in Figure 2.

![Figure 2](Image)

**Figure 2.** Question for students: “Have you noticed the difference between quizzes/tests created in Edmodo and Schoology?”

They immediately noticed the following features: Attempt limit (specifies a limit to the number of times a student can take a test/quiz) and Resumable (option that allows students to resume an incomplete submission).

Once a student starts a quiz/test in Edmodo, it cannot be paused; when the allotted time runs out, the quiz/test will no longer be accessible to the student. The teacher can allow students to retake a quiz/test.

The main advantages and disadvantages of the Edmodo Learning Management System are shown in Table II.

Schoology offers elaborate reports and statistics on students’ improvement via Gradebook. As shown in Figure 3, students are using the Gradebook option available in both Edmodo and Schoology. Teachers can grade assignments, quizzes/tests and discussions directly in the Gradebook, and students can easily view these grades under their Grades tab. Moreover, the students’ progress can be evaluated against specific instructor-defined objectives.

The majority of students didn’t like using Media Albums from Schoology portal for different course topics as shown in Figure 4. When asked why, they said that viewing different media content was interesting, but they didn’t want to participate in creating course content. First reason was that they needed to explore course materials and the Internet to create content. There were students who thought that their grade will depend on the quality of created content because all students didn’t have equal technical and/or creative skills for creating course content.

Nearly the same result was shown for using the Discussion option in Schoology as shown in Figure 5.

Most of the students didn’t like to participate in discussions.

The main advantages and disadvantages of the Schoology Learning Management System are shown in Table III.

Our research has shown that students preferred using Schoology when doing quizzes and tests because they could resume an incomplete submission. Both Edmodo and Schoology allow students to easily access course materials. As the research has shown, students in general didn’t like using Media albums and Discussions, a feature that can only be accessed via the Schoology portal.

As shown in Figure 6, there was a slight difference in opinion regarding a question: “Do you prefer using Edmodo or Schoology?”.

V. CONCLUSION

Although we are currently using both Edmodo and Schoology learning management systems for ninety-three students from 13 to 18 years of age, depending on the needs of a specific subject, in the future we plan to completely switch to the Schoology portal because it is more organized. When creating quizzes/tests, Schoology LMS offers more features. Although most of the students didn’t want to use Media albums and Discussions, these Schoology features allow teachers to create an interesting course content.

Figure 6. Question for students: “Do you prefer using Edmodo or Schoology?”
Abstract - Nowadays, in the period of the digitalization and knowledge economy development, majority of activities result in the increase of data that should be captured. In each area of business, there is an increasing urge to extract the knowledge from data in a timely manner in order to be able to make shifts that ensure a competitive advantage. Thus, the knowledge of methods and techniques of big data processing is currently a tool of a modern economist. Courses oriented to how to use machine learning tools in the economic practice should become a part of a study plan at universities of economics and business. In our paper, we propose the concept of teaching of machine learning techniques using software Weka as a possible solution to integrate this issue into the study plan based on the example of problem-based learning.

I. INTRODUCTION

Digitalization of the surrounding reality has become a matter of course of the current information society. Modeling of real situations and events in the modern economy allows faster and more effective dealing with rapidly-increasing requirements regarding their fast processing. Properly designed model of real events allows predicting the future values. This feature is among fundamental assumptions of decision support systems which have taken their place in almost every aspect of life. Nowadays, information represents the most valuable commodity and this is why knowledge and the ability of its extraction from the amount of collected data is not only useful but in the today’s competitive environment it could be marked as must-have, or existential.

Processing of huge amount of data and information extraction from given data set is a scope of research of Business Intelligence. Business Intelligence includes processing of Big Data, methods and techniques of Data mining, design of prediction models and decision support systems. In order to master the techniques of data processing, it is necessary to link mathematical skills, statistical knowledge and computing skills. This knowledge and ability to use abovementioned methods should be in the skillset of the modern economist and thus teaching of these fields as a part of educational process of universities of economics seems to be the natural trend. 81% of companies with appropriate analytical talent claimed that business analytics creates a competitive advantage [1]. However, report of Universities UK [2] adverts that there is a shortage of graduates with the right combination of analytical skills in terms of transforming data into meaningful insights that has a business value for the employer. Moreover, study by Manyika et al. [3] projects the shortage of talent, particularly of people with deep expertise in statistics and machine learning, and the managers and analysts who know how to operate companies by using insights from big data. In 2018, the demand of deep analytical skills in the US is projected to be 50-60% higher than supply. This equals to 140,000-190,000 professionals. In Canada, there is a talent gap estimate between 10,500 and 19,000 with these skills for the roles like Chief Data Officer, Data Scientist, and Data Solutions Architect. Moreover, there is a gap for professionals with solid data literacy at 150,000 (for the roles Business Analyst or Business Manager) [4]. Based on these predictions, it is obvious that students with particular skills in machine learning can gain a significant competitive advantage on the labour market.

II. THE CHOICE OF MACHINE LEARNING TECHNIQUES AND DATA SETS

Machine learning is a multidisciplinary area involving artificial intelligence (AI), probability, statistics, information theory, philosophy, psychology and neurobiology. The goal of machine learning is to solve real-world problems with the use of model that provides a good data approximation [5]. Currently, there are plenty of machine learning methods that could be integrated into the study plan of universities of economics. In their paper [5], Dhage – Raina presented an overview of basic machine learning techniques. In terms of our university course, we decided to include the methods that (1) we think are understandable and manageable by students; (2) are supported by proper software available free of charge; (3) are useful for common economic practice; (4) are described in the case studies which ease both the teaching and learning process.

When it came to selection of the right techniques, mathematical and statistical background were another criteria we took into account. As our students previously took part of courses Mathematics I., Mathematics II., Probability and Statistics and Statistical Methods in Economic Science, we assumed they have enough knowledge to start with methods proposed by us without necessity to learn fundamentals. From the wide range of methods, for the purpose of course, we decided to choose the following:
a. Linear regression  
b. Logistic regression  
c. Factor analysis  
d. Cluster analysis (hierarchical and non-hierarchical)  
e. Naïve Bayes algorithm  
f. k-nearest Bayes algorithm  
g. Market basket analysis using apriori association rules

As the abovementioned methods are commonly known and widely used, the details regarding these methods could be found in fundamental machine learning books and studies.

In order to successful acquirement of proposed techniques by students, we assume that it is important to motivate them by stressing the information/value/insight they can gain from conducted analysis. We also assume the option to compare the results with the results of the example problem is important in order to have a reference about steps taken during the analysis. The selection of problem sets was important in order to arouse the interest and curiosity of students. Although the course is intended for students of faculty of economics, the problem sets and selected data sets were not selected with the emphasis on economic problems. On the contrary, their character is more or less sociological while describing general events which might seem more attractive for the students of the 2nd grade.

Based on the abovementioned arguments, we decided to embrace well-known and verified data sets that have been analysed broadly and there are many information and additional comments regarding their usage. To name a few, we decided to choose data sets Titanic, Affairs and data set from website Kaggle (www.kaggle.com), such as European Soccer Database, IMDB 5000Movie Dataset, 2016 US Election, World University Ranking, as much as well-known data set Iris Species.

III. THE CHOICE OF SOFTWARE TOOLS

There are many suitable software tools to teach machine learning techniques, such as SaS, The R Project, Rapidminer, Weka etc. In order to select the right software tool, we evaluated several criteria that are critical in case of software implementation in the academic environment. As students meet with the machine learning techniques for the first time, simplicity and user friendly user interface are basic criteria that have to be included. Availability and ease of installation were among evaluated factors, too. In order to assemble the course that is perceived to be useful, it is necessary that user base is large enough and technical support of software developers is available reasonably. The existence of large amount of study materials, tutorials, demo problem sets and examples is among the most significant factors we evaluated. This kind of accessibility is important in terms of further development of downstream courses or personal development of students themselves. In case they will consider the course to be valuable for their further career, they can extend their knowledge in the field. Regarding the software and platform independence, we selected software that can be installed and executed on the operation system Windows. The last but not least, the price was the last criterion we took into the account. In case the software license would have to be paid, we assume that students would be less motivated to install the software at home (out of the scope of the course). Moreover, the free solution could help them in their career life, as to prove their knowledge, it will be easier to get management buy-in.

After careful considerations, we decided to choose the solution The Waikato Environment for Knowledge Analysis (WEKA). It is well-known and broadly used software developed by University of Waikato in New Zealand. Dhage – Raina [5] consider Weka to be a platform that embodies best practices for process, configuration and implementation of machine learning algorithms and in addition, it meets all abovementioned criteria.

Weka is a comprehensive software solution containing many state-of-the-art machine learning and data mining algorithms included in the Java class libraries. Weka could be downloaded from the Internet free of charge. Moreover, accompanying book explaining the included algorithms has been published [6]. Weka can be installed and run on any computer that supports Web browsing regardless of the computer platform. As the software is written in Java, the choice of computer platform is up to the user’s preferences.

Classification algorithms, decision trees, association rules and data clustering algorithms are among primary methods included in the software. The core package contains classes that are accessed from almost every other class in Weka. The most important classes are Attribute, Instance, and Instances. An object of class Attribute represents an attribute - it contains the attribute’s name, type, and in case of a nominal attribute, all possible values.

Ability to select relevant functions to be included in the model induction is an essential component of applied machine learning system. The Weka software provides three feature selection systems: a locally produced correlation based technique [7], the wrapper method and Relief [8].

Weka contains an implementation of the Apriori learner for generating association rules, a commonly used technique in market basket analysis [9].

The objective of clustering methods available in The Weka is not to predict the particular classes. Instead they try to divide the data into homogenous groups called clusters. The Weka contains implementations that could be used for variety of tasks, e. g. EM algorithm (commonly used for unsupervised learning) or Naïve Bayes (for more information refer to [10]).

IV. EDUCATIONAL PROCESS

There are several previous studies describing the machine learning teaching process:

• students of Artificial Intelligence, Computer Science and Information Science [11];
• students of design [12];
• diverse audience [13].

However, we weren’t able to find any paper describing the teaching process in terms of the students of economics or business administration.

Machine learning techniques are part of the process of the knowledge extraction from databases (data sets). These techniques are fundamental for the Data mining process. Data mining is considered to be one of the six steps regarding the knowledge discovery in databases [14]. The process of knowledge discovery in databases could be considered as a part of Business Intelligence which is crucial for leveraging the intellectual assets of companies by creating, storing and sharing obtained knowledge for effective decision making. It is a process of obtaining the knowledge from the databases that are valid in the statistical meaning, currently unknown, and potentially useful for specific purposes. [15], [16], [17].

Process of KDD may consist of different number of steps and their specification vary based on the author [18], [19], [20], [21] and [22]. Paralič [14] defines KDD as a process of the following 6 steps:

1. Definition and analysis of the task
2. Gathering of relevant data and its understanding
3. Data pre-processing
4. Data mining
5. Evaluation of examined patterns and identification of knowledge
6. Application of knowledge obtained and evaluation of its use

In the educational process of machine learning techniques we focus on the 3rd and 4th step of KDD. However, for the complex understanding of the problem and for motivation, it is necessary to address each step of KDD.

The first phase of the educational process is connected to the determination of the problem or research task by lecturer. Afterwards, the relevant dataset is made available. Students will use the dataset to complete their research tasks.

The second phase of the educational process is analysis of the research task in order to fully understand it. As a part of this phase, decomposition of the research task and analysis of the dataset should be done. The main focus of this phase is to choose a proper machine learning technique/techniques that will be used for the data analysis and the consultation about the method selection with the lecturer.

The third phase of the educational process is pre-processing of the available dataset. In this phase, students are going to use software program MS Excel. This phase will result in cleansed dataset in the format suitable for processing in Weka. We chose MS Excel for the variety of reasons for this phase. MS Excel is broadly used tool and students are familiar with its basic functions. Moreover, by pre-processing the dataset in MS Excel, we can improve the knowledge in terms of its use by students.

The fourth phase is the application of machine learning techniques on pre-processed dataset with the use of Weka software. The outcome of this phase should be results of analysis.

The last phase of the educational process is the evaluation of obtained results and their comparison based on the use of particular machine learning methods.

The course is intended to be a part of the educational process of the students of the 2nd grade of the study major Finance, Banking and Investment at Technical university of Košice, Faculty of Economics. Currently, there are several courses of statistics and econometrics available at Faculty of Economics. However, we have chosen to propose the new course based on the following:

• statistical courses in the 1st grade cover only basic methods and lack touch with business reality;
• statistical courses in the 2nd and 3rd grade miss machine learning methods and are taught using software that is not freely available. The same applies for courses in the higher grades;
• econometrics course in 4th grade is taught (in our opinion) too late. Moreover, in order to perform analysis, R is used. It involves programming and causes troubles for students in this very first step.

The course is an elective subject. In the pilot run, there will be 12 students involved in this course. Based on the number of students in the course, we selected educational methods that allow individual approach towards students. We consider this approach to be the most suitable regarding the character of the course. This method has been marked as expository-problem method and research method [23]. Expository-problem method will be used in the first half of the course in which we will outline the problem situation and research task. The expository part will be focused on the introduction of the fundamentals of knowledge extraction from databases with the theoretical framework oriented toward machine learning techniques. Students will learn how to work with the dataset during the pre-processing phase (with the use of MS Excel and Weka). In the second half, we decided to apply the method of research. Students will select the research task that will be specified by the particular dataset. The emphasis will be put in knowledge extraction with the use of selected machine learning techniques. When research task is handled properly, students will present the method they chosen, the procedure and results obtained by analysis.

V. EVALUATION OF EDUCATION PROCESS

The success of this pilot course and its sequel strongly depends on the course and methods rating of students themselves. Questionnaires and feedback polls are inevitable in order to improve the course or make changes that will lead to the better overall perception of the course by students. We decided to put the “startup approach” in place. The primary aim of the pilot project is to set some
sort of the MVP (most viable product) - the university course that will be iteratively improved based on the feedback of the customers – the students. Due to the small sample of course participants, we decided to use semi-structured interview in order to determine student’s expectations regarding the course. At the end of the course, we will distribute the questionnaires among students that will try to map the following areas connected to the educational process:

- the suitability of selected problem sets (datasets and techniques);
- the suitability of selected teaching methods;
- the difficulty of the course content;
- the practical applicability of the course;
- the suitability of chosen software tools and their difficulties;
- the evaluation of the student’s results by lecturer;
- what was the degree of satisfaction with the course in terms of meeting the students’ expectations.

Results obtained from questionnaire survey will be compared to the results of the interviews conducted in the beginning of the course. The survey will not be anonymous as we would like to follow up with the students that can provide us with additional insights regarding the course quality improvement. It is a vital step not to expect students to be the only ones working with the data. It is also our duty to practice what we teach and responsibility for the proper intellectual development of the future generations of economists.

VI. CONCLUSION

As was presented in the beginning of our paper, there is a shortage of people with data mining skills. The use of machine learning methods is currently necessary in all fields, including economics and business. Based on the abovementioned state on the labour market, we assume the machine learning skills to be a competitive advantage of students when applying for the job. In our paper, we propose the design of the course with the focus on machine learning techniques. The course is designed for the students of Faculty of Economics. The course consists of several steps necessary in order to execute proper data analysis. We also suggest a particular range of methods that would be taught and executed in software Weka. Weka is a significant step in the transfer of machine learning technology into the workplace. We selected the software based on the criteria that was set prior the course. In order to improve the satisfaction of students and utility of the course, we would like to apply selected methods for obtaining valuable feedback that will help us adapt the course.

Abstract - In today’s world virtual online educational platforms emerge literally on daily bases and many offer MOOC-based courses. With the appearance of MOOC, educational platforms have gained an additional boost, a new aspect in their evolutionary process, which has opened a new field of research thanking to the extraction of logging information within the frames of data mining. It has become clear that educators will be able to tailor their courses by merging the two previously mentioned fields and by carrying out MOOC-based data mining, targeting pedagogical aspects. This field of research seems promising and important, thus a faculty at the University of Szeged has created its own MOOC educational platform which has been set to facilitate data mining by implementing a wide range of logging algorithms. The data would be processed through a complex Artificial Intelligence program, which, in the short term, could reveal new and exciting pedagogical findings, while in the long run, the supervisors could put together a platform that would help and notify educators about relevant information. It would become possible to create adaptive educational materials, as well. This work aims at clarifying how such platforms function and what the steps of data collection and evaluation are.

I. INTRODUCTION

In today’s world virtual online educational platforms emerge literally on daily bases and many offer MOOC-based courses. Mushrooming as a scalable lifelong learning paradigm, Massive Open Online Courses (MOOCs) have enjoyed significant limelight in recent years, both in industry and academia [10]. With the appearance of MOOC, educational platforms have gained an additional boost, a new aspect in their evolutionary process, which has opened a new field of research thanks to the extraction of logging information within the frames of data mining. Plenty of research at various institutions in the last 8 years seem more than promising with a significant breakthrough. Its origin dates back to the Educational Data Mining conference in 2008, where the idea of educational data mining of MOOC courses first emerged. All the findings since then have been published in the form of research papers and scientific journals underpinning that it is worth digging even deeper.

It might be asked what the reasons are that brought this interdisciplinary field of sciences to life. The main reason is that MOOCs are open education platforms, in which the participants are self-motivated to complete courses [24]. However, learning outside the framework of an educational institution and the supervision of a teacher may bring about certain obstacles. Learning in a MOOC requires that students apply self-regulation [23]. Among the most debatable issues are the high drop-out rates, this has been proven by dozens of researches. [3][7][9][11][13][23][25]. From this standpoint, one could easily question the existence of MOOC courses; nevertheless, there is pressure in higher educational institutions to provide up-to-date information to achieve institutional effectiveness [20]. Online platforms are among the most important tools to gain insight into how online education functions.

Ironically, the problem can be solved through the online platform itself because its structure allows all around logging of student activities, which may lead us to some so far unknown tools of pedagogical research. This idea has been grounded in the investigation of Romero & Ventura who think that learning management systems accumulate a great deal of log data about students’ activities [20]. The system can automatically record whatever student activities are involved, such as reading, writing, taking tests, performing various tasks, and even communicating with peers [26]. In short, MOOC big data is a gold mine for analytics [18]. On the other hand, data mining technology has been proved effective in CMS pedagogical research as well [13].

Science that deals with verifying such data is called EDM (Educational Data Mining), with many prominent names of the field and outstanding research achievements. Berland et. al suggest that EDM may have the potential to support research that is meaningful and useful both to researchers working actively in the constructionist tradition but also to wider communities [16]. Data collected from learning systems can be aggregated over large numbers of students and can contain many variables that data mining algorithms and techniques can explore for model building. [22] Working from student data can help educators both track academic progress and understand which instructional practices are effective [5].

Educational data mining (EDM) is a research area which utilizes data mining techniques and research approaches for understanding how students learn [22]. In recent years, there has been an increasing interest in the use of data mining to investigate scientific questions within educational research, an area of inquiry termed educational data mining [2]. The scope of educational data mining includes areas that directly impact students [19]. An emerging field of educational data mining (EDM) examines the unique ways of applying data mining methods to solve educationally related problems [19].

It must be stated that the primary goal of research is not just to obtain information but to keep as many students
as possible signed up to our courses. Through his investigation into the relevant papers, Huebner reveals works that suggest how learners can be kept in the learning environment, efficient educational techniques, and better course books in the future which may help reducing the drop-out rate in a predictive way [19]. Along this line of thought, researchers at Bowie State University have assigned risk factor points to each learner which demonstrated who would have difficulties [6].

The authors’ research takes this route to test e-learning platforms by putting together two MOOC courses (Conscious and Safe Internet Usage - TÉBIA, Database Management) a logging platform to register online activities. This paper has been written to investigate EDM opportunities and to develop the authors’ own logging system dealing with how the steps of data recording, cleaning, and pre-processing are done.

II. WHAT IS EDM AND WHY IS IT IMPORTANT?

While thousands of students have been attracted to large online classes, keeping them motivated has become a challenging endeavor [13]. Thus, it is of paramount importance to understand student motivation or why it is lost. A tool to gain access to such answers in Data Mining. In order to find out what this notion is one may quote Baker who states that Data mining, also called Knowledge Discovery in Databases (KDD), is the field of discovering novel and potentially useful information from large amounts of data [2]. Knowing that EDM has existed for only a decade, it is advisable to take a close look at it to reveal what it really means. Its meaning depends on how it is defined, however a common meeting point has been established, which seems to be digital education. Educational data mining is a research area which utilizes data mining techniques and research approaches for understanding how students learn [22]. EDM is an emerging tool and technique used to comprehend and represent educationally related data [19]. Furthermore, data mining is a series of tools and techniques for uncovering hidden patterns and relationships among data [27]. Data mining is a multidisciplinary area in which several computing paradigms converge: decision tree construction, rule induction, artificial neural networks, instance-based learning, Bayesian learning, logic programming, statistical algorithms, etc. And some of the most useful data mining tasks and methods are: statistics, visualization, clustering, classification, association rule mining, sequential pattern mining, text mining, etc. [21]. Educational data mining is an emerging discipline that focuses on applying data mining tools and techniques to educationally related data [1]. A large number of researchers within EDM focus directly on course management systems and how they can be improved to support student learning outcomes and student success [19]. Data mining is the process of efficient discovery of non-obvious valuable patterns from a large collection of data [12].

Interactive e-learning methods and tools have opened up opportunities to collect and scrutinize student data, to ascertain patterns and trends in those data, and to formulate new discoveries and test assumptions about how students learn [22]. Researchers have found that they can apply data mining to rich educational data sets that come from course management systems such as Angel, Blackboard, WebCT, and Moodle. Numerous studies have shown that data mining can be used to discover at-risk students and help institutions become much more proactive in identifying and responding to those students [14]. Educational data mining is defined as the area of scientific inquiry centered around the development of methods for making discoveries within the unique kinds of data that come from educational settings, and using those methods to better understand students and the settings which they learn in [2]. Online learning systems log student data that can be mined to detect student behaviors that correlate with learning [22].

Four main axes can be identified along which EDM methods may be helpful for constructionist research:

- EDM methods do not require constructionists to abandon deep qualitative analysis for simplistic summative or confirmatory quantitative analysis;
- EDM methods can generate different and complementary new analyses to support qualitative research;
- By enabling precise formative assessments of complex constructs, EDM methods can support an increase in methodological rigor and replicability;
- EDM can be used to present comprehensible and actionable data to learners and teachers in situ.

In order to investigate those axes, the first step is to describe one’s perspective on compatibilities and incompatibilities between constructionism and EDM [16].

The strengths of EDM systems can be traced back to their tools, primarily logging methods that provide information to researchers, who would in turn reveal so far unknown pedagogical conclusions. Baker sums up (Table I.) what is known about those tools and result [2].

TABLE I. The Primary Categories of Educational Data Mining
The system presented in this paper was built on the basis of Moodle which is an open-source, free, well supported, popular e-learning platform. It has a long history, given that the first version came out in 2002. The platform is known for its robustness, though its user interface is little less modern than it is expected in these days. This is the underlying reason for completely replacing its font-end and develop a new one, which calls the Moodle’s back-end. One module of its front-end is responsible for logging, which is the focus of this article.

This logger front-end collects and process events, and calls its back-end part via HTTP to store them. This back-end part – which is completely independent from the back-end of the Moodle - is developed in NodeJS and uses MongoDB to store events (Figure 1.).

Every log entry is an event. Each of the events classified the system into different types, and depending on the type, they store different parameters for it. For example, a "textinput" event has a parameter, which stores the typed text, called text:

```
{
    type: "textinput",
    data: {
        target: "search-target",
        text: "database"
    },
    time: "2017.01.23. 16:01:28.242",
    page: "https://...",
    userid: 1876
}
```

There are some parameters, which are stored for all events:

- **userid**: the ID of the user, who has executed the operation, or 0, if there was an anonymous user
- **time**: the date of the event
- **page**: the URL of the page, where the event was happened
- **type**: the type of the event (see below)

The type of the events, and their parameters can be the following ones:

- **load**, **unload**, **focus**, **blur**: they are generated in the case of loading or unloading of the page, and getting and losing the focus.
- **resize**: it means resizing the browser window. It has two parameters: x, y (the new size of the windows).
- **click**: it represents a mouse click. Its parameters are x and y.
- **testClick**: it signifies a mouse click to an answer of a quiz. It is a preprocessed event: this javascript event handler automatically recognizes if the mouse click happened over an answer, and generates a testClick event, not a simple click event. Its parameters are: question, answer, correct, choiceCleared.
- **download**: it is generated in the case of downloading a file. Parameter: filename.
- **textinput**: this event represents a change of a text input field. Parameters: target (id of the text element), text (actual value of the text element).
- **textinput focus**, **textinput blur**: they are generated when a text input gains or loses the focus. Parameters: target (id of the text element), text (actual value of the text element).
- **passwordinput**, **passwordinput focus**, **passwordinput blur**: similar to the previous ones, but because of security consideration, the value of the password text input is not stored. Parameters: target (id of the text element), and length (of the text element).
- **mousemove**: mouse moving event. Parameters: x, y, xDistance, yDistance, realDistance. The system stores only two mouse events in a second.
- **scroll**: means scrolling the page. Parameter: top. The system stores only two mouse events in a second.

There are video events, as well. The system supports two kinds of video: html5 video element and embedded YouTube video. Events:

- **videoSeek**: means seeking in the html5 video element. Parameters: seekTime, videoId, totalTime, src.
videoPlay, videoPause, fullscreenOn, fullscreenOff: html5 video playing events. Parameters: actualTime, videoId, totalTime, src

youtubePlay, youtubeEnd, youtubePause, youtubeBuffering: youtube video playing events. Parameters: actualTime, videoId, totalTime, src.

youtubeQuality: changing youtube video quality settings. Parameters actualTime, videoId, totalTime, src, quality

youtubeRate: parameters: actualTime, videoId, totalTime, src, rate

IV. DATA

Two courses have been created in order to test the logging platform. In the first part of the research, a pilot study was conducted between the dates of March 1 and May 30, 2016, while the second study was recorded in the interval of October 1 to December 10, 2016. Altogether 163 students took part in the pilot study and 347 student signed up for the two courses in the Autumn semester. The details about the course are presented in Table II below. The learning material for both courses comprised a three week study period. One of the courses, which ran under the name ‘TEBIA,’ included 4 + 1 (embedded) videos, while the other course, with the name ‘Databases’ had 7 (embedded/Youtube links) videos with attached embedded texts, or external links.

The primary point of interest for the researchers lay not in the drop-out rate, instead the aim was to discern how the platform functioned and how the learners would behave. It can thus be concluded that 99.8% of the learners who had signed up for the course, had also completed it.

The logging system during the two courses registered 4,663,120 logs, out of which 26 variables were generated and assigned to the users. These were the following:

Data, Page, Pid, Time, Type, User, Data.realDistance, Data.x, Data.xDistance, Data.y, Data.yDistance,

V. PRE-PROCESSING

The e-learning platform of the University of Szeged is a website which provides a wide variety of services, including video lessons to every courses, however it does not have a complex platform such as Coursera or edX. This is the reason why is was not possible to close the e-learning portal after the pilot study and the two courses. Thus, as a consequence, the platform used for this research could not only be accessed by those students who had signed up, but it was accessible to but external users, as well. This led to the recording of 1,443,817 (404 Mb) logs, while during the second time the system had 3,219,303 (936 MB) recorded logs. The portal recorded...
1229 students and lecturers, out of which only 513 were relevant. The contaminated raw data had to be put to serious data cleaning procedures. The file was cleaned and sorted out by examining students’ IDs, user behavior, and sign-in tendencies. Table III demonstrates a simple but effective algorithm that filters relevant and usable data:

**TABLE III. USER BEHAVIOUR, AND SIGN-IN TRENDS**

A deeper study of this JSON file revealed further important information. This includes the user activities showing that 54% of the logs were generated by 10% of the users. The comprehensive diagram of user activities shows the distribution of active and passive participants (Figure 2).

**Figure 2. Number of clicks by user**

This fact is not surprising since one of the side effects of a MOOC course is the uneven distribution of active and passive students. Anderson et al. created 5 categories [28]:

- Viewers, in the left mode of the plot, primarily watch lectures, handing in few if any assignments.
- Solvers, in the right mode, primarily hand in assignments for a grade, viewing few if any lectures.
- All-rounders, in the middle mode, balance the watching of lectures with the handing in of assignments.
- Collectors, also in the left mode of the plot, primarily download lectures, handing in few assignments, if any. Unlike the Viewers, they may or may not be actually watching the lectures.
- Bystanders registered for the course but their total activity is below a very low threshold.

If the student activities and other data are converted to percentages, one would gain deeper knowledge in this topic. Figure 3 shows these findings. In order to complete a test, an average user generates approximately 400-2000 log files, which demonstrates that 58% of the learners do not aim at having a thorough understanding of the material but want to complete to course as soon as possible, while only 10% can be categorized as superusers according to Zhu et al.[24].

**Percent**

![Figure 3. Student activities/ logging data](image)

VI. CONCLUSION

At this stage of the studies, the authors were able to add a functioning logging system to a Moodle platform with weak tools of analyses, which would serve well for similar portals to live up to current measuring requirements. The data obtained and analyzed from students’ logging could reveal some unexpected pedagogical aspects thus helping educators and learners in the process of course planning and learning. The analysis of the pile of data amounting to millions of logs recorded during the pilot studies and the autumn courses could help the authors design an artificial intelligence (machine learning) that would automatically process input data without human intervention and which could intervene if extreme values emerge.

The aim of the redesigned and modified website is to enhance student motivation, learning achievements, and output results. After examining the relevant literature, the authors were able to sort out errors and potential opportunities that were unknown to them, like predictive analysis through clickstream [4], [7], [8], [15], [17] or feedback buttons by Chang et al. [11] which improved student concentration in the long run. A total of 1.2 GB of data was collected, enabling the authors to make the next step of designing a suitable mathematical model to their MOOC system. This would help to provide a full-scale predictive background support to educators who would upload their learning materials, and would help learners who sign up to a course. It is expected that the spring semester of 2017 will bring more users to this platform, which would double the amount of collected data. After quantitative and qualitative data analysis the new findings will also be published in a research paper.

REFERENCES

Abstract - The degree of including information, knowledge and technologies into all human activities is very high. New skills for new society are not only classical literacy (reading, writing, counting), but also information competencies and digital/computer literacy. According to ACM Europe Working Group in our “digital world”, information is available anywhere at any time, computer power is ubiquitous, communication of vast amounts of information is almost instantaneous, and storage capacities seem infinite. But these powerful possibilities only benefit those who have learned to use them effectively. That is why all students need to be educated in both: fluency with computer tools and the Internet and the science behind information technology, to use ICT and its devices intelligently. Educational system should be able to react appropriately to the development and trends. However, the required state and the reality do not meet. This article summarizes the results of the research of information and digital competence/literacy of secondary school graduates who entered the first grade at the Faculty of Economics, Technical University in Košice. Our research problems are as follows: What are the information competencies and students' knowledge gained during their school informatics education? How can they use this knowledge and their competencies?

I. INTRODUCTION

The Information and Communication Technology (ICT) sector plays an important role in a country’s economy and welfare. The ICT sector relies on highly performing technical infrastructures but also needs skilled people who are able to understand its complexities and are fully capable of making the best use of its potential [1].

The role of ICT on productivity and standards of living seems to be critical, because e-skills shortages, gaps and mismatches as well as a persistent digital divide will affect negatively productivity growth, competitiveness, innovation, employment and social cohesion in Europe [5].

As we can read in [6] and [7], Europe is facing a growing lack of e-skills and it is predicted that there will be an overall shortage of supply of about 800 000 ICT professionals in the EU by the year 2020. The European Commission confirms a growing demand for ICT professional skills.

New skills for new knowledge society are not only classical literacy - reading, writing, counting, but also computer and digital literacy and good creative, logical and critical thinking.

Computing enables and empowers new methods of data and information processing that have led to monumental changes across disciplines, from art to business to science [19].

The educational system should be able to react appropriately to the development and trends. The most recent National reform program in the Slovak Republic, adopted in 2014, presents actions to fulfill targets contained in the Europe 2020 strategy [16]. Another government document released in 2013 is Digipedia - a concept of informatization of the educational resort with an outlook until 2020. The concept presents digitization as one of the most effective tools for Slovak teachers and scientists how to achieve better results in education and research [13].

The most important targets and priorities of society development should be imported into the basic curricular documents as well as into the Educational framework which adjusts lessons allocation so that the declared efforts could be transformed into educational process. However, if we take a look at the, for example, Educational framework for secondary schools [14], the real situation does not testify to the proclaimed interests and efforts.

II. PROBLEMS OF RESEARCH AND DATA COLLECTION METHODS

In our research we focus on the real ICT skills and informatics knowledge – computer and digital literacy of secondary school graduates at the age of 18/19 years. Our research problems are as the follows: What are the information competencies/digital literacy and students knowledge gained during their school informatics education? How can they use these knowledge and competencies? What is the level of computer/digital literacy of secondary school graduates?

As a research tool we use a questionnaire administrated on the first seminars of Informatics I Course. We search for both the extent and content of compulsory education in the field of informatics/computer science and ICT at secondary schools. We have created
the questionnaire entries based on legislation, pedagogical documentation, and standards [14], [15], [3]. Our questionnaire is divided into several parts. Within the first part of the questionnaire our students are asked the following questions: What type of secondary school did you attend? How many obligatory informatics lessons did you take per week at your secondary school in particular school years?

In the second part of the questionnaire there are the following questions: Did you meet these terms in the informatics lessons at the secondary school? (Possible answer yes/no.) We focus on students’ knowledge in the field of basic terms of informatics, hardware architecture, operation systems, text editors etc. In the third part we want students to describe their experience with information systems.

Our aim is to compare results, developments and improvements in a longer time period. For this reason we did not modify the questionnaire entries during the research and we provided some formal modifications in a minimum possible way.

The sample of our research consists of all secondary school graduates who entered their first year at Faculty of Economics Technical University of Košice in 2003 - 2015. Students in the studied sample are from the Eastern Slovakian Region in more than 95 % of cases. Numbers of respondents in the research period, and type of graduates’ secondary schools are presented in Tab. 1 in detail. Letter “G” stands for Grammar School, “B” for Business School, and “O” for Other/Vocational School (low number of these graduates in our sample is due to the practical focus of these schools).

Within the first part of the questionnaire our students were asked the question: How many obligatory informatics lessons (lesson = 45 minutes) per week did you get at secondary school in particular school years? As we can see in Fig. 1, despite the increasing importance of Informatics and ICT competencies, the number of lessons devoted to this subject at secondary schools is still very low.

The conceptual framework which has been used to analyze further data follows [1], [2], [12]:

- Computer literacy means skills that are fundamentally necessary for the effective use and application of common ICT systems, devices and software tools in support of our own work and personal interests. Broadly speaking, these cover the term “ICT user skills”, which refers to the confident and reflected use of ICT for work, leisure, learning and communication.

- Information competencies/digital literacy represent skills that are necessary for researching, designing, developing, planning strategically, managing, producing, consulting, marketing, selling, integrating, installing, administering, maintaining, supporting and servicing ICT systems. These also refer to the abilities needed to exploit strategic opportunities by using ICT technology (especially the Internet), to assure stronger performance of organizations and to research capabilities for new ways of improving or implementing business, administrative and organizational processes.

### III. Evaluation of Students’ Computer Literacy

Standard of European Computer Driving License (ECDL, [4]) version 5.0 and basic pedagogical documents mentioned above were the base for designing the next part of the questionnaire concerned on finding out the level of
students’ computer literacy. In this part we focused on working with basic applications and programs: operation systems, text processing, spread sheet programs, presentation and graphic programs, web browsing and network communication via internet services. Questions in this part of the questionnaire were formulated as follows: Did you deal or work with these programs and applications?

Within Fig. 2 we present achieved percentage of students who had some experience in the mentioned programs and applications. We show an evaluation of the students’ answers expressed as a percentage number of response, "yes".

As we can see in Fig. 2, in the last years of our research gradually almost all secondary school students worked with text editors and spreadsheets, used the internet services (email, www), and the application for web browsing. Fig. 2 also shows an increase in the ratio of students who worked with software designed to make presentation. The proportion of students who work with graphic programs is basically the same in the research period – only about 40 %. Surprisingly, working with the operation systems in recent years, has not been indicated by 100 % of the students.

The graph shown above illustratively presents shifts which occurred or did not occur during estimated time periods in particular fields. Based on our findings and consistent with other surveys (e.g. [23]), we can say that in our sample the proportion of students working with basic applications and programs falling under the computer literacy is increasing. On this basis, we can assume that the basic level of computer literacy is growing.

IV. ASSESSMENT OF STUDENTS’ INFORMATION COMPETENCE/DIGITAL LITERACY

In this section we focus on working with applications requiring higher level of the cognitive demands and complexity of the tasks. At the same time, the range and nature of the tools and applications that the students are required to use to come to a solution are more complex. We examined whether the students had dealt with basic concepts of informatics (data, information, knowledge), with Von Neumann computer architecture, topology and typology of computer networks, the functioning of the Internet (internet protocols), coding and encryption, as we can see in Fig. 3. Our research shows that a higher level of ICT competency/digital literacy achieved significantly
lower proportion of high school graduates, as in the case of computer literacy.

In the area of coding, knowledge of the computer/hardware architecture, topology and typology of computer networks as well as the functioning of the Internet, the situation has not been improved. Slight improvement occurs in the ratio of students familiar with the basic concepts of Informatics.

Working with program languages - programming, algorithm creation, web sites creation and work within the database system represented the highest level in our investigations. The difficult tasks in these parts tended to involve transferring information from one application to another, knowledge application and requiring the student to follow a relatively complex sequence of actions. The results of our findings are presented in Fig. 4. As we can see, the situation observed for relatively long period is not improved dramatically in any of the monitored areas.

In the next part of the questionnaire the students had to indicate whether they had worked with any information system (IS), and if they had met with the definition or typology of IS. On average only about 20 % of the students had already encountered with the term information system and about 10 % with information systems typology. Despite the fact that nowadays most secondary schools use electronic classroom books, electronic pupils’ books, electronic library systems, and IS is widely used in everyday life (e-shops, transport, search for information, entertainment etc.), 80 % of the students, on average, had failed to give an example of a particular IS.

In general, development and output of our educational system in the field of Informatics and using ICT at national level can be seen for example in [21]. Slovakia can be compared with other countries via results of international surveys, for example OECD PIAAC Survey of Adult Skills - Problem solving in technology rich environments [17].

Our research shows that a higher level of information competencies/digital literacy achieves significantly lower proportion of secondary school graduates as in the case of computer literacy.

V. DISCUSSION

Information society starts to transform into a different, more organized form, so called knowledge society. From the development so far we can expect, that this form will be characterized by an urge in making the information more and more available for public, by using not only information but also knowledge stored and processed by information technology according to users’ requirements. Computer technology will obviously dominate even in discoveries, formulation and gaining of new knowledge [11].

Nowadays informatics education is essential for all of us - citizens of information and upcoming knowledge society. That is why Informatics, not only computer literacy is essential for all students of all types and all levels of schools.

Although computer science has been a regular subject at school for a relatively long time, there is still more and more discussion on how to teach computer science and what to teach: Should computer science education be oriented more towards its applications or more towards its fundamentals or more towards its social effects [20]?

Many authors make a distinction between information technology - deals with the use of the computer and its applications and Computer Science/Informatics - deals with the design of informatics products or more theoretical objects. This is often related to difference between users and designers with underlying idea that designers are „those who know“ and users are „those who don’t need to know“. We agree with the author of [9] that it is necessary to go beyond this dichotomy, which is undesirable from the education point of view. According to [9] „Informatics education for all“ means informatics education also for students who will not necessarily become computer science experts.

“Computational thinking could be added to the traditional three Rs: reading, writing and arithmetic as an additional basic skill needed especially by university students – they will be better prepared to choose a future career not only as a computer specialist but also as a specialist in other disciplines, who professionally, according the needs of her/his profession, can use computing methods and tools professionally.” [21]

If we consider changes in the ICT use and the Internet communication - network security issues, and the issue...
e.g. concerning of promotion ideas of extremism etc. - the development of critical thinking via increasing the level of digital literacy is considered crucial. Critical thinking is a complex process of deliberation which involves a wide range of skills and attitudes. It includes, according to [3], identifying other people’s positions, arguments and conclusions; evaluating the evidence for alternative points of view; weighing up opposing arguments and evidence fairly; being able to read between the lines, seeing behind surfaces, and identifying false or unfair assumptions; recognizing techniques used to make certain positions more appealing than others, such as false logic and persuasive devices; reflecting on issues in a structured way, bringing logic and insight to bear; drawing conclusions about whether arguments are valid and justifiable, based on good evidence and sensible assumptions; synthesizing information: drawing together your judgments of the evidence, synthesizing these to form your own new position; presenting a point of view in a structured, clear, well-reasoned way that convinces others.

The expansion of the digital literacy can stimulate the development of creativity, which can be understood as a multidimensional phenomenon that manifests itself in many fields and contexts, from arts and crafts to design, science, research and entrepreneurship. It is regarded as a cognitive ability, but it is not the same as intelligence. It involves the ability to synthesize and combine data and information, but also requires confidence to take risks. In general, we can say, that creativity is the process of having original ideas that have value [8].

The benefits of better ICT skilled users and employees for companies and organizations can be noticed for example in the following areas:

- Higher productivity and performance of the company/organization.
- Possibility of implementation new organizational forms, e.g. development of business nets, participation in supply chains.
- Increased added value of the product or services.
- Entry to new markets. Utilization of new business channels.
- New products or services, changing business processes.
- Responding to new business activities of competitors [18], [22].

In recent years, several advanced countries have declared the intention to transform their ICT school subject into a new Computer Science, Informatics, or Computing education, with the emphasis on developing computational thinking, programming, designing computational systems and other basic concepts of Informatics. In Slovakia the theoretical conception of the school Informatics at the primary and secondary stages can be approximately characterized by the following principles:

- It is not the ICT in education, but Informatics. Both components are necessary in modern education: integration of ICT into learning processes, and also a separate subject focused on the concepts of Informatics/Computing.

- Informatics is a general (opposed to vocational) subject, for every student, without regard to his or her future professional profile and the degree of achieved education.

- Programming is considered an inseparable and core constituent of the school Informatics [10].

It is necessary to transform these ideas into the real informatics education.

All of these suggestions imply that the learners, teachers and educators, employers and policy makers feel jointly responsible for improving the quality of existing training and developing new initiatives in the field of increasing computer and digital literacy level [1].

VI. CONCLUSION

From the questionnaire evaluation we derived that the education of Informatics at secondary schools is focused on handling different packages of applications’ programs. There is a lack of understanding the basic terms, working with data on higher levels and understanding the informatics principles through the creation of programs and algorithms. Algorithmic approach, using of knowledge for creating “something new” and interdisciplinary relations are often missing.

Students are not able to identify that they are working with IS regardless the fact, that they work with it in some form “every day” in school and in the common life.

Especially in the field of higher degree - digital literacy, the situation does not change, improvements are negligible, according to our findings. We can see that the real situation does not testify to the proclaimed interests and efforts. The subject Informatics has the second lowest lessons allocation which is only 3 lessons in the 1st up to the 4th year in the higher secondary educational stage. Insufficient is the ICT integration into the tuition of other subjects, acute is also lack of competent qualified teachers in the field of informatics and ICT use.

Our students will probably face several paradigm changes in their future careers and life. Their acquired school knowledge and skills might become obsolete within a short time. That is why they must be robust enough to meet the challenges of the latest fashion, and also enable the students to cope with changes [20].

We hope that our work has helped to raise public awareness and to put the higher levels of digital literacy topic on the agenda of education policy makers, academics and teachers.

Abstract - In the European Union development strategy formulated in the Europe 2020 document (European Commission, 2015) it was indicated, that the smart growth of the EU as a whole should be reached through the realization of three priorities: the increase in employment, the increase of productiveness and the social cohesion and specialized agendas: Digital Agenda, Education and Learning, E-skills and Employment. The main documents identify main weaknesses and risk areas. One of the most significant was described as the early school leaving of Roma minority members. Roma constitute Europe’s largest transnational ethnic minority with an estimate of ten million people. Learning outcomes of this minority are significantly lower than outcomes of the majority. As one of the reasons for early school leaving of Roma, insufficient understanding of learning materials is identified. The result is that most of the Roma community members drop out of education before attending a secondary school and continue their lives as unemployed or enter the labor market as unskilled workers. Within the paper will be presented the CloudLearning project that represents an alternative and innovative educational method: the way of the SOLE method implemented in their education. This paper will include partial results from the pilot tests realized these days.

I. INTRODUCTION

The European Commission (EC) has identified three key drivers for EU growth: smart growth, sustainable growth and inclusive growth within the Europe 2020 document [14]. One of the headline targets that is hoped to be achieved is pushing the rate of the early school leavers below 10%, because educational skills acquired during the higher stages of education (vocational and upper secondary), improve employability and reduce poverty [12]. Also for this reason, educational systems should be able to react appropriately to the developments and trends in the today’s knowledge society in close connection to the targets contained in the Europe 2020 strategy [16].

The ability to work with information and its transformation into knowledge can massively affect the further development of everyone [17]. In this regard, ICT plays the role of a mediator in education – it is helpful for cognitive development, enhancing the acquisition of generic cognitive competencies as essentials for life in our knowledge society. Students using ICTs for learning purposes are more involved in the process of learning and more and more students use computers as information sources and cognitive tools [6].

Roma people represent Europe’s largest ethnic minority (with an estimate of 10 – 12 million people). Despite of different strategies and action plans signed in and after 2010 and concerns with improving their fundamental rights and advancement their social integration (for example “European Commission communication on social and economic inclusion of Roma” [11], “EU Framework for National Roma Integration Strategies up to 2020” [9], [8]) and further progress evaluation documented in [15], [11], [13], many Roma still face severe poverty, profound social exclusion, barriers to exercising their fundamental rights and discrimination. These problems affect their access to quality education, which, in turn, undermines their employment and income prospects, housing conditions and health status, curbing their overall ability to fully exploit their potential. [15] In particular, areas with high proportions of Roma in the population show high rates of early school leaving, and it is estimated that 89 % of Roma leave school early [15]. Based on results of PISA tests [18] it can be concluded, that about 80 – 95% of Romani-speaking students have not acquired basic cognitive skills and competencies and have thus limited possibilities to find qualified employment and cope with the complex demands of today’s societies [20], [10].

Early school leaving of Roma is therefore a critical issue with direct social and economic impact. There are a number of reasons for early school leaving like e.g. cultural or cognitive differences. These lead to insufficient understanding of learning materials because of unacquaintedness with linear text, inappropriate ways of presenting knowledge by teachers to this group, and lack of interest, energy and motivation of teachers to use innovative teaching methods. Based on [15], the socio-economic reasons (e.g. poor infrastructure and shortages of equipment, geographical distance to schools and the lack of available public transport), individual reasons (language and communication problems, low confidence in schools, early marriage and childbirth or the necessity
of contributing to household income) of early drop-out of education are often aggravated by teaching styles or curricula that do not resonate with the real-life experiences of Roma children.

Improving the educational situation of Roma is a critical test of the EU’s ability to achieve progress in the inclusion of all extremely marginalized and socially excluded groups.

II. PROJECT CLOUDLEARNING

The mentioned challenges of the target group in education were the motivation of the consortium of the project “Head in the Clouds: Digital Learning to overcome school failure” (short “CloudLearning”; https://brainsintheclouds.eu) to design a program, which would use an alternative educational approach to research its potential of improving the above numbers in school failure. If successful, the approach implemented should prevent students from leaving school and increase their basic and transversal skills. It should enhance digital education in the work with the target group, mainly members of the Roma minority group. In the long run this project therefore wishes to support a breaking of the vicious circle created when educational disadvantages and exclusion are later manifested in an exclusion from society in general and specifically from the labor market.

The project (an Erasmus+ strategic partnership in the field of school education) was initiated and is coordinated by the Vienna University of Technology, which implements it together with the Verein Offenes Lernen (Austria), Technical University of Kosice (Slovakia), GAIA (Kosovo), Fundatia Crestina Diakonia Filiala Sfântu Gheorghe (Romania), Sukromna zakladna skola (Slovakia) and www.scio.cz SRO (Czech Republic). It is being implemented in three locations in Kosovo, Romania and Slovakia by three of the partners who were already before the project directly working with the target group and therefore were familiar with their educational challenges and needs [1].

A. Educational Approach

To reach the above described aims the program is based in the education method of Self-Organised Learning Environments (SOLE) [1], which was developed by Sugata Mitra initially with a “hole in the wall” experiment starting in 1999. In walls in villages and urban Indian slums Mitra incorporated computers with big screens at a height that made it easy for 8 to 13 years old children to use them. Next to these computers he placed signs telling children that they could use them freely. Over a time period of 5 years Mitra observed how the children learned by themselves how to use the computers, downloaded media, played games and researched information online. Collaborating in groups the children showed educational achievements while working in this unsupervised environment. What can be described as interactions in a chaotic manner therefore turned out to be what Mitra named “self-organizing systems” [7].

The reason for the CloudLearning team to choose this approach is the desire to engage students in their own learning process [1], because a learning process driven by students themselves is curious, collaborative, engaged, self-organized and facilitated by adult encouragement. In the case of SOLE this means that students, encouraged by the educators, use the internet to find answers to what Mitra calls “big questions”. He refers to questions without an easy way to answer them. They have to be tricky and open, and many times they connect two subjects. The objective is not finding a clear answer, but to capture the children’s attention and encourage them to discuss a topic deeply, from which they learn working collaboratively and thinking critically [21]. In this context the learning objectives of an activity are not predefined [19], but SOLE among other things aims at enhancing computer literacy. It also aims at improving skills in presenting and interpersonal skills [21], which belong among the transversal and basic skills the CloudLearning project wishes to improve [5].

In a SOLE per four students there should be one computer, of which all have to have a connection to the internet. Since there is not one computer per person the students will automatically have to work together [7]. To create an environment for free exploration of a topic it is furthermore important that the process is characterized by self-discovery, spontaneity, sharing [21], openness and flexibility [19]. There are only 5 rules: 1. the children receive a big question, or are encouraged to come up with their own big question; 2. the groups in which students work are chosen by them and throughout the activity they are free to change groups at any time; 3. they are free to move, interact and exchange ideas with each other; 4. the students can explore the topic in whichever direction they choose, as there is not only one correct answer; 5. and in the end of the activity the groups have to present their learning points [21]. They also have to hand in a report of one-page length summarizing their findings. In case the educator wishes to add to these learning points he or she can do so at another moment [7].

The SOLE experiments have come to the conclusion that learning in a group helps memory recall [21]. Crawley and Mitra, e.g., in a study show the tendency of students to retain the knowledge that they have gained even three months after the SOLE activity. They mostly test higher on the subjects three months after, which Crawley and Mitra referred to as an “anomalous expansion of understanding”. The reason for this is that students, after the lesson, kept discussing the subject with others in their class as well as their mother and father, and did further research in their free time [7]. By implementing a SOLE activity, students should get motivated to study a variety of ideas and subjects [21], and the mentioned data seems to confirm that. Research has also shown that learning in unsupervised groups can make up for inadequate teaching in school [22] and a study in England showed that many students react to
SOLE positively and they view it as different from what they perceive as a normal lesson [19].

The authors of [19] observe that SOLE can be perceived as an educational innovation in two aspects:

1. Technological: The educator is not on the central stage anymore and needs to incorporate technology into his/her teaching practices; and
2. Autonomy: The students are expected to be more autonomous because the approach is based on enquiry.

The teacher therefore has more the role of a mediator than an instructor in the learning process of his/her students. SOLEs are considered to make it more possible to have a curriculum closer related to the experiences, interests and questions of the students [19].

The SOLE experiments indicate that children often have the capability to understand more than the adults would have thought. Working with the internet and the right encouragement children are able to answer almost any question [21]. It has been experimented with in for example in Argentina, England, Italy, Australia, Chile, Brazil, India, Uruguay, China and the USA. In all these places the children seemed to be able to work on big questions that were on a level usually considered a couple of years above their age, as long as they had internet and could work in unsupervised groups [7]. After many years of research Sugata Mitra was the first to receive the TED Prize [21] 2013, because he has inspired educators around the world with his ideas [19], just like he inspired the CloudLearning team.

B. Needs Assessment

The first phase of the CloudLearning project was fully devoted to the needs assessment of the participating partners and students. The implementing partners gathered information about the students, their families and living circumstances, knowledge of computers, IT in general as well as language skills. Another aim of the needs assessment phase was to learn about the partners’ expectations from the outcome of the CloudLearning project. This information played a vital role in developing the content of the SOLE-boxes in order to assess the local context and provide material that addresses the shortcomings of the students’ current education standard.

1) Romania

In the case of the Romanian partners, students and their families were asked to fill out a questionnaire in order to gain insights into the students’ living circumstances and educational background. None of the students from Romania have access to computers or IT at their schools, while one student out of five has access to a computer at home. The students speak in the Hungarian and Romanian languages. Their knowledge in the Roma and English languages are very minimal. Among the expectations from the Romanian Project partners they hope to achieve at the end of the program one can find capabilities such as developing computer skills and familiarity with technology for both students and teachers, increasing students’ level of creativity, advancement in English, and the implementation of new learning and teaching methods [2].

2) Slovakia

The Slovak Partners’ needs assessment showed that the students’ native language is Roma and the school curriculum is also taught in the Roma language. The students struggle with the Slovak language and do not speak or understand English. The participating school is very eager to start the program in order to: increase students’ computer literacy, incorporate new technologies in the learning process, and receive new PCs—current PCs are depreciated and often not compatible with software. The Slovak Partners expect the project to focus on computer science, geography, English, music, and the Roma language. The school would like the children to learn how to search for information online and develop long-term thinking habits with an emphasis on thinking about the future, not just living in the moment. Many families migrate to England or Belgium for employment and better living circumstances. Therefore, linguistic skills in English are very beneficial for the students [2].

3) Kosovo

The needs assessment from the project partners from Kosovo showed a strong desire to incorporate music into the SOLE-boxes. With regards to expectations they would like their students to develop music skills and connect with other children in the project in addition to society at large. Moreover, they would like their students to enhance their creativity, self-expression, and video making skills. This will strengthen the voice of the children and youth. The project partners from Kosovo want their students to explore the world through the CloudLearning project as the students suffer from isolation and they have no resources for travelling. Moreover, it is important for the participating organization that the students learn about renewable energy. They hope the outcome will reduce the gap between ethnic groups and promote the inclusion of children from majority ethnic groups into minority groups; promoting a different approach [2].

4) Overall Outcomes

The needs assessment process clearly indicated that there are five common expectations that need to be implemented in the CloudLearning project. First, the development of computer skills and learning how to obtain information online. Second, learning English, the country’s official language, and their native language. Third, teaching students more about real life topics such as basic hygiene, steps necessary to get a passport, environmental protection etc. Fourth, enhancing their creativity and stimulate their thought process. Fifth, encouraging the students to work together and develop social skills.

C. Project Progress

Based on the needs assessment, the SOLE approach and additional research the team discussed how best to structure and to implement the educational program for the target groups [5]. It was decided to divide the program in eight topics (educational “boxes”), each of them lasting two months [4]: two boxes deal with video
making and editing, one with the English language, one with the environment and one with “real life challenges” like getting a passport, health etc. While all these boxes automatically increase digital literacy because of the use of technology and internet, three of the boxes are specifically aimed at digital literacy and approach for example the topic of programming [5].

To ensure a smooth implementation of the project and establish the direct contact and exchange between the educators directly working with the target group, the developers of the educational boxes and the team evaluating and documenting the outcomes, a training for teachers and youth workers took place in Romania a month before the start of the work with children and youth. During the training the team also had the chance to meet with the local group of children that would later participate in the project and visit the location [3].

In October 2016 the implementation was kicked off with the first box being brought to the students. Since then in all location between 3 and 6 hours a week are dedicated to this project in the after school hours or on weekends. In Slovakia 12 children attend the sessions regularly, in Kosovo 37 and in Romania 30. Both in Romania and Kosovo the children are of different ages between 8 and 13, in Kosovo also some of them above, the eldest being 17 years. In Slovakia the groups consist of children attending the 6th or the 7th grade [5].

1) Tracking the Progress

In his trials of SOLE, Mitra usually performs tests with the students before they participate in a SOLE activity and then does tests with them after [19]. The same is being done with our target group. The project partner SCIO has developed a detailed and specifically for this project designed evaluation plan. It consists of

- a demographics questionnaire,
- two creative activities to learn the hobbies of participants (beginning and end),
- a tool to support teachers and youth workers in observing developments in the learner autonomy of each student,
- one evaluation of the free time of the students,
- an accomplishment questionnaire and a personality questionnaire to be filled after each educational box
- as well as structured interviews with the educators every two months.

Additionally, to observing the achievements of the students and therefore evaluating the success of the approach tested, the team uses a hand-in application designed and implemented by the partner Verein Offenes Lernen in which the students regularly upload their answers to questions, whether these are in picture form, written or documented as a video. The uploads make it possible for the team to document the learning activities, showing not only what are the results of the students’ research, but also giving the information of who did what activity when and with whom. Each task is also connected to a set of competences that the student develops in the set task. The competences are based on standards such as the ATC 21st century skills and the CEFR English competences. The data is furthermore connected to a system of learning analytics which makes it easy to observe all this information and draw conclusions from them [5]. SOLEs should empower students in taking ownership of their own learning experience [21], which is a central goal of the project. This ownership is supported through the ability of the students to access the documentation of their work and see the progress they have made [5].

2) Case: Videobox in Košice

As mentioned above, developed SOLE boxes need to be tested in real educational settings. One of the pilot testers is the project partner Súkromná Základná Škola, placed in Košice, Slovakia [23]. The school is focused on the education of Roma pupils. The school has 206 students, aged from 6 to 17 years, who study in 11 classes from grade zero until the 9th grade.

The pilot testing of SOLE boxes started by testing the first box, dealing with video making. (The first experiences of Roma students with ICT and SOLE boxes was recorded and is available at [4].)

In the pilot testing 12 students and 2 teachers were involved. During 8 lessons the box covered a series of topics, e.g.:

- The “Getting Started” tasks to encounter and understand QR codes, mobile devices, taking and editing pictures or movies using mobile devices.
- Do you want to be a YouTuber? – tasks for registering a Google account and YouTube channel, downloading the YouTube application, recording and publishing video.
- Why are some videos good, and others are not? - tasks about making scene plans, creation of scenarios, planning and recording the video, discussion on how to improve it.
- Be a professional movie editor! - movie editing with other videos, sounds, subtitles and pictures tasks.
- Finally, they will give a feedback to other classmates like a professional movie reviewer and at same time they also receive the feedback from others.
The tasks were, as previously mentioned, created in a way that children could be able to work on them independently without the intervention of a teacher. The teacher in this case acts only as a mentor, especially in cases where children can’t cope with the task alone, i.e. do not understand the text of the task and respectively they can’t find appropriate information to solve the task on the Internet.

After finishing the pilot testing an interview with the teachers was done in order to learn about their experiences and impressions from the first SOLE box implementation. The most essential findings from the Slovakian partner are the following:

- “The pilot testing started slowly, because there was a problem with internet access. This problem is in process of resolving. But that was the reason why we needed more time for the particular tasks. The teachers had to stay after the lessons at school and upload the files instead of children to the portal.”

- Using the SOLE box was smooth, tasks were written clearly and were very interesting for the children. They tried to solve them individually (within their skills and abilities).

- Some children have problems with reading comprehension and therefore help was needed.

- It was best to create small groups of children, preferably pairs.

- The most interesting task was picture editing – creating of picture collage.

3) Observations made

As the project is currently only in the fourth month no quantitative conclusions can be drawn yet, but some qualitative observations in all three implementing groups have been done. Also it should be considered that, as Mitra himself observed, it can take students some time to adapt to the new way of learning [21]. The CloudLearning team has been working with the children and youth for almost four months now, and while it is continuously learning to adapt the tools to the needs of the participants, most of them very much enjoy the approach already [5].

Four main challenges have been identified so far:

1. In his SOLE toolkit Mitra mentions the improvement of students in the fields behavior, abilities to solve problems, language, creativity and reading comprehension [21]. Our target groups are specifically challenged in reading comprehension and language [5]. Mitra also foresaw this problem happening in some places and suggested to encourage students to consult with groups that have a higher reading level and to look for alternative solutions of finding answers on the internet. By doing this he hopes that children will not see a lack of reading capabilities as such a big barrier in the future which can reduce their presentation anxiety [21]. In fact, e.g. in the Kosovarian group the phenomenon of supporting each other is very present. The children with higher reading levels help the others and the others also look for their support.

2. Initial internet problems because of remote locations and because of weak routers are being solved or have already been solved.

3. On a similar level challenging in the beginning was the wrong expectations as to how many smartphones the students would have. E.g. in the Slovakian group the educators had expected that half of the group would have smartphones and as it turned out almost none of them actually did. Steps to solve this problem have been taken.

4. The fourth problem is an intercultural challenge, as some of the tasks given were not understood because of concepts that were included in the tasks like “famous person”, “person on TV” or “role model”. Also this is being discussed in the team designing the boxes together with the implementing partners. Each newly written task is evaluated based not just whether the language is simple enough but also whether the concepts behind the questions will be understood by the students.

Generally, it can be said that the students are excited about the new, different and surprising way of learning. Some of the tasks posed to them so far they loved, some they did with less enthusiasm and some they were not interested in. The team is evaluating the common points of the favorite tasks to learn from these best practices for the next boxes, and for the moment it seems students like those tasks the most where there is a concrete outcome. This refers to tasks where in addition to understanding something new the students also produce something, like a video, a drawing etc. This current assumption will have to be confirmed or proven wrong in the future.

Very positively we can also mention the observations of educators of how much children have already learned, e.g. in the field of digital literacy just by needing to learn what a QR code is and how it works to be able to use the hand in application. The teachers and youth workers also report that after an initial encouragement and some explanations or hints where needed the students are mainly able to do tasks working independently without further guidance from the educators [5].
III. CONCLUSION

Based on the experience of other educators of SOLE and its effects the team considers the approach to be the right fit in creating a learning environment and support for students who like Roma are statistically more likely to leave school. In creating an environment that encourages a different, more active and self-organized learning and encouraging learning through new methods the project hopes to spark an interest in learning and to fulfill learning needs that the children and youth might not feel answered in the school lessons. The project develops the transversal and basic skills of participants and aims at sparking interest for learning. By doing this it hopes to lower school drop-outs and improve employability of a disadvantaged group of European society. The results will show the possibilities and impact of this approach.

The CloudLearning team believes that through methods of computational thinking, programing skills, group activities, board games, and the utilization of stand of the art technology such as robots, the educational boxes can represent a curriculum that would address the concerns mentioned above in addition to introducing long-term innovative tools and methods to their learning process. The team believes in a playful and exploratory approach to education throughout the project.

ACKNOWLEDGMENT

C based laboratory for teaching Digital Signal Processing to Computer Engineering Undergraduates

* University of Novi Sad, Faculty of Technical Sciences, Novi Sad, Serbia
** RT-RK Institute for Computer Based Systems, Novi Sad, Serbia
dejan.bokan@rt-rk.uns.ac.rs

Abstract – This paper describes experience and lessons learned from teaching introductory Digital Signal Processing course as a part of Computer Engineering curricula using C based laboratory exercises. Matlab based laboratory exercises are substituted with a series of hands-on experiments which include implementation of signal processing algorithms using programming language C and DSP development boards, and the analyses of implemented systems. The theoretical content of the course and the topics covered by the laboratory exercises have remained unchanged. Main goal of a new set of exercises was to enhance student performance, motivation, as well as their understanding of theory. Results are measured by comparing student final grades on this course with grades of students who enrolled in Matlab based course. After finishing the course both student groups were given a survey on experience and satisfaction with the course. Survey results indicated that students who enrolled in C based laboratory course rated the course better and were more interested in Digital Signal Processing topics.

I. INTRODUCTION

Computer engineering (CE) is a field which covers design, construction, and implementation of both hardware and software components of computer-based systems. It is traditionally regarded as a combination of Computer science and Electrical engineering, which managed to evolve as a separate discipline. To solve problems covered by computer engineering area, one needs a wide knowledge on hardware, software and the way those two interact. That is why designing a CE curriculum represents a challenging task. A joint task group formed by ACM and IEEE created curriculum guidelines for undergraduate degree programs in CE. First version [1] was released in 2004 and the second, updated version [2] in 2016. Both [1] and [2] introduce DSP (Digital Signal Processing) as one of the core disciplines incorporated in CE curriculum.

One of the main tasks of modern engineering education is providing students with essential knowledge and skills, and enabling them to meet industry demands. Rapid technology changes are particularly present in the field of computer engineering and computer science.

Alongside with the constant development of new learning processes and improvements of the existing ones, it creates a necessity for frequent revision, changes and upgrades of academic courses. Documenting experience and results of different teaching approaches in different universities is essential for further research in the field of CE education.

In this paper experience and lessons learned from teaching introductory Digital Signal Processing course as a part of computer engineering curricula at the Faculty of Technical Sciences, University of Novi Sad are described. Results are obtained with the students which participated in the course in years 2014/2015 and 2015/2016. In between these two school years a major change in teaching process was made. The change includes using programming language C instead of Matlab for implementation of digital signal processing algorithms as a part of laboratory exercises. Matlab based simulations were replaced by execution of implemented algorithms using real hardware. The results of the above mentioned changes were obtained by comparing students’ grades in two successive years, and by using a survey on experience and satisfaction with the course.

The rest of the paper is organized as follows: section 2 gives the motivation for introducing C based laboratory exercises into existing course and choosing DSP hardware. Section 3 shows a short overview of an introductory DSP course. Section 4 gives detailed description of laboratory exercises. Section 5 contains description of evaluation method and obtained results. Finally, section 6 gives some concluding remarks.

II. MOTIVATION

Digital Signal Processing is a mature field. There is a range of textbooks which cover DSP fundamentals. Next to the theories and algorithms, a significant knowledge for any computer engineer is DSP implementation and its application in practice. In order to meet industry demands students need to learn how to implement, optimize and apply different signal processing algorithms. That is why a number of authors expanded their books with a set of projects and simulations for demonstrational purposes, as in [3-5].
In [6] different approaches to teaching signal processing are analyzed. It reports on lessons learned from observations made by Texas Instruments over the past 25 years. It highlights providing practical experience with both algorithmic and real-time signal processing concepts as one of the key components in learning process. One method of providing practical experience is using mathematical software packages like Matlab or Mathematica. Such is demonstrated in [7]. Similar approach was used in Digital Signal Processing course in Faculty of Technical Sciences in the years 2011-2016.

The main motive for reorganizing the course laboratory experience was to increase students’ motivation for participating in the course. A study by Huettel [8] shows how introducing hands-on experience with DSP hardware in laboratory increased student’s level of interest in the field of signal processing for 80% of students. Although there is a short learning curve required to become familiar with hardware, it allows students to become aware of many real-time concepts at an early stage. Using hardware also shortens the time of simulation in comparison to software simulation.

An approach Huettel used was using development environment which enables compiling Matlab code to binary files which are downloadable to hardware. Students who represent a test subject, take introductory Digital Signal Processing course as part of the fifth semester. At this point CE students have a basic knowledge of Matlab and a very good knowledge of programming language C. Also, students which passed the Matlab based laboratory course tended to struggle with implementation of the same algorithms in C with real-time constraints as a part of the following courses. In order to resolve this problem and to eliminate the learning curve needed to get familiar with Matlab, a set of new laboratory exercises using programming language C for algorithm implementation was designed, which uses programming language C for algorithm implementation.

In order to choose a hardware platform to be used, several already existing approaches were considered. Features taken in consideration, apart from hardware capabilities, were price and development tools availability. There is a recent work [9] showing the usage of ARM-based development boards in combination with CMSIS-DSP library to create a low-cost hardware laboratory setup for teaching DSP. A number of universities, as shown in [7], are using TI-based discovery kits as a central hardware component. Experience with using different TI signal processors for teaching Digital Signal Processing is shown in [10-12].

In order to deliver hands-on experience described in this paper, the authors have used TMS320C5535 [13] fixed-point DSP processor hosted on a Spectrum Digital eZ-DSP evaluation board (shown in Fig. 1). This DSP architecture achieves high performance while being suitable for low power applications. Development board is equipped with TI TLV320AIC3204 stereo codec which supports two channels AD/DA with sampling rate up to 48 kHz. It also contains buttons, switches and LCD display which enable interaction with student during code runtime. Connection between processor and a host computer for the purpose of downloading or debugging application is achieved using XDS100 USB connector which is mounted on the board. The board is supported with an integrated development environment and a set of runtime libraries for controlling processor peripherals.

III. COURSE OVERVIEW

As already mentioned, introductory Digital Signal Processing course is positioned within fifth semester. The course covers the fundamental topics in Digital Signal Processing. The course outline is given below:

- Introduction, Continuous signals and systems, spectral analysis of continuous time systems and signals
- Sampling, aliasing and reconstruction
- Discrete-time signal representation, quantization
- Discrete Fourier Transform, spectral analysis of discrete-time signals
- Fast Fourier Transform
- Z – transform
- Discrete-time linear systems, discrete convolution, frequency response of discrete-time linear systems
- Filter theory, Finite Impulse Response (FIR) filters
- Infinite Impulse Response (IIR) filters
- Adaptive filters and application

The course consists of traditional lecture and laboratory experience. Laboratory exercises are designed in such way that they require students to be actively involved. Students
have the possibility to collect 40% of total exam points in laboratory. The rest of the points are collected through tests and final exam. The grading system is presented in Table I.

### IV. LABORATORY EXERCISES

This section describes the new set of laboratory exercises developed for the course. A set of exercises consists of a tutorial on using environment followed by 8 different exercises each containing demonstrational part (which is given) and a set of tasks which are implemented by students on their own. After completing these 8 exercises student is given a final project which needs to be realized during 4 weeks.

Single laboratory station is equipped with a PC, TMS320C5535 eZ-DSP evaluation board, headphones, microphone and a 2 x 3.5 mm audio cable. In addition, audio spectrum analyzer is used for debugging purposes. Main software package used in this course is Code Composer Studio (CCS) integrated development environment (available at [14]). It is a proprietary software package developed by Texas Instruments. It includes support for C code development, an integrated toolchain for TMS320C5535 processor and a set of tools for code debugging and signal visualization (frequency and time domain). Additional software package which is used is Audacity (available at [15]), an open source application which enables audio playback, recording, signal generation and analysis.

As mentioned, first exercise represents an introduction to laboratory, where students are being introduced to development environment and evaluation board. The rest of the exercises are described as follows.

#### A. Basic discrete-time signals

The goal of this exercise is for students to see how elementary signals are presented in discrete-time domain and how they can be generated using programming language C. Signals which students generate and analyze are: sine wave signal, square signal, Dirac impulse, multitone signal and a frequency sweep signal (linear and logarithmic). Generated signals are sent to DA convertor so students can hear those using headphones, or record and analyze using PC. This exercise helps students get familiar with circular buffering concept and signal generation using look-up table.

#### B. Sampling and aliasing

In this exercise a sampling theory is introduced to students. Signals generated in the previous exercise are given as an input, and are sampled using different sampling rates. Students analyze the signal in time and spectral domain. Aliasing effect and the impact of sampling rate to spectral resolution are demonstrated.

#### C. Quantization and signal format

This exercise demonstrates the impact of signal quantization on signal quality. Students are introduced to different signal presentation formats. Different signals are being quantized using different number of bits and using linear and non-linear quantization. Students calculate quantization noise and signal to noise ratio (SNR), and compare the values with memory needed to store uncompressed signal. Finally SNR values are compared to hearing experience.

#### D. Discrete Fourier Transform

In this exercise students are introduced to a DFT implementation in C. They learn how to use DFT for spectral analysis in real-time. The impact of using different window functions is shown. An example of FFT implementation (Radix-2 with decimation in time) is also given. Students compare computational requirements of the two algorithms. The last part of exercise is reconstruction of signal from spectral coefficients using the overlap-add method.

#### E. Discrete-time systems

Goal of this exercise is getting to know basic discrete-time linear time-invariant systems, and how they can be implemented using programming language C. Given examples are audio effects based on delay: echo and reverberation. Discrete convolution is introduced with convolutional reverberation effect. Students are taught how to analyze given systems by calculating impulse response, magnitude and phase response.

#### F. FIR filters

During this exercise students are introduced to practical use of signal filtering. Different order low-pass, high-pass and band-pass filters are applied to input signals, and students can analyze the output. Students are given a task to create their own Nth order FIR filter implementation using programming language C. Finally, students are shown how an array of filters can be used to split signal into frequency sub-bands (simple filter bank).

#### G. IIR filters

In this exercise IIR filters are introduced. Students get to know first and second direct form implementation of second order IIR filter. After that a cascade realization of higher order filter using second order sections is shown. Magnitude and phase response, so as computational requirements are compared to FIR filters. All-pass filters are introduced. A way of using all-pass filters to create simple half-band structure is demonstrated.
It uses voice-frequency between telephone equipment and other communication (dual tone multiple frequency) generator and receiver. DTMF represents a method used for communication (DA/AD), filtering and signal analysis.

One example of given project assignment is DTMF signal detection unit based using Matlab. It consists of two sine generators and one addition unit. Create DTMF signal detection unit based using FFT. Add noise generators to transmitter. Design filter to remove generated noise. Apply filtering at the receiver side, before executing DTMF signal detection algorithm.

Examining the success rate of DTMF tone detection depending on the value of SNR.

After successfully finishing a project assignment, a student is awarded maximum of 30 points, which is 75% of all the points achievable through laboratory exercises.

### Adaptive filters

In this exercise a concept of adaptive filtering is demonstrated. An implementation of LMS and NLMS algorithms is shown. One task for students is to use adaptive filter for simple echo cancellation. The second one is to use adaptive filter to approximate response of unknown system watched as a black box.

### Project assignment

After finishing previously described laboratory exercises students are given a project assignment. Each student needs to complete his assignment in 4 weeks. Idea behind the project is to make student use the knowledge obtained during previous weeks to create a software implementation for a given signal processing algorithm. Projects are designed in such way that they include signal generation, signal transport between two DSPs (using DA/AD), filtering and signal analysis.

One example of given project assignment is DTMF (dual tone multiple frequency) generator and receiver. DTMF represents a method used for communication between telephone equipment and other communication devices and switching centers. It uses voice-frequency band. Student assignment consists of the following tasks:

- Create DTMF signal generator. It consists of two sine generators and one addition unit.
- Create DTMF signal detection unit based using FFT.
- Add noise generators to transmitter.
- Design filter to remove generated noise. Apply filtering at the receiver side, before executing DTMF signal detection algorithm.
- Examine the success rate of DTMF tone detection depending on the value of SNR.

</tbody>
</table>

The survey is shown in Table II. It was explained to students that the term “quality” refers to the quality of accompanying materials, environments to perform exercises and the presentation by the lecturer. Group of students who attended the course in 2014-2015 and took the survey counted 14 students, while the group of students who attended the course in 2015-2016 and took the survey counted 27 students. Table III contains survey results. Q1-Q6 stands for the question (as in Table II). A1-A5 stands for each of the 5 offered options for the given
question. A value in each cell \([Q, A]\) shows percentage of students who have selected answer \(A\) for a question \(Q\).

Students who were part of 2015-2016 group rated the laboratory exercises quality with average grade of 4.0, while other group of students gave average grade of 3.86. When it comes to the second question, C based laboratory achieved average grade of 4.11, while Matlab based laboratory was given average grade of 3.71. A conclusion that can be drawn based on these results is that although both sets of exercises were prepared with similar quality from students’ point of view, C based laboratory exercises which included real hardware were more interesting to CE students. When it comes to project assignment students from the 2015-2016 group gave an average grade of 4.0 for quality and 4.22 on how interesting it was. Group which took the Matlab based laboratory gave an average grade of 4.14 on quality and 3.79 on how interesting it was. So although the quality of Matlab simulation project was considered to be higher than the C based project, it proved to be less interesting to students.

When asked if laboratory experience provided better understanding of DSP concepts, both groups gave similar answers. In Matlab group 72% agreed (29% SA and 43% A), 21% was neutral while the rest 7% disagreed (0% SD). 67% of those students who participated in the C based laboratory agreed to previous statement (37% SA and 30% A) while 22% were neutral. 11% of students disagreed (7% D and 4% SD). But when the overhead introduced by chosen technology was in question C based laboratory achieved more positive result with 63% who strongly disagree, 19% who disagree and 11% who were neutral. Only 7% agreed. Students from the other group answered 36% for SD, 14% disagreed, 21% were neutral, while 30% agreed (21% SA and 7% A).

Finally, grades of students who passed the course were compared. Final grades of students who have passed the course, but haven’t participated in the survey were also taken in consideration. Total number of students whose grades were taken in calculation is 18 in 2014-2015 and 33 in 2015-2016. Students who participated in the course during 2014-2015 achieved an average grade of 7.94, while the students who participated in course during 2015-2016 achieved an average grade of 7.74. It is important to notice that an additional factor that influenced final grades of the students is that in 2015-2016 there weren’t lower boundary for number of points in the final exam, while in 2014-2015 it was 50% percent (or 15 points). The result was that in 2015-2016 39% of students had a minimal final grade (6), while in the 2014-2015 that percent was 17%. As far as the number of students who achieved the highest grade (10) is concerned, in 2015-2016 that number reached 30% of the total number of students, while in 2014-2015 it was 17%.

VI. CONCLUSION

This paper described a new set of laboratory exercises developed with the purpose to provide hands on experience in teaching DSP concepts to computer engineering students. Having C based laboratory exercises which included real hardware was positively accepted by students. Evaluation showed that students considered this approach more interesting than the laboratory exercises based on Matlab simulation. More students were motivated to achieve the highest grade. Finally, evaluation results showed that using programming language C instead of Matlab shortens the learning curve, and reduces overhead in learning process for CE students. In order to get more reliable conclusions, continuous evaluation of described laboratory exercises should be performed over the following years.

Abstract - Nowadays, in our fast-paced world there are countless MOOC courses in the Internet with various topics that have been designed to broaden our knowledge. One of the most powerful tools for effective learning are online videos. Many case studies have been carried out in order to specify the qualities of a good educational video. Philip J. Guo, Juho Kim and Rob Rubin published an article (How Video Production Affects Student Engagement - An Empirical Study of MOOC Videos) on their experience during edX courses. They analyzed the optimal length of a video and determined which videos were preferred by the students. Our research group from the University of Szeged has developed a logging system which records student activities in online courses to analyze learning styles and behaviour when watching a video. In our research, we did a literature review about on-line videos and introduced the system to log student activities, focusing on video views.

Key words: on-line videos, video views, MOOC courses, electronic curriculum

I. INTRODUCTION
E-learning (Electronic Learning), in our times, is perceived as a new technology in the field of education, which makes possible sharing and reaching learning content, practicing and measuring acquired knowledge, and finally communicating between members of courses. Education in case of E-learning is computer supported which allows individual learning pace cancelling traditional school timetables for the benefit of the most convenient time to acquire knowledge. In order to develop E-learning, not only the promotion of LLL (lifelong learning) was crucial, but it was necessary to promote quality education, to advocate international education; though the most important factor was the accelerated progress of information technologies [1].

Another notion has also gained ground that advocates learning through mobile devices, the so called M-learning. It emphasizes that knowledge is not only dependent on time but can be acquired regardless of location [2]. Such technological advancements could simplify the achievement of lifelong learning, since advanced studies will become accessible side by side with full- or part-time jobs. An increasing number of universities launch online courses, which have penetrated even to secondary and primary schools where teachers incorporate experimental online courses in their curriculum.

We may differentiate between virtual and mixed methods. Sharing learning materials and communication with this virtual method comes off in the virtual learning environment (VLE) with the help of sharing messages and participating in forum discussions. Thus, learners do not meet with their tutors or with each other, which is not a problem in adult education, but is not convenient for the K-12 age-group that cannot neglect supervision and meeting peers for mutual learning. In this latter case a mixed method, Blended learning, would be more beneficial, since it would imply classical school lessons within an accepted curriculum, however some elements still can be allowed to be acquired through online methods and individual time-tables regardless of location. Blended learning makes it possible for learners to deepen their knowledge that can be measured by testing and seems to be more durable [3]

II. AUDIO-VISUAL CONTENTS IN ONLINE COURSES
Audio-visual contents target listening and visual capacities in order to trigger information acquisition. Such tools and learning materials appeared after the I. World War as object lessons, though in those times slide-projectors were already in use accompanied by a recorded
audio tape. The mass popularization of the television in the 60s and 70s peaked just in those times on the Hype cycle representing increased expectations. Most of the studies conducted in the United States tried to prove that education through watching television is more efficient than traditional methods, but it was quickly revealed that a single most effective system does not exist [4]. Later, as personal computers appeared in households and Internet coverage spread out covering the entire globe, new opportunities came to life in the 90s, when viewing and sharing video materials helped establishing the first online courses.

First generation digital learning materials were nothing else than scanned traditional school books and digitalized educational videos, while second generation tools were put together exclusively using digital media and content optimized for computer use. Criteria for the third generation digital educational materials were the following: interactivity, inclusion of a wide range of motion pictures and audio recordings, the use of links for enhanced navigation, methodological guidance, all of which created an independent learning material. The fourth generation puts emphasis on interactivity and collaboration whose products did not originate from a single author, but could be derived from various multicultural communities [5]. Real breakthrough in this field was noticeable after the launch of online video sharing sites, like YouTube, since thereafter educational videos were easily accessible. For instance, video shares by Khan Academy were visited 663 million times on YouTube since 2006. The expression MOOC (Massive Open Online Course) became widely known around this period which comprises web-based courses with unlimited participation and accessibility for free.

We can differentiate between four types of educational videos:

- classroom lessons, which are basically records of school lessons or university lectures
- "think talk" type recorded videos during which tutors give lectures from their office teaching a pre-established learning material
- digital table file format, popular at Khan Academy with animated digital tables for teaching
- traditional PowerPoint presentations [6]

The studies of Guo, Kim, and Rubin [6] provide an insight into the following important findings:

- Shorter videos are more appealing to students. The optimal length of videos have been established at 6 minutes (3 and 9 minute are still acceptable). Longer videos lower the amount of time spent on them proportionally with their length.
- Learners, surprisingly, found those videos more interesting that visualize not only presentations but also tutors. It is purposeful to record the tutor as well as the presentation by turns to break monotony.
- The target audience prefers homemade videos that seem more personal than professional studio recordings
- An environment that resembles to digital tables of the Khan Academy is more popular than simplistic presentations.
- Recordings from school lessons that were not intended for a MOOC course are not popular at all.
- Also more support is given to recordings in which lecturers are skilled orators and can catch the attention of the audience.
- There is also a qualitative difference between lecture like videos and presentations, so called tutorial videos, since lectures are usually watched only once, while presentations are consulted several times.

It has been established that visual and audio information strengthen each other, still videos have a quality of showing operations in a chronological order simulating how a user would see them on their own device. This approach creates a so called easy-to-follow model [7]. Van der Meij and Van der Meij [7] carried out a study measuring fifth and sixth grade learners (average age: 11.8 years), altogether 111 children (56 boys and 56 girls). Four groups were established of whom two groups worked following a mixed method (videos and paper-based), while the other two groups respectively used videos or paper-based activities exclusively for learning, after which they were given a test. Those students who were learning with the help of paper-based materials achieved a test score of 65.4%, while those who were learning by consulting videos, on average, scored 89.7%. The latter group seems to have acquired deeper and long lasting knowledge also shown by a post-test (76.8% to 55.6%).

In general, the appearance of the communication media did not alter how people use learning platforms, since they are similar to already existing ones, for instance, digital materials in the beginning of television broadcasting were nothing more than filmed radio programs, while digital books were scanned books. This traditional approach was maintained when the first tutoring videos appeared being recorded lectures. They were later refined adding more creativity in order to get the most out of this wide-spread media [6]. According to Don McIntosh, videos may enhance the effectiveness of the learning momentum, however the price/benefit ratio must be thoroughly examined [8].

So far, we have dealt with so called on-demand videos stored locally and available from the Internet, however it is necessary to mention video conferences as a category of real-time audio-visual contents, which are also suitable in an educational environment. Though, a webcam can only forward visual information, devices at video conferences are equipped with broader interactive possibilities connecting participants more successfully.
Studies carried out by Athabanca University in 2002 revealed some weak points of this system, namely software support and bandwidth; furthermore they noticed a considerable amount of functional errors in forwarding video and audio content due to a slow internet connection when they tested free services and products. We shouldn't neglect the fact that similar errors occurred with some payable pieces of software, too [9]. Nowadays, most of the users have access to a broadband Internet connection, and software in general has undergone a huge development penetrating into the field of education.

III. TECHNICAL BACKGROUND OF THE VIDEO LOGGER MODULE

Our research group and the team of the Software Engineering Department at the University of Szeged prepared a Moodle based system which is capable of creating a log file of learner activities to be later saved for further study and evaluation. The system uses a JavaScript solution that records individual user activities (click, download, mouse move, video views, etc.) with the help of a userId, the type of action initiated, the exact web location and time of the activity. A study carried out by Esztelecki Peter (2016) may provide some further information related to this topic. A paper on Big Data in Education are published in the same research [10]. We used Moodle as a e-learning framework extended with own modules. One of these modules is responsible for logging and is composed of two parts: a client-side part and a server-side part. Both of them are implemented in JavaScript: in the first case we used jQuery, in the second NodeJS with Express.

![Image of the video logger module diagram]

The client part of the code handles all JavaScript events, processing and storing them in a buffer (event buffer). If the buffer is full, or the user closes the page, or it is passive for 5 minutes, it sends the content of the buffer to the server-side part via an HTTP request. The server-side part is very simple: it just stores the given events into a MongoDB database for further processing.

Our system supports two kinds of videos: html5 video elements and embedded Youtube videos:

```html
<video id="video1" controls>
  <source src="movie.mp4" type="video/mp4">
</video>
<iframe id="video2" data-videoid="62rWxTfjcKc" src="https://www.youtube.com/embed/62rWxTfjcKc">
</iframe>
```

The system is able to log both of them by catching JavaScript events, processing and storing them in a JSON format. For example here is a videoPlay event:

```json
{
  type: "videoPlay",
  data: {
    actualTime: 95.458972,
    videoId: "video1",
    totalTime: 956.48,
    src: "/elearningdata/oktatok/sd/13.mp4"
  },
  time: "2016.07.18. 09:04:57.884",
  page: "https://...",
  userid: 942
}
```

The event has a type parameter, and the following parameters:

- **userId**: the ID of the user who has executed the operation, or 0, if there was an anonymous user
- **time**: the date of the event
- **page**: the URL of the page where the event occurred
- **type**: the type of the event (see below)
- **data**: optional parameters, depending on the type of the event.

In the case of an html5 video element, the system catches the following JavaScript events for processing:

- **play**: in this case a videoPlay event is generated, with the following parameters: actualTime, totalTime, videoSrc and videoId, as in the above example.
- **seeked**: the system generates a videoSeek event, with the following parameters: seekTime, totalTime, videoSrc, videoId.
- **pause**: a videoPause event is generated. Parameters: actualTime, totalTime, videoSrc, videoId.
- **webkitfullscreenchange, mozfullscreenchange, fullscreenchange**: it would mean a fullscreenOn or a fullscreenOff event. Parameters: actualTime, totalTime, videoId.
- **volumechange**: it generates a volumeChange event, with the same parameters as above having a newVolume parameter, as well.

In the case of embedded Youtube videos using the JavaScript API of the Youtube, the system catches the following events and generates events with the following parameters: actualTime, videoId, totalTime and src:
As an example, we are providing the structure of the YT.PlayerState.PLAYING code:

```javascript
function onPlayerStateChange(event) {
  if (event.data == YT.PlayerState.PLAYING) {
    pushEvent({
      type: 'youtubePlay',
      data: {
        actualTime: event['target'].getCurrentTime(),
        videoId: event['target']['a']['id'],
        totalTime: event['target'].getDuration(),
        src: event['target'].getVideoUrl()
      }
    });
  }
}
```

These events are stored in the “event buffer” (using the pushEvent method), and later submitted to the server to be written into the database.

IV. PILOT COURSES AND LOGGED DATA

Our team comprised pilot courses for students at the University of Szeged touching upon two topics: Conscious and Safe Internet Use and Databases. We did the best to fix any errors that might have occurred during the pilot research in order to build a stable and reliable logging system. Even at the test phase, we were able to accumulate a log file with a volume of 1.2 GB recording more than 4.5 million lines of raw data. It has to be noted that beside collecting data from the two pilot studies other logs were also saved that were coming from Moodle courses announced and executed by the University.

During the evaluation of the JSON file, our team revealed a system error which was related to the process of filling in the tests and playing the videos, namely these events were not recorded. Later, this error was fixed allowing us to save such data to a log file during a live course session in the future.

Soon we found out that raw data had to be cleaned and changed appropriately despite the fact that they were not analyzed using Data Mining algorithms. Esztelecki Péter, for this reason, developed a PHP based program that converts a json file into a csv (comma separated values) file, which is a format that database management and data mining tools can both easily handle. The program allows users to choose which courses or course data should be converted to a csv file; furthermore it is also possible to decide which events are to be put into the output file. The conversion process generated a stats file that indicates how much data was processed from an event and how much time it would consume to convert data, etc. To convert a file of 1.2 GB that contains the information of all the courses and their events on an Intel (R) Core (TM) i7-2630QM with 2.00GHz processor and 6.00 GB RAM took us 6 minutes. This time volume could be further reduced if an SSD system replaced the current 5400 RPM SATA II harddisk composition since most of the consumed time was spent on harddrive processes (writing and retrieving data).

The method of data mining will be used to process raw data and to acquire new pieces of information in order to map learners’ behavior and achievement more precisely.

We would furthermore classify and put participants into clusters to create groups where students would be taught in a more personalized environment and later to establish a platform for adaptive learning.

Using regressive calculations, it is possible to envisage the outcome results of a participant with high precision based on learner routines. The same process can be done using statistical matching which assigns a learner or learners from the database to the appropriate subject.

Our future plan is to move our research courses to secondary schools in Southern Hungary and Vojvodina in Serbia to enlarge the pool of participants to a couple of thousand making it possible to analyze a larger volume of data.

V. CONCLUSION

Broadcasting media offer a wide range of learning opportunities in public education; however it must be stated that the appearance of the audio-visual content meant a giant leap in the field of distance learning. Another great achievement was the spread of the Internet that brought about tools provided by Web 2.0. Finally, the founding and popularization of video sharing websites have to be also mentioned. Guo, Kim and Rubin [6] used different methods to record their educational videos, and later came to the conclusion that shorter videos are more appealing to learners; furthermore they prefer lectures where tutors and presentations follow each other. Nevertheless, much depends on the communicative skills and dynamics of the tutors how they deliver their lectures. The authors also realised that studio recordings were less popular than homemade recordings; moreover learners did not cherish classroom recordings that were clearly not intend for a MOOC platform.

The logging system created by our team makes it possible to entirely reconstruct learner activities in the Virtual Learning Environment opening the field to data mining tools to analyze learners’ behaviour and their learning styles.

We share the expectations of Mark Van Rijmenam according to which Big Data analysis will revolutionize the way students learn and teachers teach [10][11].

REFERENCES

[1] Pfaff A. (2013), Az E-learning az Európai Unióban és Magyarországon. URL:

Abstract - Information and communication technologies revolutionized the ways of providing financial services. Modern technologies instigated the rise of electronic banking and electronic finance and their development continues to bring new forms financial services provision. Students of finance, banking and investment fields of study should keep in touch with newest forms of electronic finance to stimulate their interests in the area of the newest technologies in banking and finance. In the process of education in electronic finance, the use of information and communication technologies is undoubtedly required. The aim of this paper is to present how modern electronic financial services are introduced to students in educational process at our faculty in a novel way. A course named Electronic Services in Banking is provided to students, during which students gain theoretical knowledge and practical skills in the area of electronic finance and banking. The course uses multiple eLearning methods such as using learning management system, virtual bank, training videos, online demos etc. The course is provided for several years already and is continuously updated and adjusted as new technologies emerge. Students have the opportunity to come into contact with various forms of electronic services in finance. During the course is emphasis laid on the security of electronic finance usage, including the principles of digital signature and biometrics. Before and after the completion of the course, a survey is conducted to detect students' awareness of electronic finance services and their advances in knowledge of the subject. The evaluation and a comparison of the survey results in recent years is the main output of this paper. Furthermore, the results serve as a feedback, which provides important suggestions for changes in the educational process.

I. INTRODUCTION

Information and communication technologies (ICT) revolutionized the ways of providing financial and banking services. Modern technologies instigated the rise of electronic banking and electronic finance and their development continues to bring new forms financial services provision.

The main characteristic feature and the biggest advantage of modern electronic financial and banking services is a continuous all-time access for all clients. It gives the opportunity to carry out fast and safe payments, get loans regardless of whether the client is home, in work or on holiday, virtually from anywhere in the world. These services are independent of opening hours of institutions providing them and allow convenient and rapid communication between provider and client or user [1]. Electronic finance represents providing and using financial products or services by electronic means including electronic payments, electronic money, deposits, lending, financial advisory and many other. Modern financial services sometimes even erase difference between users and providers of financial services, for example when using peer-to-peer lending services [2].

When speaking of electronic financial services, the communication between financial service provider and its user is conducted by electronic communication media like a mobile network, a public data network or the Internet. Electronic financial services are generally more cost- and time-effective for both involved sides. Financial services’ providers might charge lower fees or interests for all the operations carried out electronically than the fees for traditional branch operations [1].

Important preconditions of electronic financial services are the technologies allowing their provision. Modern electronic financial services require hardware (computer, smart device etc.) and software equipment (e.g. application compatible with operating system of users’ device). Use of electronic financial services in Slovakia is lagging behind EU average, for example in the case of using internet banking, the EU average is 49% while usage Slovakia is at level of 46% [3]. Many other electronic financial services are often even less penetrated in Slovak population [4].

Fast changes in the field of electronic financial services must be reflected in education of students of finance, banking and investment. At our faculty, the course of Electronic Services in banking are taught for several years already [1]. Emergence of new electronic financial services in recent years invoked changes in educational process of this course also. The use of ICT brings many opportunities to innovate educational process. New technologies such as contactless payments, p2p lending and payments or cryptocurrencies are now included in curricula of the course.

In general, ICT is intensively used in educational process at our faculty. Information and communication technologies support process of education not only in informatics, but also in multiple other subjects of study.
provided to the students at our faculty [5]. Information technologies facilitated creation of e-learning courses that are used in our distant learning form courses [6]. Similarly ICT certainly supports daily based face-to-face education at our institution to help future professionals in the field of finance, banking and investment to develop their skills in all necessary areas of their expectant professions.

In this paper, the new form of the Electronic Services in Banking (ESIB) course is presented to provide education in the field of electronic financial services to future professionals in areas of finance, banking and investment at our faculty. It aims to inspire innovative ways of e-learning in area of banking.

II. THE ELECTRONIC SERVICES IN BANKING COURSE

The course of Electronic Services in Banking (ESIB) is provided at our faculty to students in the specialization of Finance, Banking and Investment for several years already. Turbulent changes in the field of electronic financial services must be expressed in education process of students of the area, too. New ways of providing banking and financial services developed during recent years invoked continuous changes in content of ESIB course. Initially, various forms of electronic banking were in the scope of the educational process in this course. It included getting practical experience with e-banking forms like SMS banking, Homebanking, WAP and GSM banking that were current at the time. These topics were novel at the time and the course provided first touch with these technologies for the students. However during following years a lot of content became outdated and was amended. However, the name of the course was not changed yet.

Now, the course of Electronic Services in Banking provides combination of skills’ acquisition in e-learning environment with theoretical seminars on topics related with electronic financial services and partially in public administration. Any additional topics of students’ interests are discussed in forms of essays as integral parts of this course. These essays reflect students’ real-life experience with chosen topic related to electronic financial services. Students still get to know various forms of electronic finance in both theoretically and practically. Great importance is attributed to the security of electronic services’ usage, as it is significant factor of trust-building process [7]. Safe setting-up and usage of electronic financial services is an integral part of their security [8] and therefore is emphasized in the course. Various forms of authorization elements are introduced to students regarding all forms of electronic financial services. An accent is further laid on the use of a digital signature as a very secure form of authentication and authorization.

Multiple studies (e.g. [7], [9]) indicate that perceived usefulness and awareness of given technology positively influence acceptance of electronic banking or similar technologies. Furthermore amount of information available on e-services significantly affects their adoption [10]. Furthermore security and safety of various electronic services supports their adoption by potential users [11], [12]. All these aspects are therefore discussed and analyzed during our course to support the adoption of e-services in finance and banking by the course attendees.

Moodle learning management system is used to allow e-learning support of this course (see [13]). Moodle is used as a standard e-learning platform at our faculty and other courses use it in the same or lesser extent with long-term positive experience not only for the educational purposes [14]. For a provision of certificates for digital signing, the faculty’s certification authority based on EJBCA open source authority is used. It provides the possibility of digital signature certificates issuance and their management and strongly supports part of the course dedicated to digital signatures and electronic communication with financial institutions [15]. Furthermore, virtual bank is used for e-learning purposes of ESIB course, which supports several electronic banking forms. Similarly, virtual bank supports digital signature authorization. However, the banking software of the virtual bank is outdated and therefore virtual bank serves only to show some of its features comparable with current technologies (internet banking, digital signature authorization). Its old features like homebanking, WAP banking or SMS banking are only briefly demonstrated. The ESIB course further involves usage of open source software GPG4win for digital signature certificate management. Several other software applications are used to support or demonstrate various forms of electronic financial services.

Then, the main themes of the Electronic Services in Banking course are following:

A. Security of electronic financial services,
B. Internet banking,
C. Smart banking (Mobile banking),
D. Modern electronic financial services.

A. Security of electronic financial services

Main emphasis within the course is given to the security of electronic financial services. Both theoretical knowledge and practical skills in the field of security are possible to gain by students during our course. Secure communication during provision of a financial service between service provider and its user is the very important precondition of e-finance services provision and usage [16]. Students acquaint in this part of the course with topics of authentication and authorization processes, symmetric and asymmetric encryption (RSA), digital and electronic signature, Public Key Infrastructure (PKI), its legislation and software applications.

Following forms of authentication and authorization elements used in e-finance and e-banking are theoretically introduced practically used during the course:

- Static passwords and codes
- One-time passwords and dynamically generated codes (both software or hardware generated)
- Biometric elements (fingerprints, voice biometrics, biometric signature etc.)
• Digital signature

Their combination with provider’s predefined limits of e-services usage creates the level of security of given forms of electronic financial services [8]. Usage of these authorization elements is discussed from the security and amenity points of view.

Multiple options of digital signature usage are theoretically introduced and further discussed. Signing, signature verification as long as encryption and decryption are practically demonstrated and checked out by students. Email encryption/decryption and signing/verification is demonstrated with use of Mozilla Thunderbird. Same processes with electronic files are exhibited and then tested by students using GPG4win freeware. The process of acquisition of certificate for digital signature is showed using faculty’s certification authority. The course’s students apply for a certificate and get it from the certification authority to test its usage practically. All study materials regarding this topic in course are available to students in electronic form in Moodle LMS and at certification authority webpage.

Further students get information on detection of valid e-banking websites and applications and prevention of credential thefts when using electronic financial and payment services. Several applications for secure communications on mobile devices (e.g. OpenKeychain, Decrypto etc.) are checked out by students during the course.

B. Internet banking

Internet banking makes banking services accessible from anywhere in the world when using with an internet connection. In this topic, the safe usage of internet banking is discussed. Principles of user’s safe behavior when using it are explained in this part of the course. Students experience several authentication forms used in internet banking, such as GRID card, SMS code, OTP token or digital signature stored on a safe device. Authorization is traditionally secured by user name (login) and password assigned after registration in the virtual bank. Students then practically examine all aspects of usage of internet banking available in faculty’s virtual bank (including delayed payments, permanent payments), collections, electronic statements etc.). Besides the payment services, also financial services available in real-life internet banking (such as e-investment, e-deposits, e-loans etc.) are presented. Obligatory practical task in this part of the course is to accomplish a pair of opposite transactions (payment and collection) over student’s account authorized by a digital signature via internet banking within our virtual bank to prove gained practical skills. All theoretical information on internet banking is provided via LMS Moodle in form of text or instructional videos.

Some of ESIB course students come to touch with internet banking for the first time, because of their young age and their lack of experience with any bank or financial services before. Many of the students already have some real life experience with internet banking, when they take in the ESIB course, but still they indicate to gain new and valuable knowledge and skills from this part in feedback gathered at the end of the course.

C. Smart banking (Mobile banking)

Smartphones and smart devices became common object of a daily use in recent years. Besides the changes in communication they found broad application in e-commerce and e-banking [17]. Group of the electronic services commonly indicated as mobile banking undergone rapid development since its first introduction. This fact is related with fast changes in technologies available in area of mobile devices. In this part of Electronic Services in Banking course students get in touch with the most modern form of mobile banking called in Slovakia the Smart banking. This represents the form of electronic banking services provided on smart devices (smartphones, tablets etc.) via dedicated application using online data transfers over the internet. This form of e-banking became the most popular in recent years in Slovakia overcoming the usage of internet banking in a number of log-ins over period of time [8]. Smart banking is not supported by faculty’s virtual bank therefore it is practically tested on demo application. Students are encouraged to use a real life smart banking application to fulfill voluntary task for extra points. Safety and security precautions for using e-banking are accentuated in this part of the course. The usage of a biometric authentication in smart banking is demonstrated to the students.

Besides these two major forms of e-banking other forms are mentioned and briefly demonstrated to show fast progress in this area of banking and finance. Specifically Homebanking, WAP banking, SMS banking and GSM banking are briefly introduced to students allowing them to remark rapid development in the field. Various demos, emulators and simulators of these forms are further used in these parts of the course.

D. Modern electronic financial services

Furthermore, modern electronic financial services are outlined during the ESIB course. Particularly peer-to-peer (p2p) lending or p2p payment services are mentioned. Definition and usage of cryptocurrencies is shortly noted. Another important area mentioned are contactless payments both card or smartphone based. Pros and cons of these modern electronic financial and banking services’ usage are discussed. Further students prepare a semestral essay on the topic of modern electronic financial service usage which is then presented by author to other students in the study group. This essay should not be only of a theoretical character, but it should contain the real experience of a student with given topic expressing his own opinion regarding the theme. Furthermore, all semestral essays are available through LMS Moodle to all other students to allow experience sharing between them. Students’ essays are a source of many reflections of electronic services from basic user’s point of view and provide feedback on the course contents in this area.

It is understandable that it is not possible to provide practical real-life experience with all modern e-services in finance and banking to the course attendees with limited sources of a public educational institution. However, the
course creators try to provide any free demos, video tutorials, free software applications or any suitable materials on given topics to students.

III. THE ESIB COURSE FEEDBACK

During each year of the ESIB course provision, feedback on the course is gathered. This feedback contains a survey committed before the beginning of ESIB course and after its completion investigating students’ experience and knowledge in the field of electronic financial services. Questions in the survey are about attendees’ knowledge about electronic services, their experience and opinion on their usage. The willingness to use and actual usage of electronic financial services is investigated before and after the course completion. Component part of the survey is getting reactions from students on the ESIB course. Relevant suggestions from respondents’ feedback are implemented into educational process in following years after the course completion.

In 2016 following results of survey were gathered. The survey was conducted in electronic form using Google Docs questionnaire. Respondents of the survey were students attending the ESIB course in both distance learning and face-to-face learning forms of the ESIB course. They were addressed with the questionnaire through LMS Moodle. The usable answered questionnaires were gathered from 217 respondents what represents over 98 percent of students in the given year of the ESIB course. Therefore, the results of the survey very high informative value.

Firstly the demographic data of respondents were gathered and are presented in following table:

<table>
<thead>
<tr>
<th>TABLE I. DEMOGRAPHIC DATA OF SURVEY RESPONDENTS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gender</td>

</table>

Source: own survey

Almost 56 percent of survey respondents were women. The gender composition of the course attendees reflects the trend of slightly prevailing female students at the faculty. Both internal and external study form students were included in the survey, what caused a bigger variety of respondents’ ages, since students of distant or external form of study are often of higher age in comparison with internal students. However, over 86 percent of respondents were students below 25 years of age, thus high school graduates, who immediately continue to study at the university. The residence of students in Slovakia might affect availability of broadband internet services to them. Almost 30 percent of respondents are from smaller towns under 40 000 citizens, where the availability of broadband internet is not perfect in Slovak conditions. This fact might affect their attendance in the course in distant form as long as their usage of electronic financial services.

Since the survey was conducted before the course completion and after it, the pre-course results will be presented firstly and then compared with the results after the completion of the ESIB course. General usage of electronic services in finance and banking were investigated at first group of questions. Almost 80 percent of the course attendees adduced using of some form of electronic financial service. The most of them, 74 percent of all respondents, used internet banking at least once before the course, mostly for basic services as payments or checking the account balance. Over 17 percent indicated usage of smart banking application in some of their smart devices.

The respondents that did not use any e-services, where asked for the causes. Above 5 percent of all respondents admitted that they do not use financial and banking services at all yet. All of them were in the age group from 16 to 25 years of age. It suggest that these students did not have any non-cash income yet before. Almost 9 percent adduced mistrust to e-services expressing their concerns about security and safety. Over six percent of respondents admitted preference of usage of financial and banking services in person and not via electronic communication channels. The frequency of e-services in finance usage was further investigated. Around 49 percent of respondents use electronic services at least once per a week and almost 22 percent at least once per month. The rest of respondents use it less frequently. Over 72 percent of respondents prefer electronic (card or mobile) payment forms before cash payment. Over 45 percent of respondents are willing to use e-deposit services, over 31 percent credit e-services and 27 percent investment services via electronic media. Approximately 57 percent of the ESIB course attendees adduced that e-services are important for their decision about financial services provider.

Another part of the questionnaire was aimed at the area of electronic services security. The preference of quick and user-friendly authorization solutions was detected. Over 61 percent of students admitted usage of static codes preference, followed by dynamic passwords (in any form of delivery) with 24 percent, 12 percent for biometric authorization and only 3 percent by digital signature technology.

Survey respondents mostly failed in identifying the level of security of each element used for authorization and authentication. Over 29 percent of respondents stated as the most secure and at the same time simple way of securing of e-services the static codes or passwords, 38 percent would prefer dynamically generated codes, 21
Respondents’ concerns with using electronic financial services were investigated in addition. The most of them (72 percent of respondents) fears of abuse by a third party, 31 percent has anxiety of technical imperfections of IT solutions of e-services and 18 percent fears of abuse by employees of financial institution. Almost 95 percent considers protection against computer viruses and other harmful software as important for e-services safety. On the other hand, over 55 percent of respondents admits their own failure to adhere or even to know the safety rules when using e-services.

The usage of digital signature for electronic communication by respondents was also investigated. Over 60 percent of respondents considers digital signature as suitable for e-government applications, but only 47 percent expect its usage in various electronic financial services provision. Further stated results were acquired from survey after the ESIB course completion. These results are further compared with above stated results of the survey gathered before the course. Demographic data remained the same, while for comparison were used only the surveys from students who answered it both before and after the course (above 98 percent of attendees).

After the attending the ESIB course the percentage of users of electronic financial services between attendees of our course rose to 86 percent. Several forms of electronic financial services were used by more respondents after the course completion than before its start. Over 80 percent of respondents added internet banking usage. Now more than 30 percent of respondents uses smart banking increased from 17 percent before the course. Almost 10 percent of users indicated shifting to more secure forms of authorization in any financial e-service used like dynamically generated codes or biometrics. Mistrust of electronic provision of financial services was indicated only by less than 3 percent of respondents, what is significantly lower than above 9 percent before the course completion. There was detected increase in frequency of financial e-services usage to 58 percent of users on weekly basis.

Almost 9 percent of respondents indicated usage of a digital signature in electronic communication or for e-services authorization. Respondents’ concerns with using electronic financial services decreased in all observed cases. Fear of abuse by a third party decreased among the respondents from 72 percent to approximately 58 percent, 25 percent has still anxiety of technical imperfections of IT solutions of e-services in comparison to pre-course 31 percent and only 8 percent fears of abuse by employees of financial institution, what represents decrease of 10 percent from pre-course level of 18 percent. All respondents indicated protection against harmful software as important for e-services safety (increase from 95 percent). After the course completion, less than 42 percent of respondents admitted their failure in adherence of the safety rules for financial e-services usage presented and discussed during the ESIB course. These results suggest positive shifts in students’ knowledge, skills and behavior thanks to the course attendance. However the results might be biased by students’ remembrance of the questions in the questionnaire from the first pre-course responding in the survey.

FIG. 2. Frequency of usage of financial e-services before and after the ESIB course completion.

Further feedback gained from students on the ESIB course attendees was acquired within the survey after the course completion. Students mainly suggested to abandon any remarks of outdated forms of e-services. However even in this area were contradictory opinions gathered. Many respondents would welcome practical demonstrations of mobile contactless payments using NFC supporting devices, this however is beyond technical possibilities of hardware equipment available at our faculty. They are however encouraged to adapt this technology in praxis during the course. Similar situation happened in the areas of p2p lending e-services and e-payments. Any applicable suggestions will the source of improvement of the ESIB course in following years. The respondents indicated being satisfied with the ESIB course in 82 percent. Such feedback is very valuable for improvements in the course.

Besides this survey, there was also the theoretical and practical knowledge tested before and after course completion to measure students’ improvement. The test consisted of 20 questions with one or multiple correct answers. This test is used since the year of 2009 with continuously updated composition of questions. Fig. 2 illustrates success rate of students in this test before and after the course during the years of the ESIB course provision.

FIG. 2. Test success rates of the ESIB course students.
The average success rate in the year of 2016 rose from less than 50 percent before course to level slightly above 65 percent after it. In all years of testing the increase of knowledge was detected in the area of electronic banking and electronic finance among the ESIB course attendees. These results suggest that our course improves the knowledge and skills of its attendees in the field of electronic financial services and further increases their adoption of these services.

IV. CONCLUSION

Students of our faculty find their job placements mainly in the area of banking and finance after the graduation. They often lack practical experience in particular area, in this case the experience with electronic financial and banking services [6]. Innovated course of Electronic Services in Banking provided at our faculty aims at education of future professionals in areas of finance and banking and provides them knowledge and practical skills development in the field of electronic financial services with a support of e-learning methods. Changes in the course during the years of its provision were invoked by rapid changes in ICT usage in area of e-services in finance. The course attendees get the opportunity to test multiple electronic services in finance and banking using virtual bank, certification authority, several demos, simulation software and video materials. Furthermore, the course is built in the way that students in both forms of study (face-to-face and distant learning) get virtually the same learning experience. This paper aimed to share the experience from ESIB course and to present results achieved by this novel form of the course provided by our faculty.

In 2016 was the questionnaire survey conducted within the course to reveal students’ knowledge and skills development in two time moments: before the course and after its completion. Its results show several positive improvements in students’ knowledge and suggest practical skills acquisition. The course further increases the awareness of electronic services in finance and banking among the students and their consequential adoption. The survey was a source of important feedback including suggestions for changes in the educational process of the course in following years. The testing of students and their average results over the recent years again show progress in knowledge of the area in each year.

The course combines multiple information and communication technologies to provide education in the area of banking and e-finance in a novel way. Contribution of the course consists in a combination of usage of virtual bank, private certification authority and real-life e-finance applications. Emphasis laid on security of electronic services appreciate course attendees even in their private usage of given services.

REFERENCES

Abstract - Nowadays, huge amounts of data are produced within shortest time. Especially modern production and measurement systems daily generate a big volume of data, which is growing exponentially. In many cases the challenge is not just obtaining the data, but an appropriate analysis, which is necessary to extract the significant information for enterprises and institutions. The added value of information is zero, if the employees of a company are not able to effectively evaluate the collected data.

In this paper a didactic concept is presented, how master students become familiar with methods of modern data analysis. A complete and systematic approach starting with data acquisition, database management, extraction, up to evaluation and interpretation is shown. For better understanding the used complex and theoretical multivariate algorithms are applied to illustrative examples. This gives the students the opportunity to establish a relationship with these methods and the ability to transfer them to practical industrial problems.

I. INTRODUCTION

Many publications and teaching methods at higher schools and universities are merely theoretical introductions to the subject of statistics and often require a high degree of abstraction from the student. However, the application of statistical methods is becoming more and more important due to the increasing amount of data and performance of today's computers. To a large extent, especially multivariate evaluation procedures can only be executed effectively by the enormous calculating power of current technologies.

The present article proposes a different, practice-oriented approach to selected industry relevant topics of data analysis, which should help to overcome the reservations and prejudices towards statistics being a “secret science”.

The basic idea of the educational concept is to prepare the groups for statistical thinking by describing a real problem and motivate them to solve it initially without external help. This creates a close relationship to the respective subject and improves the attention for the solution significantly.

Based on numerous examples, the groups interactively learn different mathematical techniques and the corresponding field of application. Therefore an education in mathematics and computer science with bachelor level is a necessary prerequisite for the course. Occasionally, group members are surprised by the information hidden in special datasets. The goal is to enable the master students to uncover the maximum of information concealed in the sample data.

II. CONCEPT IMPLEMENTATION

An essential pillar of the didactic concept is to explain the entire data management chain occurring in industry. Fig. 1 gives an overview of all important parts.

![Figure 1. Overview of data management chain occurring in industry.](image-url)
• Especially a full working data management system including a server operation can be set up straightforward.

In the first session, the students have to prepare the Raspberry Pi for the tasks to be solved. In detail, the following topics were addressed [1]-[5]:

• Installation of Raspbian OS
• Basics of Linux and Python
• Apache2 Webserver
• PHP plugin
• SQLite
• PhpLite Admin DBM

The next step was the implementation of an ultrasonic distance sensor including the corresponding Python code. This experimental setup was taken from [6] and adapted to our purposes.

The objective of this experiment was to check, if the measured ultrasonic sensor data could be immediately and automatically stored in a previously defined SQLite-data base, which was also realized with the Raspberry Pi. In addition to this data, real (anonymized) production datasets were considered as well. After setting up a client–server architecture, the students were able to extract any dataset out of the database by applying a specific SQL (Structured Query Language) command, sent by a remote computer. The necessary SQL skills were also trained in the class. SQL is a widespread industry standard.

At this point, a challenging exercise must be tackled: the connection from the database to MATLAB, our evaluation software. Although MATLAB offers a SQL modul in the database toolbox, this tricky problem could not be solved satisfactorily until now and was outsourced to a different project. Instead, a workaround was found.

Now, a new section of the course was started: the statistical evaluation of different types of datasets with MATLAB. The primary job was the preparation of data. This is a typical situation in industry. The extracted dataset is often not directly suitable for the evaluation due to missing values, incorrect entries or outliers. Sometimes datasets from other sources must be merged with entries of the database. Furthermore, in certain cases computed columns must be appended. All these preparatory activities could be summarized under the heading “basic data manipulation”. This also includes z-standardizing of matrix, ranking, grouping, eliminating missings and winsorizing, just to name a few examples. MATLAB provides a lot of options for this task.

Now, the actual evaluation was performed. Starting with univariate statistics, basic calculations like central tendency and dispersion as well as the corresponding graphical representations, such as histogram, stem and leaf plot, boxplot, cumulative frequency and probability plot, were carried out [7].

The investigation of bivariate datasets led the students to the fundamental concepts of variance and covariance. The terms “(linear) statistical dependence” and “independence” were defined and could be demonstrated by the basic properties of variance. Especially the discussion on the variance of the sum of correlated variables results in interesting opinions of the participants. An appropriate simulation with MATLAB clarified the question.

The presentation of an industry related example at the end of the section deepened the understanding of covariance and correlation matrix. The student’s task was to automatically find a predetermined pattern within a group of samples. Such an issue occurs in the quality control of surfaces, where scratches must be detected and the product concerned must be scrapped.

Fig. 3 shows the scratch pattern scenario. The first subplot defines the search pattern. Blue areas are marked as “not relevant” and must be suppressed by the automatic analysis. The green part of the search pattern labels the non-affected area, whereas the red points represent the scratch. Subplots 2-6 show five different measured (fictitious) surfaces. The algorithm, presented in the lecture and worked out by the students, is able to assign surface 3 (subplot 4) to the predetermined pattern with a correlation coefficient of 1.
Now, the next typical work in daily business of companies was treated: several machines of a production line, which perform a particular process step, should lead to the same process result. A suitable method to attack this problem is the ANOVA (analysis of variance). A fundamental requirement for understanding this statistical technique is the knowledge of distribution functions. The theory of distribution functions is mathematically demanding and not really helpful for solving the specific issue. Instead, a MATLAB simulation based on simple considerations was started and compared with the exact mathematical solutions. The advantage of this procedure is an intuitive access to statistical distribution functions. Fig. 4 gives an impression of the comparison between the simulation and the exact solution, using the example of the F-function.

Moreover, other distribution functions like the Student-t- and the Chi²-distribution were explained in a descriptive manner and subsequently simulated. After this preparatory work, the initial ANOVA-task could be solved. Fig. 5 displays a boxplot of a characteristic measurement value grouped by the equipment used.

The question arises, whether there are significant differences between the machines or not. The appropriate statistical method is the F-test, whereby the test value is calculated as the ratio between variance of the treatments and variance within the treatments. The participants of the class immediately grasped the mathematical approach, because they already completely understood the F-distribution. For didactic reasons, a manually performed analysis was done and compared with the results of the “ANOVA”-function of MATLAB. This assures that the students could interpret the results of the software package.

In the last section of the course, the outstanding importance of multivariate statistics was discussed based on complex datasets. A typical task in this context is the question, which and how strong variables are correlated with other variables. Often engineers are interested in the (very complex) influence of many predictors on the yield of a product. The method of choice is the so-called “multiple regression”. However, a major challenge for the application of multiple regression is to overcome the problem of multicollinearity, which means, that two or more predictors are highly correlated [8].

In the lecture, this was shown by an easy example: it was assumed that two variables $x_1$ and $x_2$ linearly depend on each other with a correlation coefficient of $r=1$, e.g. $x_1=x_2$ for simplicity. Now the response variable $y$, e.g. yield, was also assumed to be directly correlated with $x_1$, e.g. $y=x_1$. Consequently, $x_2$ is directly correlated with $y$ as well. Obviously, any linear combination $y=ax_1+bx_2$ with $a+b=1$ represents the response variable $y$. It is immediately clear that the problem cannot be solved uniquely.

A solution approach is based on the idea of finding new predictor variables $w_1$, $w_2$, …, $w_p$ as linear combinations of the original predictors variables $x_1$, $x_2$, …, $x_p$ with the property that $w_1$, $w_2$, …, $w_p$ are pairwise uncorrelated. This task can be managed by the mathematical formalism of a suitable orthogonal transformation.

A two-dimensional example was presented in the course. The original dataset is shown in Fig. 6.

Figure 4. Comparison of simulated and theoretical curve of F-distribution, displayed for two degrees of freedom, df=2, df=5.

Figure 5. Graphical MATLAB-output of One-Way-ANOVA: different machine behaviour is clearly visible. The significance is estimated by the F-value.

Figure 6. Original two-dimensional dataset, $x_1$ and $x_2$ are highly correlated.
After the application of an orthogonal transformation, which is a 45° rotation in this case, the variables $w_1$ and $w_2$ are uncorrelated, see Fig. 7.

In high dimensional spaces, it implies the solution of an eigenvalue problem. The underlying mathematical formalism is called “Principal Component Analysis”, abbreviated PCA, and the transformed coordinates $w_1, w_2, \ldots, w_p$ are called principal components $PC_1, PC_2, \ldots, PC_p$ [9].

This algorithm can be used to reduce the dimension of the data space. Directions with a low level of information, in Fig. 7 the $w_2$ coordinate or $PC_2$, can be neglected for the benefit of a lower memory consumption without losing essential information. Especially in image processing, the principal component analysis is also called “Karhunen-Loève transformation”. The higher the involved principle component, the smaller the loss of information.

In the class, the PCA-algorithm was programmed in MATLAB by the participants with support of the lecturer and applied to an image of TRUDI, our rescue robot, see Fig. 8.

The result of the PCA is shown in Fig. 9 for a different number of principal components. The effect of data reduction and the improvement of significant information with increasing PC can be clearly seen from the images.

At the end of the course the principal component algorithm was applied to an audio file as well. The acoustic result was impressing for the students and demonstrated the wide field of application of principal component analysis.

### III. SUMMARY

In this article, the basic ideas of our new data analysis course including the practical implementation were presented. The concept of the course was and will also be in future strictly based on industry-related issues. At the beginning, the installation and configuration of a database were performed. A Raspberry Pi served as the hardware platform with the advantage of being a cost-effective solution. In addition to its task as a database server, the Raspberry Pi was used to generate datasets in combination with an ultrasonic distance sensor. The complete system including data storage and extraction was successfully tested. A data connection to MATLAB could be established.

The second part of the course dealt with the evaluation and interpretation of the data. Knowledge of univariate, bivariate and multivariate techniques was imparted to the participants. A lot of practical exercises performed with MATLAB enabled the students to independently select the correct method adapted to the problem and apply the mathematical concepts.

### IV. FEEDBACK

Finally a few statements of the students on the course are cited:

“This is an interesting course from the practical aspect...”

“Good entry in the world of big data and data science...”

“The data science course is done in a practical manner close to real applications...”
“Also the use of state-of-the-art software is important to stay in touch with current technologies that are used in industry...”

“...I think the MATLAB as well as the Raspberry Pi part were really good prepared...”

V. FUTURE ASPECTS

A concept for measuring the learning outcomes will be developed in cooperation with industry partners. Also pedagogical improvements are planned for future courses, especially a time slot for more interactive, workshop-like collaboration with the participants is intended.

VI. CONCLUSION

We are convinced that the practical mastery of statistical evaluation procedures is an increasingly necessary skill in engineering education due to the information content of mass data. Therefore, it is of tremendous importance for companies, to extract significant information at an early stage in order to obtain advantages over competitors.

ACKNOWLEDGMENT

The authors thank Christian Madritsch for the implementation of all Raspberry-Pi-related topics and Marcus Ungermanns for reviewing this article.

Abstract - Learning to program is a challenging task. Novices need to have an accurate understanding of the program execution at the conceptual level provided by the programming language. This level of execution is often referred to as the notional machine, which is often easier to understand through program visualizations.

Currently one of the most popular programming paradigms is object-oriented programming, which introduces a number of advanced concepts. In addition, in order to increase student engagement, teachers have started to introduce graphical user interface (GUI) applications into programming courses. This brings its own set of challenges, mostly related to a significantly larger number of application states, which are more difficult to keep track of. However, most existing programming visualizations do not cover all necessary concepts for teaching object-oriented programming, nor have they considered visualizing complex GUI applications. For this reason, we present our own concept of a visualization system that addresses these shortcomings.

In this paper, we have: i) extended an existing notation for a notional machine to support learning of advanced object-oriented concepts inheritance and polymorphism; ii) presented our own concept of a visualization system that introduces the source code into the notional machine, thereby making the relationship between source code and the visual representation more concrete; and iii) proposed solutions for reducing the cognitive overload introduced by GUI applications.

I. INTRODUCTION

Learning to program is difficult [1, 2]. It requires novices to learn logical and computational techniques, the syntax of a new programming language, as well as developing the understanding of how a concrete program is actually executed by the machine [3]. During the acquisition of these techniques, novices often develop incomplete or incorrect understanding of programming concepts, called misconceptions.

Currently, one of the most popular programming paradigms in the software industry is object-oriented (OO) programming, with Java as one of the most popular programming languages taught at universities. At some universities OO programming is taught as a part of introductory programming [4]. However, for novices this increases the cognitive load, as OO brings about its own concepts such as classes, objects, encapsulation, inheritance, and polymorphism. A study on misconceptions related to inheritance and polymorphism reveals that even teachers with years of experience in procedural programming have difficulties in understanding those concepts [5].

A common technique to increase the motivation and student engagement is the introduction of Game-based learning [2, 6, 7]. Game-based learning facilitates the acquisition of programming concepts through developing and playing games rather than solving often tedious and repetitive tasks. Although text-based games exist, they are not as popular and have a lower motivation potential than those based on a graphical user interface (GUI). Therefore, students often learn to program GUI applications before moving on to games. This alone might increase student motivation as they might have a greater sense of achievement by building programs similar to those they interact with every day. However, GUI applications, and particularly games, often have a significantly larger number of states which may cause cognitive overload for novices.

To achieve programming proficiency, novices need to understand how the program is executed on the level of abstraction provided by the programming language [3]. This abstraction provides a sufficiently detailed understanding of program execution and is often referred to as the notional machine [8]. It is a construct formed from concepts provided by the programming language [3], which allows programmers to understand and explain the execution of a program in terms of those concepts. When discussing imperative and procedural programming, Du Boulay recognized the notional machine as a source of most programming misconceptions (e.g. related to assignment, variables, and arrays) [9]. Therefore, it is important that novices construct a valid mental model. This becomes increasingly important when learning OO programming.

When addressing learning OO programming, Sorva [8] discusses the need for two notional machines. The first notional machine should be an extended version of the notional machine used in imperative or procedural
programming languages, and should feature variable assignment, expression evaluation, call stack, object reference, etc. The second notional machine should abstract out these details and focus on object interactions during program execution.

In general, the majority of difficulties faced by novices can be attributed to the lack of understanding of how programs are executed [8, 10]. One way of facilitating the understanding of the dynamic process of program execution is through program visualizations. Program visualizations are often software tools that graphically represent the execution of a program. Most existing program visualizations for programming education have focused on helping students in introductory programming courses, which teach only a limited set of OO concepts, such as classes and objects.

In this paper, we present a concept of a visualization system with the goals of: i) helping students comprehend important OO concepts, such as classes, objects, inheritance, and polymorphism; ii) making the relationship between the source code and the visual representation more concrete; iii) facilitating the understanding of GUI aspects, both classic as well as game development. In order to fulfill these goals, we have: i) expanded the notation for the notional machine introduced in [11] with notations for inheritance and polymorphism, ii) designed a visualization system that overlays the source code with the notional machine, and iii) discussed and proposed solutions for visualizing applications that have a large number of objects and executions, such as GUI and especially game applications.

This paper is structured as follows: in section 2 we introduce existing program visualizations, and section 3 discusses inheritance and polymorphism along with related misconceptions. In section 4 we present our prototype visualization of a notional machine for OO concepts. Finally, section 5 concludes the paper and presents possible future work.

II. RELATED WORK

As expressed in [3], software visualization refers to the use of graphical elements in order to provide assistance with the construction of mental representations of software. According to their purpose, software visualizations can be classified as either algorithm, code, or program visualizations. Algorithm visualizations are used to visualize programs at a high level of abstraction with the goal of explaining how the algorithm works. Code visualizations are used to visualize source code and its features. Finally, program visualizations are graphical representations of the notional machine. They are our primary focus in this paper.

The literature review conducted by Sorva [12] identified forty-six different program visualizations since 1979 to 2013, out of which only fifteen were reported as active at the time and only nine supported OO programming concepts to a certain degree. This was expanded with a recent literature review [3] that identified seven new program visualizations that appeared in the period between 2013-2016. We focus on a few that we have found particularly interesting: UUhistle [10], Online Python Tutor [13], Jeliot 3 [14], JaguarCode (formerly JavelinaCode) [15], JIVE [16], and Novis [17].

UUhistle [10] is a visualization system that provides two operating modes. In the first one, the system visualizes the execution of a Python program. The user can step back and forth through the visualization and observe program changes at a low level. In the second mode, the system allows the user to take on the role of the machine and manipulate the graphics in order to execute a given program. Sorva refers to this exercise as visual program simulation.

Another very popular visualization tool is the Online Python Tutor [13]. Currently, it supports the visualization of both versions of Python, and six other programming languages. The system itself is web-based and can be embedded into other web pages. Furthermore, Online Python Tutor allows users to visualize their code line by line or an entire program automatically via a live programming mode.

Jeliot 3 [14] is a visualization tool for Java programs aimed to help students learn procedural and OO programming. Program execution is visualized line by line. One of the newest visualization systems is JaguarCode [15] which is a web-based visualization system for Java programs. The system visualizes the class diagram and the execution of source code by line, similar to Online Python Tutor and Jeliot 3. JIVE [16] is a popular Eclipse plugin used to generate Unified Modeling Language (UML) diagrams from code. However, JIVE is targeted primarily at professional programmers and is not adapted for novices.

Novis [17] is a visualization tool that has been integrated into BlueJ, an integrated development environment (IDE) designed for educational use. The tool visualizes a class diagram and notional machine of a Java program. The visualized notional machine consists of objects and their fields and values assigned to them. In case a field’s value is a reference to another object, the field and referenced object are connected by an arrow. Novis also supports viewing the notional machine at different levels of detail, where at the lower level only objects of complex types are displayed. As opposed to the previously mentioned visualizations, the minimum step granularity in Novis is that of a method call. The system visualizes only the methods that are part of the currently active call stack.

Although the aforementioned visualization systems support the use of inheritance and polymorphism in the program code, they do not explicitly visualize them. This makes them inappropriate for providing conceptual models for these concepts.

Furthermore, none of the visualization systems mentioned above have taken into consideration the possibility of visualizing GUIs. Because GUIs tend to consist of a large number of objects, the visualizations provided by these systems would become increasingly cluttered, which would make them difficult to comprehend.

We present our ideas on how to tackle these shortcomings in section 4. However, before we describe our proposed extensions to the notional machine, in the next section we discuss advanced OO concepts: inheritance
and polymorphism, as well as misconceptions related to them.

III. INHERITANCE AND POLYMORPHISM

Inheritance and polymorphism are considered advanced OO programming concepts [5]. Inheritance is a mechanism which allows the definition of a certain relationship between classes, through which one class, called the derived class, reuses the behaviors of another, called the base class [18]. Through these relationships a class hierarchy is constructed [19]. In statically typed programming languages, this allows a variable to refer to an instance of its subtype, which is called subtype polymorphism.

Although inheritance allows the reuse of behavior, there are situations when a reused method needs to be re-implemented. This is done through overriding. Hence, it is up to the runtime to decide which method implementation in the class hierarchy should be called. This is another form of polymorphism called dynamic dispatch.

Liberman et al. [5] studied the difficulties related to inheritance and polymorphism. They categorized the identified misconceptions into four clusters. We briefly summarize their findings.

The first cluster contained misconceptions related to “simplistic alternative programming models”, which were probably caused by the participant’s prior knowledge of procedural programming [5]. Within this cluster, four alternative models related to overriding and variable types were identified. In one alternative models the variable type determines which method will be dispatched. However, this model ignores the effect of overriding on dynamic dispatch. Another model caused participants to view variable types as irrelevant, and believed that method invocation depends only on the class from which the object was instantiated. Other models included beliefs that overriding is redundant, and that overriding eliminates the method that was overridden.

In the second cluster, the authors placed misconceptions related to using analogies. These included analogies to everyday life and to procedural programming [5]. Related to the latter, some participants believed that an array can store references of any type, unrestricted by the class hierarchy. This is probably due to an assumption that all references are of the same type.

The third cluster contains misconceptions related to inheritance [5]. Some participants thought that inheritance is used to change the values of fields, rather than for creating relationships between classes and reusing behaviors. A misunderstanding of this relationship caused participants to mistake class composition for inheritance.

In the final cluster, the authors placed misconceptions caused by misunderstandings of previous OO concepts [5]. These may be related to overloading, object creation, etc. Some misconceptions may be caused by certain teaching methods, e.g. using a single example to explain a concept and its uses.

We believe that some of these misconceptions could be resolved by visualizations that facilitate the acquisitions of valid mental models related to inheritance and polymorphism. In the remainder of this paper, we extend the notional machine notation proposed in [11]. Our extensions have been designed with the aforementioned misconceptions in mind.

IV. EXTENDING THE NOTIONAL MACHINE

In this section, we outline our extensions to the notional machine notation in order to support novices learning of polymorphism and inheritance. We further present a visualization system which introduces source code into the visual representation of the notional machine as needed. This should provide a tighter integration of source code and the notional machine visualization. We end this section with a discussion on how GUI applications may be visualized.

A. Extending the notional machine notation

An existing notation for a notional machine [11] provides a convenient and compact view of various instantiated objects, their states and call chain. However, it lacks some details required to visualize advanced OO concepts. For example, the existing notation isn’t sufficient to visualize the execution that includes inheritance and polymorphism. We extend the notation by including details such as property types, inheritance and dynamic dispatch, in order to tackle the misconceptions discussed in the previous section.

Our first extension to the proposed notation of the notional machine is concerned with the visualization of inheritance. Although the basic notation visualizes the state of an instantiated object, it doesn’t differentiate the ownerships of the inherited fields and methods. We tackle this by visually separating the fields and methods that originate from different classes. An example, along with the corresponding code, is depicted in Fig. 1. The example is taken from an assignment that students needed to complete in their OO programming course. The code in Fig. 1 is abbreviated for clarity. It can be seen that the object was instantiated from the class Cat which inherits the property Age from its base class called Animal. Methods are, as in Novis, shown only when they are a part of the currently active call stack [11, 17].

![Figure 1](image-url) An example implementation of a class (left) along with its visualization (right)

Unlike inheritance, object composition is depicted as an instance of one class referencing an instance of another via
some field. An example is given in Fig 2. The difference in notation should help novices distinguish between inheritance and class composition. It can be seen that an instance of Form1 holds a reference to an instance of a Cat, and Cat inherits from Animal. Note that object composition by itself is visualized the same way as in Novis [17].

The figure shows the call of a method with multiple implementations. The currently executing expression (cat.Talk()) is emphasized; the details about the callee object (cat) are shown (Cat in Fig 3.), as well as the dispatched implementation of the method Talk(). Both methods are visible in order to emphasize the fact that overriding doesn’t eliminate the overridden method.

Integrating the source code into the visualization of the currently active method should reduce the gap between the code itself and the program state. Furthermore, this should reduce cognitive load as it allows the programmer to focus only on the part of the code that is currently being executed.

C. Visualizing applications with a graphical interface

Due to their simplicity and low overhead, console applications are often used by novices when learning the basics of programming and program execution. In turn, based on our experience most existing program visualizations for education are designed to visualize relatively simple console applications. Recently, educators have started to include GUI applications into their curricula, with the goal of increasing student engagement and motivation. However, GUI applications often have a much larger number of objects, program states, and executions. This means that existing program visualizations are often not particularly adapted to visualizing GUI applications, and they can overburden the novice with too many, often irrelevant information.

When tackling the complexity of visualizing GUI applications, we need to decide i) which subset of program executions we wish to visualize; and ii) which objects and fields are relevant for a particular execution.

Our visualization consists of two views. The first view shows the whole program execution as a series of events, where each event transforms the internal state of the program. Showing each change of the program state during event execution would cause cognitive overload in students due to a large number of changes. Because of this, the view shows only the transformations made by the event handler, that is for each object modified by the event handler we show the initial and final states of that object. This shows how the event-handler has transformed the program state.

In certain cases, we may wish to know how a series of events transforms the program state without looking at each individual event. Hence, a sequence of events may be grouped to show how the whole sequence transforms the program state. This view is depicted in Fig. 4.

The second view provides the students with the opportunity to view each step of the execution of a single event. This corresponds to standard visualizations of the notional machine. However, objects that are influenced by a single event may have a large number of fields, which is why our visualization displays only those that participate in the event handler execution.

The use of two views corresponds to Sorva’s discussion [8] related to the use of two notional machines for OO programming. Because GUI applications are driven by the user’s actions, the first view can be considered a higher-level notional machine for event-driven applications,
whereas the second is a more detailed notional machine of the execution of a particular event.

V. CONCLUSION

In this paper, we have discussed the importance of visualizations in facilitating the understanding of the notional machine as a conceptual representation of how programs are executed. We have reviewed state-of-the-art visualization tools and have highlighted some of their shortcomings for advanced OO concepts, as well as applications with a large number of states, such as event-driven GUI applications. In order to tackle these shortcomings we have presented our own concept of a visualization system that: i) introduces notation for inheritance and polymorphism into the notional machine, where each object visualizes the ownership of inherited fields and methods, and each variable and field show their current type to emphasize the difference between reference type and instance type; ii) integrates the source code into the currently active method; and iii) includes two views on program execution to reduce cognitive load. The first presents a high-level view of program execution by visualizing the transformations carried out by a group of events on a set of objects. The second gives a detailed view of the execution of a particular event by visualizing the method call stack along with the objects and fields that are relevant to the execution.

For future work, we plan to make a pilot study with students in order to determine the influence of our proposed notional machine extensions on their understanding of event-driven, object-oriented programs. We expect to further re-evaluate and develop the visualization in accordance with the prototyping approach in software development [20].

We will follow that with the development of a tool that would automatically visualize the notional machine in the context of arbitrary event-driven object-oriented programs. Finally, we will evaluate the effects of the visualizations provided by the tool in an educational setting.

We also plan to investigate the use of the high-level view as a notional machine for visualizing other programming paradigms.

Abstract - Visual programming languages (VPLs) are becoming more popular and making the transition from the informal to conventional educational settings. One of the important features of VPL is that novices are not required to remember a list of commands or complex syntax since everything they need is just there in the environment. The objective of introductory computer programming courses at the university is to teach students how to develop solutions in high-level computer programming languages such as C#. However, they also need to acquire problem-solving skills. Since computer programming and problem-solving are both challenging, schools and universities often make use of VPLs combined with game-based programming. Students will eventually need to transfer programming concepts learnt from VPL into a high-level programming language. A transition from VPL to the text-based high-level programming language is not seamless and additional tools and efforts are required. This paper presents prototypes we have developed for undergraduate university students to enable mediated transfer from VPL to high-level programming language by using the idea of mini-languages.

I. INTRODUCTION

Visual programming languages are gaining popularity as the possible solution for novice programmer’s difficulties. The purpose of this paper is to provide a better understanding of the advantages and limitations of using visual programming languages in formal educational context and to suggest a potential model for teaching programming at the University undergraduate programming courses. The model is using a visual programming language, and it is based on the established didactical strategies such as didactic reduction and transfer of learning [1, 2].

Teaching programming at the university, specifically teaching introductory programming courses does not promote novices to expert programmers, and while researchers argue that such process may even take ten years [3, 4], the more concerning problem is students’ poor performance after completing the first course [5]. Teachers may not expect such poor performance, but it is not uncommon. Sometimes the problem lies in the belief that all students should be able to program, or that weaker students cannot learn to program, so teachers eventually let them pass the course. Although some authors claim that some students will never learn programming, others, in the context of computer literacy, argue that most of them should be able to acquire fundamental programming skills and knowledge without expecting them to become experts [6].

The next section contains related work and didactical strategies that motivated us in designing the prototypes described in this paper. The pilot testing described here is the follow-up research to the three years study on the influence of visual programming languages and game-based learning on the students’ achievement in programming courses. The study was conducted at the Faculty of Science, the University of Split from 2010 to 2013 [7]. Researchers expected that transfer of learning is going to happen spontaneously, but the influence of game development in visual programming languages on programming courses taught in professional text-based programming languages was weak. As suggested by the previously mentioned research, we have developed prototypes and conducted pilot testing with the students majoring in computer science (CS) who will become teachers of CS upon graduation. Because teachers learn from other teachers, this is also the opportunity to transfer the experience [8].

II. RELATED WORK

Case studies in computer science education are often small-scale studies within one course, and many studies are reported in “Marco Polo” style while arguing for one approach over the other [9]. Long-term studies dealing with the implications across different courses and long-term effects are not that common [7]. To better understand the whole process of learning and teaching programming it is important to put things into perspective, or a model. The conventional model for teaching programming is represented by “didactical triangle”. The didactical triangle consists of (i) student (who to teach), (ii) teacher (how to teach) and (iii) content (what to teach) [9, 10]. The whole triangle also belongs to the context [10].

For example, if a teacher chooses the strategy of problem-based learning for teaching programming, selected problems should be based on real world situations whenever possible. Otherwise, besides abstract nature of programming concepts and language constructs, students also have to deal with the task of analyzing and understanding some unknown abstract problem. Game-based learning (GBL) or gamification is often used as motivation [7]. Playing educational games and game development are two different types of GBL. Most of the students consider games as fun.

However, while thinking of using game design in the course of object-oriented programming, we have realized that even simple game development in general-purpose languages like C# or Python is very complex for novices. It
usually requires using extensive additional libraries, so besides basic language constructs and programming concepts they struggle with, novices are burdened with other subject matter. The focus of the next section is the first part of the triangle related with our educational settings, that is undergraduate university students.

A. Teaching undergraduate students programming

The student in the triangle represents learning process, student’s previous knowledge, skills and experience and other characteristics that influence learning. Teaching children and adults is different. Learning programming at the university is concerned about adult students who require a different approach, more student-centered, active learning and problem-based learning which shifts teacher’s role into facilitator or guide [11].

Besides learning some programming language, the important goal of introductory programming courses is to develop problem-solving skills [12]. Computer programming used for problem-solving skills is the part of computer literacy [13].

Most of the first year undergraduate students at the Faculty of Science (FOS) at the University of Split are novices without any previous experience. Novices often acquire superficial knowledge, they approach programming “line by line”, have trouble planning and understanding programming concepts focusing on the specific programming language syntax. That is somewhat understandable since introductory programming textbooks are often structured according to the programming language constructs [14]. However, students born after the 1980s belong to the new millennial or net generation that is often more trained in media and computer literacy [15]. Even if teachers were successful in learning programming using console applications, that doesn’t mean that students will share the same enthusiasm.

B. Teaching strategies for programming

Teacher in the didactic triangle represents overall teaching process, choosing strategies, decisions about content selection and presentation while considering both the content and the student. Novice programmers must learn various new and abstract concepts in programming which is difficult [16, 17]. Teaching object-oriented programming is considered difficult, and some of the identified problems are teachers’ lack of experience, unfamiliarity with the paradigm, lack of textbooks, unsuited software tools or environments, focus shift from algorithms to software engineering point of view [18].

One of the instructional strategies we have considered applicable for our settings is known as didactic reduction, and it represents the teaching approach where some aspects of learning are simplified [1, 19]. The strategy is applied when learning a complex subject and implies that additional details are discovered subsequently step by step. Computer programming is complex, and we believe this strategy might help students to avoid cognitive overload [20]. The idea of using didactic reduction comes in handy with the transfer of learning strategies or teaching for transfer.

1) Transfer of learning

Transfer of learning is the ability to apply knowledge and skills acquired in one context to new contexts. It occurs when learner recognizes common features, links information in memory and sees the value of using familiar concepts from one learning situation to another [2]. Positive transfer occurs when one context improves performance in the other. Negative transfer is the opposite, but it happens in early stages of learning and learners usually correct it through the experience. Two strategies help with the transfer of learning: hugging and bridging. Hugging exploits low road transfer when conditions in both contexts are similar, and bridging exploits high road transfer when learner must create abstractions and consciously search for connections between contexts. Bridging is the more complicated process, and instead of waiting for students to achieve it spontaneously, teacher interferes and mediates the transfer. In this paper, we believe that mediated transfer should include hugging as well since the combination of the both strategies is expected to produce a better effect.

One of the approaches in the attempt to explain teaching programming is called semiotic ladder which emphasizes tools (programming or modelling language) with learning stages [21]: (i) syntax, (ii) semantics and (iii) pragmatics. Semiotics studies the signs and symbols in linguistics and communication. The syntax is about combining symbols into programming language instructions, semantics about instructions’ meaning or functionalities, and pragmatics is about the application. Each step of the ladder is based on the previous. Although very simple, this approach is mostly about a programming language. It is not the critical issue since all parts of the triangle are important, but studies have demonstrated that students struggle with syntax far more than we expect which leads them to focus on writing code without understanding its functionality [22]. Tools which students use for programming (language and the environment) may have a significant influence on their thinking [13]. The first encounter with the programming is sometimes the crucial moment when teachers win or lose students’ interest in the programming, so there is significant responsibility for teachers in choosing the appropriate language for introductory programming courses.

C. First programming language

The content in the triangle represents the learning objectives, evaluation of the achievement and actual content which in programming consists of basic concepts such as variables, conditions, loops, decisions, etc. including programming language specifics. Sometimes the content is identified with a programming language. For example, if we ask students or teachers what they learn or teach in the programming course, the answer is often just the name of programming language. The choice of the first programming language is important for motivation [23]. Tightly coupled with the language choice is also the programming paradigm which affects the way student analyzes the problem and creates the solution [24]. Students should learn programming concepts independent of programming language or the environment [24].

The standard approach for teaching programming using professional programming environment and language.
results in low effectiveness because of the following difficulties [25]:

- language complexity – large amount of language concepts and its specifics,
- inappropriate feedback for novices – the process of program execution is hidden which makes understanding semantics difficult for novices (some sort of visual feedback would be preferable),
- inappropriate feedback for novices – the process of program execution is hidden which makes understanding semantics difficult for novices (some visual feedback would be preferable),
- problem types – language orientation on number or symbol processing makes developing interesting “real-world” applications difficult because it requires learning a substantial amount of language concepts, mastering programming environment and writing complex programs.

Many general-purpose programming language constructs are too abstract for novices. Papert developed Logo programming language with the purpose of simplifying learning programming for beginners [26]. Such smaller languages are called mini-languages [25]. Designers of mini-languages are not limited by the syntax or semantics of any complex language. Mini-languages resolve all three difficulties: they are small with simple syntax and semantics, and preferably with visual feedback. Visual feedback is usually represented by a visual actor (e.g. Logo turtle) that exposes semantics while performing visible actions. Logo and turtle graphics influenced many other mini-programming languages that are being used for teaching programming to different age groups ranging from elementary to university students. Successors of Logo are visual programming languages (VPLs) such as Scratch, Snap! [27], Blockly [28], Alice, Greenfoot etc. VPLs can be entirely visual where commands are represented by blocks and are referred to as block-based languages or hybrid with text-based commands. Greenfoot has a visual run-time environment (with visual actors), but coding is performed in Java programming language.

Scratch [29] is developed at the MIT Media Lab and launched in 2007 [30]. Scratch 2.0 can be used directly from a web browser, and no installation is required although the offline version is available. Scratch environment consists of sprite list, block palette, script area and stage. Blocks in the palette are grouped by their purpose into different colored categories like motion, looks, sound, etc. Each sprite has its script area which may contain multiple scripts. Users design scripts by dragging blocks from palettes and assembling them like puzzles in the script area. Shape enforces the syntax.

Potential weaknesses are simple data structures and functions, but it is not an oversight, language designers are following the idea of Logo to keep it simple and more intuitive for children. Scratch supports advanced CS concepts in the simple two-dimensional environment, while Alice three-dimensional world is more complex [31].

Since universities are interested in drawing more students into programming, one form of motivation is lowering the first barrier by avoiding complex syntax. Courses using Scratch have been taught at Harvard University [32] and the College of New Jersey. The extension for Scratch was developed at the University of California, Berkely called BYOB (Build Your Own Blocks) with the advanced handling of functions. BYOB was intended for university students with the support for first-class data and more explicit support for object-oriented programming. The successor of BYOB is ”Snap!” which was redesigned in JavaScript. In Scratch 2.0 users can create custom blocks that represent functions in conventional programming languages. However, custom blocks in ”Snap!” are far more customizable. ”Snap!” lists and functions are both first-class data elements and both can be assigned to variables, passed as arguments to other functions, and also returned from functions as a result.

Since VPLs are getting more popular, it is important to understand how to effectively include them into conventional classrooms [33, 34]. The goal of introductory programming courses at the universities is to introduce students to programming quickly. University teachers aim to teach students some of the professional text-based programming languages, and they are interested in the transfer of learning from block-based to text-based languages. Although some VPLs had success motivating these transitions, it is not clear that any of these languages are the best means to support it [22] [12]. An important advantage for VPLs is low barrier. Students without any prior experience in programming can quickly start programming in VPL [35].

Lack of syntax is a key feature that makes VPLs more appropriate for young novice programmers by focusing on the problem solving, but some research shows that it merely delays syntax problems or even makes students believe that syntax errors are not that important causing them to submit assignments that could not be compiled [36].

Google Blockly can be translated into different programming languages from block representation such as JavaScript and Python. Some researchers suggested that transfer in both directions is better [37] because students with lower self-evaluation of their programming skills choose block-based editor more often if given the opportunity, but most students gradually migrate to text-based programming language [12]. However, introducing text-based interface and free typed text in these environments would re-introduce syntax errors. Scratch supports over 60 languages, so the transition to text would complicate translation [38].

The research in [13] was focused on high school students where researchers have conducted the experiment with “Snap!” using programming in JavaScript. Students later transferred to Java programming language. A majority of students perceived block-based programming easier than text-based. Students emphasized some features as advantages, e.g. there is no need to memorize commands and the text on the blocks was in natural language. Students had difficulties with designing more complex programs.

There is a difference in motivation between younger students in elementary school and older students in high school and university. Older students are concerned that block-based programming languages are not “real” [37],
although they use a variety of programming structures and concepts [22]. On the other side, a group of students perceived this environment as friendly and playful causing them to feel more relaxed and thus become more productive. Design space which blends text and block-based features should be more explored since students’ transition to text-based programming environment is not straightforward [13]. "Drag and drop" was found to be time-consuming since users had to look for the appropriate block in the particular palette [39]. Some of the users avoided using global variables and message broadcasting to trigger some code parts and duplicated code snippets. Such solutions created problems in editing multiple copies of the code.

Graphical blocks used in VPLs take more space than text. That is preferable if blocks are intended to be used by young children using touch screens, but is not so practice for adults [38]. It is harder to navigate and often impossible to search for a particular statement in the code. The palettes with blocks help novices to discover all available commands, but more experienced programmers complain that after learning that rather small set of commands, dragging blocks out of palette takes more time than typing. Searching for the desired block in visual languages involves visual scanning of the palette, and the process may interfere with student’s thinking about a problem.

Although Scratch is used as the motivational tool for engaging novice students in programming, it is clearly not suitable for professional development, and some researchers report difficulties even with the transfer from Scratch to pseudo code and flowcharts [40]. Students were confused and their test results were much lower than in Scratch.

Snap! is more complicated for young students in elementary school but offers more advanced features. A simple improvement is searching for blocks to avoid visual scanning of the palette and hiding of the useless blocks thus supporting the idea of didactical reduction. Researchers in [35] exploited some of the advanced features in the effort to introduce concepts of parallel programming, and some of those features are also available in Netsblox [41]. Advanced handling of custom blocks (equivalent for functions) with the lists and functions as first-class data provided the opportunity to design a custom environment for students. Using "Snap!" experimental codification support that enables block mapping into text-based programming language [27] we have developed custom blocks that generate text snippets of code that can be copied into targeted environment which is described in the next section.

III. PROTOTYPE FOR MEDIATED TRANSFER

Students at the Faculty of Science (FOS), University of Split, as novice programmers have similar problems as any other adult novices. They differ based on their study majors: mathematics (M), Physics (P), Technical science (T), Informatics (I), and also combinations such as: MI or IT. All first-year student with majors mentioned above learn Python and procedural programming during course Programming I (P1), and in the second semester during course Programming II (P2) they are introduced to object-oriented programming paradigm and C# programming language. Since both the language and switch to the object-oriented paradigm are complex, the course P2 is also considered introductory. Students with major in informatics have additional course IT Project I (IP1) in the first semester and learn VPLs and simple game development using languages from Scratch 1.4, BYOB, Scratch 2.0 to “Snap!”. First version of Scratch was simpler and lacked some of the functionalities. BYOB introduced custom blocks, recursions and clones (run-time sprite instances) and was more appropriate for university students.

In the third semester, students enroll the course Object-oriented programming (OOP) with the project-based teaching based on GBL. Using additional game development frameworks such as Unity proved to be too complex, so we have developed our own two-dimensional (2D) game development framework in C#.

Although some students learn VPL and design 2D games during the first semester, OOP course is in the third semester, so the time frame of the whole semester is too long to expect any significant transfer. Hence, in this paper, we present prototypes of the environment designed to support the transfer of learning from visual language to a text-based professional language, namely Python and C#. "Snap!" programming environment has a built-in feature for code mapping, but it is necessary to design each command while respecting the syntax rules. The Fig. 1. a) depicts for-loop blocks developed in "Snap!" environment and an example of mapping those blocks into Python and Fig. 1. b) represents a snapshot of custom designed blocks and the result of the block "C#". Green blocks named “C#” and “method BearFollow” are parts of the implementation. However, mapping feature was not enough to obtain desired features for C# translation, so some additional effort was required. JavaScript language was used with the block “JavaScript function” for running JavaScript code. In Fig. 2 there is a screenshot of developed framework running in the Microsoft Visual Studio (MVS) professional environment using Python tools and Pygame module. Fig. 3 represents C# game development framework.

The goal is to keep students in familiar environments, both “Snap!” and professional environment of the MVS without creating additional applications and students have access to the source code. The result windows represented in the Fig. 2 and Fig. 3 are windows that look a lot like Scratch or Snap! stage. Both frameworks run in MVS environment, and classes and methods mirror "Snap!" programming constructs. For example, students can use methods like bear.Move() or bear.GotoMousePoint() in

![Figure 1. Translation of Snap! blocks to a) Python and b) C#](image-url)
both frameworks and blocks with same functionalities are available in Snap! too. However, MVS does not support a visual designer for forms and controls in Python and students are not able to “drag and drop” controls on the stage like they are used to in VPLs and sprites are visible only during runtime (like in Fig. 2). C# sprites are windows controls and students can position those controls and resize them in MVS designer.

The C# framework was presented to the 29 first year students in the last three weeks of the course IP1 after 12 weeks of experience in Scratch and no experience in C#. Students were first introduced to "Snap!" and the transition from Scratch was almost seamless. Students only asked where to download their solution because the menu was different. They were introduced to advanced features of custom blocks in "Snap!" and had a task of designing for-next loop which does not exist in Scratch or "Snap!". This was a very complex task since students were required to pass scripts as arguments, save the script into variable and use run block to run. Naming the variable as “action” was helpful because they understood that the block would “run actions”, and they had to put those actions into C-shaped block.

During the second week, C# game framework was presented to the students including "Snap!” assignment with the limited set of custom blocks that were translatable into C#. The Snap! project contained only custom blocks and a subset of the standard block set necessary for the solution. The task was to create a simple game consisting of two sprites, one bear and red apples. The red apple was called “good” because bear gets points for catching it, and if he misses three apples, the game is over. Students were required to solve the known problem in this limited environment and use special blocks to generate C# code and copy into MVS environment. They were familiar with this type of game because they solved few similar assignments in Scratch. However, students had different ideas about a solution than teacher predicted and they were missing some standard blocks such as the block labelled “stop-all” to stop all activity when the game finishes, and some of them were frustrated while searching through changed block palette and not finding what they expected.

In the final week, students were provided with the same environment, similar assignment, and prepared blocks for “Snap!” solution in the script area, so students did not have to browse the palette, just to reassemble the script and make it work. The game had one more sprite, brown apple which was named “bad” because bear loses points for catching it, but he was allowed to drop it. The other part of the assignment was again to transfer the solution into the C# environment. The students submitted 15 correct solutions in “Snap!” and 10 in C#. One of the students added some code to make all sprites in the C# solution stop when the game was over event it was not the part of the assignment. Students did not know C# syntax, and the reason for this testing was to examine the performance of the prototype in real circumstances with students designing possibly unpredicted solutions. The Python prototype was not tested at the time since it required an installation of new libraries and different Python version 2.7 that would possibly interfere with their current knowledge especially since students used Python 3.5 in a procedural way without learning object-oriented programming concepts.

Although the sample was small, a short anonymous online questionnaire was conducted to examine students’ attitudes towards their VPLs experience. One of the interesting questions was: Which programming languages you would choose for the IP1 course? A total of 25 answers was collected, and 56% of students chose Scratch, while the next choice was "Snap!" with C# transfer with 16%. The next question was to select the reason for their choice and most of the students selected: Simple for learning and using. Teacher expected student would prefer “Snap!” with C#” for the benefits in next programming course, but they picked an easier path for the current course.

IV. CONCLUSION

Game development frameworks were developed as a follow-up research to exploit the effect of the mediated transfer and the theory of didactic reduction. The developed prototypes translate "Snap!" blocks into C# and Python. Python was selected since it is widely used in Croatian schools (elementary and high school) as the introductory programming language, and C# is also popular in the industry. Python is an interpreter, and C# compiler language, but both can run in the MVS environment. The suggested model for transfer is expandable for other languages. The important advantage of this model as opposed to the example of Google Blockly is that the generated code can run in the professional environment with the same visual actors (sprites).

However, since block-based and text-based environments are not isomorphic and targeted languages are more complex, after discovering more complex details in the background students will need to include abstract thinking and develop connections.
Story of a 'Storyline Visualization' in High School Readings

K. Osmak* and K. Kocijan*

* University of Zagreb, Faculty of Humanities and Social Sciences / Department of Information and Communication Sciences, Zagreb, Croatia

kosmakic@ffzg.hr, krkocijan@ffzg.hr

Abstract - Storyline visualization, as a process of illustrating data that has a course of events via a visual medium, has been used in the area of film making for a very long time. Not so long ago, it has moved from the paper version to the digital word allowing for a wider usage. In this paper we propose its usage as a teaching tool in the area of literature reading for the Croatian class (primary language). We have conducted a preliminary research in five Croatian high schools of a different profile to see how storyline visualization, and visualization of school materials in general, affects students understanding of the material being studied. Each school participated with two groups of students where one group was exposed to the storyline visualization of a novel Prokleta avlija by Ivo Andrić [N=103 in total] during the reading period, and the other one was reading without the visualization [N=93 in total]. We will present our results taking into account students' gender and type of a school.

I. INTRODUCTION

Many researchers agree that an eye is an important information receiver and that our brain does a good job in finding patterns in visual presentations of data [10], [2], [5], [3]. Thus, it is by no surprise that, in this information era that we live in, we are trying to find alternative ways to present information in a visually more understandable (comprehensive) way in order to absorb more information in a much faster manner. In the recent age, as we are surrounded with more and more data, and presence of Big Data is becoming overwhelming, this obsession of visual presentation of data has become more common, and surely even expected in business domain.

But, what about the arena of education? How can we help our students to better understand and better incorporate all the information that we are feeding them with in schools? Can we use visualization as a helping tool? Obviously, the answer is ‘yes’. Visualization is not a novel thing to education and different types of visualizations have been used for different lessons trying to convey the relevant information [5]. Some of the most widely used ones are geographical maps, periodical table of elements, Venn diagram, cyclic graphs, mind maps, UML diagrams, pie charts, bar charts, tree maps etc. and their usage depends mostly on the topic being taught.

And what about storyline visualization? Is it helpful in mastering the school curriculum? In what subjects can it help? Is it for everyone? These are just few of the questions that motivated us in this project. The main characteristic of this type of visualization is that it helps to demonstrate when and where did certain characters meet during the course of the story. So far, it has mainly been used to show movie character interactions. The professional illustrators would draw a board with characters moving through time and space to get an insight into the story flow. These lines where usually drawn by hand, but recently several software tools have been introduced that are able to draw the story line automatically after parameters like characters, places and time are provided as an input [17], [18].

In order to test our hypothesis that storyline visualization can be used in classrooms and can help in better understanding of a story, we have conducted a small scale research on 196 high school students. In the following sections, we will first provide some information on visualization giving a special attention to storyline visualization and its usage throughout history. Second, we will describe in more details how we designed a storyline visualization for a novel Prokleta avlija by Ivo Andrić and how we conducted our research. Before we conclude, we will present and discuss our results.

II. STORYLINE VISUALIZATION

A. Short History

Storytelling through visualization is not a novel approach to telling a story. It can be traced all the way back at the very beginnings of humanity. We can talk about visualizations when we talk about drawings in the old caves like Altamira or Lascaux, and later in the old Egyptian pyramids, and up to the more modern times in children story-books. Some of the most known visualizations are Galileo’s sun spot map, Descarte’s coordinates system, New Chart of History by J. Priestly, John Snow’s map of cholera appearances in London, or Florence Nightingale’s diagram of cause of death of soldiers fighting in Crimean war.

In spite the fact that most visualizations are understandable to different language groups, and that visualization can be regarded as a universal language, it is surprising that its usage was not always as popular or as widely spread as today. Although since 15th century it has been mostly on a raise, since the end of the 19th and up to the middle of the 20th century it had its modern dark age period when it showed a sudden decline, probably caused...
by two Wars [8]. Speedy raise in science and technology, and production of immense quantities of data since the 2nd half of the 20th century made a fertile ground for the raise of visualizations as well.

This brings us to the modern age of computers which are almost unthinkable without different graphical presentations, from disc free/occupied space and disc defragmentation process, or schema of folders and documents to visualization of different social network happenings and phenomena. All of these examples use very large numbers of information and our brain is much better in finding patterns and making sense of those information if presented visually than via text or pure numbers [10], [13]. The main intention behind these visualizations lies thus in accentuating data’s features, finding “patterns, and simultaneously showing features that exist across multiple dimensions” [2]. It is about informing in a fun manner in order to motivate an action.

B. From Visualization to Storyline Visualization

A new approach to storytelling through visualization is a method called storyline visualization. Although it shares a common ‘DNA’ with other visualizations [5], it differs in the number of details it can show, but also in the type of information we can learn from it. Its main task is to give us an overview of a number of events and/or people over a period of time. Tanahashi and Kwan-Liu [18] define it as “a technique that portrays the temporal dynamics of social interactions by projecting the timeline of the interaction onto an axis”. Almost like a specialized timeline in which lines presenting characters converge where characters interact.

The storyline visualization strives to show the main structure of a story flow with the accent on interactions between characters without giving any sentiment or interpretation of a story. During the design process, it is important to refine the data and select only events and characters that are important for the story. Then follow the selection of a software for visualization, choice of colors, positions, sizes and intuitive symbols that will be used, and finally a legend where appropriate.

The most obvious application of a storyline visualization can be in the movie-making industry, where film directors, actors and script adapters can benefit from it [14]. However, that is not the only area that may find it informative. Visualization of linguistic shift [15], genealogical data [11], presentation of dynamic relationships of politicians over time or visual summary of events in informative context in data-driven journalism have also been proposed. One of the most famous storyline visualizations is associated with the war related data, particularly Napoleon’s troops marching toward Russia by Charles J. Minard and it dates back to 1862. A very thorough description of this visualization is provided by Sandberg [9] and with six different types of data it provides, it is well suited for both history and geography classes. But, as we are proposing in this paper, these two subjects are not the only ones where storyline visualization can find its place. Display of a historical or a fictitious story through storyline visualization should be the same since we have the same type of parameters needed for this type of visualization. Thus, it is our strong belief that storyline visualization can find its place in portraying a story flow of a novel as well as in showing how different genres appeared throughout the time of literature, or how different theories in biology, chemistry and other sciences appeared with their main influencers interactions.

III. BUILDING A STORYLINE VISUALIZATION FOR A NOVEL

The use of technology in class does not necessarily mean that students and teachers have to use computers or tablets during lectures. It can also include preparation for class such as making materials which will help students to understand the school subject in an easier way and later to help students review the subject matter before exams.

Until recently, it was only possible to draw storyline visualization either by hand or by using a simple drawing software like Paint or some other similar program. In recent years, several authors have either proposed software built specifically for the purposes of storyline visualizations [7] or have proposed some modifications towards improving the layout of a visualization [4], [16], [18]. Since the readability of a storyline visualization is of an extreme importance, it is not surprising that much thought needs to be put into ordering the characters among themselves and on the visual presentation as a whole.

We have tried to incorporate all the best practices in our visualization of a novel Prokleta avlija (Figure 1) in order to best show the flow of the main story and two additional stories that happen in the middle. In this, we have tried to follow the three main principles for constructing storyline visualization proposed in [18].

![Figure 1. - Storyline visualization of a novel Prokleta avlija](image-url)
A large amount of information can be obtained from just looking at the visualization and analyzing it, without even reading the book. So, for example, one can see how many plots exist in the book since every plot is positioned in its own rectangle in a different color, who are the characters and which of them meet, and finally where and when they meet in the book. The legend provided at the bottom of the visualization contains explanations of the symbols used in the visualization such as deaths, marriages and births of characters where this information is given through the novel.

IV. PREPARATIONS AND SURVEY IMPLEMENTATION

Our research was conducted through five distinct phases. The first phase included a search for high schools that would be willing to participate. We asked each school that was willing to participate in the research to send us a list of readings they planned to do in the 1st half of the 2nd term in order to find the one book they had in common. Since it was important for us to have different profile of high schools, and that there are at least two classes in each school, we included those parameters as well while selecting our final five schools (one Natural Sciences High school, two Technical High schools and two Gymnasiums). One class from each school would receive the visualization with instructions on how to use it - test group, while the second class was to read the book without the visualization and would receive the visualization after they take the test – control group (in order to answer some questions from the questionnaire).

During the second phase we had to reread the novel and draw the visualization by hand trying to define all the character relations that we believed to be important for the story. The book that turned out to be in common for our schools was Prokleta avlija, a historical novel written by Ivo Andrić. This novel is also one of the mandatory books on the matura exam that Croatian students need to take in order to get their high school diploma. This was an additional bonus for choosing this particular book since we believed that students would be more willing to read it and participate in the research.

The third phase included the process of transferring the visualization from the paper version to its digital format using graphic design software CorelDraw X7. After the visualization was finalized we prepared two sets of test questions and two sets of questionnaires together with the visualizations for each student. Both tests consisted of 16 questions, 8 of which were linked to the visualization and would receive the visualization after they take the test – control group (in order to answer some questions from the questionnaire).

In the fourth phase, 103 students who were reading with the visualization have been given the printed copies of the storyline visualization together with the instructions on how to use it. The other group of students (93) did not receive any information on the visualization or the research being conducted. Originally, 217 students were to participate in the research, but 21 student was absent from the school at the test day, so their tests were returned empty. On the test day, both groups of students were first given the tests. The test group received the questionnaires immediately after finishing the test. The control group was first given the visualization after finishing the test and then the questionnaires.

In the final phase, after tests and questionnaires were returned to us, we transferred the answers to our database and prepared them for further data analysis. Our findings with a short discussion are presented in the following section.

V. RESULTS AND DISCUSSION

The main purpose behind this pilot research was to find out if storyline visualization can help students better understand and memorize the timeline of the story and movement of its characters throughout the novel than the conventional way of just reading a book and then analyzing its content in class. We also wanted to see if students of different gender and type of the high school would perform differently on the test. Additionally we were interested to learn how young people today react to an unconventional visual data representation, or in this case, to a storyline visualization of a novel and if they see some other subjects where its usage would be rewarding.

Our main hypothesis was that the students who had the visualization while reading the novel would have better understanding of the story and its characters and would thus have better test results than the students who were reading without visualization. Also, we expected male students to perform better since research shows that they are better in visual-spatial thinking as well as the students of technical profile high schools who are more accustomed to visual presentations due to the nature of their studies.

A. Test results

There were 16 test questions, eight of which have been shown through the visualization. We will discuss only them. Five of these questions were multiple choice (MC) questions, two were true/false (TF), and one required a short answer (SA).

The results for the first MC question (Which Pope was in the historic part of the novel?) were better for the students from the test group (pink sections = left sections). Also, male (M) students (54.14%) performed better on this question than female (F) colleagues (45.86%) (Figure
In the visualization, we have used a special symbol showing a change of the pope to mark this occurrence.

The second MC question (How many times did Camil's mother got married and how many children did she have) gave similar results: test group performed better and male students performed better (Figure 3). A special symbol was also used to show a wedding of a character.

The third MC question was about Cem Sultan, the son of Sultan Mehmed II. His fate was a tragic one and at one point in his life he had been sold to the enemies of the Ottoman Empire. The final three MC questions are about his first owner (Who is the first owner of Cem Sultan), the number of people who wanted to buy him (How many people want to buy Cem Sultan) and what happened to him in the story (What happens to Cem Sultan). The graphs (Figure 4, Figure 5 and Figure 6) show the results for these three questions in the same order as aforementioned.

There are two TF type of questions. The first one was used to find out if there are characters in the story whose fate was not revealed to us (a special symbol was used to show this in the storyline visualization) (Figure 7).

In the 2nd TF question, a set of five statements was given that needed to be marked as true or false. These five statements, marked 11.a through 11.e, tested if two characters met in the story or not, and if they have met after a specified event. Results are shown in Figure 8.

In the SA category of questions there was only one question where students were asked to write how many stories there were inside the main story. In this historical novel there is one main story inside which three other stories occur. Each story in the visualization was marked with another color. We used white background for the main story, yellow for the jail story inside which two more stories occurred (orange was used for story about Camil and dark pink for Cem Sultan’s story). Although a high percentage of students without visualization performed well on this question, still there were more students with the visualization with the correct answer and among them, more male students (Figure 9).

Our results show that we have been right to assume that students with visualization would perform better on the test and also that male students would perform better.
than female ones. However, overall test scores show that technical school students did not perform better on the test, as we have expected them to.

B. Questionnaire results

We prepared two sets of questionnaires: one for the test group and the other for the control group. The main goal was the same – to find out how students feel about presenting data from a novel through storyline visualization and what other subject areas they feel it could be useful for. The test group questionnaire also had questions about the visualization (if it was presented in a clear manner, if they find it helpful for preparing for the test, during the reading of a novel and for better understanding of relations between characters). Since the control group was given storyline visualization only after they took the test, their distinctive questions were whether they think it would have helped them during the reading and in better understanding of relations between characters. First, we will present our findings from the selection of questions common to both groups, and then the questions present only in the test group followed by the questions distinctive of the control group.

It is important to say that 82.49% of all tested students believe to be visual types, or to be more precise 94.52% of gymnasium students, 80.39% natural science students and 75.82% of technical students. If we take a look at their overall test grades per school type (Figure 10), than gymnasium and natural sciences students performed accordingly. However, there is a discrepancy between the declaration of technical students and their test scores since the students from the control group performed better than their colleagues from the test group. This came as a surprise to us since 75.82% of these students declared to be visual type and 64.83% believe that visualizations could help better understand other subjects as well.

![Figure 10. – Distribution of average scores per school type and their declaration about being visual types](image)

If we take gender into account, than more male (45.16%) then female students (37.33%) declare themselves as visual types. This is in contradiction with their test results since overall grade for male students (15.45) is lower than for female students (15.69). However, both male and female students from the test groups had outperformed their colleagues from the control groups.

![Figure 11. - Distribution of average scores per gender and their declaration about being visual types](image)

When asked if a storyline visualization would help them when reviewing for a test, 78.03% students answered affirmative, and 7.94% of them are students who originally declared themselves not to be visual types. There are also 13.08% of visual type students who do not find such a visualization as a good tool for test reviews.

There are 86.92% of students (10.28% of nonvisual type) who believe that storyline visualization would be helpful in better understanding even the more complex novels and 73.96% of students (6.98% of nonvisual type) who believe that it would help them in some other subjects as well. When asked in which subjects they could find such a visualization as a helping tool to better understanding of the material being studied 50 listed history, 23 listed biology, 18 listed chemistry, 15 listed physics, 15 listed mathematics and 36 of them stated that it could be useful in all subjects. There were up to 9 students that also listed one or at least one of the following subjects: sociology, geography, technical subjects, psychology, logics, art of music, visual arts and philosophy.

A larger portion (81%) of test group students found the storyline visualization to be presented in a clear manner. Among them, there are more male (60%) than female students and more students from technical schools (41%) than other types of school.

When asked about the down sides of the visualization their answers ranged from ‘too little of the context was given’ and ‘exact years and locations would be useful’ to ‘did not like the symbols and/or colors used’ and ‘more details about characters’. But, as mentioned earlier, storyline visualization, just like other types of visualizations, can be used to present only some types of data – not all.

If we cross reference test students’ answers, we find some discrepancies. For example, there are students who find the visualization to be presented clearly, to have helped them better understand the relations between characters and was helpful to have during the reading time. However, they did not find it helpful for answering the test questions. This may have something to do with their test scores. Unfortunately, since the questionnaire was anonymous, we do not have means to test this assumption. All the other combinations of their results are presented in Figure 12.

![Figure 12. Distribution of Test group results](image)

After control group was introduced to the storyline visualization 71.55% of them responded that it would have helped them during the reading time. More male students (53.01%) than female students (46.99%) were in
favor of this belief as well as the most gymnasium students. Their distribution regarding the school type and gender is given in Figure 13.

Even more control group students (80.17%) believe that the storyline visualization would have helped them with understanding of relations between characters. Again, more male (56.99%) than female students (43.01%), but more technical school students than others. Their distribution regarding the school type and gender is given in Figure 14.

The main purpose of this paper is to test if storyline visualization can be introduced as a legitimate educational tool for presenting information that includes a type of narration where the characters and their interaction over a period of time is important to convey. Our preliminary research results show that students would benefit from such presentation and would use it during the study period but also as a revision too. Since the majority of people rely greatly on eyes as an information receiver, storyline visualization comes as a perfect tool that can be used not only for research and business, but in teaching and learning as well. The research has shown that students from Gymnasium and Natural Sciences Highschools that used the storyline visualization while reading the novel scored better on the exam than the students without visualization. Also, opposite to our expectations, students from Technical Highschools without visualization performed better on the test than their colleagues with visualization during the reading time. Considering only gender, our female participants using visualization while reading achieved better results than male participants with the visualization. This was also in contradiction with the stereotype and our questionnaire results where more male students declared themselves to be visual learning types that female ones. The one-tailed Fisher’s exact test value (P=0.0172) show statistical significance between gender and helpfulness of storyline visualization in understanding while χ² test value (P=0.0006) for the association between school type and helpfulness of storyline visualization show high statistical significance.

ACKNOWLEDGMENT

We would like to thank teachers and students of Technical Highschools Ruder Bošković in Zagreb and Technical Highschool in Bjelovar, Natural Sciences Highschool Vladimir Prelog in Zagreb, and Gymnasium in Metkovič and Bjelovar without whose help this research would not have been possible.

Impact of ICT on Archival Practice from the 2000s Onwards and the Necessary Changes of Archival Science Curricula

Hrvoje Stančić*, Arian Rajh*, Mario Jamić*
* Faculty of Humanities and Social Sciences/Department of Information and Communication Sciences, Zagreb, Croatia
hstancic@ffzg.hr, arajh@ffzg.hr,mjamic@ffzg.hr

At the outset authors of this article investigate the influence of ICT on archival practice. All archival processes are affected by latest developments in ICT. DMS and eSignature requirements and legislation (like MoReq and eIDAS) influenced record management practice. PAIS, OAIS and storage solutions have their impact on archival management. Special audio and video format solutions influenced specialised archives. Graph databases as a more agile tool for organising information and the upcoming Records in Contexts (RiC) standard are influencing archival description. New preservation methods have emerged - Chain of Preservation model (COP) and the upcoming Preservation-as-a-Service for Trust (PaasT) model. PaasT is the result of growing cloud services. Semantic web influenced retrieval and usage of materials in all heritage institutions. The authors proceed to discuss how the elaborated changes should reflect the archival science academic curricula. They investigate what are new archival science core competences that should be taught to students and archival professionals by university teachers today, how should universities prepare their students of archival science for contemporary (digital) labour market etc. The authors offer a clear position what archival competencies, arising from the influence of ICT and cloud environment, should be built upon in the contemporary archival science curricula.

1. INTRODUCTION
ICT has had an indisputable impact on the reality of organisations and the reality of people’s lives for decades. The significant transformation of these realities from the 2000s onwards brought about a change in archival science curricula. The authors of this article investigate the extent of this influence and the magnitude of educational adjustments. Have archival professionals incorporated enough contemporary ICT knowledge into their curricula (and their daily operations) yet? Comparable impact on archival profession happened with the appearance of new storage materials and the development of new physicochemical methods in the 20th century. Those materials and methods had a substantial influence on archival storage facilities and procedures of preservation, conservation and restoration. But, what is happening now is of far more consequence to the future of the archival profession. ICT, led by fresh approaches, trends, values and practices, has moved not just those parts of archival work that were oriented towards the management of digital records, but also parts of more traditional archival practice, like archival description1, because of new possibilities of computer generation and system-to-system communication of archival finding aids2.

Digital signature and other authentication and integrity associated technologies altered management of digital records. New digital audio and video formats appeared. Electronic recordkeeping technologies related to Records Management Systems (RMS) / Enterprise Content Management Systems (ECM, ECMS) influenced organisations and supported their abilities to preserve digital records. Storage became portable, designed for massive scalability, and with archival qualities – like SDS (Software-Defined Storage), SSA (Solid State Arrays), scale-out NAS (Network-Attached Storage), and object storage. Cloud services and cloud storage have been developing for the last decade [1]. These services are today fully accepted by individuals for their personal archives and more or less accepted by corporate bodies. Concepts and standards like OAIS (Open Archival Information System), PAIS (Producer-Archive Interface Specification), PAIMAS (Producer-Archive Interface – Methodology Abstract Standard) and XFDU (XML Formatted Data Unit) are shaping the process of transfer of digital content among environments [2-6]. Semantic web and graph databases also occurred in the realm of today’s records and archive management. These fresh ICT concepts and their effect on archival science are described in the second chapter of this article. The authors consider that ICT influenced archival science considerably and that archival curricula responded to these developments to a great extent. But, do these curricular changes respond enough to the progress in ICT field(s)?

The aftermath of ICT impact is visible in the courses offered to university students on the global and European

1 Archival description refers to “the process of capturing, analyzing, organizing, and recording information that serves to identify, manage, locate, and explain the holdings of archives and manuscript repositories and the contexts and records systems which produced them” and “the products of the above process.”. International Council on Archives, “Dictionary of Archival Terminology” (Draft Third Edition/DAT III, 1999) and Multilingual Archival Terminology, http://www2.archivists.org/glossary/terms/f/finding-aid (accessed March 2017)

level (analysed in 2003 and 2016). Nevertheless, it is important to constantly monitor changes in ICT and to make timely recommendations for continuing adjustment of archival science curricula.

Next, we will firstly discuss the influence of ICT on the archival science and practice. Then we will show the effects of the development of ICT on university and professional curricula by analysing the changes that were introduced between the two research activities – the first in 2003 and the second in 2016. Finally, we will conduct a SWAT analysis, draw conclusions and offer recommendations.

II. INFLUENCE OF ICT ON ARCHIVAL SCIENCE AND PRACTICE

In relation to the processes of transfer and storage, a numerous media types were developed by the ICT industry [7-8]: glass disks, PIQL film, new types of network storage etc. Some recognised media technologies got better over time (e.g. Data Tresor Disks) while the ICT industry has abandoned some of the media types in recent years, e.g. Ultra Density Optical (UDO) disks, High-Density DVD, Holographic Versatile Disks (HVD) etc.

Record Management Systems (RMS) and Enterprise Content Management Systems (ECM, ECMS) have entered the organisations and changed their record management practices and workflows. ECMS and RMS systems are practically comparable, from the pure record management perspective, but then again ECMS systems are conceptually and functionally broader than RMS. From the archival perspective, this broadness of functions is relevant because it shapes creator’s business activities and affects archival funds. Adoption of ECMS and change in workflows can result in business process reengineering activity and change in the business (business activities, business roles etc.). For this reason, ECM systems are not just automation tools; implementations of ECMS systems in organisations are not just trivial modifications. Archivists should be well-aware of this. Recently, the ECMS solutions have been implemented in many organisations. Examples of the most spread out technologies [9-11] are IBM FileNet, Dell EMC Documentum, Alfresco One, OpenText, Hyland OnBase etc. For illustration, the FileNet ECMS implementation in the Croatian Agency of Medicinal Products and Medical Devices (HALMED) in 2013 and 2014 led to changes in recordkeeping, archival management, IT landscape, and business processes. FileNet ECMS in HALMED has been linked with XINO scanner and DPU Scan application, case management application and archival management application.

Outcomes of these integrations and interfaces are a) ability to use digitised records as a replacement for paper originals in the workflows, b) linked paper originals and digitised copies, and c) ability to archive new digitally-born records and cases. A threefold usage of various HALMED’s ECMS content happens at this time. There are users in HALMED that use ECMS and its content through its own FileNet Navigator interface, users that prefer to use their previously developed business applications (ECMS handles the content in the background), and groups of users that work with new applications developed on the FileNet platform. Rearrangement of business tasks was necessary because new applications had required different workflows (e.g. Quality Management application). Outcomes of these new workflows were new groups of records, and thus the change in archival funds.

Storage and its diversification became very complex; therefore archivists should learn more and absorb more facts about the world of storage. There are several notions about the storage archivists should be able to consider. They have to consider storage memory feature (primary, secondary, tertiary, online, offline, near-line, volatile, non-volatile); the way storage utilises equipment (SAN, NAS, virtualisation); storage hardware dependency (SDS); the question what storage really addresses (content, location, file-addressable); the question what storage actually manages and on which level (file hierarchies, objects, blocks, and entry level, business level, enterprise level). There are numerous subtypes of storage solutions [12]. Today, for archivists it is necessary to understand the software characteristics behind the typology, characteristics like scalability (of solid state arrays, NAS, object storage), hardware-independency (of SDS) etc. Archivists should also know what to do once active storage environment is set up – to apply business continuity and disaster recovery policies as well as to develop long-term digital preservation policies together with IT colleagues and to archive what has to be archived. Therefore, archivists should be acquainted with backup procedures (traditional, snapshots, cloud), replication (replication of content after its creation, host-based, array-, network-, snapshot-based), mirroring etc.

Semantic web brought requirements to semantically enrich descriptions of existing materials in order to

4 ECMS consists of document and records management, image management, collaboration tools, web content management, business process workflows, and vendor-specific components. It is also linked with business applications of organisations. Gartner report from 2016 predicts shifting major ECM solutions to cloud-based platforms.

5 Gartner MQ ECM 2014-2016.

6 Part of the IPA 2009 TAIB project preparations for eCTD and Implementation of Digital Archival Information System (in cooperation with Ericsson Nikola Tesla d.d. and AAM Management Information Consulting Ltd.).

7 Imaging subsystem was developed by EMES d.o.o., and case management and archival management applications by Omega Software d.o.o.
disseminate them in a more efficient manner. Many institutions from the museums/libraries/archives (MLA) community had started with the implementation of the semantic web a long time ago and have enabled better connectivity of descriptions of their objects of interests for different communities. The emerging archival standard Records in Contexts (RiC) represents one step toward this [13-14].

Records in Contexts standard is using graph databases [15]. Graph databases appeared as more flexible and reactive technology for processing entities and their relationships than the technology of relational databases.\(^8\) Creation of graph database (model) implies the creation of nodes (entities) with labels (entity types), relationships, and nodes’ and relationships’ properties. It is still too early to tell whether RiC will become a new description standard or just another schema in archival description. Nevertheless, it is important to understand the principle behind RiC and to be aware of these changes in the world of databases.

Archivists are often interpreters – they translate from the business language connected with a function to the ICT language that supports the function and vice versa. Some standards that are close to the archival domain, and records & archival management domain-specific languages [16], already possess this translated logic. OAIS standard represents a mixed language of such a sort. ICT professionals can build an OAIS compliant system. A person with a task to transfer records between two systems can conduct a structured PAIS project. But usually archivists have to familiarise ICT professionals with these standards. Also, archivists translate records management parts of business functions to ICT workflows and functionalities. Records contain business transactions metadata and remaining logic while business is driven by records to an appreciable degree.

An OAIS-based system has several functions – ingest of records being the starting one. Archive receives a submission from internal or external, human or computer producer. It has to be validated and transformed into the form suitable for long-term preservation. These standards can be applied [2-6]; PAIMAS to define producer-archive relationships in different phases\(^9\) and conditions of their cooperation; PAIS to formally define digital objects and specify submission models\(^10\) required for transfers into archives; XFDU to support these transfers as the precise packaging standard. Finally, there is an ISO 16363 standard [6] for evaluating the trustworthiness of repositories (i.e. digital archives). It brings to maturity OAIS, PAIMAS and PAIS standards. ISO 16363 covers ingest function, organisational infrastructure related issues and maintenance of producer-archive relationships.

Shifting the focus from the RMS systems to the digital records they are holding, it should be noted that archivists are increasingly dealing with the records having some kind of cryptographic mechanisms applied to them. Namely, the records are being signed by (advance) digital signatures which rely on (qualified) digital certificates; the digital timestamps are being added as well as digital seals. Recently implemented EU-level regulation eIDAS states that “an electronic signature shall not be denied legal effect and admissibility as evidence in legal proceedings solely on the grounds that it is in an electronic form” [21]. This means that the archivists need to know how to preserve digitally signed records in the long-term while addressing the fact that digital signatures rely on digital certificates which are valid only 2-5 years. While considering re-certification and while applying standard long-term preservation technical procedures like file format conversion, media migration, application emulation or system virtualisation they should constantly have in mind standard archival requirements for preservation of authenticity, integrity, reliability, usability and non-repudiation of digital records being preserved. All this illustrates just a fraction of ICT-connected tasks that the archivists need to proactively and successfully accomplish.

Besides the impact of ICT by itself, the authors also recognise the influence of recent professional endeavours like an education and training component of the InterPARES 3 – global, archival science research project (2007-2012) and other similar impacts on professional curricula. Projects like InterPARES laid emphasis on the need to incorporate state-of-the-art technologies into students’ and trainees’ programmes.

III. EFFECTS ON UNIVERSITY AND PROFESSIONAL PROGRAMMES

The effects of the development of ICT on university and professional programmes were analysed by comparing the two studies. The first one was conducted in 2003\(^11\) and the second one in the last quarter of 2016.

The first study aimed to analyse 23 programmes of archival science globally. They were from Australia (2), Canada (2), Finland (1), Ghana (1), Israel (1), USA (14), and United Kingdom (2). Descriptions of the total of 370 courses were manually identified, collected from the official web pages and analysed. The analysis was focused on identifying if the courses found in the archival science programmes could be relevant for the library science study or museum science/heritage study (the MLA group) or social-humanistic informatics or a combination of them. Also, the level of influence of IT was determined. The results show that:

- 62% of courses are relevant for the study of library science,
- 58% of courses are relevant for the study of museum science,

\(^8\) “Because of their emphasis on global queries, graph compute engines are normally optimized for scanning and processing large amounts of information in batches...” Robinson, I.; Webber, J.; Eifrem, E. “Graph Databases”. O’Reilly Media Inc., 2015, p. 7.

\(^9\) Preliminary phase, formal definition phase or PAIS phase, transfer phase, validation phase.

\(^10\) PAIS define types of submissions and submission containers. Actual submission implementation should be done by applying XFDU standard.

\(^11\) As part of the project HERITAGE Live (Operative programme IPA – Cross-border Cooperation Slovenia-Croatia 2007-2013).
The fact that the graduate level programmes were analysed may be the main reason why the courses are mainly based on theory – the students need to learn the basics of archival science. History is not significantly present. Instead, there are courses which are more practice-oriented and which prepare students to work at the MLA institutions (usually in the second year of the study).

The courses that are IT-focussed use the technology existing in the archives of their countries, therefore giving students the opportunity to learn how to use the technology before graduating. The analysis showed that 17% of courses have information technology aspect explicitly mentioned in the course name. Although the first and the second research did not analyse the same sample so the results could not be directly correlated the increase in number of IT-focused courses may be noticed.

To enrol in the graduate program, students have to finish an undergraduate study. Most of the analysed courses (56%) are in the programme during the first year of graduate archival science studies (Figure 1). Those courses mainly serve to introduce students to the archival science. Broadening the view of the influence of ICT we have identified 27% of courses in the second year of graduate studies that involved work with information technology used in archival practice but not fully focussed on it. This shows that IT has significantly influenced the archival studies.

In fact, when we look at the distribution of the courses per semester, 30 courses are in programme during the seventh semester, or first semester of the graduate study (Figure 2).

While the first semester of graduate study is aimed at studying the theory of archival science, the courses which involve information technology used in practice are in the programme of the ninth semester. The tenth semester is the semester when the students have their internship in the archives, so it makes sense that they should be prepared to use the technology.
Archival science courses in the analysed programmes of the second research study focus more on theory than practice, but it is clear that they follow the development of ICT. As it was detected in the first research study, here the archival science courses also do not prepare the students to work only in the archives, but in all MLA institutions as well. The analysed archival science programmes in Europe does not perceive archival science as a science that deals only with the preservation of documents, but as a science that deals with information systems, digital preservation and other activities normally conducted by other information institutions too. The analysed programmes last between one and two years, but the trend is to put less focus on courses directly linked to the current archival practices and current technology, and more focus on practical work.

**IV. CONCLUSION**

Table 1 uses a SWOT analysis template and links strengths and opportunities with knowledge and positive aptitude of archival professionals. The proposed SWOT analysis derivative outlines today’s archival corpus of knowledge related to professional ability to contribute to digital archival management and archivists’ ability to absorb IT-related knowledge. Archival professionals are strong in using classifications, so their knowledge can be used in the system design phase. For a good reason the DIRKS recordkeeping methodology [17] had assigned the same role for archivists. Although their new role in the organisational environment is being recognised, the role of the archival professional in open digital social environment has not been defined yet. Archivists’ ability to evaluate provenance and the quality of sources could be helpful in this new environment. That ability is also related to ICT and participation of archivists in training phases in pattern analysis and machine learning projects.

Weaknesses are related to archivists’ lack of knowledge of particular technologies. Threats are related to archivists’ and records managers’ way of thinking allied with the paper administration and its functioning. This refers to applying records schedule in some later stage of digital document’s lifecycle, sticking to workflows created for paper records, insisting on perfect custodial conditions in a dynamic digital environment etc. If we neglect the threats, they will turn into professional weaknesses.

Therefore, archivalists should be abreast of the rapid ICT developments. It is important to recognise and address the needs for further improvements. Opportunity for growth lies in making archival outputs more interoperable, dynamic and usable than before, by embracing semantic web concepts, graph databases concepts, machine learning tools concepts etc. Another opportunity for archivists in the complex contemporary

---

12 Archival arrangement – “1. The process of organizing materials with respect to their provenance and original order, to protect their context and to achieve physical or intellectual control […] 2. The organization and sequence of items …”, Pearce-Moses, R. A Glossary of Archival and Records Terminology (accessed March 2017)

13 “Documentary form is both physical and intellectual. The term physical form refers to the external make-up of the document, while the term intellectual form refers to its internal articulation. Therefore, the elements of the former are defined by diplomatists as external or extrinsic, while the elements of the latter are defined as internal or intrinsic.” Duranti, L. “Diplomatics: New Uses for an Old Science - Part V.” // Archivaria 32 (Summer 1991)

14 Provenance – “Archivists base their work on the idea that the origin of archival documents and records, or their provenance, must be known if the purposes of the archives to be achieved [...] The application of the principle of provenance results in division of archival holdings into particular groups of records linked to their creator. ‘The principle of provenance’” // Duranti, L.; Franks, P. C. (ed.) “Encyclopedia of Archival Science”, 2015, p. 284.

world appeared when they accepted personal digital archiving (PDA) conception and harnessed their theoretical knowledge to address PDA challenges. PDA represents a new type of archival fonds or accumulation because it differs from paper personal fonds.

How much knowledge we collect through the never-ending learning and practice makes us competent scientists and good professionals. If archivists will adopt these ICT-related opportunities, they will turn them to their strengths. That is why they have to be recognised and used for fine-tuning of curricula. The analysis of the archival science programmes and their courses in the two presented research studies showed the positive developments. In our opinion, the contemporary archival science programmes should continue adjusting to technological reality. Faculties and archival schools should embrace the new technologies and educate future archivists about them. Consequently, the archivists would be able to bring the needed changes to the archival practice, users’ preservation capabilities and the digital meta-literacy related to the preservation in general.

pauladzapo@gmail.com, miduic@unizd.hr

Abstract - The goal of this research was to explore and compare personal information Facebook publishing behaviour of male and female pupils and university students. One important finding is that very small percentage of all examinees publish items in most sensitive data types regarding the privacy: religious and political views, mobile phone, email, address. Additionally, it was established that a similar percentage of male and female pupils publish information in almost all data types. The exception is a Books data type where female pupils publish about two times more than male pupils. Also, on average, female pupils publish about 7.5 times more often information in Books data type than male pupils. Male pupils, on average, publish information in Sports data type about 4.5 times more often than female pupils. Considerably higher percentage of male students publish information in data types: High School, Apps and Games, Music, Friends, TV Shows, Movies. On average, male students publish about 8 times more often information in Sports data type than female students. Female students, on average, publish information considerably more frequently in Check-Ins data type: about 3.5 times more often than male students.

I. INTRODUCTION

Many young people use Facebook every day publishing various information about their interests, opinions, friends and other topics. The goal of this study is to provide insights about the Facebook publishing behaviour of young people with regard to their gender. These insights could help educators to better understand similarities and differences between the interests of female and male pupils and students. This could help them to create educational programs which are more closely connected with the young people’s interests and with regard to their gender.

Also, these insights could be helpful for educators to create programs for the improvement of privacy protection behaviour. Privacy is a fundamental human right. It is „the claim of individuals, groups, or institutions to determine for themselves when, how, and to what extent information about them is communicated to others“ [1, p.154]. Today, when information technology has a strong presence in our lives, privacy on the Internet is something everyone should be paying attention to. With the fast development of information technology and the creation of new devices and forms of media, such as smartphones and social networking sites (SNS), privacy of individuals becomes an issue that needs to be addressed and protected against those who want to harm it.

Gross and Acquisti said that “privacy implications associated with social networking sites depend on the level of identifiability of the information provided, its possible recipients, and its possible uses.” [2, p.73]. They stated that even if some SNS do not expose their users' identities, they still may provide information that identifies the profile’s owners [2].

On social media sites, such as Facebook, people can voluntarily disclose their personal information: their names, comments, likes, posts and photos or videos can be visible to their friends as well as friends of their friends and anyone else with Facebook account. These publicly available personal traces can be seen by many unknown persons and organizations, including advertisers [1]. Personal information can be taken from social media and used without the knowledge of users who are facing risks like identity theft, physical or online stalking and even blackmailing [2].

In the next section we will present insights from the studies about young Facebook users. In the third section we will present the research methodology used to explore the Facebook publishing behaviour of young people. In the fourth section all findings will be presented in detail. In the fifth section we will emphasize the most important findings, suggest some possibilities for using these findings and suggest several ways for additional research that could be made as an extension of this research.

II. YOUNG FACEBOOK USERS

With the rise of Facebook and other social media, online privacy of children and young people becomes an especially important issue, as they are less likely to understand the possible effects of disclosing personal information which may affect their lives [3]. In a study conducted by the Pew Research Center it was confirmed that teens share a wide range of information about themselves on SNSs, as the sites are designed to encourage the sharing of private details with others [4]. Feng and Xie [1, p.156] claim that it seems hard to stop teens from disclosing personal information on SNSs. Boyd [5] points out that the notion that teens do not care about privacy is very entrenched in the public discourse. However, the truth is that teens often do care about privacy although this can be ignored by the public and the
media [5]. Herring and Kapidzic [6] emphasized that there are concerns about the lack of parental control over teenage use of the Internet, but there are indications that more and more parents are trying to protect their child's online privacy. While older users may perceive privacy as protecting personal data from outside intrusion such as advertisers and the government, younger users perceive privacy as control over their personal space and social situations, as they are more worried about parents and teachers than advertisers and other third parties [7].

Today there are many types of social networks, but as Lenhart [8] pointed out, Facebook remains the most used social media site among American teens. Herring and Kapidzic cite the claim that “girls on average spend more time on social network sites and use them more actively than boys do” [6]. In several studies it was found that teenagers, from 15 to 17 years old, post more pictures and other personal information on their Facebook profiles [9]. Girls post more romantic pictures and the boys create more self-promotional pictures and comments with sexual content or alcohol references [6]. In a study of young adults’ perceptions of appropriate content, it was established that they expressed “little concern about sharing posts and pictures on social network sites such as Facebook. Female participants expressed more concern about future employers seeing some of their pictures and comments” [6, p.4]. It seems that young adults predominantly utilize social media to build and strengthen relationships with their peers. They are not concerned with their more formal, professional image on social media [6].

### III. RESEARCH

#### A. Research goal and methods

The research goal of this study was to explore and compare the extent to which personal information about male and female pupils and university students is publicly available on Facebook. The content analysis method was used to determine the extent to which male and female pupils' and university students' personal information of the various data types is publicly available on their Facebook profiles [10]. We determined the extent of publicly available items for various data types by counting the number of all items that were publicly published on Facebook profiles of examinees.

The method of comparative analysis was used to compare the extent to which various types of personal information about examinees are publicly available on their Facebook profiles [11]. We compared the percentage of examinees of different gender that published at least one item in a specific data type of personal information. We also compared the average number of items in a specific data type that were published by examinees of different gender.

#### B. Study participants

400 Facebook profiles were selected: 100 profiles of male university students and 100 profiles of female university students were randomly chosen from among Facebook community „Sveučilište u Zadru“ which gathers students from the University of Zadar in Croatia [12]. Also, 100 profiles of female pupils were randomly chosen from among the pupils’ Facebook community „OK je OK!“ [13]; additionally, 100 profiles of male pupils were randomly chosen from among the Facebook friends of the members of „OK je OK!“ Facebook community.

The pupils were about 10 to 13 years old and the university students were about 18 to 24 years old. The data were collected in March and April 2016. This study is a continuation of research about the Facebook publishing behaviour of young people which was presented in the year 2016 at European Conference on Information Literacy. In that presentation the same sample of Facebook profiles was used, but the data were analysed regardless of Facebook profile owners’ gender [14].

### IV. FINDINGS

In this section various findings from the research are presented in detail. Findings are presented according to following themes: items published by female examinees; items published by male examinees; comparison of all examinees with regard to gender; comparison between female and male pupils; comparison between female and male students.

#### A. Items published by female examinees

In Table 1 we can see to what extent female pupils and university students publish items in 15 most populated data types. In Part 1 of Table 1 we see that data types in which at least one item was published publicly by more than a half of female examinees are: Photos, Posts, Gender, Groups. A considerable percentage of them have published at least one item in data types about their interests: Movies, TV Shows, Apps & Games. Many of them have published about Current City (38.5%), Friends (37%) and Hometown (35%). Also, about one third of them published about their interests (Music, TV Shows, Movies, Books, Apps & Games), wrote reviews and marked their location with mobile devices (Check-Ins). It is important to note that very small number of them published at least one item in these data types: Religious Views (4%), Mobile Phone (0.5%), Email (0.5%), Political Views (0.5%), Address (0%). These most private data types of personal information are mostly unavailable on their Facebook profiles.

In Part 2 of Table 1 we see that on average a female pupil or university student has 123.1 friends, 51.4 published photos and 5.8 posts. On average, they published the largest amount of items in data types about their interests and especially about their music interests: 32 items. Other interests that have a high average of items are: Music, TV Shows and Movies. In comparison to these interests, female examinees published considerably less information about Sports, Apps & Games and Books. The following data types are also less present on their profiles: Groups, Check-Ins, Events.
B. Items published by male examinees

In Table 2 we can see to what extent male pupils and university students publish items in 15 most populated data types. In Part 1 of Table 2 we see data types in which at least one item was published publicly by more than a half of male examinees: Photos, Gender, Posts, Groups, Music, Friends.

</table>

Almost half of them have published at least one item in data types about following interests: Sports, TV Shows, Movies, Apps & Games. Only 27% of male examinees published at least one book item as well as information about their locations (Check-Ins). While almost half of them published the names of the city in which they live and their hometown, nobody or very few of them published at least one item in most private data types: Religious Views (4.5%), Political Views (2.5%), Address (1%), Mobile Phone (0%), Email (0%).

C. Comparison of all examinees with regard to gender

Table 3 presents the comparison of the percentage of female and male pupils and students for data types in which at least one item was published by more than 30 percent of pupils or students. In relation to male examinees, a higher percentage of female examinees published at least one item in three data types. In Part 1 of Table 3 we see that among these data types, Check-Ins is a data type in which disparity between items published by female and male examinees is greatest. 1.13 times more female examinees than male examinees published at least one item in this data type.

In Part 2 of Table 3 we see nine data types in which male examinees published more often than female. Music, as well as Apps & Games are two data types in which disparity between items published by female and male examinees is greatest. 1.47 times more male examinees published at least one item in these data types. They also published more frequently at least one item in following data types: Friends (proportion: p:1.39), Movies (p:1.26), Hometown (p:1.24), TV Shows (p:1.23), Sports (p:1.23), Current City (p:1.14).

Table 4 presents comparison of the average of items that were published by female and male pupils and students for data types in which at least one item was published by more than 30 percent of pupils or students. A
higher percentage of female examinees published, on average, more items in six data types. In Part 1 of Table 4 we see that among these data types, the disparity between items published by female and male examinees is greatest for TV shows (proportion: 2.52) and Check-Ins data types (p:2.49). Also, about 1.75 times more female examinees than male examinees published, on average, more items in Movies and Music data types.

In Part 2 of Table 4 we see four data types in which male pupils and university students published more items on average than female. Sports is a data type in which there is by far the largest disparity: 4.85 times more male examinees published more frequently items in Sports data type. They also published more frequently in following data types: Friends (proportion: 2.36) and Apps & Games (p:1.77).

D. Comparison between female and male pupils

Table 5 presents the comparison of the percentage of items that were published by female and male pupils for data types in which at least one item was published by more than 30 percent of female or male pupils.

In relation to male pupils, a higher percentage of female pupils published, on average, more items in six data types that are presented in Part 1 of Table 5. Among these data types, disparity between female and male pupils is by far the largest for Books (proportion: 7.57). Large disparity is also found in data types TV Shows (p:4.23), Music (3.51), Movies (2.7).

In Part 2 of Table 5 there are four data types in which male pupils published more items on average. The disparity between female and male pupils is by far the greatest for Sports (p: 4.58). Large disparity is also found in data types Friends (p:1.78) and Apps & Games (1.34).

Table 6 presents the comparison of the average of items that were published by female and male pupils for data types in which at least one item was published by more than 30 percent of female or male pupils. In relation to male pupils, a higher percentage of female pupils published more items on average in six data types that are presented in Part 1 of Table 5. Among these data types, disparity between female and male pupils is by far the greatest for Books (proportion: 7.57). Large disparity is also found in data types TV Shows (p:4.23), Music (3.51), Movies (2.7).

In Part 2 of Table 6 there are four data types in which male pupils published more items on average. The disparity between female and male pupils is by far the greatest for Sports (p: 4.58). Large disparity is also found in data types Friends (p:1.78) and Apps & Games (1.34).

E. Comparison between female and male students

Table 7 presents the comparison of the percentage of items that were published by female and male university students for data types in which at least one item was published by more than 30 percent of female or male pupils. In relation to male students, a higher percentage of female students published more frequently at least one item in four data types that are presented in Part 1 of Table 7. Among these data types, disparity between female and male students is greatest for Reviews (proportion: 1.5). The much smaller disparity is found in other three data types Check-Ins (p:1.15), Photos (p:1.04), Groups (p:1.04).

In Part 2 of Table 7 there are 13 data types in which male students published more frequently at least one item. The disparity between female and male students is largest for following data types High School (p: 2.83), Apps & Games (p:2.71), Music (p:2.48), Friends (p:2.41), TV Shows (p:2.27), Movies (p:2.1). Significant disparity is also found in data types College (p:1.85), Sports (p:1.73), Books (p:1.68), Hometown (p:1.53), Current City (p:1.35).

### Table VII. Comparison of the percentage of items that were published by female and male university students

| Part 1: Data types in which more items were published by female university students |
|---------------------------------|--------|--------|------|
| Data Type                      | Female | Male   | Proportion |
| Reviews                        | 33%    | 22%    | 1.5   |
| Check-Ins                      | 39%    | 34%    | 1.15  |
| Photos                         | 96%    | 92%    | 1.04  |
| Groups                         | 73%    | 70%    | 1.04  |

| Part 2: Data types in which more items were published by male university students |
|---------------------------------|--------|--------|------|
| Data Type                      | Male   | Female | Proportion |
| Hi. School                     | 34%    | 12%    | 2.83  |
| Apps & G.                      | 38%    | 14%    | 2.71  |
| Music                          | 57%    | 23%    | 2.48  |
| Friends                        | 53%    | 22%    | 2.41  |
| TV Shows                       | 50%    | 22%    | 2.27  |
| Movies                         | 42%    | 20%    | 2.1   |
| College                        | 48%    | 26%    | 1.85  |
| Sports                         | 45%    | 26%    | 1.73  |
| Books                          | 37%    | 22%    | 1.68  |
| Hometown                       | 49%    | 32%    | 1.53  |
| Curr. City                     | 50%    | 37%    | 1.35  |
| Gender                         | 72%    | 64%    | 1.13  |
| Posts                          | 96%    | 95%    | 1.01  |

Table 8 presents the comparison of the average of items that were published by female and male university students for data types in which at least one item was published by more than 30 percent of female or male university students. In relation to male students, a higher percentage of female students published more items on average in four data types that are presented in Part 1 of Table 8. Among these data types, disparity between female and male students is by far the greatest for Check-Ins (proportion: 3.43). Considerably smaller disparity is found in Posts data type (p:1.2).

In Part 2 of Table 8 there are eight data types in which male students published more items on average. The disparity between female and male students is by far the greatest for Sports (p:7.86), Apps & Games (p:5.9) and Friends (p:3.86). Large disparity is also found in data types Movies (p:1.91), Music (p:1.69), Books (p:1.67). In two data types: TV Shows (p: 1.1) and Photos (p:1.08), there is very small difference between two sexes.

### Table VIII. Comparison of the average of items that were published by female and male university students

| Part 1: Data types in which more items on average were published by female university students |
|---------------------------------|--------|--------|------|
| Data Type                      | Female | Male   | Proportion |
| Check-Ins                      | 8.23   | 2.4    | 3.43  |
| Posts                          | 4.25   | 3.53   | 1.2   |
| Reviews                        | 0.78   | 0.74   | 1.05  |
| Groups                         | 7.43   | 7.15   | 1.04  |

| Part 2: Data types in which more items on average were published by male university students |
|---------------------------------|--------|--------|------|
| Data type                      | Male   | Female | Proportion |
| Sports                         | 6.52   | 0.83   | 7.86  |
| Apps & G.                      | 2.36   | 0.4    | 5.9   |
| Friends                        | 265.8  | 68.89  | 3.86  |
| Movies                         | 6.64   | 3.47   | 1.91  |
| Music                          | 23.41  | 13.82  | 1.69  |
| Books                          | 1.77   | 1.06   | 1.67  |
| TV Shows                       | 5.92   | 5.39   | 1.1   |
| Photos                         | 31.83  | 29.45  | 1.08  |

V. Conclusion

A. Main insights from the research

Through this research, we acquired three types of insights about publishing behaviour of young Facebook users:

a) **Comparison of pupils’ and university students’ publishing data.** Very small percentage of examinees of both sexes publish items in most sensitive data types regarding the privacy: Religious Views, Mobile Phone, Email, Political Views, Address. In relation to male examinees, there is no data type in which female examinees publish information in somewhat (1.2<proportion<2) or considerably higher percentage (p>2). On average, female examinees publish information considerably more frequently (p>2) in following data types: TV Shows and Check-Ins. They also publish information somewhat more frequently (1.2<proportion<2) in data types Movies, Music, Posts, Photos. Male examinees on average publish information considerably more frequently in data types: Sports and Friends. They also publish information somewhat more frequently in Apps & Games data type. Regarding the most sensitive data types, both male and female examinees publish on average similar amount of information except in data type Political Views for which male examinees publish five times more often.

b) **Comparison of pupils’ publishing data.** A similar percentage of both male and female pupils publish information in almost all data types (proportion<1.2). The
only exceptions are Books data type where female pupils publish about two times more than male pupils and TV Shows data type where they publish about 1.3 times more than male pupils. On average, female pupils publish information considerably more frequently in following data types: Books, TV Shows, Music, Movies. Books data type is by far the most popular type for publishing information because female pupils publish about 7.5 times more often information in that type than male pupils. They also publish somewhat more frequently photos and posts. On average, male pupils publish information considerably more frequently in Sports data type - about 4.5 times more often than female pupils. They also publish information somewhat more frequently in data types: Friends and Apps & Games.

c) **Comparison of university students' publishing data.** In relation to male university students, somewhat higher percentage of female university students publish information in Reviews data type. Somewhat higher percentage of male students publish information in data types: College, Sports, Books, Hometown, Current City. Considerably higher percentage of male students publish information in data types: High School, Apps and Games, Music, Friends, TV Shows, Movies. On average, female students publish information considerably more frequently in Check-Ins data type where they publish about 3.5 times more often than male students. They also publish somewhat more frequently in Posts data type. On average, male students publish information considerably more frequently in data types: Sports, Apps & Games, Friends. Sports data type is by far the most popular type for publishing of information because male students publish about 8 times more often information in that type than female students. They also publish somewhat more frequently in data types: Movies, Music, Books.

B. **Some possibilities for using these findings and further research**

This study provided many insights about the characteristics of Facebook publishing behaviour of young people with regard to their gender. These insights could be helpful to create better educational programs for the improvement of privacy protection behaviour to alleviate risky information disclosure behaviour. For example, the focus of these programs could be on Facebook data types in which majority of male or female pupils and students are publishing much information (photos, posts, memberships in Facebook groups, interests: movies, music, books...). Based on insights from this study, young people educational programs could be made that are more adjusted to their gender. Various institutions (schools, universities, libraries, museums...), could use the findings to create more interesting and relevant programs with regard to their users’ gender. Promotion of various educational and other types of programs could also be improved when interests of young people of different gender (presented through their Facebook publishing behaviour) are more thoroughly known. Also, this study and its findings could be informative and inspirational for further research on the related topics. Facebook profiles of the same pupils and students explored in this study could be explored a few years from now to determine the extent of changes in their publishing behaviour. Additionally, Facebook data types that were explored in this study could be analysed by using the method of the qualitative content analysis. The research about adults’ publishing behaviour on Facebook could be compared with the behaviour of the young people of different genders. The comparisons of educational and cultural differences regarding the Facebook publishing behaviour are another way to broaden the findings related to this area.

**REFERENCES**

Abstract - In this paper, we have explored the extent to which faculty use different web sources of scientific papers, as well as their practices and attitudes related to availability and use of scientific papers. The questionnaire was sent to employees of the Faculty of Humanities and Social Sciences and the Faculty of Science at University of Zagreb. It was found out that majority of respondents use scientific papers on the web, several times a week. Google Scholar is the most used web portal for finding papers. Also, very popular are Croatian web portals. Pirate web portals (shadow libraries) are the least used, although almost half of respondents use them for various reasons: access to papers is expensive and not available; easy and fast access, etc. Only a small minority of respondents completely or partly agree that they are content with offer of international scientific journals and papers which are available in Croatia through subscription by scientific institutions. Through log analysis method, we also explored which scientific papers are requested in the Sci-Hub pirate web portal by users located in Croatia. Papers from Natural Sciences domain were most requested, while papers from Social Sciences and Humanities domains are not so often requested.

I. INTRODUCTION

Through the subscription of Ministry of Science and Education, Croatian faculty has an access to various databases of scientific journals. However, there is a problem with financing of this subscription. Therefore, the access to journals is limited. Availability of scientific journals is also problematic because higher education institutions don't have a lot of financial resources for subscribing to printed or electronic journals [1]. For example, Krajina and Markulin have established that the majority of libraries at the University of Zagreb doesn’t have an adequate budget for literature procurement. For many years Ministry of Science and Education has co-financed their procurement, but because of the reduction of those financial subventions, libraries had to reduce the number of their journal subscriptions [2]. The additional problem is that between various university libraries there is no coordinated purchase of journals and other literature, there is no agreement about the „library fond development (...), planning and rational budget spending, more comprehensive and faster addressing of user needs, avoiding of unnecessary duplication of information sources“ [2, 35]. Martek believes that the golden year of subscription to international scientific journals and databases was 2005 when many information sources were available to the academic community. Since then, the budget cuts have had considerable negative impact on the availability of international journals [3]. However, availability of Croatian scientific journals is very good, although it was not always like that. According to a study from the year 2002, among 223 analysed Croatian scientific journals, 120 journals or 54% had a web presence. Among these 120 journals only 21 or 18% were providing full text of papers [4]. According to study from the year 2009, a study conducted on the same sample of 223 journals, 174 journals or 78% had a web presence. Among these 174 journals 61 or 36% were providing full text of papers. An important factor is that 54 of those 61 journals were providing open access to papers [5]. The considerable improvement in Croatian scientific journal availability was made when the Hrčak web portal was launched in 2006. Hrčak is online journals platform which provided to publishers a simple tool for creating online open access versions of their journals. It included 170 open access (OA) journals and had an average of about 10000 unique visits per day in 2009. Approximately 50% of visitors were from Croatia [6]. On 29 January 2017 Hrčak included 430 journals with 165141 papers. From these papers 96.7% were in open access [7]. With Hrčak platform, which is supported by governmental funds, open access movement got a stronghold in Croatia. In the same period when Hrčak was launched, many government scientific agencies in the world have accepted or started to prepare the open access policy (UK, Germany, Austria, China, Canada, France, Sweden, USA...). Many OA archives began their work, as well as important online catalogs of OA archives: Directory of Open Access Repositories; ScientificCommons; OpenArchives.eu. In these catalogs, including the ROAR and OAISintr catalogs, the number of registered OA archives increased [8]. An important reason for the rise of OA movement was the unfavorable situation in academic publishing in which an oligopoly of large publishers was formed. For example, five big academic publishers have published more than half of all scientific papers in 2013. The largest academic publishers, such as Elsevier, Springer, Taylor & Francis, Wiley-Blackwell, Wolters, use their large market shares and influence to significantly increase subscription rates for scientific journals and databases. Academic libraries
and government agencies, especially those in financially lagging countries, don’t have budgets to pay subscriptions for many of these journals and databases [9]. Even universities in wealthy countries have financial problems to provide journal access for their faculty. Therefore, the scientific community began to protest against this situation as well as trying to find new ways to acquire access to scientific papers. For example, Harvard University faculty advisory council proclaimed that major scientific publishers had made scholarly communication fiscally unsustainable and academically restrictive. Therefore, the university wants its scientists to publish in open access journals [10]. One of the most recent initiatives of protest against excessive subscription prices is canceling of journal subscription of the Elsevier publisher by 60 major German research institutions. This cancellation was made at the end of 2016 and it will be continued until the acceptable subscription price is agreed [11]. Interesting idea is proposed in the analysis made within Max Planck Society in Germany. The authors of this analysis think that whole commercial, academic publishing could be replaced by open access publishing. They have calculated that if the libraries worldwide use entire budgets that they have yearly at their disposal to pay for scientific journal subscriptions, this would be sufficient financial resources to fund the work of OA journals in which all yearly production of scientific papers could be published [12].

Besides legal ways to access scientific papers, there is another way for faculty to access scientific papers. It is through pirate web portals which are called shadow libraries: „piratical text collections which have now amassed electronic copies of millions of copyrighted works and provide access to them usually free of charge to anyone around the globe“ [13, 75]. One of the largest shadow libraries is the Sci-Hub, which contains more than 50 million papers. Bohannon wrote that Sci-Hub was created in 2011 by Alexandra Elbakyan, who was then 22-year-old graduate student of neuroscience in Kazakhstan. According to the server log analysis of 28 million documents which were requested from the Sci-Hub in the period from September 2015 to March 2016, it was established that this shadow library has users in the whole world, that it has users from developing and most developed countries. At the end of February 2016, Sci-Hub received 200000 paper requests per day! Also, Bohannon found out that a quarter of the Sci-Hub paper requests were made by users from 34 wealthy countries that are members of the Organization for Economic Co-operation and Development [14]. Users from wealthy countries probably have solid legal access to the same papers but their motivation for using a Sci-Hub may be speed and convenience in accessing papers as well as the comprehensiveness of its database. An online survey of attitudes toward the Sci-Hub was made by Science journal. Based on nearly 11000 responses, here are some of the interesting insights: Nearly 60% of respondents used Sci-Hub; 88% think that it is not wrong to download pirated papers. This opinion is held even by respondents who have never used Sci-Hub or those who are older than 51; For more than 50% of respondents primary reason for using a Sci-Hub is lack of access to journals, for about 17% it is a simple convenience and for 23% respondents the primary reason for using a Sci-Hub is dissatisfaction with the large profits of publishers [15]. In one paper Sci-Hub usage data for Latin America was analysed. It was established that in Argentina Sci-Hub downloads represent 13.3% of downloaded papers in relation to the legal downloads made through scientific databases subscribed by scientific institutions of that country. The Sci-Hub use is considerably lower in Mexico – only 2.3% of downloaded papers in relation to the legal downloads [16]. Bodó emphasized that users from Central and Eastern European countries are among the biggest per capita users of shadow libraries. According to this author, shadow libraries are a crucial resource in the modernization of these countries [17].

II. RESEARCH

The research goal of this study was to explore the extent to which faculty use different web sources of scientific papers, as well as their practices and attitudes related to availability and use of scientific papers. In order to reach these insights, online survey was used. The information about this survey was sent in December 2016 to employees with teaching responsibilities at the Faculty of Humanities and Social Sciences [18], as well as at the Faculty of Science at University of Zagreb [19]. The survey was completed by 147 respondents who work in different domains of knowledge, primarily in Natural Sciences, Social Sciences and Humanities. Additionally, we used the log analysis method to explore which scientific papers are used in the Sci-Hub by users located in Croatia. Insights from this part of the research were compared with insights from the aforementioned survey of faculty practices and attitudes. The Sci-Hub is one of the largest shadow or pirate libraries found on the Internet. Data about the use of this library from 1 September 2015 to 29 February 2016, is publicly available on web in Sci-Hub server logs [20]. To protect the privacy of Sci-Hub users, no identifying internet protocol (IP) of users was published. Regarding the user location, only countries and approximate places of residents were published (nearest city or village) [14]. We analysed which papers from Sci-Hub were used in February 2016 by users located in Croatia. Two variables were used in the analysis: paper scientific domain and date of publishing.

III. FINDINGS

A. Survey of Croatian faculty practices and attitudes

The majority of respondents are female (60.5%). Also, the majority of respondents are 30 to 39 years old (39.5%), although there are more than 20% of respondents who are 40 to 49 years old, as well as those who are 50 to 59 years old. This means that the survey was filled up by faculty of various ages. The survey was filled up by approximately similar number of respondents from both higher education institutions. Most of survey respondents are working in domains of Natural Sciences (41.5%), Social Sciences (24.5%) and Humanities (23.8%). There is a small number of respondents from the domains of Technical Sciences (2%) and Interdisciplinary Sciences (5.4%).

MIPRO 2017/CE
In Table I we see that majority of respondents download and read scientific papers on the web, several times a week (42.2%). When we add to this group the respondents who daily use scientific papers on the web, it is evident that there is a huge share of respondents who are very active in using web for finding and reading scientific papers. Respondents who use scientific papers on the web, several times a month are also not infrequent users (25.2%).

### Table I. Frequency of downloading and reading scientific papers on the web

<table>

<tr>
<td>Not every month, but several times a year</td>
<td>5.4</td>
<td>8</td>
</tr>
</tbody>
</table>

In Table II we see that there is about 25 to 30% of respondents who never ask anyone to send them scientific papers from international journals (grade 1). About 30% of respondents almost never ask anyone to send them these papers (grade 2). Also, there are about 10% of respondents who very often ask paper authors or non-authors to send them these papers (grade 5). About 10% of respondents often ask for papers (grade 4). Respondents who are working in Natural Sciences will more often ask other people to send them papers and respondents who are working in Social Sciences are least prone to ask for papers. Also, there is a notable difference between male and female respondents with regard to asking for papers. In relation to male respondents, female respondents are about twice more often asking for papers (grades 5 and 4).

In Table III we see that most popular web portal for accessing scientific papers is Google Scholar. There are about 30% of respondents who very often use Google Scholar (grade 5) and about 10% of respondents who often use that portal (grade 4). Interesting fact is that female respondents are considerably more frequent users – about 40% of them very often use Google Scholar and about 20% of male respondents very often use that portal (grade 5). Also, popular web portals are at the Faculty of Humanities and Social Sciences (FHSS cat. / FHSS DB.). Its library catalog and database list are used very often for accessing scientific papers by about 25% of respondents and often by about 8% of respondents. Other web portals are less used, although there are about 15% of respondents who very often or often use DOAJ (Directory of open access journals) and NUL portal (National and university library portal). We also asked respondents to write the names of other web portals that they use. Following portals were mentioned most frequently: Research Gate (22 respondents), Science Direct (14 respondents), Hrčak (13), Academia.edu (12), Web of Science (12), Scopus (8), PubMed (7), arXiv.org (6), EBSCO (4), Google (4).

</table>

In Table IV we see how often respondents access papers by using two large shadow libraries or pirate web portals. The Sci-Hub is used very often by about 18% of respondents (grade 5) and it is used often by about 7% of respondents (grade 4). Library Genesis is used very often by about 12% of respondents and it is used often by about 5% of respondents. About 50% of respondents have never used Sci-Hub and about 65% of respondents have never used Library Genesis. It seems that these portals are predominantly used pirate web portals. Namely, we asked respondents to write the names of the other pirate web portals they use and only four respondents indicated other portals: Bookza, booksc.org, U2-translations, Bookfi.

</tbody>
</table>

In Table V we see that there are almost half of respondents who download and read scientific papers using the pirate web portals (46.3%). There are about 10% of respondents who daily or several times a week use these portals. About 15% of respondents use pirate web portals several times a month and about 18% of respondents use these portals several times a year. With regard to gender, there are about 15% of male respondents who use daily or several times a week these portals. About 40% of male respondents never use them. There are only about 10% of female respondents who use daily or several times a week these portals. About 50% of female respondents never use them. Respondents were also asked about reasons for using pirate portals. Following reasons were mentioned most frequently: papers are not available in any other way (28 respondents); legal papers are expensive (14); easy access (10); papers are available so
why not to use them (8); fast access (8); Ministry or scientific institution doesn't pay subscription (7); it's a matter of principle: science should be available to all (5); relevancy and huge quantity of papers (5). Additionally, we asked respondents who don’t use pirate web portals, about their reasons. Following reasons were mentioned most frequently: non-awareness about the existence of pirate web portals (11 respondents); availability of papers through legal web portals (11); it's an illegal activity / respect for the legal rights of authors (8); there is no need to use pirate web portals (7); colleagues are sending me papers (4).

In Table VI we see frequency of web portals usage. It was established that legal international web portals are mostly used: about 60% of respondents use these portals very often or often (grades 5 and 4). They are followed by Croatian web portals which are very often and often used by about 35% of respondents. Pirate web portals are the least used with about 25% of respondents who very often and often use these portals. It is interesting that respondents from Humanities domain are most often using pirate web portals – about 40% of them said that they are using them very often or often. About 20% of respondents from Natural Sciences and Social Sciences domains said that they are using pirate web portals very often or often.

In Table VII are statements for which we wanted to get opinions from respondents, regardless if they use pirate portals.

Regarding the Statement 1 we found out that about 45% of respondents completely or partly agree that it's OK that scientists read and download scientific papers using pirate web portals if they don't have access to these papers in no other way (grades 5 and 4). This interesting finding indicates that despite the fact that it is not legal, almost half of respondents have a positive attitude to using pirate web portals in case there is no other way to access literature. Regarding the Statement 2 we found out that about 37% of respondents completely and partly agree that papers which they read and download using pirate web portals are usually not available in any other way. Regarding the Statement 3 we found out that about 20% of respondents completely or partly agree that they use pirate web portals because it's a fast and simple way to access scientific papers.

authors (grades 5 and 4). However, only about 35% of respondents completely or partly agree that it's OK to use the internet to share for free the scientific papers of which they are not authors (statement 3). Interesting fact is that female respondents are considerably less approving of this activity – about 25% of them completely or partly agree with this statement, in relation to 40% of male respondents. Regarding the Statement 4, we found out that only about 15% of respondents completely or partly agree that they are satisfied with offer of international scientific journals and papers which are available in Croatia through subscription by scientific institutions. Most of them think that teaching and research in Croatia could be significantly improved if availability of international scientific papers is increased through this subscription. About 80% of respondents gave grades 5 and 4 regarding statement 5. About 73% of respondents completely or partly agree that subscriptions for databases with international scientific journals are too expensive (statement 6). There is also very large percentage of respondents who think that all scientific papers should be freely available to all who are interested, without subscription payment to publishers of scientific journals – about 70% of respondents gave grades 5 and 4 regarding statement 7.

B. Scientific domains and publication dates of Sci-Hub papers which are requested by users located in Croatia

We used log analysis method to explore which scientific papers are used in the Sci-Hub, one of the largest shadow libraries, by users located in Croatia. We analysed 886 papers regarding their scientific domains. That is a sample of about 25% of papers requested in February 2016 by users located in Croatia. It was found out that the papers from Natural Sciences domain were most requested (41.8%). Papers from Biomedicine and Healthcare domain are at the second place with 23% of requests, followed by requests for papers in the Biotechnical Sciences domain (12.2%). It is interesting that papers from the Social Sciences domain are not so often requested (10%) and that the papers in Humanities domain are requested in only 2% of cases. Also among less requested papers are those in Technical Sciences (8.7%) and Interdisciplinary Sciences (2.7%). We compared these insights about use of SciHub, with insights from the survey. Analysis of Sci-Hub server log shows considerable differences in frequency of use of papers from different scientific domains. For example, papers from the Natural Sciences domain are by far the most frequently requested papers. In contrast to these findings, survey results indicate that the majority of respondents from domains of Social Sciences, Humanities and Natural Sciences claim that they approximately equally often use the Sci-Hub portal: about 60% of these respondents are not using this portal and about 20% of respondents are very often using it. These survey results are in contrast with findings from server log analysis of Sci-Hub portal where it was found out that the papers from Humanities were requested by only 2% of users, papers from Social Sciences were requested by about 10% of users and papers from Natural Sciences were requested by about 40% of users.

We also analysed 1697 papers regarding their date of publishing. That is a sample of about 50% of papers requested in February 2016 by users located in Croatia. We found out that most recent papers are considerably more often requested. The largest percentage of requested papers is published in the most recent period from 2010 to 2016 (54.9%). After that, the most requested papers are published from 2000 to 2009 (24%) and from 1990 to 1999 (13.2%). There are only 4.7% of requested papers published from 1980 to 1989. There is very small percentage of requested papers published before the year 1979 (3.2%).

IV. Conclusion

In this study, we acquired various insights about availability and use of web sources of scientific papers by teaching and research employees of the Faculty of Humanities and Social Sciences and Faculty of Science at University of Zagreb. Additionally, we explored which scientific papers are requested in the Sci-Hub, one of the largest shadow libraries, by users located in Croatia. Here are some of the main insights from the research.

Respondents are very active in using web for finding and reading scientific papers. The majority of them download and read scientific papers on web, several times a week. About two third of respondents never ask or almost never anyone to send them scientific papers. Respondents who are working in Natural Sciences will more often ask other people to send them papers and respondents who are working in Social sciences are least prone to ask for papers. In relation to male respondents, female respondents are about two times more often asking for papers. Web portals which are used most frequently by respondents for finding papers are legal international web portals such as Google Scholar (indicated by respondents as most used international legal portal). They are followed by Croatian web portals. Shadow libraries or pirate web portals are the least used. Almost half of respondents download and read scientific papers using the pirate web portals, mainly for following reasons: papers are not available in any other way; legal papers are expensive; easy access; papers are available so why not to use them; fast access; Ministry and scientific institutions don't pay database and journal subscriptions; it's a matter of principle – science should be available to all. Pirate web portal Sci-Hub is used very often and often by about one quarter of respondents. The Library Genesis is used slightly less. These portals are the most used pirate web portals among respondents. Almost half of respondents have a positive attitude to using pirate web portals in case there is no other way to access literature. About one third of respondents completely or partly agree that it's OK to use the internet to share for free the scientific papers of which they are not authors. Female respondents are considerably less approving of this activity. A small minority of respondents completely or
partly agree that they are content with offer of international scientific journals and papers which are available in Croatia through subscription by scientific institutions. The vast majority of respondents think that teaching and research in Croatia could be significantly improved if availability of international scientific papers is increased through subscription.

Through log analysis method we explored which scientific papers are requested in the pirate web portal Sci-Hub by users located in Croatia. Papers from Natural Sciences domain were most requested – about 40% of all requests. Papers from Social Sciences domain are not so often requested (10%) and papers in Humanities domain are requested in only 2% of cases. These insights are in contrast with findings from the survey where respondents from all those scientific domains said that they use Sci-Hub with approximately equal frequency.

Findings from this study indicate that many respondents are very active users of legal and pirate web sources of scientific papers. Findings also indicate that there is a major problem with availability of papers from subscription journals and web portals. Although the vast majority of respondents think that the Ministry of Science and Education as well as scientific institutions don’t pay enough for these subscriptions, it is evident from the findings that there are other important issues beside payment problems. The majority of respondents thinks that all scientific papers should be freely available to all who are interested, without subscription payment to publishers of scientific journals. Open access journals could help to expand the availability of scientific literature. Croatian web portal Hrčak is a great resource of open access papers and proof that it is possible to provide scientific papers without involvement of profit oriented publishers. Also, university faculty has various approaches for acquiring papers which are unavailable through open access and commercial databases. Many of them are exchanging papers and visiting pirate web portals. We also found out that many are using legal web portal Research Gate to access papers. It enables authors to upload and give access to their papers even if they have published these papers in journals closed behind subscription paywalls. Use of Research Gate and similar participative, scientific web portals by Croatian faculty is an important activity which should be further explored. Other findings from this study should also be further explored to better understand ways of accessing the scientific literature by Croatian faculty. For example, the impact of the differences in gender regarding the use of scientific web sources, could be more thoroughly examined. Also, other scientific institutions could be included in future surveys to compare the activities and attitudes of faculty from various scientific institutions and domains. We hope that findings from this study will enable better understanding of various issues related to practices and attitudes of Croatian faculty toward web sources of literature.

Abstract - Mobile learning is growing in popularity as use of mobile devices by students worldwide increases. At the same time the number of digital information resources such as digital collections in libraries available online has also increased. Digital collections in libraries are valuable and proven resource of information in education. As students use mobile devices more frequently it is expected that use of digital information resources including digital collections in education will also increase. To achieve this goal user interfaces of digital collections must be developed in such a manner to be easily used, especially on mobile devices. This paper presents results of the research of elements of user interfaces of digital collections in libraries in Croatia available on the Web to establish the level of their mobile usability and accessibility as a prerequisite for their potential use in the learning process. To fulfill that potential, digital collections have to support different screen sizes on mobile devices and be accessible on new and old mobile devices, offer assortment of common functions to user etc. The results of this research will help librarians in planning further development of digital collections and educators in planning use of digital collections in their curricula.

I. INTRODUCTION

Mobile learning is growing more popular as value of the learning industry (especially in e-learning) is increasing [1] and as the number of advanced mobile devices owned by students with potential for use in the learning process in higher education institutions is also increasing. Mobile technology has a great influence on students: it changes “how they communicate, gather information, allocate time and attention, and potentially how they learn. The mobile platform’s unique capabilities — including connectivity, cameras, sensors, and GPS — have great potential to enrich the academic experience” [2]. The success of mobile learning depends on several factors like better and cheaper devices capable of accessing the internet; improved global network speeds; changing customer expectations; social media; the ability of learners to connect to the internet; and on content available online, usually on the Web either separately as a standalone Web site or as a part of an information institution holdings such as digital collections in libraries. Digital collections in libraries are highly organized information resources with user interfaces which are somewhat different from the interfaces of other Web sites so it may not be easy for users to access and use easily content in digital collections unless the user interfaces are carefully adjusted to user needs. Sandnes [3] suggested that content of digital libraries should be presented similarly (in all collections) as to create a holistic unified experience for users. In order to find out the current level of development of user interfaces of digital collections to the user needs, this paper will present results from the research study in mobile usability and accessibility of digital collections in libraries in Croatia accessible on the internet for the purpose of their potential use in education.

II. MOBILE LEARNING

Mobile learning presents a step forward in development of education during which educational institutions worldwide transform into true e-learning institutions. Mobile learning “is a type of learning whose learner is determined previously, is not in a specific location, or benefits the opportunities offered by mobile technologies” [5]. Behera [4] explained that “mobile learning is sometimes considered merely an extension of e-learning, but quality m-learning can only be delivered with an awareness of the special limitations and benefits of mobile devices” (mobile learning combines e-learning and mobile computing). By using mobile technologies (and the internet), mobile learning presents a learning model which allows learners to obtain learning materials anywhere and anytime [6].

Mobile learning includes “the exploitation of ubiquitous handheld hardware, wireless networking and mobile telephony to facilitate, support enhance and extend the reach of teaching and learning” [7]. By definition, this type of learning involves the use of different mobile technologies and communication technology (ICT) thus enabling earning anytime and anywhere (Mobile learning). Mobile learning implies use of mobile devices such as “laptops, netbooks, e-readers, tablets, mobile phones, smart phone MP3/ MP4 players and internet capable handheld devices” [9]. According to Choy [10], to be referred to as mobile devices, devices should have the following characteristics: telecommunication functions such as voice, email, data services (SMS); high speed access to internet; screen for viewing and interacting with multimedia content; able to run third-party software, with PC-like functionality; GPS functions and be highly portable, i.e. without being an extra burden when a person is moving about (not applicable to laptops and large e-
book readers). Mobile devices have become relevant in daily activities including the learning process because they are convenient to use and are highly portable; they are ubiquitous because almost anyone owns a mobile phone; mobile technology is a fast-changing as it develops all the time and becomes more sophisticated and user and eventually everyone will have a smart phone; they are multi-function computing machine [10]. Fast-changing technologies [11] could impose problems on teachers and learners because they cannot all obtain new devices fast enough, there are no pedagogical guidelines and experiences derived from research about use of new technologies and there is no adequate content prepared for use by new technologies at the moment they appear on the market.

Seppälä and H. Alamäki [12] analyzed mobile learning in educational activities and pointed out important features of mobile learning: teaching and learning outside classroom, moving to another location while communicating via information networks; it enables learners to enter an information network at the precise moment when necessary by using a portable learning device and a wireless network. Same authors also suggested that “mobile environment integrates studies that take place on campus, at home or outside university facilities into one shared, flexible learning environment” [12]. Ozdamli and Cavus [6] suggested the following core characteristics of mobile learning: ubiquitous, portable size of mobile tools, blended, private, interactive, collaborative, and instant information. Anilkumar [13] enumerated a number of advantages of mobile learning: convenience and flexibility, relevance, learner control, good use of “dead time”, fits many different learning styles, improves social, easy evidence collection, encourages reflection, supported decision making, speedier remediation, easily digestible learning, heightened engagement, direct interaction with learning, context sensitive learning etc. The learning process itself can unfold in a variety of ways under the influence of mobile technology: people can use mobile devices to access educational resources, connect with others, or create content, both inside and outside classrooms. Furthermore, mobile learning has become common and is gradually becoming ubiquitous because it does not “separate the learner from their normal activities or routines; learning can be delivered in a manner that either enhances such activities or allows them to occur in tandem with that process” [14]. Learners can learn using mobile devices anytime and anywhere and be not restricted to a particular locations or a time schedule; they can be more engaged and self-directed in learning because he/she can self-tailor his/her pace [10].

Finally, mobile learning cannot be effectively carried out without content. Content is one of basic elements of effective mobile learning which (in addition to content) also include learner, teacher, environment and assessment [6]. Quality learning material needed in education can be found in digital collections in libraries. The purpose of development of digital collections in libraries is to make their content available for use in different contexts. One such context is mobile learning.

### III. Digital Collections

During the last two decades, libraries have changed significantly, from centuries old information delivery through printed materials to delivery through computers to the desktop of the user and, most recently, directly to the users’ mobile device thus freeing the information consumer from his desktop and fixed location [10]. As the number of mobile devices in the general population increases, so increases the demand for digital content adapted for use on these devices. In libraries tablets and smart phones are used for browsing online content, downloading, streaming and lending digital content from libraries as well as searching a database, downloading articles, seeking catalogs, access documents, including e-books, audio-visual objects and Websites [9]. Saxena and Yadav [15] investigated library services accessible on mobile devices and found out pros and cons of such use of library resources and services. The pros were: user-friendly aid; personalized service; ability to access information; time saving; user participation; location awareness; limitless access; access to print-disabled users. The cons were: compared to wired internet service, mobile services have relatively slow transmission speed; limited computational power; inconvenient input and output interface; insufficient contents and high price.

As much as digital content could be found anywhere on the Web, in this paper special attention is paid to digital collections in libraries as a measure of the content quality because everything that is included in digital collections goes through the process of a careful selection done by library professionals. The content is then used in libraries, at universities, at home and elsewhere. Availability of access to digital collections is particularly important for distance learners interested in library collections [16]. That is the reason why libraries are very important stakeholder in the learning process because they “could provide access to resources tailored to mobile devices and services to guide users in their self-directed learning effort” [10].

To become more accessible to students (i.e. to be reachable online) on all levels of education, the access to the digital content in library collections should be also adapted for use on mobile devices. Since digital collections in libraries are accessible mostly on the Web (and some are accessible only locally in libraries on dedicated desktop computers), their use has become part of the Web content use paradigm. Therefore, the rest of the paper will focus on usability. Aldrich [17] offered some key thoughts about the relation between the Web and mobile devices by pointing out the mobile Web characteristics and ubiquity because of which the mobile Web has become an integral part of the devices used to access it “to the point that the mobile Web refers to any Web-based content or function configured for access through mobile devices” [3]. One of the biggest problems in use of the Web is it inconsistency in content organization and use. Use of digital content on mobile devices on the Web depends heavily on Web page design.
which must present consistency in domains of appearance, controls, and functions [18]. Furthermore, user “(...) want to control graphical quality, typography, window size, location of information within a window, and everything that is important in good design” [18].

IV. USABILITY

Use of Web based content is closely related to the concept of usability. Usability is “generally regarded as ensuring that interactive products are easy to learn, effective to use, and enjoyable from the user's perspective” [19]. The goals of usability are usually the following: effectiveness, efficiency, safety, utility, learnability and memorability [19]. The most common method for achieving usability is user-centered design which includes “user-oriented methods such as task analysis, focus groups, and user testing to understand user needs and refine designs based on user feedback” [20].

The user centered design consists of the following phases or stages: 1) specify the context of use: identify the people who will use the product, what they will use it for, and under what conditions they will use it 2) specify requirements: Identify any business requirements or user goals that must be met for the product to be successful 3. create design solutions: this part of the process may be done in stages, building from a rough concept to a complete design 4) evaluate designs: evaluation - ideally through usability testing with actual users - is as integral as quality testing is to good software development” [21]. A special attention should be given to user preferences when accessing digital content in libraries on mobile devices of users because different mobile devices have different screen sizes, orientation (portrait or landscape), users use them to access the content with different network speed, software and context of use [22] thus having different user experience. User experience “refers to the overall experience users have when using a service. User experience is a very wide ranging concept but it is often associated with aspects of usability in relation to Web based services” [23]. To improve the user experience of use of a digital collection, one needs to consider the needs of your users, how they find and navigate your collections, and the tasks they go on to complete as a result [23].

McCray and Gallagher [24] recommended that every digital library (which contains digital collections) development should follow ten principles: 1.) expect change, 2.) know your content, 3.) involve the right people, 4.) design usable systems, 5.) ensure open access 6.) be(a)ware of data rights, 7.) automate whenever possible, 8.) adopt and adhere to standards, 9.) ensure quality, 10.) be concerned about persistence. As we can see, design of a usable system is one of the key points in digital library development.

V. MOBILE USABILITY RESEARCH STUDY

The goal of this part of the paper is to present results of the mobile usability test of user interfaces of digital collections in Croatian libraries accessible online.

The main idea for this research was taken from the article “Mobile Usability in Educational Contexts: What have we learnt?” written by Kukulska-Hulme [26] who suggested that mobile usability is not researched frequently and that its goal is to improve usability of the user interface or content which must adaptable to, or by, the user of the mobile device. The research hypothesis is that the user interfaces of digital collections in the Croatian libraries are not ready for use on mobile devices. The goal of this research was to detect problems in access to digital collections by use of mobile devices and to help librarians (digital collection developers) and their IT colleagues to develop digital collections highly usable by mobile devices.

During the initial phases of development of digital collections in libraries, mobile devices used today didn’t exist at all. It wasn’t until recently that library users started to access digital collections content more frequently by mobile devices. This triggered researches with focus on different but complementary issues in access to digital content for the purpose of learning. Wagner [26] analyzed implementation of mobile learning and selected a group of attributes related to the rich mobile internet experience in access to digital content. Since digital collections in libraries are accessible on the internet, most if not all suggested attributes are applicable to library digital collections and could be included in mobile usability testing to a degree: ubiquity, access, richness, efficiency, flexibility, security, reliability and interactivity. Authors like Saxena and Yadav [15] analyzed library services accessible via mobile technology and offered the following list of what such library services should offer: SMS notification services, formal education, distance learning and e-learning, database browsing, my library, e-resources with mobile interfaces, library guide, mobile document supply, text reference service, library virtual/ audio tours, QR codes on mobiles.

These examples served as a foundation for the mobile usability research study in the following part of the paper which aims to answer the following questions: 1.) are Web pages of digital collections developed for use on mobile devices? 3.) which additional Web page options or functions are available for easier viewing of the content of digital collections that can also contribute to the better functionality of digital collections? Seventeen digital collections accessible online in the Croatian libraries were selected for this research. The list of digital collections for this research was created from information about all available digital collections at the portal of Public libraries in Croatia at http://knjiznica.hr [45]. Additional digital collections in libraries in Croatia were found by help of the Google search engine. Due to space restrictions, names of digital collection in tables were replaced by numbers from the following list: Digital library SveVid (1), Digitized Rijeka newspapers (2), ViZZ – Virtual local collection (3), Istrian newspapers online (4), Digitized Šibenik library material (5), „DELMATA“ digital collection (6), Digitized local collection Spalatina (7), Split university library digital collections (8), Dubrovnik library (9), City library Poreč...
digital collections (10), DIKAZ – Digital library Zadar (11), Digital collection HAZU (12), Digital Zagreb heritage (13), Faculty of Humanities and Social Science Zagreb – repository (14), Exam literature digital collection at the Faculty of Humanities and Social Science Zagreb (15), National and university library Zagreb – digital collections (16), City library Vinkovci – digitized library material (17) [28-44].

Criteria for the analysis and comparison of the digital collections user interface elements were formed on the basis of previous use of digital collections by authors of this paper. Without the elements listed in tables 1 and 3, digital collections would lose some if not most of their functionality and usability. The research results in tables 1-3 show whether or not this is true for 17 digital collections. They were accessed, analyzed and compared by use of an actual mobile phone or a mobile phone emulator. JavaScript and HTML5 were tested by use the Website http://builtwith.com on a mobile phone.

Table 1 presents results from digital collections user interface elements basic functionality test. The results indicate that one of the main functions - download of the digital collection content - is supported by 10 out of 17 (58,8%) digital collections which is very favorable for digital collections users. Web technologies such as HTML5 and Javascript were represented differently in the researched digital collections. HTML5 was not used in any of 17 digital collections while JavaScript was used in 13 out of 17 digital collections (76,5%). Search of the content was possible in 14 out of 17 (82,4%) digital collections and advanced search was fully supported in 7 (41,2%) digital collections, not supported in 9 (52,9%) and partially supported in 1 (5,8%) digital collection. Indexing as „a process of establishing access points to facilitate retrieval of records and/or information“ [27] was present in 14 (82,4%) digital collections while metadata were included in 11 (64,7%) digital collections. Metadata search was possible in 10 (58,8%) and not possible in 6 (35,3%), and partially possible in 1 (5,8%) digital collection. The researched digital collections also supported categorization of the content: books, magazines, picture categories were found in 11 (64,7%) digital collections.

Table 2 represents the results of the research of adaptability of the user interfaces of the selected digital collections for use on mobile devices of different screen sizes. In addition to use of actual mobile phone for research, Google Chrome extension called Mobile/Responsive Web Design Tester was also used to emulate mobile devices with three most commonly used mobile device screen sizes: iPhone 6S (4,7’’), Sony Xperia M4 Aqua (5,0’’) and LG G3 (5,5’’). Research showed that only 2 out of 17 (11,76%) pages were prepared for use on smaller screen sizes though the same content was not displayed identically or even similarly on screens with dimensions of 4,7’’, 5’’ and 5,5’’. Ten out of 17 (58,8%) digital collections were not prepared for use on mobile devices so actual use of these digital collections was possible but required additional vertical and horizontal scrolling as if there were used on a desktop PC. Another method was use of the zooming option in the Web browser to scale the Web page for normal use. Such Web page use was difficult because with every click on the Web page of a digital collection it was mandatory to use the zoom option again. In case of 5 out of 17 (29,41%) digital collections, Web pages were extremely difficult to use because parts of their content were not displayed on mobile device screen correctly or Web page parts overlapped.

</table>
The following functions were observed: turning pages, jumping to particular page(s), zooming, rotating the digital object, objects filtering, printing, pure text viewing and reduced view of objects parts. Larger number of the researched digital collections provided the possibility of turning the pages function (most commonly represented in form of icons of left and right arrows). In one digital collection the function of turning the pages was enabled in form of paging of individual pictures which was not common but pages could still be turned, while in 4 other collections digital objects were available in pdf format where turning pages is accomplished by scrolling pages. In most digital collections jumping pages was not possible which made use of these digital collections harder (if an user needed to jump on page 345 of some book in 9 out of 17 (52,94%) digital collections this would require turning page by page until the desired page appeared). The zooming function has a big importance and impact in use of digital collections because letters on the Web page can be small and hardly legible or pictures can contain details which are impossible to see on a small screen. Three out of 17 (17,64%) collections did not offer the zooming function. Similar result was found when digital collections were searched for the rotating function. Five digital collections (29,41%) did not provide this function. Six out of 17 (35,29%) digital collections provided the function of getting the editable clear text out of digital objects which is useful. Only one digital collection (5,88%) showed clear text as a default option. Eight digital collections (47,05%) offered the printing function. The scaling function for pictures of digital objects were provided in 14 out of 17 (82,35%) observed digital collections. The worst situation by far appeared during the attempt to filter the digital collection content. This option was provided only in 1 out of 17 (5,88%) observed digital collections.

VI. CONCLUSION

As mobile learning gains more popularity, many scientists and educators put a number question about its implementation in different learning environments, scenarios and contexts. Ozdamli and Cavus [7] summed up their vision of achieving efficient results and the maximum performance from students using mobile learning in education in the following inspirational statement: “each of the elements of mobile learning should be prepared carefully, and the mobile learning characteristics should be planned and prepared with a knowledge of the teaching medium, learning environment and the learning activities. Otherwise, positive results cannot be expected from the mobile application”. By having these thoughts in mind as well as the results of the mobile usability research study, we can conclude that the most of researched digital collections are not developed for use on mobile devices and that some elements of user interfaces in the observed digital collections are still underdeveloped and important options and functions are
still unavailable to users which confirms the research hypothesis. Consequently, the potential of digital collections for use in education is still underused. Time waits for no-one, and libraries should increase their active involvement in education and understand their important role in providing support to mobile learning.

Abstract – All aspects of society are constantly developing while adapting to the challenges of the modern world. Education is also included in this continuous process of transformation with the emphasis on the fast information retrieval and acquisition of knowledge from multiple resources. Young people live in a digital environment where they are constantly available on some digital device. This paper presents research on the use of information and communication technology (ICT) in education. Attitudes towards the use of technology in the English language classroom were tested among elementary students. Several surveys were conducted to compare the attitudes of students who use tablets in classrooms on the daily basis with those of students who have only experienced one lesson using tablets. The results suggest that the use of ICT in education is perceived more positively among those students who use technology in their classrooms on the daily basis.

I. INTRODUCTION

The development of the Information and Communication Technology (ICT) has affected many different aspects of the society. In the last two decades, the use of ICT has completely transformed almost all forms of social and business endeavours [1], including education. Moreover, learning and teaching has been enhanced with its dynamic and interactive contents [2]. It fosters students' skills and motivation, places them in the centre of that process, forming autonomous and ambitious students. Furthermore, by using technology in the classroom students learn how to relate to the working practices [3], and lifelong education. This all indicates a crucial need to integrate ICT in modern educational system, and numerous educational institutions have already been equipped with computers and digital devices.

Today's students mostly belong to the generation of digital natives - those who own a digital device and spend hours using it every day [4]. As digital natives, students have already developed skills they need to handle such devices. Implementation of technology in classrooms simply enhances those skills. Numerous studies were conducted exploring the impact of the use of ICT on students' motivation [6] and achievement [5], [7], and testing the attitudes of teachers and students [8] towards its application in classrooms. One of the possibilities for ICT implementation are tablet computers.

This paper presents a research on application of the ICT on foreign language teaching. It aims to increase the awareness on the importance of the use of technology in second language learning and teaching in primary schools. Since the use of tablets for learning and teaching has just recently begun in Croatia, this paper proposes a possible way of using these devices to enhance the language teaching. A lesson using exclusively ICT had been prepared for English language learning and conducted in one of the Croatian primary schools.

Moreover, the purpose of the described research was also to test elementary students' attitudes towards the use of technology in classrooms and to explore possibilities of developing more positive attitudes towards the integration of ICT in classrooms.

The paper is organized as follows: Section II gives background information focusing on the ICT implementation in Croatian schools while Section III describes the research methodology. Section IV presents and discusses results of the three surveys that had been conducted to test students' attitudes towards the benefits of ICT application in English language classroom. Section V concludes the paper.

II. BACKGROUND

There are several ongoing projects with the aim of ICT implementation in Croatian schools. The Croatian Academic and Research Network (CARNet) has initiated e-Schools: a comprehensive informatization of school operation processes and teaching processes, with the aim to create digitally mature schools for the 21st century. The e-Schools programme is carried out through several projects aimed at introducing ICT into the school system in the 2015-2022 period. The e-Schools project is part of a wider e-Schools programme. The full name of the project is "e-Schools: Establishing a System for Developing Digitally Mature Schools (pilot project)". The abbreviated name of the project is the 'e-Schools pilot project'. The specific objective of the e-Schools pilot project is to pilot organizational, technological and educational concepts of introducing ICT in the educational and operational processes in selected schools during two school years and to develop, based on the experience of the pilot project, a strategy for the implementation of a system of digitally mature schools in the entire primary and secondary education system in Croatia [9].

There are 150 elementary and high schools participating in this project. The process of equipping schools include the development of a local network, the
equipping of classrooms with ICT equipment and the equipping of the teachers and administration staff with hybrid computers, laptops and tablets. Schools within the pilot project will also be equipped with two different types of classrooms, a presentation one (equipped with a PC computer, a touch screen monitor and loudspeakers) and an interactive one (equipped with 30 tablets and the presentation equipment) [10]. Also, there are educational activities and organised support for teachers and learning materials for students.

Another programme was initiated in cooperation with Apple. Since 2012 elementary school Vežica has been the part of Apple Lighthouse Schools. In this programme, the school was equipped with Apple technology (iPad tablets, etc.). Thus, Vežica became the first public elementary school in Croatia, and second public school in Europe to integrate iPads in classrooms [11]. Lessons from each subject are assisted with interactive learning contents, multimedia and Internet. Learning materials and assignments are sent to students’ e-mail addresses, and tests and readings are accessed online. Moreover, students acquire digital competences they need for the future [12]. Apple is included in similar projects, equipping and transforming education in USA.

E-Schools presents a global challenge, accepted by many different countries. Through its 2008 e-Solstvo project, the Republic of Slovenia prepared comprehensive digital content for the curricula of primary and secondary schools, which it offered to the entire educational system, and wider – as open educational resources under the Creative Commons licence. On the other hand, in 2012 the Polish Council of Ministers approved the national programme "Digital Schools" aimed at developing digital competences of students and teachers in the application of ICT with four component (e-teacher, e-student, e-textbook and e-school) [13].

### III. METHODOLOGY

#### A. Participants

This research encompassed two groups of participants; all eight graders from the elementary school Vežica in Rijeka, Croatia. The research was conducted in 2016. Participants in the first part of the research were students attending traditional classes. They use textbooks and notebooks. They don’t use technology in classroom, except for the occasional use of computers and projector. These students filled in the survey, testing their attitudes towards the use of ICT in education, immediately before the English language lesson in which they have for the first time used only ICT in language classroom. At the end of the lesson, the same group of students has again filled in the survey (henceforth: first group). There were 16 students who filled in the first survey. At the lesson were present 14 students (8 boys and 6 girls), who immediately after the lesson filled in the second survey.

Participants in the second part of the research were students who for longer time period (few years) use tablets in classroom (henceforth: second group). These students have also filled in the survey testing their attitudes towards the use of ICT in education. There were 10 students (8 boys and 2 girls) who filled in the last survey.

#### B. ICT enhanced lesson

English language lesson was held in June 2016 in elementary school Vežica in Rijeka, Croatia. During the lesson, iPads, PC and projector were used in school’s computers classroom. The content of the lesson was completely adjusted to the use of ICT in classroom. These students used tablets during the English language lesson for the first time.

The unit In sync with your parents, listed in course syllabus, was covered in this lesson. Using Articulate Storyline 2, lesson materials were prepared and presented on iPads. Before the class, the browser Articulate Mobile Player was installed on all tablets. This browser enabled teacher and students to view materials prepared using software Articulate Storyline 2. After the installation, materials needed for the lesson were downloaded and opened. The lesson material was prepared in digital format. Each click opened new content (including images that resemble phrases, additional descriptions, or audio and video clips). Moreover, new types of exercises, available only on digital devices were added (including pick many, drag and drop, and hotspot). This way the lesson was made more interesting and familiar to students.

At the beginning of the lesson, students were given iPads. Application Articulate Mobile Player and the material needed for the lesson were already lunched. The lesson started with a short revision. Students were given three different sentences with the same bolded phrase and different images describing it. After short class discussion, they came up with the meaning of the phrase, and then solved multiple choice exercises. The same pattern followed revision of all phrases covered in the previous lesson. In order to test students in their understanding of the specific words or phrases, the revision ended with two extra tasks. In the pick many task, students were asked to pick all the images that presented people who were in sync with others. In the hotspot task, students marked the picture that best described given words. They were only allowed to continue to the next slide, once they had solved the task correctly.

The main part started with the class discussion. Slide with question and central image opened up. Students were instructed to click on the image and then additional images appeared providing more ideas for the discussion (Fig. 1). Furthermore, images were followed by the list of adjectives describing characteristics of parents and children. Click on each adjective opened its definition (Fig. 2). After discussing all the adjectives, students were asked to sort them in two categories (positive and negative) in the drag and drop task (Fig. 3). Listening was accompanied with the two types of tasks: sorting and matching. In the first, students listened and sorted sentences in the correct order, and in the second they matched the expressions in the two columns. Before the video, students were presented with a family photo. Click on each member of the family opened different slide with their perspective on the family.

The lesson ended with a short video in which teenagers, native speakers, described their families. The video was accompanied with pick many and drag and drop exercises.
C. Surveys

Three surveys were conducted in order to test students’ attitudes towards the integration of ICT in classrooms. Participants who have for the first time experienced the lesson using exclusively ICT filled in the first two surveys. Second group of participants, those who attend such lessons every day, filled in the third survey in order to compare their attitudes with those of the first group. The first survey was divided in two parts. The first part questioned students’ acquaintance with the technology, whether they had a digital device, how much time they used it every day, and for what purposes. In the second part of the survey, using Likert scale, students expressed their attitudes towards given statements in order to test their general attitudes towards the use of ICT in classrooms. All 9 statements are shown in Table 1. In the second survey, students were asked express their attitudes towards the conducted lesson and ICT used in the classroom. All 13 statements are shown in Table 2. The last part of the survey offered the comment section where students were asked to write additional comments on the conducted lesson.

The third survey was also divided in two parts. The first part questioned students’ spare time and classroom technology habits. The second part offered 23 statements on the use of ICT in language classroom. All statements are shown in Table 3.

In all three surveys, students expressed their attitudes on given statements using the 5-point Likert scale (1 – Strongly Disagree, 5 – Strongly Agree).

IV. RESULTS AND DISCUSSION

According to the results of the first survey, which was filled in by the students who attend traditional classes without the use of ICT, all respondents own a digital device (PC, smartphone or tablet). At their own estimation, most of those students (37.5%) spend 1-2 hours each day using some of the digital devices. Moreover, none of the respondents spend less than 30 minutes using technology each day. At home, only 25% of respondents use digital devices for learning, while the remaining 75% use technology for entertainment (watching movies, social networks, etc.). At school, students who attend traditional classes only use computers in IT classes. On the other hand, students from the second group, besides using computers in IT classes, also use tablets in all other classes. On the other hand, general attitudes testing of the first group of students towards the use of ICT in classrooms offered divided results. Students mostly agree with the general advantages of the use of ICT in classrooms. However, they still prefer traditional classes. This can be seen from the results presented in the Table 1. Percentages for scale elements (1-5) are shown together with average result and standard deviation.

After the students had for the first time experienced English language class with the use of tablets, they filled in the second survey. Results of the survey are shown in the Table 2. In comment section of the survey, 78.57% of respondents had positive comments on the conducted lesson. Most of them mentioned the use of iPads, interesting exercises and easier acquisition of lesson as positive aspects of the lesson. On the other hand, students who did not enjoy the lesson, mentioned that they prefer classes without the use of iPads.

When expressing their general attitude towards the integration of ICT in classrooms, first group mostly agrees with the statements that technology makes learning easier and the information retrieval simpler. However, they express more positive attitudes towards traditional classes. Even though the students mostly agree with the statement that the technology facilitates learning, they claim that they learn better using textbooks than technology.
Most respondents from the first group agree with the statement that the technology interferes with learning and lead to frivolous education. Most of them prefer traditional classes because they know exactly what they are expected to do and how they need to learn. Therefore, before preparing the lesson, teachers should analyse their classes and students, and adapt the lesson materials to their needs. At the beginning of the lesson, students should be notified on the content and expected outcomes. Also, it is important to explain evaluation and assessment criteria clearly and in detail. Students pay more attention to the different options technology offers than the very content they should learn. Therefore, teachers must ensure that computers and tablets are not used in a way that distracts students from the learning process.

After the lesson was conducted in the first group of respondents, most students expressed that they enjoy watching videos on tablet. They find it more interesting to do exercises on tablets. Many students prefer traditional classes because they know exactly what they need to learn. At the beginning of the lesson, students need to be educated in the use of technology before its integration in classrooms. But it is important to say that students quickly grasped the principle, and once they had correctly grasped the principle, they could easily solve the exercises, most of them assuming that they would solve them again.

</tbody>
</table>
Taking into account that students find new types of exercises and watching videos more interesting than traditional lesson materials, it might be that the integration of more innovative lesson materials and new activities would lead to more positive attitudes towards the use of ICT in English language classroom. Some of those activities in language classroom include digital storytelling, vocabulary games (e.g. memory game), recording and listening to different speakers, and watching documentaries. Even though most students found it hard to click and follow the lesson simultaneously, the whole lesson was held in English language and there was no need for additional instructions in Croatian language. Moreover, students had easily realized the principle how the materials were designed and by the end of the lesson they were able to do the tasks individually.

The results of the first two surveys conducted in the first group of respondents, show that positive experience in using technology in classroom influences the change of attitudes of students. Most of students who expressed positive comments on conducted lesson, also expressed more positive attitudes towards the use of tablets generally in education. In order to test if the positive attitude is related to the habit and experience in using technology in classrooms, another survey was conducted in second group of respondents. This group is comprised of eight grade students who use tablets in classroom since their fifth grade. All second group respondents confirmed that they use tablets in each English language lesson. They named several applications they use in their lessons, including iTranslate, Edmodo, Quizlet, iMovie, Keynote, e-udžbenik, and Sketch.

</tbody>
</table>
According to the survey results (Table 3), students who actively use ICT in classrooom on daily basis have more positive attitudes towards the use of technology in education than the first group. Most of them agree that technology makes information retrieval simpler; they find clicking more enjoyable than writing in notebooks and reading textbooks. Moreover, unlike the first group, clicking does not hinder them in following the lesson. Most of them find the use of tablets in English language classroom more enjoyable, and they claim that tablets offer more possibilities than the traditional textbooks for the foreign language learning. Yet, they think that they learn better using textbooks. On the other hand, while the first group expresses completely divided attitudes, majority of the second group expresses positive attitudes towards the use of tablets in English language classroom and they mostly agree with the statement that all schools should use tablets in language classrooms. These results show the importance of experiencing such classes. Students need to become accustomed to the use of ICT in classrooms, students' relationship with technology in classrooms is developing, and the benefits of ICT implementation are recognized after longer period of time. Also, after just one positive experience, many students show approval of this ways of teaching. Therefore, ICT implementation in classroom should begin with useful and interesting activities at very beginning in order to assure the first positive experience that will motivate students for future uses of the technology in education.

Moreover, it is also important to mention that implementation of technology in classrooms imply more than just purchasing devices and equipping schools. Different ways of teaching require appropriate strategies, tools and resources. Therefore, teachers need additional education to acquire knowledge and skills needed for the successful implementation of ICT in classrooms. Moreover, there needs to be a detailed plan for the use of technology in education with respect to pedagogical and didactic principles. Although the final goal of using technology is to facilitate the process of learning and teaching, it is necessary to invest time in preparation so that the use of ICT would give successful results in classroom.

V. Conclusion

This paper presents the results of the research that investigated the difference in attitudes towards the use of ICT in classroom, of students with different prior experience in use of ICT in classroom.

This research showed that students who use tablets in classrooms on daily basis have more positive attitudes towards the use of technology in classroom than the students who attend traditional classes. However, attitudes of those students have become somewhat more positive after their first English language lesson that was held exclusively using ICT within this research. With the implementation of these devices in classrooms, students would be presented with new and advantageous ways of using technology. Although students mostly own and use those devices every day for entertainment, they lack the experience of the use of technology in classrooms.

Since this research was conducted with the small sample, future research will include bigger sample. Furthermore, it is questionable whether the prior experience of using ICT in classroom has effects on students' achievement. In that sense, future research would investigate the achievement of students learning the same content in four groups: with/without ICT for students who attend traditional classes, and with/without ICT for students who use ICT in classroom. Moreover, the investigation should include the impact of the use of other aspects of ICT (besides tablets) on students' attitudes towards the use of ICT in classrooms. Additionally, future research will also investigate students' motivation for active interaction in the classroom, with ICT as motivating factor.

REFERENCES

Abstract - Plagiarism is unethical behaviour that can have negative consequences on the development of science and society. It also ruins the reputation of individuals and institutions. Plagiarism can be intended or unintended. The paper will focus on unintended plagiarism that is a result of absence of that topic in the education curricula. Teaching about plagiarism is part of so-called ethical literacy that is a subcategory of information literacy. A survey was conducted with the aim of finding out about the degree of knowledge about plagiarism among the students of Library and Information Science at the Faculty of Humanities and Social Sciences, University of Zagreb. The analysis is based on an anonymous web questionnaire with 20 questions. The presumption is that the students do not know enough about plagiarism, they have not had any experiences with plagiarism during their education and they do not know what self-plagiarism is. Another presumption is that the students get detailed instructions about how to cite sources, but do not know enough about the concept of authorship. The conclusion will be made about the inclusion of this segment of information literacy in education curricula. New surveys will be proposed (on local and national level).

I. INTRODUCTION

In the networked environment, students have access to enormous amount of information. That can be a good thing if they understand what research integrity is, so they can act ethically. However, there are many challenges in the electronic environment (easy copy-paste solution being one of them). In this paper, we will not focus on intended unethical practices, but on the unintended ones. Unintended practices in the field of research integrity are based on the lack of education about ethical issues. The aim of this research is to give a short overview of literature about students’ understanding of plagiarism and authorship, to present the results of a survey of graduate students of Library and Information Science; and to conclude about their understanding of some ethical issues in academia.

Olson and Show [1] show that children at the age of 5 or 6 are capable of understanding the originality of ideas – they consider characters that copied other characters’ words as “bad”. Based on the study, Bailey [2] concludes that the best time to start plagiarism education is in the third grade (age 8). The education has to be well planned. Bailey also poses a question about the generation gap – how is it possible that young children understand the value of originality and students lose the understanding (as many studies and practices show)?

II. LITERATURE OVERVIEW

McCabe [3] conducted several longitudinal researches about academic dishonesty and cheating among students. A part of one of his researches was about North American undergraduate and graduate college students and their practices in written assignments. 36% of undergraduate students and 24% of graduate students have, at least once, copied or paraphrased Internet sources without giving credits to authors (i.e. without citing the sources). At the same time, 58% of undergraduate and 62% of graduate students think that such a behaviour is not appropriate. Risquez et al. [4] found out that 75% of students had high ethical awareness that copying text without citation was wrong. Armstrong and Delbridge [5] found out that 30-55% of students from the field of Information Science admitted minor plagiarism activity (e.g. copying a small part of another student’s paper or inclusion of a quote without in-text citation). Major plagiarism activity is reported by 9-20% of students (e.g. buying an essay from a writing service or unacknowledged summarizing of a large amount of published work). According to the survey, the first reason why students commit plagiarism is easy access to online material and the second is that they do not know what plagiarism is. They plagiarize mostly because of pressure to complete their assignments and because of poor time management skills.

Analysing the reasons for cheating and plagiarism, Dorman et al. [6] conclude that the main reasons are misunderstanding of the assignment and running out of time. Some other reasons could be lack of research skills, problems with evaluating sources, confusions about terminology, confusions between plagiarism and paraphrasing, careless notetaking, confusions about how to cite sources etc. [7]. There are four main forms of plagiarism among students [8]:
1. intra-corporeal (students cheat by copying from their colleagues in the same class);
2. collusion (student presents the paper as his own, but in fact it is the result of cooperation with another person who is not stated as a co-author)
3. extra-corporeal (students cheat by copying from external source, e.g. book, journal or a web site)
4. self-plagiarism (or auto-plagiarism – students use their own works previously submitted for another assignment without acknowledgment).
Kokemuller [9] writes how plagiarism affects students. They can fail an assignment, fail a class or even be suspended. Besides destroying student’s reputation, there can also be legal and monetary repercussions. Sometimes, if the students are involved in medical researches, plagiarism can cause the loss of human lives [10].

When students’ papers are published, authorship should be properly assigned. There are four main authorship criteria according to ICMJE: substantial contributions to the conception or design of the work; drafting the work or revising it critically; giving final approval of the version to be published; agreement to be accountable for all aspects of the work [11]. American Psychological Association (APA) published guidelines on determining authorship credit and authorship order for students [12]. The guidelines are based on the APA code of ethics. The most important is an open discussion on authorship issues among all the students and/or researchers involved in a project. In addition, student should be listed as principal author on an article based on the students’ thesis. It is possible to use authorship agreements to outline the types of contributions (responsibilities, roles, efforts etc.). Wager [13] thinks that listing contributions can make easier for editors to detect ghost authors. Ghost authors are those authors who made substantial contributions to the paper (they meet all the authorship criteria) but are not listed as authors [14]. Other forms of unacceptable authorship are honorary or guest authorship (authorship is granted out of respect) and gift authorship (offered from a sense of obligation to a person who has not contributed to the work).

Oberlander and Spencer [15] discuss how students are a special group within research community when it comes to authorship. They are in relationships with their mentors where there is a possibility of exploitation [16], because of students’ inexperience and their lack of knowledge. Oberlander and Spencer think that the best solution to discourage inappropriate authorship is education of students (as possible future scientist). They also give some recommendations for students as co-authors and for their mentors. Some of them are:
1. authorship guidelines from professional organizations and journals should be consulted
2. authorship should be discussed in an early phase of the research/work.
3. roles should be clarified
4. authorship should be based on relative contribution
5. acknowledgment section should be used appropriately
6. mentors should give some time to students to be innovative [15].

Committee on Publication Ethics (COPE) gives some advice about inappropriate authorship on students’ papers [17]. They give examples of some anonymized cases (e.g. editor of a journal gives an example of a submitted manuscript that is work of students, but supervisor is listed as the first author).

One of the author’s moral rights is the right to be stated as an author of his/her work. Moral rights are part of author’s rights, and author’s rights are basic human rights, as stated in Universal Declaration on Human rights: “Everyone has the right to the protection of the moral and material interests resulting from any scientific, literary or artistic production of which he is the author” (article 27) [18]. Besides, violating moral rights is against the law: “Author has the right to be acknowledged and specified as the author of his/her work…author has the right to oppose to the use of his/hers work that is against his/her reputation…” (Articles 15 and 16 of Croatian Copyright Act) [19].

### III. Research

#### A. Aim and scope

The purpose of the research was to find out about the degree of knowledge about plagiarism and authorship issues among the Library and Information Science (LIS) students. The hypothesis were:

H1: Students know that plagiarism is unethical behaviour, but are not sure what exactly plagiarism is.

H2: There are students that commit plagiarism, but they are a minority.

H3: Students are not sure about the authorship criteria – they sometimes think that any involvement in the research and/or paper is enough for a person to be listed as an author.

H4: Students learn about ethical issues on higher education level.

The results were supposed to be a starting point for deeper study (on national and international level) that should involve students from other departments, from other faculties and universities. The findings should be the basis for planning education on plagiarism and authorship.

#### B. Methods

An anonymous online questionnaire was sent to 75 graduate students of Library and Information Science at the Department of Information and Communication Sciences, Faculty of Humanities and Social Sciences, University of Zagreb. The questionnaire was sent in December 2016. Response rate was 76% - there was 57 responses.

There were 20 questions in the questionnaire. The first two questions were about gender and year of study (1st or 2nd graduate year). Another 18 questions were: multiple choice questions (6); one-choice questions (3) and yes/no questions (9).

#### IV. Findings

**Question 1. Gender**

There were 52 female and 5 male students in the sample. The percentage of male students is too small to make gender-related conclusions.

**Question 2. Year of graduate study**

In the sample are 36 (63%) 1st year students and 21 (37%) 2nd year students.
Question 3. Have you learned about plagiarism at any degree of your education?
The question was multiple-choice type and the answers were: in elementary school; in secondary school; during undergraduate study; during graduate study; in some other informal form of education; no, never. Majority of the students have learned about plagiarism at undergraduate level, but seven students have never learned about plagiarism (Figure 1).

![Figure 1. Degree of education when students learned about plagiarism](image)

Question 4. If yes, what did you learn?
The question was multiple-choice type and the answers were: definition of plagiarism; ways of avoiding plagiarism; plagiarism detection; procedures in cases of detected plagiarism; definitions of authorship; authorship types; something else. Forty students (70%) have learnt about the definition of plagiarism, 36 (63%) have learnt about the definition of authorship, 28 (49%) have learnt about authorship types, 26 (46%) have learnt about avoiding plagiarism, 19 (33%) have learnt about plagiarism detection and 9 (16%) about procedures in cases of detected plagiarism. Three students (5.3%) have learnt about all the topics.

Question 5. Have you ever presented other people’s words, thoughts or ideas as your own, while preparing an assignment?
Eleven answers (19%) were affirmative and 46 (81%) were negative.

Question 6. Do you consider presentation of other people’s words, thoughts or ideas as your own, ethically correct?
Forty-seven students (82%) answered negative, and the other 10 (18%) answered that it depended on the situation.

Question 7. Have you ever, before preparing an assignment, been taught about proper citing practice?
Twelve students (21%) have never been taught about proper citing of sources, 22 (38%) have been partly taught, and 23 (41%) have been taught at least once about proper citing.

Question 8. Have you ever, before preparing an assignment, been taught how to make quotations?
Forty-nine answers (86%) were affirmative and eight (14%) were negative.

Question 9. Has any of your assignments ever been rejected because of wrong citation and/or quotation practice?
Nine answers (16%) were affirmative and 48 (84%) were negative.

Question 10. Have you ever been reported to an ethics committee for plagiarism?
There are no students in the sample that have been reported to an ethics committee for plagiarism.

Question 11. Have you ever been listed as author on a paper that you have not authored?
There were four affirmative answers (7%) and 53 negative answers (93%).

Question 12. Have you ever been omitted from the list of authors on a paper that you authored?
There were three affirmative answers (5%) and 54 negative answers (95%).

Question 13. Do you know about the case of wrong authorship assignment among your colleagues?
There were 21 affirmative answers (37%) and 36 negative answers (63%).

Question 14. Do you know about the case of plagiarism among your colleagues?
There were 24 affirmative answers (42%) and 33 negative answers (58%).

Question 15. Have you ever addressed an ethical committee or similar body to notify it about suspected plagiarism?
All the answers to the question were negative.

Question 16. Do you believe that self-plagiarism is possible?
8 students (14%) think that self-plagiarism is impossible, 18 students (32%) thing that it is possible, and 31 students (54%) is not sure if self-plagiarism is possible.

Question 17. Indicate what plagiarism means to you.
The question was multiple-choice type and the answers were: quoting without citing sources; quoting with proper citation of sources; paraphrasing without proper citation; not implementing the rules of proper citing; compilation of texts with proper citation of sources; not assigning authorship to someone who authored the paper; something else. Fifty-six students (98%) say that plagiarism is quotation without citing sources; 42 students (72%) say that plagiarism is paraphrasing without proper citation of the sources; 41 students (72%) think that plagiarism is when authorship is not properly assigned; 41 think (72%) that plagiarism is when the rules of proper citing are not implemented; one student (2%) thinks that quoting is plagiarism even if proper citing is
applied and one (2%) thinks that compiling texts is plagiarism even if proper citing is applied. Results are in Figure 2.

Table: What is plagiarism?

<table>
<thead>
<tr>
<th>Criterion</th>
<th>Percentage</th>
</tr>
</thead>
<tbody>
<tr>
<td>quoting + not citing</td>
<td>56</td>
</tr>
<tr>
<td>paraphrasing + not citing</td>
<td>42</td>

<tr>
<td>not assigning auth.</td>
<td>41</td>
</tr>
<tr>
<td>no rules of proper citing</td>
<td>41</td>
</tr>
<tr>
<td>quoting + citing</td>
<td>1</td>
</tr>
<tr>
<td>compilation + proper citing</td>
<td>1</td>
</tr>
</tbody>
</table>

Figure 2. What is plagiarism?

Question 18. Mark all the criteria that are, in your opinion, criteria for authorship?

The question was multiple-choice type and the answers were: contribution to the concept of the work; writing the first version; financing of the research; collecting data; statistical analysis; giving final approval; technical support; something else.

Table: Authorship criteria

<table>
<thead>
<tr>
<th>Criteria</th>
<th>Percentage</th>
</tr>
</thead>
<tbody>
<tr>
<td>data collection</td>
<td>52</td>
</tr>
<tr>
<td>concept</td>
<td>51</td>
</tr>
<tr>
<td>first version</td>
<td>43</td>
</tr>
<tr>
<td>statistic analysis</td>
<td>38</td>
</tr>
<tr>
<td>final version</td>
<td>16</td>
</tr>
<tr>
<td>technical support</td>
<td>9</td>
</tr>
<tr>
<td>financing</td>
<td>7</td>
</tr>
</tbody>
</table>

Figure 3. Authorship criteria

Fifty-two students (91%) think that collecting data is authorship criteria; 51 (89%) think that contribution to the research is authorship criteria; 43 (75%) think that writing the first version is authorship criteria; 38 (67%) think that doing statistical analysis is authorship criteria; 16 (28%) think that approving final version is authorship criteria; 9 think that giving technical support is authorship criteria and 7 (16%) think that financing is authorship criteria. Results are in Figure 3.

Question 19. Mark the applications you have heard about:
Plagiarisma.net; iThenticate; Text Compare; Copy Leaks; Plagiarism Checker; MyText; Google Checker; nothing.

Thirty-nine students (68%) have not heard about any of the applications; four (7%) have heard of PlagiarismaChecker; three (5%) have heard of GoogleChecker (the software does not exist!); two (4%) have heard of Plagiarisma.net and one (2%) has heard of iThenticate.

V. DISCUSSION AND CONCLUSION

Students mostly do learn about plagiarism during higher education. Only two students have learned about it in elementary school. That is the basic problem – children should be taught about ethics and plagiarism in elementary school, as it is showed in the Bailey’s research [1]. Lack of early education about ethical issues seems to be problem in the later stages of education. When they learn about plagiarism, they are mostly taught about basic definition (of plagiarism and authorship) but not enough about detecting plagiarism and about procedures in the cases of suspected or detected plagiarism.

The lack of education is the most probable reason why:
- 19% of students have at least once presented other people’s words, thoughts or ideas as their own, while preparing an assignment;
- 8% of students think that sometimes (depending on situation) presenting other people’s words, thoughts or ideas as their own can be ethically correct;
- 16% of students have at least once experienced rejection of their assignments because of wrong citation and/or quotation practice;
- 42% of students know at least about one case of plagiarism among their colleagues, but have never declared plagiarism;
- 37% know about at least one case of wrong authorship assignment among their colleagues, but have never declared it;
- 5% have at least once been omitted from the list of authors on papers that you authored, but have never declared it;
- 7% have at least once been listed as authors on papers they have not authored, but have never declared it;
- 86% do not know what self-plagiarism is;
- 93% do not use plagiarism detection software.

The limitation of the survey is that definition of plagiarism and/or authorship can be differently interpreted, since 30% of the students have never learnt about academic misconduct. However, 70% of the students claim that they have learned about the definition of plagiarism and high percentage of students can detect different forms of plagiarism (quoting without proper citation, paraphrasing without proper citation etc.). Sixty-three percent of the students state that they have learnt about the definition of authorship, but in fact, they are not sure what the authorship criteria are (e.g. 91% think that collecting data is important for assigning authorship and
67% think that doing statistical analysis is important for authorship). Another possible limitation of the survey is the use of self-report methodology. It is the most commonly used methodology in similar surveys [20] – students are mostly asked to answer anonymous questionnaires and to express their attitudes and experiences. Therefore, biased opinions are possible. Despite small sample of the survey, results can be compared to some other studies. In 2011 Schrisher et al. [21] published results of a plagiarism survey from one US university. They concluded that academic misconduct is on the rise for many reasons, and the most important reason is that students think information on the Internet is public knowledge that is no one’s intellectual property. However, most of them understand it is unacceptable to submit a paper written by someone else.

In Fish and Hura [22] 2013 survey, percentage of students that have used another author’s phrases or ideas without citing the source is higher (60% of students have at least once done that) than in our survey (about 20% of students). Fish and Hura found that college students consider some types of plagiarism as more serious than other types. Frequency of plagiarism is overestimated by students and therefore students are more likely to plagiarise. It is important for students to have accurate information about the frequency of plagiarism in their classes and institutions because such information could reduce the number of plagiarism incidents.

A study made by ReIME service in 2016 [23] among almost 5000 US students shows that more than 50% of students have lost points for incorrect references (e.g. using the wrong style or not submitting full reference list). The survey has similar result to our survey where students were asked about lack of information on referencing (14% of Croatian and about 20% of American students report lack of the information). There is a difference in the students’ usage of plagiarism detection software – 88% of Croatian students do not use it while 54% of the US students do not use the software.

Bretag [20] describes various surveys noting that the rate of plagiarism among the students vary widely (from 18% to 81%). International students and students for whom English is not their native language are more likely to commit plagiarism. Important conclusion of our survey is that ethical issues are not part of education curricula. That is the reason of low awareness about ethical issues, namely plagiarism. Students should learn about authorship criteria and they should use plagiarism detection software more often. This survey was focused on unintended plagiarism, i.e. cases when students plagiarise without knowing they are doing something unethical or even illegal. Unintended plagiarism is undoubtedly result of lack of education.

The situation is similar in some other countries. Bretag [20] shows that 20% of postgraduate Australian students have never heard of academic integrity and 40% do not know whether their university has an academic integrity policy. As Adam et al. [24] assert – it is difficult to define plagiarism and there are no many researches that show the differences between institutional and student understanding of plagiarism.

Future researches of plagiarism in higher education should concentrate on:
- students’ understanding of plagiarism;
- finding out how, where and when students learn about academic misconduct;
- finding out which teaching methods and techniques are (and should be) used for teaching about plagiarism;
- analysing ethics policy documents in academic institutions;
- investigating and analysing higher education curricula;
- finding out what tutors/teachers/professors know about plagiarism and what they do (or do not do) to avoid it in their work.

As mentioned earlier, the most commonly used methodology is self-report methodology (mostly questionnaires [22] and interviews [24]). Other methods should also be used, e.g. content analysis ([24] and [25]) where university policy documents are analysed; or experiments [26] that could help to investigate students’ practices.

This research has a small sample and several upper mentioned limitations, but it can be used as a pilot study of students’ plagiarism awareness in Croatia. New researches should be done with different samples – among students of other studies at the Faculty but also among students of other faculties and universities in Croatia. Comparative analysis should be conducted and it should be a basis for some changes in educational curricula.

In conclusion, ethics literacy is one important part of information literacy – it is not enough to know how to find and evaluate information without knowing how to use it in a proper way, i.e. without violating anyone’s basic rights. Therefore, action should be undertaken by educators, policy makers and funders of higher education institutions in order to raise knowledge and awareness of unethical nature of plagiarism and to deploy students’ skills of avoiding plagiarism.

A platform for supporting learning process of visually impaired children

A. Kavčič*, M. Pesek* and M. Marolt*
* University of Ljubljana/Faculty of Computer and Information Science, Ljubljana, Slovenia
{alenka.kavcic, matevz.pesek, matija.marolt}@fri.uni-lj.si

Abstract - Although ICT supported tools and e-learning material are widely available in schools to support teaching and learning, there is still a lack of specific tools and material designated for children with impairments. The costs of adapting and preparing such material is often economically not justifiable due to a small number of such children, and commonly, for the best learning outcome the material has to be adapted for each individual child and their deficits and level of impairments. Our solution to this problem is a web platform for delivering customized exercises intended for visually impaired children. There are two sorts of exercises already prepared: a tutorial for learning and practicing Braille and ten-finger typing, and various exercises for practicing vision, memory, and motor skills. For each individual impaired learner, the teacher can select appropriate type of exercise and customize it by adjusting visual aspects of the exercise, setting the specific content (e.g., words for typing, or items to sort), or selecting the level of difficulty (e.g., set timing, complexity levels, or number of shown images). A set of such customized exercises is given to a learner for practicing and their progress is constantly monitored and saved for later inspection.

I. INTRODUCTION

Various ICT supported tools and e-learning material for assisting teaching and learning are becoming commonly available in schools and are a new standard in the teaching process. Although their availability to teachers and students is nowadays indisputable, there are still groups of potential users that cannot take a full advantage of such teaching and learning approaches.

Inclusive education and access to e-learning tools and material is also an important strategic issue. "Promoting equity, social cohesion and active citizenship" is one of the strategic objectives of the EU Strategic framework for Education & Training 2020 [1]. For more than ten years, the European Agency for Special Needs and Inclusive Education has been helping member states to improve inclusive policies and practices in the field of education. Even though the EU and local governments are promoting equity and inclusion of impaired learners, there is a gap between the state legislation, strategies and policies, and the classroom practice.

Beside accessibility, the main challenge with educational tools and material is the level of their adaptability. This issue is important not only to suit the individual needs of the impaired students, but also to keep the content up to date and in line with the educational process in class. Most educational materials include fixed content, which is not modifiable by the user. Such content may soon become obsolete and consequently its usefulness in the educational setting degrades.

In this paper, we introduce a novel web platform for inclusive and accessible educational games intended mostly for visually impaired children. The platform offers a variety of games for vision and memory training, learning braille, and extending the typing skills. All games are flexible and allow for modification of the content, which permits teachers to use the game in several teaching domains, and update and adapt the game to the current needs in the class. Besides, the platform and the games provide accessibility support for the blind and visually impaired. Each game can be further customized by adjusting its visual aspects, the level of difficulty, or employing the individual user preferences.

A. Related Work

Bocconi et al. [2] discuss the issue of accessibility and usability of educational tools by visually impaired students. After examining different educational products, they claim that the issue of usability is poorly addressed and needs more attention. Not only the interface features but also the product’s basic functionalities have to improve their usability. Moreover, they argue that different types of visual impairments lead to different needs and therefore ask for different solutions.

Several initiatives are actively promoting braille literacy. American Foundation for the Blind has launched the Braille Bug®, an interactive web site for teaching braille concepts through activities and games. Milne et al. [3, 4] present some examples of learning games for blind and visually impaired children on mobile devices. However, all these approaches focus only on accessibility and usability for visually impaired, yet lack the option of altering the content of the educational games.

A key skill for digital literacy is also the ability to use a standard keyboard. Typing is an important psychomotor skill, required not only for smoother inclusion of visually impaired children, but also for all digital literates as one of the basic practical skills. Ratatype typing tutor is one of the many web-based educational environments that

1 https://www.european-agency.org/

2 http://braillebug.afb.org/

3 http://www.ratatype.com/
encourage users to learn touch-typing through various educational game settings. Nevertheless, they all use a predefined content not customizable by the teacher.

Another interesting initiative is All Abilities ePlaygrounds, an online space offering games for children of all abilities. Although the example web-based games are all accessible, the customization and personalization opportunities are still limited.

We can see that the existing approaches focus more on the accessibility issues, but less on the usability. They do not provide sufficient support for the content customization, especially for teachers that are not IT experts.

II. PERCIEVECONCIEVE PLATFORM

In the PercieveConceive project, we cooperated with the Institute for Blind and Partially Sighted Children Ljubljana, the main institution in Slovenia in the field of education of children and young people with visual impairment. The PercieveConceive platform was designed to meet the needs of the teachers and visually impaired children and is used directly in the Institute’s adapted education programs.

The main goal of our platform is to provide a variety of modifiable educational games, which include concepts that can be applied to a number of learning domains [5]. The platform provides a special interface for teachers, which enables preparing specific instances of the game suited to a particular student and their specific needs. A teacher can take a game template and define the parameters of the game, like the learning domain, shown items, or visual look. Besides, the game instance is also personalized based on the individual student preferences, adjusting colors, text fonts, text size etc. Several predefined styles have been prepared: default, blind, inverted colors, high contrast, protanopia, tritanopia, and achromatopsia. The user can select any of them in the profile settings. Moreover, the user can also define their preferred language in the settings, as the platform supports multiple languages via the use of language files.

The platform supports three different user roles: administrator, teacher and student. The administrator’s view of the platform is presented in Fig. 1. Administrators manage users (e.g., adding new users, changing roles, enrolling to classes) and classes (e.g., create new classes, assigning teachers to classes), and upload new game templates and media files (e.g., images, sounds). Each class has at least one assigned teacher, who can edit the class information and create new game instances from the available templates. Students are regular users that enroll in the class and participate in the activities the class offers (i.e., the activities the teacher prepares for them).

All games communicate with the server via application programming interface (API) [5]. The API is opened and available to any developer who wishes to create new games and offer them through the platform.

This allows for further expanding the set of game templates by the contributing community.

Although the developer of the game template has full control over the adaptability of their game and how the predefined user styles are processed in the game, the use of the entire available range of customization potentials offered by the platform, through game attributes and user preferences, is highly important for inclusion of users with different impairments.

III. PREPARED GAME TEMPLATES

In the first stage, we have prepared several game templates: a tutorial for learning and practicing Braille, a tutorial for practicing ten-finger typing, and a series of repetitive games for practicing vision, memory and fine motor skills. More games templates will be developed and added according to the wishes and demands of the teachers.

A guiding light in all games is our game character in a form of a yellow personified star, which was introduced in order to encourage students throughout the playtime. The character, shown in Fig. 2, proved to provide positive stimuli on student performance and achievements.

A. Braille Tutorial

This tutorial is intended for children and their parents that want to learn reading and writing braille. Currently, the tutorial focuses on basic characters of the Slovenian braille, but it can be extended and adjusted to the specifics

Figure 2. A star character, which encourages players throughout the game. Players also collect stars as rewards for correct answers (shown in the column on the right)

---

2. http://zaznajspoznaj.si
of any language. The tutorial includes a description and explanation of this tactile writing system, including a short history, and additionally offers three types of exercises: Mirror, Hidden Character (or word), and Braille Machine for letters and words.

All exercises can be performed using the keyboard (a braille writer is not required), where the keys f, d, s and j, k, l on the keyboard (or number keys 1 to 6, consequently) are used to mark the raised dots of a braille symbol.

In the Mirror activity, the user can experiment with braille symbols. This basic interactive activity introduces braille to the user via various letter conversions. The conversion form black print to braille shows a corresponding braille symbol (an image with six dots where the raised dots are emphasized) when the user enters a letter in black print. An inverse transformation is also possible: for a given combination of raised dots (entered either using keys f, d, s, j, k, l, or number keys 1 to 6) a corresponding letter mirrors in black print. Fig. 3 shows the exercise where the user presses the key numbers 1 and 5, thus raising dots 1 and 5. Consequently, the left field displays the selected braille symbol while the right field displays the corresponding letter e in black print.

Hidden Character/Word is an activity for practicing braille by recognizing the displayed braille symbols or, in case of higher difficulty level, entire words. A user has to find corresponding letter(s) for the displayed braille symbol(s) and enter the answer within the limited time. An audio pronouncing the places of the raised dots in the braille symbol helps visually impaired users, but can be turned off any time during the exercise.

The third activity for practicing braille is Braille Machine, which is the hardest of all exercises. The user practices braille by selecting the right combination of raised dots in the symbol. A letter in black print is presented to the user together with its audio recording (which can also be turned off) and the user has to enter a braille symbol via keys f, d, s, j, k, l. If the user fails to provide the correct input in the available time, the answer is displayed to provide an immediate feedback to the user. A more challenging version of Braille Machine deals with the whole words instead of individual letters.

In all braille exercises, the teacher can select the available time for answering as well as the letters and words for practicing, thus allowing the exercise modification to meet each individual user needs and difficulty level.

B. Ten-finger Typing Tutorial

This tutorial explains the basic concepts of two-handed touch-typing and encourages practicing through a series of customized exercises.

Each exercise uses a predefined sequence of letters or words (either default or customized and prepared by the teacher) that is displayed on the screen and provided via audio dictation. The user has to type the sequence while the time is also being measured. Immediate visual and audio feedback is given on the user performance.

One such exercise is shown in Fig. 4, where the two basic letters f and j have to be typed interchangeably using left and right index finger. The progress of the user is visually marked in yellow and the mistyped letters in red. The help below the letter sequence shows the position of the next letter on the keyboard and the finger that has to be used for typing this letter. This help can be turned off for higher difficulty levels.

Each exercise can be customized in different ways. The most obvious is the content (i.e., the sequence of letters and words) that the user uses for practicing typing. Besides, the teacher can select different ways of displaying the content to the user (e.g., all at once, line by line, word by word, or letter by letter), adjust the maximum number of characters in one line, set the colors schemes for the content (e.g., foreground and background colors, the color for marking progress and mistakes), or shuffle the displayed content by enabling randomly generated subsets of the content.

C. Vision, Memory, and Precise Movement Games

An important part of the platform are various games in the form of memory games, puzzles, matching, sorting, pair identification, image understanding and description, and object navigation, controlled with fingers or keys. These exercises support practicing vision (e.g., pattern matching, standard puzzles), memory (e.g., standard memory games, finding the correct subset of the shown items, finding exact sequences, finding reverted subsets) and precise movement (e.g., object navigation, following the path through the labyrinth), and are useful directly as a

![Figure 3. The Mirror exercise for practicing braille. Selecting the combination 1 to 6 for raised dots displays (mirrors) the corresponding letter in black print](image)

![Figure 4. The Ten-finger Typing exercise for practicing touch-typing. Displayed is the sequence of letters that the user has to type, progress is visually displayed (mistyped letters are marked in red), and help (the keyboard with the marked key in question and the finger to use for pressing the marked key) is provided or hidden on demand](image)
teaching aid for visually impaired children. Fig. 5 presents a subset of available games.

Fig. 6 shows an example of a game Sequence intended for training visual memory. The player looks at the sequence of objects on one page and, when ready, continues to the next page, where the perceived sequence has to be reconstructed from the available images. The game starts with the sequence of two images, while an additional image is added to the sequence on each next difficulty level. The player collects stars as rewards for correct answers (displayed in the bar on the right). After obtaining the third star, the player can progress to the next level.

All games are adaptable by setting various attributes, from the available topics (e.g. tools, fruit, animals, sports) and images (e.g. the selection of images can vary from color to black-and-white and line drawings) to difficulty levels (e.g. number of levels, number of images on the first level, number of additional images on the next level) and the speed of progress between levels (i.e. how many stars have to be collected before going to the next level). Therefore, the games can be adapted to each individual player, their level of difficulty, and specific deficit. This individual adaptation can be set on two levels. One level are the individual settings for the game that are prepared by the teacher, taking into account the student’s impairment, performance ability, level of background knowledge, age and social background. Another level of adaptability are the student’s individual settings that include pre-prepared styles according to the student deficit (e.g. changing the color scheme or contrast) and language settings, both affecting the interface presented to the user.

IV. EVALUATION

The PercieveConceive platform is still under development, thus only one preliminary evaluation on end users has been conducted so far. We evaluated user experience, while testing the platform’s games for vision, memory, and precise movement. The focus was on the games for visual perception.

Three visually impaired children, two boys and one girl, participated in the evaluation. Their average age was 10 years and all had severe low vision on both eyes. One teacher, who was an expert for teaching visually impaired children, participated in the evaluation as the leader of the testing and support for participating subjects. A solution designer had a role of an independent observer in the evaluation. The tested subjects were video recorded, observed while playing the games, and interviewed. The teacher prepared observations and notes on tested subject’s performance and completed one evaluation questionnaire for each tested subject.

Evaluation tests were prepared for usability testing according to the specifics of working with and teaching the tested population. We combined three types of metrics in the tests: performance metrics (e.g. efficiency in playing the game, error frequency while playing the game, efficiency of interactions, ease of learning), issue-based metrics (e.g. why the user did not finish the task, level of satisfaction and level of frustration) and self-reported metrics (e.g. did the user like the game and wished to play again). Consequently, the evaluation questionnaire had four parts: game usability and efficiency (e.g. percentage of tasks completed, number of errors, success with performing the tasks), game effectiveness (e.g. number of help requests, number of tries before giving-up), student satisfaction (e.g. want to play more), and student dissatisfaction (e.g. student frustrations and uneasiness). The time needed to perform a task was not measured in these tests as it is not a relevant success criterion for the focus group of visually impaired children.

The main objective of the evaluation was to overcome the standard guidelines and to develop a user interface as well as to design graphic solutions that enable a visually impaired child such a user experience that is comparable to the one that children without impairments experience when interacting with didactic games.

As the tested subjects were observed while playing a specific game and performing given tasks, we could determine problematic navigational, functional, and content related elements in the application. We encountered several problems (e.g. some content elements
were not visible or not understood, some user activities did not lead to the correct solutions, problems with magnification, problematic counting of images) and identified a number of suggestions on how to improve the games. Therefore, the results of this evaluation impacted directly the development decisions and the application was improved accordingly.

The analysis of the user experience from the viewpoint of success and difficulties in interaction with the application showed that the platform and the games were adequately designed. Main disturbing factors that in some aspects restricted tested subjects from accomplishing the tasks and caused major problems were essentially related to cognitive-behavioral characteristics of our target group (e.g. age, visual impairment, social background) rather than to the game design solution.

The evaluation results [5] show that all three children were excited to play the game and the game character (shown in Fig. 2) proved a valuable visual motivation. Nevertheless, the children still needed additional verbal support during the game, especially when playing the games for the first time. Particularly, the games for visual perception are in general more difficult for the first-time players, thus an expert teacher has to be present for additional help and guidance. Later the player is more autonomous and help is needed only occasionally.

We intend to perform a more comprehensive evaluation after the winter school break. The evaluation is planned on two levels: first with the teachers that use the platform in the educational setting, and later with the impaired children that use the customized games for exercising.

The first study will focus on the teachers and will measure user acceptance and usability of the platform. We plan to gather the data for this evaluation via a questionnaire, using a set of questions from two validated questionnaires: the technology acceptance model (TAM) questionnaire [6] and USE (Usefulness, Satisfaction and Ease) questionnaire [7].

The TAM model is valuable for explaining usage behavior, as it measures the perceived usefulness and perceived ease of use, which are two fundamental determinants of user acceptance [6]. On the other hand, the USE questionnaire will help us measure usefulness, ease of use, ease of learning, and user satisfaction with the platform [7].

The second study will focus on visually impaired children and their use of the customized games for exercising. We intend to measure accessibility of the games, student engagement, and effectiveness of the games as a teaching tool.

V. CONCLUSION

PerceiveConcieve is an open-source platform for accessible and inclusive educational games. The platform is designed to support accessibility, adaptability, and customization of the games by the use of game templates. This way, even the less IT skilled teachers are able to freely adjust the games and modify their content, thus customizing the games according to the educational setting and the needs and preferences of their visually impaired students. The use of the PerceiveConcieve platform enables teachers to include motivating and accessible elements of game-based learning into inclusive learning scenarios, and consequently enrich and diversify the learning process.

The preliminary evaluation of the platform on target groups has shown positive acceptance by teachers and visually impaired children. The platform proved to be well designed, with appropriate graphic design as well as prepared content. We are preparing the next stage of evaluations, a more comprehensive study that will focus on user acceptance and usability of the platform.

ACKNOWLEDGMENT

The work was co-funded by the European Regional Development Fund of the European Union and the Ministry of Education, Science and Sport of the Republic of Slovenia. The operation was carried out within the Operational Programme “Strengthening Regional Development Potentials” for the period 2007-2013, Priority axis “Economic Development Infrastructure”, Priority Focus “Information Society”.

REFERENCES

Abstract - This paper presents the web application for time telling and results of its usage in the second grade of primary school in Croatia. The paper analyses the usage of the web application for time telling in classroom described with both qualitative and quantitative data. The research was done in order to gain a detailed perception on how the application and other parameters influence the children's test results and studying habits, as well as an insight on what are the convenient forms of technology-enhanced learning for children of certain age.

I. INTRODUCTION

From the very first grades of elementary education, teachers apply various teaching methods to foster learning. In modern days, technology-enhanced learning is introduced mostly as an additional method to the traditional ones, but it is slowly approaching more school subjects. In order to successfully develop a useful application for educational purposes, a developer must know which subjects are in need for such teaching approach, which user interface designs and manipulation methods are suitable for specific users and what goals have to be achieved with the use of the application. As for any other application, it is recommended to collect data about the user experience for future updates and new development ideas. Ultimately, technology-enhanced methods of learning might not result in a significant increase in learning outcome, but can bring diversity and fun to traditional classroom lectures.

II. WEB APPLICATION FOR TIME TELLING

A. Description and purpose

The web application for time telling was developed by Ana Ćobić using web technologies: HTML [2] for structure, CSS [3] for style and JavaScript [4], in combination with GreenSock GSAP and Draggable libraries [5], for interactivity and dynamic effects. The application's purpose is to facilitate learning of time telling. In the Republic of Croatia, students learn to recognize and determine time using analog clocks in second grade. Therefore, the application was developed for the second grade elementary school children, aged between seven and nine. By that age, they have gained enough mathematical knowledge to be able to understand the time telling lesson.

Taking into account the student's age, no detailed textual user instructions are provided in the application. Because of that, the user interface (see Figure 1) is simple and designed to ensure fast and unambiguous understanding of activity flow. Also, the application is launched through a web browser, keeping the technical requirements on a minimum. It can be used equally on desktop and mobile devices. The goal behind the development was to achieve greater quality and speed in the process of learning a specific lesson and also to ensure learning flexibility depending on the student's needs.

Figure 1: User Interface

The application can be compared to traditional methods of time telling teaching and learning such as drawing, multiple choice tasks and practicing through paper or cardboard imitations of analog clocks. In all three cases, supervision is necessary in order to check the student's answers and provide them adequate feedback, which can be time-consuming especially in larger classes. The developed application contains two main features which enable the students to learn independently, without supervision. The first feature is the result check which verifies the input and provides the user with a simple feedback regarding the given answer. The second feature is the possibility to display the correct answer. This feature can be used every time a false input has been entered. By using the drawing method the student needs more time to present his solution than he would need to come up with it. That way the focus is being shifted more onto drawing and less on time telling. By using the application the solution is being entered synchronously with the thinking process. Ultimately, the application provides an unlimited number of random tasks and enables the students to adapt the learning time to their needs. Further testing of the application's features was done by questioning the students and analyzing their behavior. The methodology, results and conclusions are presented in the following sections.

B. Usage flow

The application's user interface, contains a digital and analog clock, initial guideline message (see Figure 2), solution check messages and buttons for starting a new game, checking the entered solution, trying again and requiring the solution reveal (see Figure 3 and Figure 4). Currently, the application is available only in Croatian. Therefore, its usage is limited to Croatian students only.
As depicted by the usage flow diagram (see Chart 1), it is visible that the application has no formal end, but the solution verification will eventually lead to the start, i.e. new task.

![Image](image1.png)

**Figure 2: Guideline message**

![Image](image2.png)

**Figure 3: Incorrect solution form**

![Image](image3.png)

**Figure 4: Correct solution form**

When the application is launched or a new game begins, a short message is displayed, instructing the user to adjust the analog clock hands. The user is than supposed to position the clock hands by rotating them in both directions according to the randomly set numerical time on the digital clock. When the user is confident with the given answer, the solution is being verified if clicking on the check button, which is also the only one available at that stage. Depending on the verification outcome a message, displaying a short feedback stating if the answer is correct or not, shows up. In the case of a correct answer, the only option is to start a new game by clicking the new game button, after which the page is being reloaded and a new task is assigned. If the case of an incorrect answer, the user can choose between the option to display the correct solution or try again. If the display of the correct answer is selected, the clock hands rotate to the position equivalent to the set numerical value and the only remaining option is to start a new game. In the case of another trial, the application counts how many times the user used this option on the same task and by the fifth time, the display of the correct solution is being imposed. Otherwise, the user can continue where he/she left off.

**Chart 1: Usage Flow**

III. Testing

A. Testing methods

In order to contribute further development of similar applications, this application has been introduced to targeted users and tested. The testing has been conducted in two second grades of primary school Škola Trnjanska in Croatia, during regular learning time in the classroom, on a sample of 26 students. Chronologically, following methods of data collection have been performed:

1) pre-test,
2) introduction,
3) competition,
4) post-test,
been noticed in keeping the student’s interest to solve tasks. Nevertheless, a deficiency has been observed when the application clock, needed less time to repeat the time telling lesson. The students expressed excitement and anticipation to use the application, which was also visible during the competition phase. The students competed in two teams by solving a task individually on the smart board. The knowledge test, which followed few days after the previous introduction, has been composed by the teachers and is part of the regular assessment program. The test has also been compared to the pre-test as well as analyzed in comparison to the data collected from the second questionnaire. Two questionnaires regarding the students have been handed out. The first one contained three descriptive questions concerning their opinion on the application and learning preferences. The second one contained five multiple choice questions relating their preparation for the test and the application usage at home. An additional questionnaire has been handed out to the teachers to get an insight into their opinion on the application’s usage and technology-enhanced learning in general.

B. Behavioral analysis

The introduction and competition have been used to gain a direct impression of the application’s acceptance and ease of use. By solving examples on the smart board, the teachers explained the usage steps and the application’s features. During the introduction, it has been noticed that the smart board, because of its size, serves as a useful teaching tool and that the teachers, by using the application clock, needed less time to repeat the time telling lesson. The students expressed excitement and anticipation to use the application, which was also visible during the competition phase. The students competed in two teams by solving a task individually on the smart board. They showed rather an interest in going to the board to use the application than fear of failure in front of the classroom. Even though the overall result (40% correct answers given) is considered low, the students kept the same interest to solve tasks. Nevertheless, a deficiency has been noticed in keeping the students’ attention while not being the one solving the task on the board. Approximately a half of the students lack in concentration, which might be an indication that the application should be more dynamic and contain more versatile elements. A minority of the students also had problems with the touch manipulation of the clock hands for which they have to continuously hold the clock hand and drag it. To solve this problem, a more convenient method could be to choose a clock hand and then its desired placement by clicking, i.e. touching, each time once.

C. Test results

Pre and post-test results were compared to analyze the impact of learning with the application. On the Chart 2, a comparison is displayed showing differences in results. It was observed that exactly six students got higher scores in the post-test, and four students a lower score. Furthermore, the absolute score was 2% higher in the post-test.

D. Questionnaire analysis

Two questionnaires have been handed out to students in order to collect data regarding their learning routine for this particular lesson, their opinion on the application and preferred learning methods. The first questionnaire was composed out of three questions and given to students after the testing. In the first question, they were asked to evaluate the application. Their answers confirmed the positive reaction noticed during the introduction and first use on the smart board. With the following two questions, they were asked to give descriptive answers about their preferred way of learning and desired subject to learn by using similar methods as the one introduced for time telling. It was not expected to acquire concrete and...
accurate answers, but to analyze their thought flow right after the use of the application. On both questions, the students gave a variety of different answers. For the desired subject to study with technology-enhanced methods, a repeated answer was Croatian and Mathematics. These two are considered main school subjects which take up more time in the school program and require more effort and learning [1]. This may be an indication that they seek a more convenient and interesting way of learning Croatian and Mathematics, as well as that there is room for adjustments in teaching these two subjects. By the given answers and many of them being drawings instead of declarative sentences, it was obvious for the student's preferred way of learning to be through games.

In the second questionnaire was given to students to fill out after the final exam. The students were asked to answer five questions by picking one option. The questions referred to the way they studied for the exam, time they spent learning, learning location precedence, device on which they used the application and application assessment. The questionnaire answers were combined and analyzed with the knowledge test grades to detect possible frequencies. Based on that, following regularities were noticed:

- 11 out of 26 students used the application as a primary source for studying at home and achieved an average grade of 4.36. The next method was practicing with a real clock. It was used by seven of students who achieved an average grade 3.57. Drawing on paper used two students and one did not learn at all. Five students used an undefined method and achieved an average grade 4.4.
- 58% of students studied less than one hour for the exam. The same percentage corresponds to the students who claim to have gained most knowledge at school. In both cases, their average grade is greater than the one of the students who have studied more than an hour and claim to have gained most of the knowledge at home.
- 73% of students have used the application for time telling at home as a primary or secondary source of studying. Their average grade is 4.11, while the students who have not used the application at all gained 3.71.
- Counting only the students who have used the application at home, 53% used it on a computer, 37% on a mobile phone and 10% on a tablet. Also, 63% of students consider the application easy to use, but 32% had problems with the manipulation of the clock handles. One student reported difficulties to solve the tasks correctly. Analysis of his/her knowledge test resulted in a low-grade and meaning that the student’s answers were neither accurate on paper. Because of that the problem was not considered to be too strict accuracy requirements for clock handle positioning, but his acquired level of knowledge. The students who had issues with clock handle movement used the application on mobile phones as well as on computers. Because of the range of device sizes used, the problem may rather be the previously described continuous dragging method of the clock handles, than the device size.

The questionnaire answers were also compared to the recorded fluctuation of test results per each student. Due to the variation of emerged patterns on a relatively small sample, no other proof of the application being the cause to positive or negative result outcome was found.

As a source of knowledge about the student's behavior and development requirements, two teachers were also given a questionnaire to describe their opinion regarding the application and technology-enhanced learning in general. They consider the application appropriate and easy to use. For future generations, they would include it in the whole process of learning the lesson. Advantages are seen mostly in the size when used on a smart board because it enables all students to clearly see the clock, and quick setup since the drawing and erasing on a regular board requires time, which now can be used more efficiently. Regarding technology-enhanced learning, they support it as long as it is lesson appropriate. They pointed out it should be time restricted to enable the students to develop all their skills.

IV. CONCLUSION

Based on the test and analysis results it is concluded that the application has advantages compared to traditional teaching methods. It enables better time management in the classroom, as well as adjusted learning time and speed. In addition, it was observed that students show interest when faced with new learning methods, which differ from the regular routine. Because of that, they were motivated to actively participate in front of the board. The lack of detailed instructions on the user interface did not present a problem to the students since the teachers gave a short application introduction. For further development, it is planned to implement a single-touch manipulation of interface elements since continuous movement might add difficulty to the usage for students. Considering the test results and the fact that students, in general, take more effort in preparing themselves for the test that is being graded, it is not proven that the positive outcome is due to the use of the application. However, the experiment results indicate the students who showed interest and had the possibility to use the application at home achieved better results.

APPENDIXES

APPENDIX A
ACKNOWLEDGMENT

We thank Aron Belsö for designing the application’s images, and the teachers Ivanica Tajsl Dragicevic and Kristina Vlah for assistance during the classroom testing.

Integration of the future technologies to High schools and Colleges

Primož KURENT, BSc Engineering
ŠC Kranj, Višja strokovna šola, Kranj, Slovenia
kurent.primoz@gmail.com

Abstract

Science and technology are progressing with the speed which seems to be unfamiliar to us. What seems to be science-fiction some 30 years ago is now becoming our everyday reality. 3-D printing, O-led technology, modern communication, smart materials, mind recognition etc. How to follow the progress and all novelties and what is more, how to integrate them into the educational systems of high schools and colleges, is practically an art.

Article addresses the mind recognition system, EMOTIV Epoc technology, and its integration in the educational process.

Mind recognition device EMOTIV Epoc, (https://www.emotiv.com/the-science/) works in way to recognize brain activities in specific brain parts and sends this information to the computer. The computer processes the information and produces appropriate exit signals, whereas by strengthening the latter machines and devices can be controlled. Next to mind recognition, the device also has integrated the gyroscope and system for facial movement recognition.

In ten years such technology could thoroughly change the life of disabled people and the operational working processes in industries, as by controlling the mind, human would be able to control more machines than today by using hands.

Main obstacle for quicker integration in the practical use is the reliability – repeatability. For successful use in industry the rate must be at least 99.5 %, whereas it currently reaches only roughly 70 %.

Key words:
Mind recognition, EMOTIVE Epoc technology, brain activities, future technologies.

I. INTRODUCTION

A constant challenge professors and teacher in school are constantly facing is, how to present new technologies being developed to students, since the main teaching method, frontal method, is no longer effective. Currently prevailing methods are based on practical experiences, where students have the opportunity not only to gain theoretical knowledge, but also to test their own practical skills. We are talking about case studies, team work, and project management approach, whereas the addressed topic needs to be interesting and current.

II. INTEGRATION OF FUTURE TECHNOLOGIES TO HIGH SCHOOLS AND COLLEGES

At School Center Kranj we have thus decided to join the two concepts: we searched for a technology of future (i.e. Mind recognition device EMOTIV Epoc) and integrate it to curriculum by using modern teaching methods (i.e. project and team work), which is also what I wish to address in my article.

A. Mind Recognition Device EMOTIVE Epoc

The brain is a very complex system. The frontal cortex is the part where most of our conscious thoughts and decisions are made and it conducts much less than a tenth of the total activity in the brain.

Planning, modelling of your surroundings, interpretation of sensory inputs up to and including your perception of reality, memory processing and storage and the basic drivers of your moods and emotions all occur in many functional regions distributed around the brain, including the visual cortex at the rear, temporal cortex at the sides, parietal cortex behind the crown of your head and the limbic system deep inside the brain. The limbic system controls your basic moods and emotions, your fight/flight response and deeper long-term memory encoding as well as control of basic bodily functions such as breathing and heartbeat.

Most of these deeper functions interact intimately with different parts of the cortex, the outer layer of which is accessible to EEG measurements, however the interaction is quite complexly distributed. In order to map the true activity of the brain it is very important to measure signals from many different cortical structures located all around the brain surface. It is not possible to map these signals purely from the frontal and temporal regions. Determination of the user’s complete mental state is very poorly approximated unless signals from the rear of the brain are also considered.

With proper coverage and electrode configuration, however, it is possible to reconstruct a source model of all important brain regions and to see their interplay [1].
EMOTIV Epoc is a new approach to the design and development of mobile EEG systems. It consists of hardware, which collects data, and software, which analysis the data.

B. Hardware:

The award winning EMOTIV Epoc+ is a 14 channel wireless EEG, designed for contextualized research and advanced brain computer interface (BCI) applications. The EMOTIVE EPOC+ provides access to dense array, high quality, raw EEG data using our subscription based software, Pure EEG (Picture 1).

C. Software: Detection algorithms

EMOTIVE EPOC+ offers different kinds of detection algorithms, all of them built on extensive scientific studies aimed to develop accurate machine learning algorithms to classify and grade the intensity of different conditions.

Facial Expressions – muscle artefact, which commonly get rejected in laboratory EEG studies, are diverted and classified to map the activation in different muscle groups and eye movement events. Our universal detections can be fine-tuned for each individual to indicate 12 different facial expressions or events. Individuals with partial paralysis or unusual musculature can custom-train the activations. These events can be used to animate an avatar, detect specific responses and they may be tasked to execute commands.

Performance Metrics – EMOTIV EPOC+ currently measures 6 different emotional and sub-conscious dimensions in real time – Excitement (Arousal), Interest (Valence), Stress (Frustration), Engagement/Boredom, Attention (Focus) and Meditation (Relaxation). Performance Metrics algorithms are being continuously improved and upgraded.

These detections were developed based on rigorous experimental studies involving at least 20-30 volunteers for each state, where subjects were taken through experiences to elicit different levels of the desired state. They were wired up with many additional biometric measures (heart rate, respiration, blood pressure, blood volume flow, skin impedance and eye tracking), observed and recorded by a trained psychologist and also self-reported. EMOTIV Performance Metrics have been validated in many independent peer-reviewed studies [1].

Mental Commands – based on unique and highly efficient methods, EMOTIV has developed a system for users to train direct mental commands where the user trains the system to recognize thought patterns related to different desired outcomes, such as moving objects or making them disappear. The system can be trained to recognize a single command in less than 20 seconds.

EmoKey – the custom software allows untrained users to be able to link their mental commands and emotional reactions directly to keystrokes, mouse operations or gestures within the host machine, allowing non-programmers to incorporate mental commands and mental state detections directly into existing applications.

Combined with the on-board motion sensor it can provide a hands-free brain-controlled mouse, adjust music volume or track skip depending in mood, and many other options.

D. Integration of the future technologies into learning process (curriculum)

Mechatronics is a new science combining engineering, electrical engineering and computer science. We wished to include the technology of the future EMOTIVE Epoc as cross-curricular connector during Mechatronics classes. Since this is a rather complex process, we integrated it through project work.

Project work, however, requires exact definition of goals, activities, sources and timeline [2]. We approached to realize our goals through the following phases:

- Task definition,
- Allocation of groups,
- Timeline,
- Conceptual design,
- Plan creation together with description of working, materials etc.
- Device making,
- Device testing,

Task definition:

Aim of the task was to create a mobile robot (car), which will be mind-controlled:

- Mobile robot (car),
- Size: length cca. 70 cm,
- Carbon made,
- Functions: forward, backward, left, right
- Additional functions: facial expressions recognition (with LED we show 😊, 😞), steering with gyroscope,
- Autonomous functioning (battery charged),
- Wireless connection with a computer,
- 4 wheels.

Allocation of groups:

We divided the project to four lots, whereas each lot is being led by one of the professors – mentors.
• 1st Lot: Computer science (Mentor Andrej Arh),
• 2nd Lot: Electrical engineering (Mentor Jožef Polak),
• 3rd Lot: Mechanics (Mentor Aljaž Rogelj),
• 4th Lot: Project Management (Primož Kurent).

Timeline
Well prepared timeline of the corresponding activities, responsibility allocation and costs management is main foundation of successful execution of a project.

Conceptual design
As aforementioned the EMOTIV Epoc senses the brain activities and only transfers to the computer the signals which require further analysis. Such program was written by students. With the help of one of the soft wares, the computer can be taught which impulse (brain activity) means which order (e.g. forward, backward etc.). Using wireless, the computer then sends the order to the vehicle. The vehicle holds a recipient, which strengthens the signal and sends it to electro engine, causing the vehicle to move. (see Picture 2: Scheme of components connection).

1st Lot: Computer science (Mentor Andrej Arh)
The computer science group studied the functioning of the mind recognition device EMOTIVE Epoc, with installed gyroscope and facial movement recognition system. The signals, which EMOTIVE Epoc transmits, were changed by a software program designed by students, to the extent that they can be transmitted to the computer holding the wireless data transfer system. This system was developed by the electrical engineering group.

2nd Lot: Electrical engineering (Mentor Jožef Polak)
The electrical engineering group developed a system for wireless data transfer. (Picture 3: Device for wireless data transfer.) [3]. The system has four different speeds, based on the number of signals. In practice this means, if we think “forward”, this represents speed 1, if we think “backward”, this is speed 2, etc. The same logic applies for the gyroscope: when we move head forward, this is Speed 1, if we move it forward again this is again another speed etc., whereas if we move our head backward, this reduced the speed level.

3rd Lot: Mechanics (Mentor Aljaž Rogelj)
The mechanics group had to develop a physical model of the vehicle. The vehicle is made out of carbon fibres, representing another challenge on its own Student Luka Kondič is well skilled in vehicles design and he drew a roadster sketch (Picture 4: sketch of the vehicle), after which a 3D model was designed with the help of a computer. To produce the vehicle we first needed to make a model out of Styrofoam in the scale 1:1. This model was made with the help of the School Center Celje. Later on, we applied carbon and resin to the model which gave us the vehicle model as seen on Picture 5: Vehicle made out of carbon. The physical model was made by a student with the help of company Fanell, d.o.o..

III. CONCLUSION
In the article I presented a new, innovative approach of integration of future technologies in high schools and colleges. We developed a mechatronic device steered with by human mind.

Picture 2: Scheme of components connection.

Picture 3: Device for wireless data transfer.

Picture 4: sketch of the vehicle.

Picture 5: Vehicle made out of carbon.
The system entails a device which is being put to a person’s head and recognizes the electrical impulses from brain when we think of a certain thing/object/feeling. These impulses can be transmitted to a computer and processed accordingly. We can form exits which manage different actuators. This gives us endless possibilities to develop new and interesting devices which are mind controlled. The device also holds a gyroscope and has the possibilities of facial activities recognition.

Knowledge and experiences which we gained with this project brought us to a level, where we practically have endless possibilities for various applications in the future; from medicine to mechanical and entertainment industries.

All involved participants learned something new in this project. Talented students, full of interests, gained new skills and insights into industry, whereas mentors gained new pedagogical and professional skills. It was a great pleasure to work with students full of enthusiasm, which also brings quality and promotion to the school.

I believe that such projects are necessary in the future and this is why we will proceed with such successful practice also in the upcoming years.

Preschool Children and Computers: Who lives in a meadow?

Barbara Strnad
Gimnazija Novo mesto, Čarunalkn - Društvo za napredno uporabo računalnikov, Novo mesto, Slovenia
barbara.strnad@gmail.com

Abstract - In recent years, most developed societies have realized that it is very important for students to acquire the skill of algorithmic thinking and the basic knowledge of computer programming. Nowadays we have numerous ways that allow us to teach programming with appropriate first steps. The paper will present one of the possibilities which we have to introduce basic programming concepts to younger children – with lego robots and a topic Who lives in a meadow?

I. INTRODUCTION

In order for children to become active creators in computer science and informatics, it is necessary to learn the algorithmic way of thinking. Knowing the basic steps of programming is one of the best ways to do it. The purpose of this paper is to present a project we did in a kindergarten with Lego WeDo, which is a great tool to start introducing the world of programming to kids [1], and is practically suitable for all age groups. Most of the activities are based on a game and co-working. Lego robots allow us to do many cross-curricular links, including topics related to life, physical science, Earth science and space technology.

II. COOPERATION WITH PRESCHOOL CHILDREN

A. Lego WeDo 2.0

Lego® Education WeDo 2.0 [2] basic set (Fig.1) is designed primarily for elementary school students, but we can also use it for working with preschool kids and high school students with no prior experience. The kit allows us to create and programme simple Lego® models. The set contains more than 280 items, including WeDo 2.0 Smarthub, one motor, a motion sensor that can detect objects at a distance of 15 cm and a tilt sensor that can detect six different positions.

Smarthub is the electronic system, which is part of the product Lego® Power Functions (LPF) 2.0, a new technology platform for the program Lego® Education.

It has a built-in low-energy bluetooth technology that connects smarthub with software. Energy can be obtained via two AA batteries or rechargeable batteries. There are two I/O outputs, through which you can connect external motors, sensors or any of the other LPF 2.0 components. Built-in RGB light area can display 10 different colors, which can be controlled by software.

It is an excellent tool for introducing the basics of robotics and enables interdisciplinary cooperation. It has the option of documenting and sharing. Programming is based on the principle of drag and drop.

B. Starting the activity

We start with an exciting polygon, where children try to lead a live robot. First, we choose a volunteer and blindfold him. Then we place a dynamic polygon made of tables and chairs in the classroom, which enables them to securely lead "a live blindfolded robot" (Fig.2). At first glance it may not be immediately apparent, but there are some programming concepts already hiding in the game.

The aim of the game is that the children learn from the experience what are the good and sufficient detailed instructions that enable successful and fast crossing of the polygon. Sometimes we can prepare a polygon in such a way that children can use the instructions in the loop or a conditional statement....

Children can see through this activity that some instructions are understood completely clear by some of them, while others may be misinterpreted and that there are also several procedures for the solution of polygons ...

Figure 1: Lego WeDo 2.0

Figure 2: Polygon
We further discuss how we perceive space when we are blindfolded and what is the role our senses. Children usually figure out what is the connection between the robot and our game. An interesting topic is also to talk about the differences between robots and humans.

C. Robots in everyday life

We continue with a conversation about robots in everyday life. Children often say that they have not yet met a robot, but after some consideration they soon think of a robotic vacuum cleaner. They have already heard about or seen a robotic lawn mower or industrial robots... Then we talk about how we command the robots. The most thorough analysis of the robot’s function can be carried out on a robotic vacuum cleaner that children know best. They know that robotic vacuum cleaner has a sensor for not falling which prevents falling down the stairs. Children can describe its moving really precisely. They know the cleaner uses a profiled rubber bumper to detect obstacles. They even know that it is necessary to lodge a border wire in areas where we do not want the robotic lawn mower to mow.

D. Creating our own robots

Our robots, which we will build, will also require sensors for better orientation in space. We introduce two sensors in the kit, a tilt sensor and a motion sensor (Fig.3).

It is time to build a robot and equip it with sensors. The focus is firstly on commands which will tell the robot how to move. We use printed command blocks on a bigger format. Children try to conclude what each command means just by observing the image (Fig.4). Most children are very good at observing. They identify a motor which rotates in the clockwise direction or in the opposite direction. They connect the engine with the hourglass and with the length of time that the motor will spin. They explain that the command block which determines the engine power shows the engine and power meter pointer.

We proceed with the assembly of lego bricks. Following the instructions first robots are made and programmed to move, and then equipped with a motion sensor and a tilt sensor.

III. Creativity of preschool children

We had quite a few meetings with preschool children (Fig.5), where we build different robots: a frog, a mantis, a spider, a caterpillar, a bee... Members of Ćuranački were teaching children how to build correctly and follow the instructions and we did some basic programming.

First we started with the topic: Who lives in a meadow? We divided the children into six groups, each group picked one animal – bee, spider, snake, caterpillar, mantis, and firefly. There were four children in each group. Two groups worked on a robot, while the other two groups worked on modelling an animal’s environment, a meadow with a pond (Fig.6). The last two groups learned about a chosen animal, explored how they live: how bees take an active role in plant reproduction, they researched different stages in the life circle of a frog, butterfly, ... Groups rotated on each session.

Before visiting the kindergarten, we elected all needed bricks for creating a specific robot, so the children didn’t spend too much time searching, and they did not lose interest in searching among too many bricks. Group members that were constructing and building robots had different tasks: they had to find the right bricks, one had to put the next page of instructions on the tablet, and another had to check if pieces were joined correctly. The children did all of the tasks alternately, except the search for needed parts, which was everybody’s job. They built alternately; some children had more experience following instructions and better spatial performance. They helped children with more difficulties and they were «supervisors».

Once we constructed the robot, we wrote simple programs, where animals were moving forward and backward, they were making different sounds and the RGB light surface on Smart Hub changed colors. The children then tried to modify programs.

Because of a major interest and enthusiasm among the children, we added two more topics: jungle, and working machines and heavy-equipment vehicle (Fig. 7).

We experienced major progress in following building instructions, better spatial performance, and better motoric skills when putting bricks together. The children were excited and they happily presented their work to other kindergarten groups and their parents.

The reactions to the project we did together were extremely positive. Children were satisfied, because they really assembled their own robot, wrote a program and
created an environment for the robot-animal in the meadow. Meanwhile they visited some interesting experts. They visited a beekeeper and they molded their own wax candles. Children learned a lot about animals in the meadow. They were able to use their imagination and creativity. Children enjoyed in the implementation of their own ideas and comparing their products. After completing the project, the children were excited and eager for new meetings.

IV. CONCLUSION

Panellists on computer literacy in primary schools this year agreed that the school system is in urgent need of change in the field of computer skills, because without these skills, students will not be competitive in almost any field of expertise. There is almost no activity associated with digitization, so computer skills are vital.

We introduce children to the world of programming and algorithmic thinking through attractive robotics by programming small robots. In this way there is a connection between the mind maps and the physical world. Learning about computer concepts and developing procedural way of thinking help students acquire knowledge and skills that are much more durable than the rapidly evolving technology.

REFERENCES

Abstract: The improvement of communication and the exchange of teaching resources between teachers and students has developed a model of web services based on cloud computing technology. Today's models and systems (in the application approach) are used according to the user's needs, while the rest of the time computing resources remain not used. Such services are characterized by extremely high level of security and synchronization of files that are continuously exchanged. The infrastructure that is based on cloud technology provides uninterrupted simultaneous work of great number of different virtual machines on which are installed different systems and application software. For the purposes of the experiment, teaching resources are offered in the form of a virtual machine. Experiment included approximately 500 respondents in the territory of the Republic of Croatia and Bosnia and Herzegovina. The experiment results show that the system for e-learning (online education) developed in cloud environment is more scalable and shows better performance from the currently used classical server oriented system.

I. INTRODUCTION

With the rapid development of information technology we see a strong ongoing need to improve the current state of information systems in education. Cloud computing or cloud technology is the answer that fulfill the above mentioned need in order to increase the capacity and provide new features on the existing infrastructure without investing in new infrastructure and personnel. This technology has enabled customers to use additional computing resources using only a web browser (e.g. Internet Explorer, Chrome or Firefox) thereby using the existing computing resources. Cloud technology is a kind of technology mainly oriented to end users and is implemented through a number of services like providing additional disk space, memory and network capacity as well as providing quality free software applications.

One of the biggest benefits of cloud technologies are new opportunities in business, economics and education. A simple exchange of information and collaborative work on documents (teaching materials) has increased flexibility and has enabled faster execution of tasks. Therefore, there is no longer need to invest in expensive IT and logistics infrastructure, we can use cloud services only when needed, which greatly reduces costs.

Based on several research papers conducted by well-known analysts, manufacturers and IT users of cloud computing and according to the National Institute of Standards and Technology (NIST) [1], this modern cloud computing technology can be said to represent:

The shape of this cloud technology over the existing internet browsers delivers a multitude of applications to end users. Using this model, users do not have to invest in new server and network resources and licensed programs. Cost of service providers are in fact lower than in the traditional service of data storage on a separate server.

II. THE LOGICAL ARCHITECTURE OF THE SYSTEM - WEB SERVICES

Applications must manage all resources of Cloud Computing infrastructure in order to ensure quality services to end users (students). Applications are to be developed for various platforms: Android mobile platforms, Linux, windows and other. The applications would depend on existing Cloud Computing infrastructure, and would be integrated with the root computer of end users (LDAP) which contains accounts for access and relies on web services, what allows future development of other applications that have similar purposes and capabilities [2]. Through the comparable method, a similar application would be developed as well as the web applications with the same purpose.

The application would primarily benefit students chosen to conduct the research experiment, which would allow them to schedule and run predefined virtual machines with all the installed operating systems and necessary software that is required for the particular course.

The software application would use the service-oriented architecture, which allows comparative development of web and mobile applications. The mentioned approach to software development would lead to the creation desktop applications and integration with more some existing system.
Web service has the primary role in business logic and system integration. It integrates the following components: OpenLDAP user directory, Moodle LMS, and MySQL databases [3]. System architecture for execution of the application is shown below (Figure 1)

![System architecture](image)

The end user (student) can access the system using two channels, web applications and mobile applications. In the future, it would be possible to increase the number of channels access to the system.

The complete administration of the system would be conducted through web applications [4] [5]. One thing that would be needed is to ensure that the end user is assigned rights of system administration. Administrators would be able to define the exact DVD image of the operating system stored on Cloud Computing infrastructure and the ultimate users would be able to reserve and initiate the OS image through the application. Since the system would be integrated with Moodle LMS, Virtual machines can be grouped according to the available Moodle courses.

In order to ensure greater scalability of the system and the introduction of opportunities of new services for customers (students) the ultimate Cloud Computing infrastructure would be presented [6]. The complete software for the management of this infrastructure is package Eucalyptus. The complete software code is labeled as open source software and that is a strong advantage of the entire project as it significantly reduces the economic costs of the implementation of this software solution.

For the purposes of evaluation of the developed model of IT infrastructure for education we have conducted an experiment. The experiment covered high school students of third and fourth years as they have been divided into experimental and the control group. Students have voluntarily consented to participate in the experiment. The experiment will be carried out in the municipalities of Stitar, Zupanja and Vinkovci (Croatia) and Samac, Orasje and Odzak (Bosnia and Herzegovina) in the academic year 2015/16. The experiment will include about 470 teachers and students.

The main goal of the experiment is eliciting answers to the following questions:

- In what measure does this online e-learning system stored in the cloud affect the results which students achieve on their final exams (main hypothesis);
- Are the teachers satisfied with the implemented infrastructure for e-education in privately developed Cloud (secondary hypothesis);
- Do we see the expected performance of the implemented system of e-education in the privately developed Cloud (secondary hypothesis).

In order to determine the degree and properly assess the performance of the infrastructure for e-education in privately developed cloud and its effects on the recently achieved results of the students, we shall compare the students’ results which are grained in the environment of the privately developed cloud where the students could have used all the available educational services to those students’ results gained through the system for e-education developed on classical infrastructure, in which new services had not been available (Table 1). Students of the experimental groups had the possibility of using educational resources which are offered through virtual machines. For the control group, the selected students are those who have attended the same courses as the previous generation. The students belonging to the control group have only used the classical system Moodle LMS without accessing the resources and services that our developed platform offers in the privately developed cloud.

In order to estimate the performance of the implemented system of e-education in privately developed clouds we have used a sophisticated software tool - Ganglia. This tools (Ganglia) is for gathering and representation of performances of the server resources. This particular software tool
allows for deeper analysis of all the performance attributes such as the stability of the system, availability, speed and the analysis of performance of its processors (Table 2).

Table 2. Indicator of performances and the system stability

The research survey for researching the selected teachers' attitudes on electronic education system in this private cloud has been developed to contain five questions total. The questionnaire is confirmed using the well-known Cronbach alpha coefficient, which is 0.814, in this particular case. All the survey questions are formed so as to elicit answers in the following areas: teachers' productivity during the preparation phase of the course, teacher productivity during the course realization phase, feedback on technical support satisfaction, feedback on customer experiences of the e-learning system and the general opinions of the developed infrastructure for e-education. All research questions are formed with the well-known Likert five-scale (Table 3).

The experiment or the test covered all the students of the controlled and experimental groups. The testing approach has been used in order to present the statistical significant difference between the results results of the controlled and experimental group. The tests are made for each observed course (Databases, Internet technology, Programming languages). Cronbach alpha coefficients are 0910, 0875 and 0890, respectively. The same tests had been used during the previous five years for the observed courses. Pupils had been enabled to use the provided services in this context of the given environments of private clouds: portal service, e-mail, file management system, service for database management, services for communication and cooperation. These services provide the educational resources, and provide students with:

- Easy access to a variety of useful information and educational services;
- Open interaction between users;
- Information sharing of all the common activities;
- Learning Management system integration

The Strategy of Creation of Educational Resources is defined for needs of each course in context of the electronic education. For each course (Databases, Internet technology, programming languages) we have defined expensive virtual machines with specific hardware and software requirements. Those setup virtual machines contain the names, descriptions, roles and types of virtual machines for each of the three discussed courses.

With the development and realization of the above mentioned IT model of infrastructure for e-education, we have effectively provided contemporary services from the IT sphere and from the sphere of communication technology in order to improve the main educational work. To all the registered tutors, teaching staff and administrators we have provided and made possible a unique, fast and easy access to all the teaching resources and network services and thereby increasing the overall efficiency, safety and quality of the education process.
The procedure of integration services in electronic education in the cloud environment and conducting the electron learning:

Educational courses are created by all the teachers through Home LMS system. After that, for each course we prepare the instructional materials, activities and tasks. Also, we prepare the most specific software tools needed for each course. All the pupils’ accounts are created in the Home LMS and integrated with LDAP directory linked to the educational institutions. After that, we prepare the virtual machines with the main operating system, application software and tools necessary for each individual course. Following up, we prepare virtual machines stores as DVD images deposited in the private cloud. Students use the familiar and user-friendly web interface or mobile application interface to book some courses from the predefined virtual machines. Finally, teachers and administrators of the system can see and analyze the final results of the students performance in the system and only store the results in the private clouds.

Table 4. Students’ results achieved after the testing phase

For testing the existence of the significance difference variable between the obtained results gathered from the students of the controlled and experimental groups we have used the variable of analysis. The final results show (Table 4) that there are significant statistical differences between the achieved results of the controlled group of our students and the experimental group of our students for all three observed courses:

- Database: $F(1,929) = 16.648$ (p <0.05)
- Internet technology: $F(1,482) = 4.130$ (p <0.05)
- Programming languages: $F(1,345) = 4.930$ (p <0.05)

III. CONCLUSION

In the process of analyzing all the collected information from the recently conducted surveys of teachers, we can conclude the following:

- Most teachers agrees that this infrastructure of private clouds enhances the productivity in preparing for the courses intended for e-education experience. However, several teachers have had contrary opinions. Those teachers are mainly the individuals who have had to invest more efforts in preparation of certain teaching themes like setting up specific virtual machines for the given teaching themes;
- When considering the application possibilities of this infrastructure stored in private clouds for realization of electronic education, most teachers agree that the implemented infrastructure enhances productivity when conducting electronic courses;
- The technical support used in the given infrastructure of the private clouds is at an adequate level for most of our teachers. However, several teachers have not been satisfied with the quality of the provided technical support;
- The reporting channel implemented in the system of electronic education is at an adequate level for most teachers. However, there has been a significant number of teachers who have had different opinions on reporting. Those are mainly the teachers who did not need to use the reporting services;
- not was teachers which think that realization infrastructure private clouds not suitable for e education. most teachers you agreed that is infrastructure very suitable for system e-education;
- Our teachers are satisfied with the quality of the system for identity management. Most teachers agree that in order to access all the necessary resources, one can easy access them over the integrated system for management of identities.

The Struggle with Academic Plagiarism: Approaches based on Semantic Similarity

Tedo Vrbaneč1, Ana Meštrović2
1Faculty of Teacher Education, University of Zagreb, Croatia
2Department of Informatics, University of Rijeka, Croatia
tedo.vrbaneč@gmail.com, amestrovic@inf.uniri.hr

Abstract - Academic plagiarism is a serious problem nowadays. Due to the existence of inexhaustible sources of digital information, today it is easier to plagiarize more than ever before. The good thing is that plagiarism detection techniques have improved and are powerful enough to detect attempts of plagiarism in education. We are now witnessing efficient plagiarism detection software in action, such as Turnitin, iThenticate or SafeAssign. In the introduction we explore software that is used within the Croatian academic community for plagiarism detection in universities and/or in scientific journals. The question is - is this enough? Currently software has proven to be successful, however the problem of identifying paraphrasing or obfuscation plagiarism remains unresolved. In this paper we present a report of how semantic similarity measures can be used in the plagiarism detection task.

Keywords: academic plagiarism, plagiarism detection, obfuscation plagiarism, natural language processing, semantic similarity

I. INTRODUCTION

Academic plagiarism is nowadays one of the most pressing problems of the academic community. Many successful plagiarism detection tools and software products have been developed. However, the detection of paraphrasing or obfuscation plagiarism remains a challenge because most of the existing tools are only able to detect copy-paste cases of plagiarism. Plagiarism is not just the direct copying of one's text. It can be far more complicated if it is a case of paraphrasing or obfuscation. According to [1] high-obfuscation plagiarism can be realised by modifying original text by reduction, combination, paraphrasing, summarizing, restructuring, concept specification and concept generalization.

Due to this, there are serious drawbacks of systems such as Turnitin or SafeAssign. More precisely, these tools cannot deal with the vocabulary problems such as synonymy, homonymy, hyperonymy and hyponymy. There are many various approaches in the area of natural language processing (NLP) that may offer a solution for this task.

However, there is still lot of room for improvement. This is why we are focused on paraphrasing and obfuscation plagiarism detection. We analyse various approaches that may identify paraphrasing and obfuscation by means of semantic similarity measures. Some are based on external knowledge resources such as WordNet or ontologies, and others are based on statistical NLP techniques.

The goal of this paper is to analyse the possibilities of existing semantic similarity measures and somehow classify existing approaches. This is just a preliminary study of this wide domain with the further goal of providing an extensive overview and classification of all semantic similarity measures of text and possible approaches in paraphrasing identification. In addition to this, we give a short review of the situation with academic plagiarism in Croatia. This is important because the struggle against academic plagiarism nowadays is on-going and there are frequent clashes.

In the first part of the paper we describe the problems of academic plagiarism. Furthermore, we give a brief review of academic anti-plagiarism efforts in Croatia. In the second part of the paper we are focused on various approaches for plagiarism detection based on semantic measures. After this we give an overview of other papers which try to resolve plagiarism detection problems with NLP techniques and semantic similarity. Finally, the sixth section contains a conclusion and possible directions for future research.

II. ACADEMIC PLAGIARISM

Academic plagiarism in other words the plagiarism of digital text is most often the target of plagiarism during education and in academic papers. Academic plagiarism is a syntagma which indicates the plagiarism of a complete or part of documents of the following kinds: of programs in the source programming code, seminars, critical reviews, professional or scientific papers and non-literary books. The first tagmeme of syntagma - academicaly, points out that this kind of plagiarism most often appears in the academic community. At the same time it means that in the academic context plagiarism is a particularly worrying phenomenon which attracts the attention of all academic structures.

Below we provide a list of the methods of academic plagiarism and after that comment upon the anti-plagiarism efforts in the Croatian academic community.
A. Methods of Academic Plagiarism

The most famous plagiarism software manufacturer Turnitin [2], distinguishes academic plagiarism methods and research paper plagiarism methods. As academic plagiarism methods it lists:

- the submission of someone else’s work as one’s own, in order to fulfil a specified teaching obligation,
- the copying of words or ideas without giving credit to the original author,
- copying the majority of the words or ideas that compromises the work,
- submitting an already submitted work (e.g. from another colleague),
- not using quotation marks when quoting,
- giving incorrect data about sources,
- the use of someone else’s sentences by using substitute words,
- using someone else’s ideas without referencing.

Turnitin also lists the research plagiarism methods [2, Pt. 1, p. 5]:

- “Claiming authorship on a paper or research that is not one’s own.
- Citing sources that were not actually referenced or used.
- Reusing previous research or papers without proper attribution.
- Paraphrasing another’s work and presenting it as one’s own.
- Repeating data or text from a similar study with similar methodology without proper attribution.
- Submitting a research paper to multiple publications.
- Failing to cite or acknowledge the collaborative nature of a paper or study”.

B. Software solutions used in Academics

In order that the academic community could effectively fight the modern plague in science and education – plagiarism, it is necessary [3, p. 123] (1) “to form warnings and measures in the education of students and scientists” … “at all levels of education” [4, p. 108] and (2) to develop or use existing software systems for plagiarism detection. According to [3], [4], the most widely used software products in the world are: iThenticate, SafeAssign and CrossCheck. All the papers checked by Turnitin are stored in a database for further comparison. SafeAssign is optional in this regard. CrossCheck uses a large database of papers which have been handed over for the use of scholarly publishers affiliated to their CrossRef organisation. In return they can use the plagiarism detection system free of charge. Individuals do not generally have some cheap or free of charge choice. One of the possibilities is the Viper desktop application, which only works in the Windows environment.

It is known that with the software detection of plagiarism there still exists the insufficient detection of so-called intelligent plagiarism cases [3]: the plagiarism of ideas, complex paraphrasing, and plagiarism between multiple languages. This is trying to be resolved in existing commercial software systems with the adding of translation modules, however the solution is in a qualitative upturn: the detection of semantic similarities between documents.

C. Academic Anti Plagiarism Efforts in Croatia

In the EU and around the world, plagiarism is a very worrying phenomenon against which educational, preventative and restrictive methods are used. In 2015 The Council of Europe supported this effort by establishing the Pan-European Platform on Ethics, Transparency and Integrity in Education (ETINED), the aims of which priority activities are, amongst others, [5]: “Ethical behaviour of all actors in education” and “Academic integrity and plagiarism”. In this context the European Commission led a project (2010-2013) in which Croatia did not participate: The Impact of Policies for Plagiarism in Higher Education Across Europe (IPPHEAE) “whose aim was to explore policies and systems of assuring academic integrity and deterring plagiarism in a system of higher education” [6, p. 5].

However, in Croatia as a member of the same EU, it is possible that the secretary of a parliamentary party, a rector of a university or a member of the Constitutional Court use plagiarism, yet in doing so are not sanctioned, what’s more – they continue to perform their high office. And this is all despite the fact that in 2006 a Committee of Ethics in Science and Higher Education was established as a body of the highest legislative authority in Croatia (Parliament).

Turnitin has been used by the University of Rijeka since 2014 [3, p. 12] and immediately after by University of Osijek. The VERN Polytechnic and the Zagreb School of Management use Turnitin, too [6, p. 12], as well as by individual faculties of the University of Zagreb, where there is unfortunately no joint financing, although the Rector announces it. In the meantime, individual faculties autonomously negotiate plagiarism checking services at their own expense. For example, the Faculty of Teacher Education in Zagreb used Ephorus for several years, however due to its high price and it crossed over to the cheaper solution: desktop only and Windows only application Plagiarism-Detector Personal.

The University of Split planned to begin using some software from 2015, but since the beginning of 2017 they have still not done so, due to the high prices. On the level of collaboration between Croatian universities, the president of the Rector’s Assembly announced the collaboration of projects of mutual interest and a reduction of the burden of cost to each university.

Some unspecified plagiarism checking software is used by the School of Dental Medicine and the Faculty of Political Science [7, p. 2]. Furthermore, some scientific journals in Croatia use plagiarism detection software systems, e.g. Biochemia medica [8], the journal of the Croatian Society of Medical Biochemistry and
Laboratory Medicine which both use iThenticate since 2013.

Members of professional committees for (re)accreditation from abroad are participating in the processes of the (re)accreditation of Croatian higher education institutions. Usage of plagiarism detection tools is one of the parameters for measuring the quality of professional and scientific work in academic institutions. This has prompted many of them to start using some plagiarism checking software or to consider options of using it. Surely the best solution for all of them is to unite, as many educational institutions as possible, in a common approach to suppliers, i.e. service providers, because in this way individual institutional usage is the cheapest, and further on, the database of documents – the corpus, as the basis for software comparison, becomes more complete. The current practice is that individual universities or faculties sign contracts with the software dealers or manufacturers, usually in three years’ contracts, for a price that is of much greater than if they bought together and without less limitation of usage.

III. SEMANTIC SIMILARITY

The concept of semantic similarity is fundamental and widely understood in many domains of natural language processing [9]. It can be defined as the degree of taxonomic proximity between terms [10]. The terms that can be also used instead are semantic proximity or semantic distance as an opposite concept. According to Resnik [11], semantic similarity represents a special case of semantic relatedness. He gives an example that cars and gasoline seem more closely related than cars and bicycles, but the latter pair is more similar.

Semantic similarity can be measured in terms of numerical score that quantifies similarity/proximity. In existing research’s various semantic similarity measures (SSMs) have been defined and many semantic similarity computational models have been proposed. Semantic similarity measures have been widely used in many NLP and related fields such as text classification, information retrieval, information extraction, word sense disambiguation, machine translation, question answering, plagiarism detection, etc.

Semantic similarity can be calculated on different levels of granularity (between words, between paragraphs or between whole texts/documents).

In the case of plagiarism detection, semantic similarity should be expressed on the text level as the final result. The score of semantic similarity between suspected document and one or more other documents may indicate the existence of plagiarism. The whole procedure of plagiarism identification, semantic similarity can be calculated on the sentence and paragraph level.

IV. SEMANTIC SIMILARITY MEASURES

In this section we will give an overview of different measures and approaches in measuring the semantic similarity of texts. Semantic similarity measures are defined in the domain of NLP for various tasks. One of the first application of SSMs was obtained in 1970s seventies for the task of information retrieval [12].

There are various approaches in detecting semantic similarity. According to [13], there are two main approaches in measuring the semantic similarity of texts: corpora-based and knowledge-based. There is also a class of ontology-based semantic similarity measures extensively described in [10]. These measures also belong to the class of knowledge-based measures. Here we present another approach in which we classify measures it two categories: SSMs on the concept/word level and SSMs on the document/text level (Fig. 1).

![Figure 1. Simple classification of semantic similarity approaches](image)

A. Semantic similarity on the concept/word level

Semantic similarity on the concept or word level is based on the hierarchy between concepts or words. It is usually defined for the taxonomy such as WordNet or for some more extensive ontology [10]. These measures assume as input a pair of concepts or words, and return a numeric value indicating their semantic similarity. Based on word similarities it is possible to compute the similarities of texts according to variously defined equations [13].

If we have an ontology or “IS-A” taxonomy with a set of concepts C. The similarity between two concepts can be computed by taking into account the edges (edge-based measures) or by taking into account the nodes (node-based measures).

Edge-based measures estimate the similarity of two concepts according to how near these two concepts are. The simplest way to measure semantic similarity of two concepts c1 and c2 is to estimate the distance of two concepts as the shortest-path between them [14]. There are more sophisticated approaches that take into account the possible weights of edges between two concepts. In most cases, the semantic similarity of two concepts is
estimated as a function of the depth of the Least Common Ancestor (LCA) or Least Common Subsumer (LCS) [10]. An example of this approach is Wu and Palmer metrics [15] with a very simple similarity measure of two concepts:

\[ \text{sim}_{\text{WPM}}(c_1, c_2) = \frac{2 \text{depth}(\text{LCA}_{c_1, c_2})}{\text{depth}(c_1) \cdot \text{depth}(c_2)}. \]

Node based approaches can be divided into two categories: a feature-based and one based on information theory.

In a feature based approach a concept is described with a set of features \( F \). Thus, two concepts can be compared in terms of classical binary or distance measures. An example of this approach is the Concept-Match similarity measure defined by Maedche and Staab [16]:

\[ \text{sim}_{\text{CMatch}}(c_1, c_2) = \frac{|F(c_1) \cap F(c_2)|}{|F(c_1) \cup F(c_2)|}. \]

Approaches based on information theory are based on Shannon’s theory. The similarity of concepts is defined according to the amount of information they share. Resnik define a measure:

\[ \text{sim}_{\text{Resnik}}(c_1, c_2) = \max_{c \in S(c_1, c_2)} \left[ -\log p(c) \right], \]

where \( S(c_1, c_2) \) is the set of concepts that subsume both concepts \( c_1 \) and \( c_2 \).

Pointwise Mutual Information is proposed by Turney [17]. It is based on word co-occurrence using counts collected over very large corpora. For two words \( w_1 \) and \( w_2 \), their PMI-IR is measured as:

\[ \text{sim}_{\text{PMI}}(w_1, w_2) = \log_2 \frac{p(w_1, w_2)}{p(w_1) \cdot p(w_2)}. \]

There are many other concept level measures, named by their authors, amongst whom the important ones are: Leacock & Chodorow, Lesk, Wu and Palmer, Resnik, Lin, Jiang and Conrath, Zhong, Nguyen and Al-Mubaid, Caviedes and Cimino, etc.

B. Semantic similarity on the document/text level

Similarity measures on the document or text level are mainly based on the approaches developed in the NLP domain. Most of these approaches have their roots in machine learning. In this section we briefly describe the most used approaches for calculating the semantic similarity between two documents.

One of the first approaches in measuring semantic similarity between documents was vector space model (VSM) originally proposed by Salton et al. [18] for the task of information retrieval domain.

In the VSM each document is a point in an \( n \)-dimensional space. For a given set of \( k \) documents \( D = \{ D_1, D_2, ..., D_k \} \), a document \( D_i \) can be represented as a vector \( D_i = (w_{i1}, w_{i2}, ..., w_{in}) \). In the classical word-based VSM, each dimension corresponds to one term or word from the document set. Weights may be determined by using various weighting schemes; TF-IDF is usually used in the word-based VSM. The similarity between two documents \( D_i \) and \( D_j \) can be calculated as cosine similarity:

\[ \text{sim}_{\cos} = \frac{D_i \cdot D_j}{\|D_i\| \cdot \|D_j\|}. \]

The main drawbacks of this model are high dimensionality, sparseness and vocabulary problems. Therefore, there are various modifications and generalisations of this classical version of the VSM.

Another approach is Latent semantic analysis (LSA) proposed by Landauer (1998). It also exploits the vector space model, but in this approach it uses a dimension reduction technique known as Singular Value Decomposition (SVD) of the initial matrix. In this way LSA overcomes the high dimensionality and sparseness of the standard SVM model. The similarity between two documents is again calculated as a cosine similarity as in equation or some other similarity measure.

One more recent approach is deep learning. Similarly with the previous methods, in deep learning documents or texts can be represented as vectors by the using document to vector technique (doc2vec). Moreover, words are also represented as vectors by using the word to vector strategy (word2vec). There are variations in learning word vector representation; one is the matrix decomposition method such as LSA; another is context-base methods such as skip-grams, a continuous bag of words. Furthermore, there is an unsupervised algorithm that learns representation for documents or smaller samples of texts (paragraphs, sentences). At the end, vectors can be compared using cosine similarity or some other similarity measure.

There are also other similar measures for text similarity such as Explicit Semantic Analysis (ESA), Salient Semantic Analysis (SSA), Distributional Similarity, Hyperspace Analogues to Language, etc.

V. RELATED WORK

There are attempts to identify plagiarism by semantic similarity measures. Researchers have approached the problem of determining plagiarism through semantic similarity in a multitude of ways. Many have used ontologies, usually WordNet with some additions like fuzzy similarity measures, a combination of WordNet with morphological and syntactic analysis, machine learning from examples or with hashing, etc. Others have turned to intrinsic methods, citation-based plagiarism detection, graphical representation, natural language processing, deep learning and even multidimensional approach.

Shenoy et al. (2012) [21, p. 59] “proposes an automatic system for semantic plagiarism detection based on ontology mapping”. They invented an algorithm which is capable of learning ontology from documents using Web Ontology Language OWL and then applying it to ontology mapping to “detect correspondences between the various entities” [21, p. 60].

WordNet has been used by more than a few researchers. Al-Shamery and Gheni (2016) [22] consider that finding synonyms (over WordNet) on the same place in comparing documents is to be the proof of semantic plagiarism.

Alzahrani and Salim (2010) [23] presents “plagiarism detection method using a fuzzy semantic-based string similarity approach”. They pull potential source documents using shingling and Jaccard coefficient, then compare them to the sentence granularity, simultaneously computing fuzzy degree of similarity with the help of WordNet a (different words gets 0, WordNet synonyms gets 0.5, the same word gets 1 fuzzy degrees).

Marsi and Krahmer (2010) [24] suggested the semantic similarity method for analysing comparable text that relies on a combination of morphological and syntactic analysis, WordNets, and machine learning from examples. They analyse semantic similarity between sentences “by aligning their syntax trees, where each node is matched to the most similar node in the other tree (if any)” [24].

Czerski et al. (2015) [25] proposed using an algorithm based on sentence hashing but the approach was combined with replacing some word for some representative ones using synonyms and the WordNet, thesaurus and “IS A” ontology, so the number of sentences in the document is reduced and the remaining sentences consist only from lemmas.

Eissen and Stein (2006) [26, pp. 566–567] used the intrinsic method of semantic similarity discovering: stylometry analysis, using five categories of stylometric features: “(i) text statistics, which operate at the character level, (ii) syntactic features, which measure writing style at the sentence-level, (iii) part-of-speech features to quantify the use of word classes, (iv) closed-class word sets to count special words, and (v) structural features, which reflect text organization.” They also introduced a new stylometric measure: averaged word frequency class, as "the most powerful concept with respect to intrinsic plagiarism detection" [26, p. 567].

Gipp et al. (2013) [27, p. 1119] noticed that plagiarists “usually do not substitute or rearrange the citations copied from the source document”, so they developed several Citation-based Plagiarism Detection algorithms using citation patterns within scientific documents “as a unique, language-independent fingerprint to identify semantic similarity” with reasonable success in detecting disguised plagiarism.

Osman et al. (2010) designed a method of detecting plagiarism based on graph representation. For two documents their method [28, p. 36] “build the graph by grouping each sentence terms in one node, the resulted nodes are connected to each other based on order of sentence within the document, all nodes in graph are also connected to top level node” which is “formed by extracting the concepts of each sentence terms and grouping them in such node”.

Chong et al. (2010) [29] applied several NLP techniques on short paragraphs to analyse the structure of the text to automatically identify plagiarised texts. They proved that NLP techniques can improve the accuracy of detection tasks, although there remain challenges such as multilingual detection, synonymy generalisation (word sense disambiguation) and sentence structure generalisation.

Gharavi et al. (2016) [30, p. 1] proposed a “deep learning based method to detect plagiarism” in the Persian language. “In the proposed method, words are represented as multi-dimensional vectors, and simple aggregation methods are used to combine the word vectors for sentence representation. By comparing representations of source and suspicious sentences, pair sentences with the highest similarity are considered as the candidates for plagiarism. The decision on being plagiarism is performed using a two level evaluation method” [30, p. 1].

Mihalcea et al. (2006) presented a method that outperforms a vector-based similarity approach for measuring the semantic similarity of texts using two corpus-based and six knowledge-based measures of word similarity which they used “to derive a text-to-text similarity metric” [13, p. 775].

In [1] Kong et al. (2014) tried to detect high obfuscation plagiarism with a Logical Regression model. The proposed model integrated lexicon features, syntax features, semantics features and structure features which are extracted from suspicious documents and source documents.

VI. DISCUSSION AND CONCLUSION

In this paper we want to describe our preliminary research on semantic similarity measures and their possible usage for paraphrasing detection in the task of plagiarism identification. We analyse some existing measures for quantifying the semantic similarity of texts. There is a plethora of measures and approaches proposed and we divided them into two basic categories with some subcategories. All these measures are defined for different purposes in NLP domain. However, according to the related work, it is obvious that some of these measures can be utilized in the task of plagiarism detection.
One possible approach is based on external knowledge represented in some formalism. External knowledge can be represented in ontology or simpler taxonomies such as WordNet. However, the formalism is not limited to these classical ontologies/taxonomies; it can be any kind of graph representation of lexical relations [31]. Another approach is to use statistical methods designed in the domain of NLP. In the section about related work we present all the approaches that have been used recently for plagiarism detection.

There may be one drawback of the approach based solely on the semantic similarity measures. We need to point out that, perhaps these semantic measures are not enough, and that they can be combined with classical approaches that may identify copy-paste plagiarism.

For further research we plan to experiment with the NOK method [32] or some other graph based formalism for lexical relation representation [33]. Additionally, we would like to experiment with the approach that we try with an ontology-based information retrieval in which the classical VSM is projected onto a smaller vector space [34].

Abstract - The methodologist's cognitions achieved by experience in education resulted in the fact that the centre of education must be transferred from a teacher to a student. The result of such an approach is the development of personal environment for learning. Former generations of the learning system by which introduction of information technology is introduced into educational process points to the need for introduction of individual approach to learning by development of personal environment for learning. The results of the most important researches implemented at the European universities are presented. Current leading systems for the development of personal environment for learning and tools for creation of personal environment for learning are described. The directions of development of educational environment and guidelines for future researches are established.

I. INTRODUCTION

Transferring and acquisition of knowledge is an individual process for persons who transfer and those who acquire knowledge. It is expected that identical way of transferring the same material on the homogeneous group provides approximately the same results in learning and it is not a repeated case. Actually, individual differences among single individuals are the main reasons for that. The levels of acquisition of new knowledge are conditioned by differences in characteristics of personality, cognitive abilities, learning styles, previously acquired knowledge and skills as well as the level of motivation what is the base for further learning of new materials [1].

There are four types of learning within Croatian qualifying framework and those are:
- Lifelong Learning which denotes the all forms of learning during life and for the purpose of improving the knowledge and skills
- Formal Learning denotes an activity of authorized institution which is carried out according to the approved programs and for the purpose of improving the knowledge and skills and for which a public document is issued
- Non-formal Learning denotes the organized learning activities for the purpose of improving the knowledge and skills, but a public document isn’t issued
- Informal learning denotes the unorganized activities of acquisition of knowledge and skills, as well as an adequate self-reliance and responsibility resulting from everyday experiences and other influences and sources from an environment, for personal, social and professional needs [2].

Comparing researches on education in adult almost 70-80% of learning is acquired informally [1]. The importance of informal education regarding population is definite. Such way of acquiring knowledge, with regard to percentages isn’t irrelevant, but the leading way of knowledge acquisition.

We differ three generation of Learning Management System (LMS). The first generation was only the distribution of material. It had possibility of very remote or none communication and integration way communication among attendants and teachers were developed and is still being developed in period which is very similar for all attendants without taking into consideration individual differences. From the absences of the second generation arises the third generation which allows user to create an individualized contents and transfers centralization from the position of teacher upon attendant [3, 4].

LMS systems are included into institutional education. The use of that tool initiated consideration on defects and possibilities of improving. One of more important defects is the inflexibility of the contents [5]. Development of personal environment for learning contributes considerably in elimination of such defect. The reason for the development of PLE are enormous defects of LMS what is pointed out by Comacho and Guijana in their work considering that LMS reproduces teaching where a teacher is in the center of a closed model, so attendants are joined in standardized system [6]. Dabbagh and Kitsantas pointed out the defect of the system which doesn’t allow attendants to manage the education space. It is impossible to show your own works to others neither to go through other works [7].

Chapter 2 defines the term of the Personal Learning Environment (PLE) after which the approach of implementation is presented in chapter 3. Chapter 4 analyses the most important approaches to implementation of PLE. Chapter 5 contains guidelines for further work and future researches. The work is closed with chapter 6 by conclusion.
II. PERSONAL LEARNING ENVIRONMENT

PLE can be described as personal environment where somebody learns. That environment must be set and designed according to the user’s needs, that is according to his style, needs and contents [3, 8]. It isn’t a technological tool, but pedagogical approach which is based on technology [9]. Today, PLE has become more than an approach to how people learn. It is a system which helps a student to take control over his learning. It includes setting your own goals, control of learning, communication with other participants in the learning process. Its strategy to understand and promote formal, informal and self-regulated learning of students, is of great interest. It’s important to emphasize the relevance of social media in sharing learning achievements and making sense of them [7]. PLE can be compiled on one or more systems. As such it can be a desktop application or the set of systems placed on the Internet [10].

PLEM (Personal learning environment manager) is a personal learning environment that supports students in creating personalized spaces. In PLEM we distinguish four types of elements of learning: educational materials, educational services, educational experts and educational community [11].

In a personal environment a person can engage, organize, and manage formal, informal and by informal educational materials, tools and experiences.

PLE consists of a client and server parts. In the client part there are applications which communicate with web servers. Applications lead students according to increasing flexibility and effective environment. The server’s part is responsible for the data that is stored locally on the PLE web server.

A. Main Function of the PLE model

Fig.1 shows a model of the main functions of the PLE, and it consists of:

- Searching- it includes searching the Internet content archives and the organization of content
- Organizing- includes labelling, reference management, archiving, either on disk or cloud.
- Creating- includes all activities that are directly related to teaching, writing, producing releases, messages, posts, blogs.
- Communicating, collaborating- interaction, discussion, debates, comments, team work.
- Publishing and sharing- The publication on the Internet when the materials and work are finished
- Project management- defines the settings of learning, rate of learning and learning goals [8].

During the time of formal and informal education the student is a part of the community which allows him to communicate with all the elements of the educational process, but in informal education student learns independently, he manages the complete process of learning without anyone’s monitoring.

PLE is neither specified nor completed system and the best is to use it in order to get sooner and easier new insights. It’s the concept of using different technologies and applications in the process of independent learning, and a key determinant of the concept is that the user independently determines which applications will be used and for what purpose.

In PLE a student should use a simple set of tools, adapted to his needs and characteristics in his personal environment. The tools should enable the student to:

- Learn with other people by determining relationships with other people and other persons as well as the share of the relationship among the contacts that are not a part of his formal educational network,
- Control his resources for learning and allow them structuring, sharing, commenting on sources which were found by their side or by side of the age mates
- Manage with activities in which they participate, providing them with the opportunity to set up and join in activities such as studying groups or gathering of certain groups of people with appropriate resources,
- Integrating learning: allow them to combine learning with different institutions or allow the connection between the formal and informal education [12].

Finally, the environment has to be enough easy for use, maintenance and administration, but still has to enable the collection and linking of the resource that the user will use and store so that he could adapt the computing support to learning processes, with an emphasis on informal learning [13].

III. APPROACHES TO THE IMPLEMENTATION OF PLE

The learning process is unique to each individual. The student’s individuality is evident in creating learning plan and the selection of the environment in which he learns. If the student made the learning plan he needed the prior knowledge. Studies have shown that students most often primarily read mentor’s texts or the texts approved by the Organization, and only then resort to the individual tools. Such concept is the result of the use of classic LMS system and poor prior knowledge. Up to now, this
problem is resolved in a way that a master makes a plan and an environment for what he thinks will suit students.

Linda Castenada, Jordi Adell in their work did research in the way that they wanted to meet PLE from pedagogical approach. It is important to understand the learning process that is in the background of the educational system. The author investigated how students would integrate their education process in their own environment of PLE and build PLE setting tools in it. Their idea is to understand how is the PLE organized by the students, but not by technology but with the processes that take place at students. Students who participated in the study were the first year students.

The study included 30 students who were divided into 6 different groups. All school materials were involved in the LMS SAKAI. Course duration was limited to two weeks in which students participated three hours per week in classes in the classroom, and other obligations had to do on their own. The authors divided all processes into reading processes, creating and sharing and for each of them is made the cloud of the used technology. Examples of the clouds are shown in fig. 2, 3 and 4 [9].

It is difficult to made environment that would suit all students. The solution is shown through the individual monitoring of the student movement according to classic LMS. If we keep track of the activities of attendants, we could anticipate the habits of the attendants and thus ease him to make the learning environment from which he would be allowed to return to classic LMS view. Monitoring of students and proposing the material for which it is considered to be at ease and would have helped him to create a personal environment.

There are several approaches to increasing individualization of the learning environment. PLE is considered to be the educational concept that allows the student to choose methods and tools for his education.

Looking from that perspective PLE looks like a tool based on the pedagogical approach rather than a technological platform.

According to Volton’s attitude it is necessary to allow students to choose the learning methods and ways of learning. Looking from that attitude a personal environment is the informational-communicative technology. Thus Volton advocates PLE as a model, and not as a technological platform [14].

Castaneda and Soto consider that the personal environment should contain sources that the student uses in order to find information, relationships between information and relationships among the different sources. Their main focus is directed towards the mechanism and the tool that independently develop the environment for future learning [15].

Most authors define only-routing either as the ability necessary for the development of the personal environment or as an ability that is developed through the process of creating such environment.

Dabbagh and Kintsantes describe the correlation between self-directed learning and social networks. They develop a pedagogical framework for social networks. The aim of such a framework is to inform on the way how to make the PLE which supports self-directed learning. Their starting points were the students who were constantly viewing and sharing information using technology and thus become co-authors of the content [7].

Shaikh and Khaje consider that the process of building the PLE requires an equal participation of the students and teachers as well. Teachers don’t necessarily play out all the steps at managing the learning process but the focus needs to be on collaboration with students. Also it can’t be ignored competitions of teachers directed according to the nature and complexity of the tasks that students should understand [16].

Joao Paz in his research in which 20 students of the University Aberta, Portugal, took part, tried to integrate and to determine characteristics of LMS and PLE, advantages and disadvantages and ways of designing PLE by students. Total number of tools used by students was 29.

The most popular were: Skype, Youtube, Googlesearch, Side Share, Blogger. The tools that were used after its main function were used at percentage: 36% for communication, 20% for making the materials and projects, 19% for search, 11% for the Organization of the content and 9% for publishing and sharing their materials [8].

In the research that was carried out at University in Balears in Spain, students should have evaluated the use of Symbaloo EDU tools. The questions were divided in a way that it was supposed to evaluate the environment that students independently create and the environment given as a template by the University. Regarding questions on the usefulness of personal environment, about 60% of students agreed that the personal environment is useful and rated it with high grades 4 and 5. None of the respondents didn’t evaluate a personal environment with...
the lowest grade of 1, while 5% of respondents evaluated with grade of 2. The tool also got high marks as a manager of the personal education on the course and the University. 87% of students evaluated it with the mark 4 and 5. Simplicity of using tools is evaluated with high grades in 82% of the students in a situation where they had the template made by the University, but in situation where they had to make their own personal template that percentage drops to 62% [17].

In research carried out at the University of Southampton, students use social networks to divide information 30%, 29% work in network, communication 59%, putting questions 14% and replying to questions 10% [18].

Social networks analysis is a social analysis of the internet. It is a method which attempts to understand the formal and informal connection among social networks. In research attended by 41 professors from 12 countries the tools that were used to a greater extent were Facebook 78%, Twitter 76% and LinkedIn 68%. A tiny percentage of the used tools were Classroom 2.0, Tuenti and Google+. As the main advantage are pointed out two things:

- Sharing of the content what is useful for 63% of Facebook and 81% of Twitter users
- Learning new contents which is useful for 50% of Facebook users and 81% of Twitter.

Even 70% of teachers noted that Twitter could be used for the purpose of education while the same thing was recognized by 50% of Facebook users [18].

IV. ANALYSIS OF DIFFERENT APPROACHES TO PLE IMPLEMENTATION

Personal environment is possible to apply through a variety of tools. When using the tools it is necessary to take care of prior knowledge of the participant as well as popularity and capabilities of the tools. Setting up the PLE is a demanding job and requires a lot of planning. The teacher should be innovative and has to know to find material which will be able to use by trainees. Moreover, he should know why PLE is necessary, he should also know how is it possible to incorporate Web 2.0 tools into the plan and learning program in order to enable collaborative learning [19].

In an effort of implementation at high school students used the most familiar tools. So for homepage they usually chose Google, for making target folders they used Mind Meister. For making the presentations they used Prezi, while for exchanging documents they used GoogleDocs, and for exchanging videos they used Youtube. The conclusions are drawn from researches [19]:

- You don’t need to overestimate the digital skills of the students, they need to prepare themselves so that they could adapt web tools for their needs and learning activities
- You don’t need to overboard with the number of web tools in a short period of time

- Include students in design process allowing them to make decisions on learning activities and selection of web tools
- Explain the role of teachers and students in the process.

A. ROLE

Responsive Open Learning Environment (ROLE) is European collaborative project with 16 internationally recognized research groups from 6 EU countries and China.

The main objective of this project was to support teachers in development of personal learning environment for every student ROLE offers flexibility and personality in the content and of the overall learning environment and its functionality. It uses the open source approach, and any tool created by an individual is available for all those who learn by means of internet, regardless the subject they learn, learning environment, operating system and device they use.

ROLE covers five main objectives:

- Supports individual use of available educational services, tools and resources
- For research and development of psychopedagogical sound framework
- For the creation of new engineering methodology
- For development and maintenance of valuation methodologies
- For the exploitation and expanding of the result of the ROLE.

For students and teachers ROLE infrastructure allows the targeting the students to PLE and so reinforces the user’s journey towards lifelong learning across the institutions.

B. PLEF

Personal Learning Environment Framework (PLEF) system has been developed at the University in Achenu. The system enables the aggregation of data from multiple sources. It supports pupils in taking control over their own learning through management, tagging, commenting, and sharing their favorite materials in a personalized environment. PLEF is prominent among the following items:

- Uses Open ID
- Supports commenting and sharing all the PLE elements
- Access control is defined on each page separately
- Beside traditional approach PLEF offers a view of all the elements. Students can add tags to make the materials classified, categorized, searched and found again
- Supports lateral navigation bar where you can ‘drag and drop’ method drug the new element or modify the order.

Students can divide the complete content according to privacy policy and they have insight in all of their materials and those which are publicly available and which are created by other students.

C. ELGG

ELGG is free open source tool developed in New Zealand. It is based on open standards and open APIs allowing users to improve it with their own favorite tools. Courses and materials are directly displayed in ELGG. One of the major advantages is the possibility of maintenance ELGG account and when the students leave the institution. In that framework it is possible to build all kinds of social environment from the campus of the wider social networks for the university, school or college.

ELGG is free program that must be installed on your computer. It uses the GPL and MIT licenses which enable that content which is made independently by user could be sold but the client who buys that content can redistribute it.

D. Comparison of the tools

In table 1, the tools for creation of PLE are compared. The tools are compared by properties: client’s technology, identity verification, possibilities of multiple identity, commenting, user’s tags, learning plan, ways of communicating and the status of the tool on the basis of production.

V. DIRECTIONS OF PLE DEVELOPMENT

Educational environments are becoming more flexible and more decentralized. In that development, all the processes are directed towards students and their interaction. A large number of the authors explore the tools and systems which are the most common in the student’s choice. If we understand the path of construction of student’s personal environment it is possible to understand his style of learning and adjust our methods to those styles.

We can conclude how the student’s learning process has the following phases:
- Students first read professors’ documents
- Engage in independent creation and solving the problems
- They have need to share their work with others.

Changing educational process can be motivating and prosperous process, but at the same time even very responsible process. The result of that educational process is hardly measurable size and it is showed through a certain period of time but not through one variable.

Pascoa wonders whether we understand how quickly and dramatically the world changes and do we understand that in ten years today technology will be out of date. Furthermore, he claims that the top ten most popular jobs in 2010. didn’t even exist in 2004. [20].

In consideration with the fact that education must be available 24 h a day continuously with social connections.

Downes (2010.) points out that teacher should change himself in the way to become more varied and that his action is spread in different functions. Teachers need to make the most of desirable technology and be aware of the importance of pedagogy so that it can effectively support the learning in the new context [21].

Lagarto (2012) believes that an educational strategy dramatically changes its paradigm and today offers broad opened options. He sees teachers as persons who will need to have also the good functions of the on line content manager and at the same time the environment that is most appropriate for his students [22].

Attwell (2012.) the future of e-education is seen not only in involving of that process in basic, secondary and high education (formal/informal) but as a part of the long life educational process [23].

In research of materials used by students at SAPO campus, it was shown that students chose materials and platforms which were supported by the institutions. They believe in the institutions and their selection and only when they have control over content engage in the independent selection of applications and other systems [24].

Two interesting results are shown in the CAPPLE, four-year research project. The majority of students use strategies related to work on paper much more than digital ones. Some changes are evident in the trends of use of online tools, among senior university students. One of the main changes relates to the preference for using personal instant messaging, rather than forums [19].

Guidelines for further work are directed towards the individual approach to learning and thus according to learning styles. The content that students review in classic LMS system or on the internet is necessary to divide into several groups. Division of materials is possible according to:
- Type – categorization of materials according to look: picture, video, text, animation….
- Importance – the ranking of materials by the institutions
- Successfulness – other student graded materials through which they passed.

The biggest disadvantage in the presented research, as the students evaluated, was the creation of the environment itself. If the system would follow the user and suggest him the further steps, look and materials, it would greatly assist the attendant. According to user’s opinion in that way would be ironed out the biggest former disadvantage. Such categorization of information is possible through evaluation of the materials by students who spend their time on it but also the success of process. The success of the material is difficult measurable for reason that we can never be sure which material was that one which most helped the attendant to come to the finish line. However, the classification according to parameters, time he spends on certain materials, or his subjective grading information as well as the grade of authorized institutions, if you bring that into relationships, certainly has some weight.

From such a system would be possible even analyses of LMS, PLE and other tools in pedagogical researches from which it would be possible to run the methods and the ways of work of the pupils and attendants.

VI. Conclusion

Today, students have the possibility and opportunity to participate in education that is no longer controlled by the institutions. In that way students build and then upgrade their own identity.

PLE includes technological and methodological processes. PLE isn’t a technological tool but a pedagogical approach that is based on technological approach. That means that it is necessary to develop a system that will track movements and a student’s knowledge that is taking place in the monitoring of the materials by tutors, of renowned institutions and other relevant sources. Such knowledge would be of great benefit primarily the student who would structure their knowledge all in one place with further links and connections. Beside students, the system would be of great benefit to educators who could track the habits and movements of students from which could be developed concrete theories about acquiring new knowledge and upgrading the existing ones.

The system should be completely individualized but should enable to suggest some trusted paths. The attendants would be self-rated contents according to relevance and the system would suggest them the content after efficiency. Linking of learning materials with other students from different groups would set up a system without limits and restrictions.

Abstract - Significant benefits, like an IT cost savings, security, customability, knowledge sharing, can be achieved through the introduction and use of Free/Libre and Open Source Software (FLOSS) in high schools. By using FLOSS, level of students’ innovation, computer literacy, knowledge and creativity could be increased. That benefit could be important for developing countries as a chance for strengthen local IT industry. This paper shows differences regarding FLOSS and proprietary source software treatment in a computer science classroom in high schools with curriculum in Croatian language in Bosnia and Herzegovina (BiH). In this paper survey of computer course teachers’ interest and their knowledge regarding use of free and open source software was conducted by on-line questionnaire. The FLOSS presence regarding operating systems and office package at computer classrooms was also explored. An additional analysis of curriculum in secondary education in schools with curriculum in Croatian language in Bosnia and Herzegovina was performed.

I. INTRODUCTION

Free and open source software (FLOSS) gives the user the freedom to use, copy, distribute, examine, change and improve the software. These rights are stipulated in licenses like the General Public License (GPL) which is created to protect access to the source code and free use in contrast to copyright that protects the property rights of software. GPL represents a copyleft – protects the freedom of copying, distribution and modification of programs [1].

FLOSS has become very popular in public sector of EU countries in last fifteen years, but its usage in schools is almost nonexistent. EU tries to encourage the FLOSS usage in its administration.

The European Commission has its strategy for internal use of Open Source Software and plan to increase the role of this type of software internally. The Commission will ensure that open source solutions and proprietary solutions will be assessed on an equal basis, being both evaluated on total cost of ownership, including exit costs [6].

FLOSS has many advantages in comparison to commercial software. Significant financial savings and the reduced share of illegal commercial proprietary software can be achieved through the introduction and use of Free and Open Source Software. Also, by using FLOSS older computers can be re-used and newer will work faster and better. FLOSS expands the horizons of knowledge. By using FLOSS the latest information and communication technologies become available to everyone, regardless of their financial status [2].

FLOSS can provide a chance to develop a local IT industry and to develop young FLOSS specialist who can offer their services on EU job market. There is a significant growth potential for IT service providers and demand for SME use and develop FLOSS.

According to Ghosh, 54% of firms employing software developers have FLOSS in production. Worldwide, 71% of developers use FLOSS, and 68% of firms from IT-intensive sectors in Europe incorporate FLOSS in their own software-based products [4].

There is no research regarding FLOSS usage in secondary education in Bosnia and Herzegovina, but similar researches of FLOSS usage in primary education were done in Croatia.

According to Croatian results on primary education, there is no reason why pupils should not use non-commercial and even open source software for every task in their computer science courses. The problem lies in schools: each school (elementary, secondary) has a freedom to make their curricula the way they feel fit [3]. One of the main problems for ICT teachers is that syllabi are based entirely on the commercial proprietary software. In contrast to that, the primary education curriculum of the Republic of Croatia does not prescribe, order or decree any specific software for use in teaching [2].

Unfortunately, the vast majority of schools at Bosnia and Herzegovina do not have the financial possibility to invest in new ICT solutions. Having in mind FLOSS advantages for developing countries and a poor economic standard at BiH, and constant requirements for cost reduction in public sector, we wanted to analyze the usage of software in secondary education based on sample of three cantons in BiH. In addition, the paper provides an analysis of education curriculum in secondary schools in Croatian language in BiH regarding specific software for use in teaching. Moreover, the paper shows the analysis of survey on teachers’ attitude and knowledge regarding FLOSS adoption in schools. These experiences are valuable for stimulating teachers and school managers to increase usage of FLOSS at schools.

Hypothesis was that use of FLOSS in secondary education could increase students ICT knowledge and
reduce IT costs, which would help local economy. If schools do not have to pay for software then this money could be spent for IT innovation, student projects and IT services to local IT SMEs, which could push local economy.

II. Survey

A. Methodology

The data is collected through an on-line questionnaire on a representative sample on secondary school with curriculum in Croatian language (January 2017 – February 2017). The sample included secondary schools in three cantons in BiH: Herzegovina Neretva canton, West Herzegovina canton and Herceg-Bosnia canton (also known as Canton 10). Main reason for such sample selection is because in those cantons are majority of secondary schools with curriculum in Croatian language in BiH. These schools were the main target of this survey. There are 41 public secondary schools with curriculum in Croatian language in BiH, out of which 30 schools are located in aforementioned three cantons. The survey has been conducted on sample of 20 computer teachers who teach in 22 secondary schools which present a 53% of all secondary schools with curriculum in Croatian language in BiH. A 65% of respondents were from secondary schools located in Herzegovina Neretva canton, 20% were from West Herzegovina canton and 15% of respondents were from Herceg-Bosnia canton.

Online questionnaire was presented to computer course teachers with eight questions grouped in line with survey purpose: computer course teachers’ attitude regarding FLOSS, FLOSS treatment in secondary education curriculum, FLOSS usage vs commercial software at classroom related to office packages and operational system, obstacles for FLOSS adoption at schools.

Computer course teachers attitude regarding FLOSS were tested with four questions (1, 2, 3 and 4). For first question the Lickert scale was used and second to fourth were closed answer type (for two questions multiple selection were offered). FLOSS treatment in secondary education curriculum was tested by fifth question which was closed answer type (four answers were offered plus other answer as option). FLOSS usage at classroom was tested by sixth and seventh question. For each software type (office packages and operational system) teachers were presented with several names of programs with multiple answer option. The participants were asked to select software used for computer course at their schools. Obstacles for FLOSS possible increased FLOSS adoption at schools were tested by eight questions which were single selection answer type.

B. Result and discussion

The results were then collected and each answer counted, analyzed and displayed as a chart. The most of computer course teachers are interested in FLOSS (interested 85% and very interested 10%), but 5% of respondents have no information about FLOSS (Graph 1).

![Graph 1. Number of computer course teachers interested in FLOSS](image)

While being interested in FLOSS (95%), only 55% of computer course teachers use FLOSS in the classroom teaching (Graph 2).

![Graph 2. Computer course teachers using FLOSS at classroom](image)

The main reasons for using FLOSS (Table 1) are the following: it is free (37%), it is available (33,3%) and quality of FLOSS software (25,9%). Reasons like openness of its source code and security have no or low importance for respondents.

According to responses, main reasons for not using FLOSS in teaching process (Table 2) are: teachers have obligation by curriculum to teach only commercial software (25%), teachers do not need FLOSS because they have existing quality commercially software (18,8%), lack of books and training regarding FLOSS (25%) and...
teachers do not have enough knowledge about FLOSS (12.5%). Other important reasons against using FLOSS are: a lack of customer support and IT specialist on local market (6.3%), incompatibility to commercial software formats (6.3%) and other reasons (8.3%). Other reasons are related to lack of quality hardware and computer course classes.

Table 3 shows results related to FLOSS treatment in computer course curriculum. The respondents do not have clear opinion on this point. The majority of respondents said that FLOSS usage is not clearly defined by curriculum (40%) but the significant part of teachers consider that curriculum requires explicitly teaching on commercial software (35%). Also, 20% of respondents consider that curriculum equally treated FLOSS and commercial software and 7.1% of teachers said do not know.

Education in BiH is decentralized and it is responsibility of regional authorities (cantsons, entities). On the state level there is Agency for pre-primary, primary and secondary education (APOSO) as an advisory body. APOSO is responsible for advising, monitoring, promoting and developing the common core curricula as minimum nucleus of all existing regional curricula, syllabus and teaching plans. The Common Core Curricula in Technics & IKT [7] advice and defines a minimum of topic which has to be introduced by computer course teaching plans and local syllabuses, but regional authorities make final decisions and create syllabus and curricula.

Considering that the scope of survey was FLOSS at secondary schools with curriculum in Croatian language, we examined the syllabi and curricula for computer course only in secondary schools with curriculum in Croatian language curriculum in BiH (based on sample of schools at Herzegovina Nerevta canton, West Herzegovina canton and Herceg-Bosnia canton).

Computer course syllabus exists only for gymnasium. Other secondary schools, except gymnasiums, do not have unique syllabus and every canton and each school have its own curricula for computer course.

Analysis showed that the Syllabus for Gymnasiums with curriculum in Croatian language in BiH explicitly prefers commercial software (regarding operation system and office packages). Mentioned commercial software is property of the one foreign company. Furthermore, the Syllabus does not allow a lot of possibility to teach using FLOSS.

Although other secondary schools do not have strict rules, they also prefer commercial software in the classroom, according to survey results in Tables 4 and 5. Computer teachers have the right to choose software for teaching and they mostly prefer a commercial software.

On the other side, there is no mention what type of software should be used in The Common Core Curricula in Technics & IT (http://www.aposo.gov.ba/en/2015/10/15/development-of-the-common-core-curricula-in-technics-ikt/). This document defines that computer science courses in secondary school should, among other things, result with a following learning outcomes: students have to be enable use the software for word processing, spreadsheets, presentations, and for modeling, making and using of databases. The Common Core Curricula in Technics & IT only says what kind of outcome should be reached, so there is no reason why students should not use FLOSS in their computer science courses.

Commercial software are widespread in operating systems area, based on the data in Graph 3 (commercial software are present on 91.4% desktop at classrooms and Linux is present on 8.6% of classroom as a dual boot operating system). Students are taught Linux only on extra computer course classes at two schools while in regular computer course classes they are taught proprietary operating system.
Almost identical result is on office packages on computers classroom in high schools (Graph 4). Commercial software is installed on 88,7% desktops and open source software packages (LibreOffice/OpenOffice) are present on 11,3% desktops (only present at two schools).

Although, a half of respondents use FLOSS at classroom its usage regarding operating systems and office package are a low.

Graph 4. Office packages on desktops at classrooms

Graph 5 shows that the most important precondition for an increased adoption of FLOSS software in teaching is an increased number of computer course classes (37%). Those answers are related to fact that the most of student attend computer class during one or two of four years of high school. Other important preconditions are related to increasing of customer support for FLOSS at local level (18,5%) and the increasing popularity of FLOSS among students (18,5%). Furthermore, 14,8% of respondents consider that a decision of the local ministry of education is important to increase FLOSS presence at schools, while 11,1% of them consider that "teachers need to learn FLOSS and have further training regarding FLOSS".

Graph 5. Precondition for an increased adoption of FLOSS software in teaching

III. CONCLUSION

Despite the fact that the computer course teachers are interested in FLOSS, its usage in classroom at secondary schools with curriculum in Croatian language in Bosnia and Herzegovina is scarce. Key obstacles for higher FLOSS usage at secondary schools are: insufficient number of computer course classes; gymnasium syllabus requires usage of commercial software; lack of knowledge and popularity of FLOSS and lack of activities by local ministries of education to introduce FLOSS in schools. As a result of obstacles mentioned above commercial software is preferred by most of teachers.

By unequal software treatment teachers and students are not given an opportunity to choose software to be used for their own learning, work and play. Consequently, a lower students’ computer literacy and their IT skills will be achieved. Teaching only using commercial software results with the increased IT cost in secondary education. Also, without right to choose students are taught only for software consuming instead to encourage software developing among students through access to source code.

Considering that the most of computer course teachers are interested in FLOSS, FLOSS software should be introduced into curriculum and classroom in secondary education. But before that, number of computer course classes should be increased. An increased number of classes and teaching using FLOSS provide opportunities for developing of students advanced IT skills (like coding or system administration). Secondary education mustn’t teach students to use only commercial software of only one multinational company. Today there are so many quality open source software that is used for educational purposes. These measures provide an opportunity to increase students’ knowledge, ICT literacy and also reduce IT costs at schools. Savings on an IT costs could be spent for IT innovation, student projects and IT services to local IT SMEs which could push local economy.

Teachers are mostly required to use commercial software in already constrained time reserved for ICT classes in the Curricula. FLOSS is left only to teachers’ enthusiasm in extra classes offered to pupils in some schools in Bosnia and Herzegovina.

E-Learning of Mathematics, Problem and a Possible Solution

V. Dedić* R Cvejić* and M. Andelkovic*
* School of Strategic and Operational Management, Belgrade, Serbia
velimir.dedic@fpsp.edu.rs

Abstract - This paper presents the introduction into theoretical founding of an e-learning system that uses principles of transactional analysis (TA), designed for e-learning of mathematics. TA is both theory of personality and a practical approach to managing numerous problems that are arising from inadequate communication patterns. We believe that the key problem of low mathematical performance found in Serbian learners is not in mathematics but in promoting and maintaining non-functional communication patterns. Internet and e-learning are seen as good arena in which a new battle for better math knowledge should be lead and won.

I. INTRODUCTION TO TRANSACTIONAL ANALYSIS

Transactional Analysis (TA) is both one of many psychological schools of thought and a practical therapeutic approach, as well as theory of personality and human communication established by Eric Berne in 1950s. Many aspects of human activities have been analyzed in terms of TA and there is vast body of knowledge on the application thereof.

TA has been grounded by declaring philosophical foundations that are usually stated as follows: i) everyone is OK; ii) everyone has ability to think and make decisions; iii) everyone decides about his own steps; iv) we can always revert decisions if found wrong. It is clear that TA philosophy comprises both individual responsibility and ability to change, what makes dynamic quality of TA approach, especially in educational realm of application [2].

The concept of “being OK” should be understood that no one should be discounted for what he or she is and should be accepted as a valuable human being, as such.

Human interactions are modeled as series of transactions. Transaction, on the other hand, is a basic TA concept, for purpose of this paper we will define transaction as one, atomic, elemental unit of communication. Transactions are also means of fulfilling one of basic human needs, a need for a stimulus. Berne [2] claims that hunger for stimulus is so deep and inherent to human nature that we have developed a mechanism for satisfying stimulus hunger, used both for bare survival as well as for higher social practices. This mechanism, used for satisfying our need for stimuli, is known as a stroke. Also, a stroke can be understood as a basic unit of social recognition, meaning that it is not required for a stroke to be verbal. In our daily activities we are giving and receiving strokes in many ways, ranging from just recognizing someone's presence to explicitly praising someone's attitude, result or behaviour. But, should we be deprived of real strokes, received by human beings in active and meaningful social interaction, we will reach for a rich pool of back-up strokes, usually by playing games, in TA sense. Strokes received by playing games are just surrogates, but our hunger for stimuli will rather accept any strokes than no strokes at all. Basically, every communications interaction can be decomposed into sequences of the basic communication pattern, consisting of transactions, which is: A commences communication by sending a transaction (stimulus), B reacts by sending a transaction (reaction to stimulus), and A reacts on the previous, by another transaction (reaction to reaction). It is interesting to investigate conditions required to have any communication: TA finds that by a bare fact of being close enough to communicate makes communication not only possible, but rather inevitable. It is only required that participants in any form of communication share common communication field, which can be formed by simply sharing the same space (a room, a waiting room, a dentist's office lobby), but also can be shaped as being online or being immersed into some form of virtual presence. Before we can begin sharing transactions, we need to define how are we going to communicate – note similarity with protocols in telecommunications – it is said that communications relationship is to be established. Finally, should we refuse to communicate, this also will be understood as a single transaction.

It is absolutely impossible to give meaningful input on any TA-related subjects without relating to the concept of ego-states. Ego-state, according to Berne [3], is state of mind and related behavioural patterns. Three ego-states are defined: Parent, Adult and Child. Adult is a functional ego-state, because it reacts to reality as it is and makes decisions here and now – it makes an individual functional into society and fosters autonomous, active participation into daily and more complex activities. Parent is what we have adopted from what we have heard and experienced from important others in our childhood. But, it is important to understand that Parent expresses itself as someone else's voice, not as our individual critical voice. Child is formed out of petrified misconceptions we have had as small children, for we have not being able to fully and accurately comprehend the words – neither we have had enough information nor our cognitive apparatus was completely developed. But, nevertheless, we are using all
of our ego states and if balanced properly and used adequately, Parent, Adult and Child are powerful ways to interact effectively.

![Diagram of Transaction exchanging between Parent (P), Adult (A) and Child (C) ego states](image)

**Figure 1.** Transaction exchanging between Parent (P), Adult (A) and Child (C) ego states

Fig. 1 depicts how ego-states for two persons exchanging transactions (P-parent, A-Adult, C-Child) are presented by a standard ego-state diagram. Transactions are modelled as arrows protruding from a corresponding ego-state that initiates communication (stimulus transaction) and ending into other party ego-state that receives a transaction. This example depicts transaction exchanging in the following sequence: 1) left sends a transaction from his Parent to right's Child, 2) right responds from his Child to left's Adult. We see that, in fact, ego-states are exchanging transactions, and not persons, and also that any ego state can respond to any ego-state's stimulus.

Not all Parents are the same: discrimination between Nurturing Parent and Critical Parent is usually made, depending on functional role of the active Parent. This role may be comforting and nurturing, what is sometimes naturally needed, and behaviour-shaping, what is usually perceived as criticizing. Both modes can be functional and positive, if used properly, ie functionally. We will usually reach for the Nurturing Parent when asking for unconditional recognition of ourselves as we are (everyone is OK), and Critical Parent will functionally implement useful modelling of behaviour, what is always a very important part of the learning process.

Transaction is always initiated by an ego-state and always responded by an ego state. This makes it possible to model different ineffective communication patterns and to understand ways to prevent further undesired course of interaction. Transactions are said to be simple if exactly two ego-states are involved into communicating (eg. Parent A sends a transaction to Parent B) or complex if more than two ego-states are involved. But, how more than two ego-states can be involved into one basic transactional pattern? Transaction can take place into one of two realms: social and psychological. If we say: “Well done!” to our daughter after she had presented results of Math test this could be said in at least two ways: if said sincerely with smile and calm voice, this really means congratulations, but some other father might have habit to say “Well done” even if the result is not commendable, then his voice will be altered, sarcastic, and his daughter will learn that what daddy really meant was “You failed again”, and that what he has said is irrelevant. “You failed again” is a psychological transaction and this is the one that is much more important than a social one. People respond and react to psychological transactions more sensitively and the character of communication is measured from the perspective of exchanged psychological transactions.

Communication will be smooth and can last practically endlessly as long as ego-states are flawlessly exchanging transactions. Fig. 1 can be used to analyze the exchange of non-smooth transactions. Left could say something like “I said that number 7 is written with crossed line” while Right could use his Adult: “Can you give me arguments for it”? Obviously, Right did not answer from his Child, but instead has called his Adult – this will typically be recognized as “rude” by Right. It is said that Right has crossed the transaction.

Humans have an inherent need to structure own time [3]. One of the most widely found time structuring patterns is playing a game. Of course, term game is precisely defined in this context and can be understood as a series of transactions with predictable outcome. Games are always destructive, to some extent, for reason of masking and substituting active, productive and meaningful life activities. It is required to have some form of an unresolved conflict we are trying to solve by playing the game, but it always fails. Games are played for a real, or fictitious, payoff, and always include a dramatic switch. What is also consistent with playing games is a “bitter feeling” afterward – games are reinforcing inadequate believes and making us even strongly entrenched in the determination that nothing can be changed, so the next iteration of the same game can be experienced as more dramatic and more painful. The circulus vitiosus in it's worst presentation.

The game we are going to use as a model of ineffective mathematics learning is Drama Triangle. Drama Triangle requires three participants, namely Victim, Persecutor and Rescuer. Typically, helpless Victim asks for a help, benevolent Rescuer helps her and mean Persecutor reveals as the one who is the reason for both Victim's misery and Rescuer's saving. It is very important to understand that Victim, Rescuer and Persecutor are not adequately named in real life, here and now, there is no real persecuting going on – this is a game in which participants are taking roles, and we will see that there will be no gain to anyone. What makes this specific game relevant to our approach is that it serves as a perfect model for perceived behavior of typical participants in math learning context, namely typically student asks for a help after have perceived mathematics as very difficult, his or her parents are helping by providing a private tutor while school teacher becomes a kind of enemy. It is not very difficult to see that roles of Victim (a student), Rescuer (a tutor) and Persecutor (a teacher) are clearly shared as in the model. Moreover, first problem in the student-tutor relation causes first switch of roles, Rescuer becomes Persecutor while Victim stays helpless. The most important conclusion is that as soon as we play games, no mathematics can be really learned.

994
Mathematics and TA

Serbia makes not so great job when it comes to learning mathematics. PISA testing 2012, for example, places Serbia below average achievement. Mathematics is not liked in schools, it is perceived as difficult, meaningless and impractical. This can be found in other cultures also [8]. What is problem here, is the fact that having low average mathematical abilities in general active population can have devastating effects on economy – we can take a look at completely different case of Finland, where economic boom coincided with the radical twist in educational system, which fostered much more meaningful and effective mathematical training [9].

Similar case can be analyzed in Singapore and 11 more countries [5]. Sierpinska [7] argues that models of Finland and Singapore are not to be simply copied and implemented into other societies because of different set of values required to foster either Finnish or Singapore model, and we can agree, but, on the other hand, if we accept that the basic problem is within the communication realm, what is discussed in this paper, cultural difference might be not so important.

What makes mathematics troublesome for learners? It the science itself would be the reason, than we would not expect so dramatic differences per counties or regions-it must be something related to how mathematics is taught in schools.

Analyzing the communication patterns that take place during a typical math-learning process [6], we can filter out three basic participants: Learner (child), Teacher (schoolteacher or tutor) and Carer (normally father or mother). In the most basic setup, child is helpless (Victim), mathematics is too difficult to be learnt (personified in a teacher, who is Persecutor), and asks for a help. Carer (eg. Mother) helps and puts herself into position of Rescuer. Drama triangle is formed and can start it's own toxic cycle. Positions of participants are non-effective and highly dependable on other positions: this makes them less realistic and more dramatic, Victim must be helpless, Rescuer will help at any cost and Persecutor is over demanding. Now, as real parent reaches for a tutor to provide practical help, we have new setup: child is even more helpless, even desperate, tutor (now Rescuer) “does all he can”, math teacher stays cold and demanding, while real parent become by-stander. Many twists and switches are now possible: parent may get angry with tutor and switch to Rescuer position, while tutor fails to Victim, now child (who got friendly with tutor along the way) now helps him and becomes Rescuer. Later on, unhappy tutor may start chasing parents for not “pressing this little devil a bit” (Persecutor), real parent is now Victim, and a child tries to reconcile them (Rescuer). Many more twists and role castings are possible. What makes it even worse is that younger child in the family, if present, will likely adopt this non-functional behaviour even faster [8].

Drama triangle is always analyzed as a dynamic structure of exchanging transactions. Archetypal roles of P-Persecutor, V-Victim and R-Rescuer are just taken by different persons depending on the phase of the game. But this casting is never functional.

What have we learnt from this example? It is evident that the real reason for gathering of this triad was never to learn mathematics. The real reason was to play the game, to spend some time exchanging transactions and, the most basic reason is to reinforce false believes about own abilities and attitudes. What is important – there is no mathematics here as a real actor, mathematics is just an excuse for playing a real thing – ineffective, futile, time-wasting game.

The real reason for ineffective learning of mathematics, for a negative attitude and consequently low performance is practice of implementing non-adequate time-structuring and playing TA games instead of active doing. Playing in Drama Triangle can be very time-consuming activity giving simulated effect of investing efforts and yielding no result, in fact non-yielding is the key argument against meaningfulness of he effort.

Possible Solution

What can be seen as a good starting point when discussing interventions, is considering communication environment that learners are familiar with. We strongly believe that Internet makes one. Today, Internet can be perceived as an universal IT platform, a tool having standardized and well defined interface and as a communication environment. This might mean that if we could design such a system, particularly e-learning system, that emulates selection of ego-states from which communication is commenced, or a received transaction responded, we would be able to model, to shape communication patterns for those involved into exchanging transactions.

Also, such a system would be able to foster person-to-person communication that minimizes non-functional transactions and therefore shifts communication process towards its declared goal, being learning mathematics effectively.

Many contributions in this filed have been made, ranging from purely theoretical work, to an operational software product [4].

OK matematika project was conceived, designed and implemented by paper's authors as both school of mathematics based on TA principles, and as e-learning service making it possible to learn mathematics in OK way using internet as communication environment. Selection of basic unit of delivering knowledge has lead us to the conclusion that video is the best match. Video has the richest content, comprising verbal and non-verbal communication channels, and can be filmed and edited in the way that fosters desired manner of communication. This system can be accessed at www.matematika.edu.rs

Videos are categorized in three main categories: serious video (communicates from Adult), nurturing video (communicates from Parent) and free video (communicates from Child). It is not enough to communicate from Parent, nurturing and encouragement is needed, as well as is fostering of free creativity, therefore all ego-states had to be implemented.

Special Learning Management System (LMS) had to be designed and implemented. Basic features of this LMS
should have fostered exchange of functional transactions between a learner and the LMS. And indeed what was achieved is that transaction exchange is systematically implemented in our solution.

The system is designed in such a manner that any modern user interface can be used, ranging from computers to smartphones. This enhances reach of the system to the intended audience. Series of focus group sessions have been held in order to select the best user interface selection and comfort of the user. Also, video lessons are regularly checked for quality, both in technical and user-perceived quality metrics. Small sample, pilot-level tests of system acceptance within audience have already been conducted, but we will not publish the results before proper statistical analysis is done.

LMS implements classical functions met with similar systems (Moodle, Blackboard and many in-house designed systems): user management and tracking, security, learning material stocking and management, lessons composition and distribution, progress tracking, reporting, and general administration. On top of this, our LMS has enabled, as features designed and implemented, video material metadata management, lessons sequencing, material reusability management, playlists creation, and many personalization services directed to learners.

Figure 2. LMS implementation screenshot

Fig. 2 is here to give impression of the implementation of LMS, depicting video material delivery module. Besides design and implementation of LMS, there is a team of professional mathematicians who are dedicated to authoring video material according to the aforementioned principles.

Since we wanted to eliminate possible differences in quality of service offered on-line compared to in-classroom classes, LMS had to implement also live-sessions of mathematical classes. Having system designed in such a manner, we believe that there is no reason for a significant difference in quality of service experienced on-line and off-line. There is also the challenge to test this hypothesis in practice.

IV. FURTHER RESEARCH

Further research will take place along with active life of the OK matematika system. Data collection along with statistical analysis will be logical next step in the research.

Main fields of further research are summarized as follows:

- contrasting and comparing service offered on-line and off-line
- learners' attitudes towards the system
- learners' achievements
- learners' time structuring improvement
- ability to recognize Drama Triangle and refusing to participate
- refusing to participate in Games
- quality of video learning material
- quality of supports
- general attitude towards mathematics

Main goal of this LMS development and usage is to foster more productive communication patterns, and to avoid falling into games while learning mathematics. We believe that e-learning of mathematics based on principles of TA can improve learning experience and be of help in reaching better results.

No user generated data has been gathered since for testing purposes. The main goal of our next step of research is data gathering and analysis.

Abstract: Within this paper, we consider recent developments in methods of research and consider the context of how students are introduced to this compared with late 20th Century methodologies. We compare these strategies and consider why changes of approach have occurred and what this means for the quality of research. Finally, we suggest two further routes that will help in this analysis which are likely to provide yet more insight in to how to develop better research strategies.

1. INTRODUCTION

Work looking in to the development of research across the last few decades is an area of great interest to both students and teachers alike. From the student point of view, there is often a daunting step into their first steps of research – most often it is through a doctoral program (which we cover in predominantly in this paper). Examples of these of these kinds of trepidations might include the body of previous material to consider being excessive or there may be no simple conclusions that can be drawn in a relatively concise way which can be presented appropriately. To overcome these, universities throughout the world have developed their programmes to ensure a broader introduction. While the stereotype of academics dumping papers on a student’s desk and asking for a report in 6 months are clearly overblown (but the adage that there is no smoke without fire also runs true), there is clear evidence that this style of research is less productive than that which is continuously developing in today’s programmes. Hence there is a keen relationship to be fostered in a better structure to doctoral degrees between: universities, whose goal is to produce quality research; academics, whose own work can be enriched by being challenged to prepare students for the rigours of an academic career; and, students, who will gain a more fulsome education designed to get the best out of them. And so, the cycle can continue as those students go on to become the academics who supervise future students, and they are employed by the universities keen to develop a research portfolio which brings the rewards in various guises. Within this paper, we will reflect on recent developments in the approach to doctoral studies and suggest further improvements to the work being developed.

2. A TYPICAL PHD PROGRAM

In previous years, it was common to finish a master’s degree and then for those who wished to continue in their studies, the next four or five years would be spent working towards a doctoral degree. Those five years were spent learning new materials, teaching undergraduates, working as a lab assistant, and doing research for a dissertation. According to the science and communications blog Figure One [1], a decade ago it was very rare for a dissertation program to take longer than seven years. Today however, a person entering a doctoral program can expect to spend at least six or seven years earning that degree. In Humanities, as seen in [2], this can be extended to over 9 years, while for an Educational doctorate, the length of time can be just shy of 13 years. In the US, the NSF commission an annual report, in [3], which compares from 1957 to 2015 both the number of PhDs awarded and the length of time PhD completion takes. It is notable that in the 15 years of data from the year 2000, to see that while more PhDs, by mean, per institution, are being awarded, compared with the previous 43 years, that the length of time taken has gradually increased. There are 3 questions which suggest themselves to this: firstly, why are PhDs taking longer?; secondly, what conclusions can be drawn in terms of the types of graduates who complete their Bachelor’s or Master’s degree that continue to pursue a PhD?; and, finally, what can be done to improve the preparations for research being undertaken to ensure better quality research is produced in a quicker timeframe?. I will deal with the first of these questions last as it is important to consider overall educational changes as well as other factors once we have the answer to the other two questions.
3. **Changes to a PhD Program Since 2000**

For our purposes, the systems in the Europe and the USA (which make up the majority as a percentage of PhDs produced) are the obvious places to start. In [4], the authors look at, and provide tips on, PhD research and what will be involved in the process. Depending on the student, there are various ways to enable the study of a PhD. We will concentrate on those who have completed a related subject-specific undergraduate degree who then go on (either with or without a Master’s degree) to study for a PhD. There are, of course, different requirements across the spectrum of research areas: for example, most Mathematics programs require a 1st Class Bachelor’s Degree and a Master’s degree before consideration of a PhD program, while in some other subjects, they are less stringent with entry requirements. A broad sample of university entrance requirements booklets has given an average of an Upper Second Class Bachelor’s degree as a starting point. Within this paper, this is our standard starting point. We will assume the role of a student with a 2:1 degree and consider what a PhD program entails now compared with pre-2000. Finally, we have considered 12 Universities throughout Europe and the US. These are listed in [5].

Following the standard application procedures, all of the institutions listed in [5] mentioned that eligibility criteria will be considered on a case by case basis subject to funding. When pressed, this suggested that those with private funds, to pay for the teaching element and other usual research costs, may be able to secure a PhD place despite not meeting the published eligibility requirements in usual documentation such as prospectuses.

Many European PhDs in Science are funded by EPSRC [6]. Funding is awarded based on merit of the applicant with support from supervisors and institutions will often bid for a pot of money which they can distribute through the usual procedures. The level of PhD funding has not grown as much as the growth in terms of numbers of students studying for PhDs and the likely conclusion from this is that the private funding options for a PhD will have increased over the past 15 years.

After an undergraduate degree, many academics will admit that many students are not at a level to immediately start reading relevant literature. Some institutions in [5], labelled with a *, have added additional teaching or research programmes to the PhD as part of a way to assist and provide support for students who need to bridge the gap between their knowledge at the start of a PhD and where they will need to be in sufficient time to submit by the time funding runs out.

As an example, take Mathematics at The University of Liverpool. At the end of their undergraduate program, all PhD students are required to complete a course during the first 2 years of their PhD which relates to both higher level Mathematics in their area (often this can take the form of tutorial type lessons with the supervisor and others in the general research area e.g. Number Theory) and then there are research projects to be completed which provide credits which must be passed before the PhD degree can be conferred [7]. Going forward, more universities are beginning to appreciate that it is not possible, given changes to undergraduate programmes, to jump in as would have occurred over 15-20 years ago.

Given that undergraduate studies have been using first semesters of first years to provide a high school equivalency programme, this has led to funding from sources such as [6] to increase their minimum funding to, firstly 4 years in around 2005, and now 5 years since 2012.

4. **Critical Observations and Comparasion – Has Output Improved?**

One of the most difficult academic tasks is to determine the borderline between PhD pass and fail. Most PhDs will be very simple to deal with: in some subjects, it will involve providing research data and analysing it in a standard way, or providing the proof of some assertion either positively or negatively. Certainly, this deterministic PhDs are easily describable to a lay person in terms of why an award has been made. More difficult is those from [2], such as Humanities and Education, where the PhD will be dependent solely on subjective critical analysis. One conclusion might be that students are struggling to adapt to the rigours and demands of the PhD program in these areas. Others might suggest that it is simply more difficult to present new research in these areas. The conclusion that is proposed here is that developments of learning and research methodology are more designed and better interpreted by students and supervisors in deterministic PhD theses as opposed to those in Humanities and Educational Research.

There are 2 reasons for this conclusion. Firstly, by nature, it is certainly easier to contribute new analysis and data by running experiments or finding a counterexample to a proposition. These skills are developed through undergraduate learning in these subject and there are clear ways to compare with the current literature in the subject. Secondly, the processes for obtaining a PhD as outlined in section 2, are better developed to provide transferrable skills across disciplines which mimic the deterministic approach of those disciplines such as Economics, Mathematics, Physics and other Scientific subjects.

The timeframe to complete a PhD is not necessarily an indication as to the quality of research or the likelihood of a student to go on to complete a research career in the given subject. Many PhD students have completed within 3 years, been
awarded their doctorate, and left academia, while many other students have completed their PhD in a much longer time and gone on to have a glittering academic career and body of research. The costs associated, however, are prohibitive to those from lower socio-economic backgrounds. This is addressed in section 4 below.

Finally, we return to our example of the student with a 2:1. Pre-2000, there is no doubt that this student would have been in a similar state to someone today in terms of reading a research article from the last year. With a better support infrastructure in place of recent times, there has clearly been a better realisation of the demands on a student at the end of their undergraduate studies. Making further progress in this arena, will unquestionably improve the readiness of a student, and is likely to enhance yet more a student with higher aptitudes than our exemplar student.

5. FURTHER DEVELOPMENTS – THE LIVING DOCUMENTS OF RESEARCH

The socio-economic backgrounds of a student are one important area of research into how research developments will occur over the next 15-20 years. If the continued growth of numbers continues, funding will be stretched further in the ways that will require gaps to be filled by other sources. Many private companies, such as those in [8], offer PhD grants and studentships associated to their area of research. The standard academic route for students is no longer the only option and this is a positive. PhDs are no longer just for future professional academics and many secondary school teachers and many industry workers, even politicians, have PhD degrees. The emphasis has shifted and this is to be commended.

We must additionally consider whether there are options for offering more incentives for the private route to be cheaper which will open the door to older researchers entering the field to contribute the experience they have. Looking solely at the age of students is not a taxing demand, but there must be more analysis on where people have come from to decide to choose the PhD route at a later stage of their working/professional lives. Also, whether this is linked to potential future earnings and future employment possibilities, should lead to companies being further supplied with incentive to offer PhD student sponsorship as this has only been a development of the last 15 years as opposed to 30-40 years ago.

6. CONCLUSION

In summary, we must consider the relative success in approach to the development of attacks at research problems into those for deterministic subjects and non-deterministic subjects. There is evidence, as presented, that for deterministic subject’s, outcomes are easily determined. As an example, the finishing mark of the solution, by Wiles, and later in conjunction with Taylor, of the famous problem of Fermat, written in the margin of a book, made newspaper headlines around the work. Similarly, descriptions of the Higgs’ boson, have received widespread commentary from many a non-expert. It seems, for these subject, the fact that amateurs can feel connected to the problem, leads to a greater interaction through arenas such as the media. No inference can be drawn as to the quality of the research, when comparing very different and diverse subjects, just because it makes the newspapers, but it is possible to conclude that an easily defined problem will lead to an easily presentable solution which can excite non-experts.

Finally, we must consider the impact on the interconnected chain of universities, academics and students and see whether we can make commentary on whether these are improved by the evidence we have. There is clear motivation from the universities to provide these programs and this development should be applauded for the wide-ranging types of programs available. In many cases, the better supervised student will be more productive in the future, and with the support of the university communities, this productivity can be nurtured for the better. The only conclusion to make must be that remain, as in Chapter 4, “living documents”, persistently refined to provide a general outline with an individual tailoring to the students.

For research methodology, this nurturing of the triskelion of components is the most fundamental of change to delivery from universities in the past 50 years.

Abstract - This paper attempts to give a survey of some free software tools for wireless sensor networks. It targets teachers and students who might have the need for education in this area. As a first stage in creating this survey, a process of software collection is presented. First collection step is search through the Shanghai list for the first 50 universities. From these universities, available information about used software for wsn-related courses is collected. Additionally, other wsn software surveys are considered. Then, only free, open source and available software are kept, because they are the easiest for students to get it. Then evaluation based on topics coverage and software features is done. Topics are selected from IEEE Curriculum guidelines, while features give emphasis on practical usage from user aspect. Selected topics are embedded systems, computer networks, operating system and system resource management. Features used in the evaluation are support for GUI and command line, programming language learning overhead, ease of installation, extensibility, and platform portability. As a result, following software tools are described: TinyOS, Prowler, Riot, Castalia, Avrora, Shawn, TRMSim-WSN, and Shox.

I. INTRODUCTION

Wireless sensor network (wsn) is a network consisted of a large number of “motes”: tiny sensing and computing devices, often severely constrained with processing and communication possibilities and energy efficiency [1]. There are various sensor network applications: area monitoring, environmental sensing, industrial monitoring, and military surveillance. A number of nodes in the network can vary from few to several thousand. Node is typically built of the radio transceiver and the microcontroller with the sensors. Node is powered by batteries or it can harvest energy from the environment [2]. Wsn is not useful on its own. Its inevitable part is some system which collects and process information from the network. It can be a single computer system [1] or the cloud system [3]. From this stage, information is distributed to the users. Also, various data mining technologies can be used to process the collected information.

Wsn is a very attractive research area and a lot of students show interest in taking active role in it. So, there is a need for wsn courses in the university curricula. Wsns could be difficult for learning in practice, because of all issues related to sensors usage (e.g. need for specific hardware, price, low level programming). Therefore, wsn software tools are very good learning starting point.

This survey selects, describes, and evaluates software tools that could be used for educational purposes on courses related to wsn. However, it is up to an instructor to decide what topics from different knowledge areas related to wsn should be presented on the course, while this paper aims to elaborate in what degree a knowledge area could be covered by the selected tools. Wsn is not an easy-to-learn area, so it is expected from students to have some previous knowledge about programming and computer networks. In order to help students comprehend wsn challenges selected software tools should have reasonably small learning curve [4].

Because, there are plenty of wsn software tools (free and commercial, open and closed software), this survey will focus on free and open source software. Advantages of the free software are apparent: students and teachers can without any fee get the software and use it without limit. Some advantages of the open source software are large developer community, and available source code from which students can learn more than from bare usage of proprietary tools. One more criterion is that software tool should be wsn specific. Non-specific wsn software tools require an extra effort in order to get the software functional for usage in wsn area. For wsn related operating systems, one extra criterion is adopted: students must be able to run the software tools on a standard PC without using specific hardware with sensors. It means that a wsn operating system must support emulated hardware or that it can be compiled as a standalone application for PC. One practical limitation of software is support availability. If the software is not under active development, it can still be usable, if the available version is stable. But, for open source software, when the last version is old, it usually means that it is not compatible with new tools (compilers, linkers or other supporting software). If examined wsn software passes all criteria, but
can’t be used because of obsoleteness it will not be selected for further examination.

This paper is organized as follows: Chapter 2 contains a description of collecting process of the selected software and descriptions of the software themselves, together with usage examples. Then, chapter 3 contains software evaluation and chapter 4 concludes the paper.

II. SURVEY OF SELECTED WSN SOFTWARE TOOLS

This chapter describes characteristics of the selected software tools and gives the usage examples. First, it lists overall characteristics and then describes every software tool. Overall software information is summarized in Table I. It lists following information: An operating system on which the software can be used for development, a programming language used for their development, wsn support, and availability. Table I also includes software tools found in other surveys. Next step is to apply established criteria on the found software from the Table I. Available, free and open source software are kept for further analyzing. If selected software is an operating system, only operating systems with support for running without a real hardware are kept. Software which passed these filters will be described in following chapters. Selected software: TinyOS, Prowler, Contiki, Riot, Castalia, Avrora, Shawn, TRMSim-WSN, and Shox. As it can be seen from the Table I, there is a number of operating systems for wsn, but only TinyOS, Contiki, and Riot are now available at all. All other operating systems mentioned in Table I and [26] are too old and are not available anymore. SENSE simulator is not compatible with new gnu toolchain (the last version is from the year 2008) and WSNet can't be compiled, so they are excluded from further examination.

Analyzed software tools can be divided into two major groups: terminal-based and GUI-based. Terminal-based software tools are TinyOS, Riot, Castalia, Avrora and Shawn. GUI based software tools are Cooja simulator from Contiki, TRMSim-WSN, Prowler and Shox. GUI based simulators can be separated into two groups: With topology and status on GUI and without topology and status on GUI. Table II shows this division into groups.

Every selected GUI-based software tool has the different screen, but their screens can be generalized. Every screen has a part for simulation control and configuration, a part for simulation status and a part for topology, if present. Figure 1 and Figure 2 show two kinds of present GUI screens. Both figures have parts for software title and menu bar. Title and menu bar are software-specific. Configuration part of the screen contains various configuration fields, check boxes, etc. which enables concrete simulation configuration. Control part must contain simulation start and stop controls. Additionally, there can be other controls like a number of cycles. Status part often contains simulation logs. Additionally, there can be timing diagrams (like Cooja). Topology part contains current topology. Simulators can use this part for animating wsn nodes behavior or to display various information about concrete topology.

A. Software tools description

TinyOS is an operating system used in low-power wireless devices. Its main parts are task scheduler and driver collection. TinyOS is developed in NesC, the extension of C programming language. This is a component-based language with event-driven programming paradigm. TinyOS have simulator: Tossim, which simulates entire TinyOS applications. Simulation levels are very flexible: from radio communication level to component level. Tossim is a discrete event simulator and a library: a Python or C++ program for configuring and running simulation must be written.

Prowler [7] supports only Berkley Mica motes. It is event driven and has two working modes: the deterministic and the probabilistic. In the deterministic mode, it can reproduce simulation results. In the probabilistic mode, it simulates non-deterministic nature of radio communication. The simulator is developed in Matlab. Nominally, there is no limit on the number of the simulated motes.

Contiki [8] is an operating system which connects cheap low power embedded systems to the network. It completely supports IPv4, IPv6, and other low-power wireless standards. It also has a simulator, Cooja. Contiki is developed in C, and applications for Contiki are also written in C. Some characteristics of Contiki are high memory efficiency (it has own memory management,
besides memory management from C), complete IP stack, power consumption tracking, wireless protocols, dynamic linking and loading of modules, sleepy routers, efficient

multithreading, file system dedicated to flash memory devices, command line shell and well developed build system.

Riot is a general purpose operating system for IoT area. It is extremely good for programmers: There is the standard set of development tools: C/C++, GCC, and GDB. An amount of hardware dependent code is minimized and particular support for POSIX are implemented. The unique characteristic is a possibility for native programming on Linux and Mac. In this usage, the whole Riot is running inside the Linux/Mac process, so development for Riot stops to be different from classic development under Linux/Mac. There is no need for virtual machines in the case of no hardware available. Riot is organized as a microkernel, maximizes energy efficiency, and supports real-time operation (extremely

Castalia is a wsn simulator based on Omnet++ platform. It can be used for testing distributed algorithms and protocols in realistic wireless channels and radio models, with realistic node behavior. Castalia is highly parametric and can be used to evaluate different platform characteristic for specific applications. Main features of Castalia are advanced channel model based on empirically measured data, advanced radio model based on real low power radios, extended sensing modeling, node clock drift and CPU power consumption and MAC and routing protocols support. Castalia takes modules and messages from Omnet++. Module’s parameters, name, structure, and interface are defined with Omnet++ NED language. Module behavior is coded in C++. Castalia cannot be used for sensor platform-specific applications. It cannot test code compiled for some specific platform, because it is designed for algorithm first-order validation, before platform-specific implementation.

Avrora is a set of simulation and analysis tools for avr microcontrollers, which are the part of Atmel and Mica2 sensor nodes. Avrora simulates and analyzes assembly programs. Main features are testing with cycle accurate execution time, monitoring, profiling and instrumenting without simulation disturbance, energy analyzer and stack checker. Avrora is a command line based simulator. It has good
documented and a rich set of options, so it is very easy to use and command outputs are simple and descriptive.

Shawn differs from other simulators with its algorithmic background instead of network stack simulation. Its main design goals are:

1) Simulate the effect caused by a phenomenon, not the phenomenon itself: For example, instead of simulating complete MAC layer, Shawn simulates only MAC layer effects on the application (packet loss, corruption, delay)

2) Scalability and support for extremely large networks: Shawn supports order of magnitudes higher number of nodes than any other available simulator.

TRMSim-WSN (Trust and Reputation Models Simulator for Wireless Sensor Networks) is a Java-based simulator aimed to test Trust and Reputation models for wsns. It allows researchers to test and compare their trust and reputation models against a wide range of wsns. They can decide whether they want static or dynamic networks, the percentage of fraudulent nodes, the percentage of nodes acting as clients or servers, etc. It has been designed to easily adapt and integrate a new model within the simulator.

Shox is a discrete-event ad hoc network simulator written in Java. It is geared towards mobile wireless networks with many nodes in both indoor and outdoor scenarios. As opposed to other general-purpose simulators, which all require a tremendous learning and training effort before first results can be obtained, Shox is very straightforward to use and makes common simulation scenarios in network design like hundreds of nodes with a specific mobility generating certain traffic patterns very easy to implement. Shox has strong GUI support and offers a collection of statistical data and automatic generation of graphical representations (graphs).

III. SOFTWARE EVALUATION

This section presents the evaluation of selected software tools. Evaluation criteria are the topics coverage and the software features [4]. Because wireless sensor network is only one knowledge unit in CE Computer Networks knowledge area, all knowledge areas from curricula guidelines for computer science [10] and computer engineering [11] are searched, in order to get a broader view of topic coverage. Topics coverage for every knowledge area is calculated with the following formula: number of related knowledge units/total number of knowledge units. Table III shows topics coverage through selected knowledge areas. Software tools relations to particular topics are not included in the paper for brevity.

TinyOS is complicated for installation and requires learning of NesC programming language. Prowler requires knowledge of Matlab. Students at the department of Computer Engineering and Information Theory at School of Electrical Engineering have poor coverage of Matlab in their courses, so they probably must additionally learn it. Castalia requires learning of NED language. TRMSim-WSN is only covered software without any command line support. All covered software can be executed on Linux and they all are extensible.

Someone can tell that there is very large number of wsns software tools to be covered with one survey. A large number of them are commercial and unavailable, so contributions of this survey are:

1) A collection of free and open source software.
2) Simulators and operating systems covered in one place.
3) The inclusion of Riot operating system, which, at the best of the author’s knowledge, does not exist in any other survey

IV. CONCLUSION

Wireless sensor networks are an emerging area in Computer Science and Computer engineering, so there is a need for students to be familiarized with it. The first step of education in this area probably will include usage of simulators and other software tools, so the aim of this survey is to help students with the selection of free
Software selection is done in two phases. First, websites of the first 50 universities from the Academic Ranking of World Universities (Shanghai list) [5] are searched. WSN related courses are searched and based on the available information, only four software tools, used at the found courses are selected. Second, other wsn software surveys [20-25] are examined and simulators and operating systems are included in this paper. The majority of them are unavailable or closed-source. At last, 3 operating systems and 6 simulators are selected for detailed description of selected software and at last evaluates them.

**LEGEND:**

OS: SOFTWARE IS AN OPERATING SYSTEM.
SIM: SOFTWARE IS A SIMULATOR.
CL: SOFTWARE HAS A COMMAND LINE SHELL, GUI: SOFTWARE HAS GUI.
PROGRAMMING LANGUAGE OVERHEAD: YES – ALMOST ANY USER WILL HAVE TO LEARN A NEW LANGUAGE, NO – ALMOST NO ONE USER WILL HAVE TO LEARN A NEW LANGUAGE, PROBABLY: THERE IS A DECENT CHANCE THAT USER WILL HAVE TO LEARN THE NEW LANGUAGE.
EASE OF INSTALLATION: C – COMPLEX, M – MEDIUM, E – EASY
PORTABILITY: L – SOFTWARE CAN BE USED ON LINUX HOST, W – SOFTWARE CAN BE USED ON WINDOWS HOST.

Selected software has very different purposes and covered operating systems can serve any application planned to be executed on wsn platforms. TinyOS is the most complicated for use, while Riot seems to be the easiest. Also, TinyOS lacks a good documentation, which is the significant drawback. Command line based software proved to be more complicated for usage, but the lack of the GUI does not make it less powerful or less useful. Selected simulators are dedicated for various purposes. Castalia test first phase of algorithm development. Prowlers can quickly prototype radio communication. Shox can simulate large networks, while Avrora is dedicated for simulating and analyzing AVR assemblies for concrete platforms. Shawn is unique with its ability for vast simulation of extremely large networks. Therefore it could be concluded that there is no one software tool or operating system that could be used for covering all topics related to wsn.

Abstract—In this paper we investigate factors that affect excessive use of Internet among elementary school students in Vojvodina. The quantitative analysis was performed using datasets from research carried out in 66 elementary schools across Autonomous Province of Vojvodina. Using a large data set on elementary school students, we have tried to describe the profile of students who excessively use Internet. Results reveal the significant impact of using Internet in non-study related purposes for differentiation between students who excessively use Internet and those who do not.

I INTRODUCTION

It cannot be overemphasized that the application of information technologies and multimedia in education is of great importance for educational system, and also for any individual in lifelong learning process. Contemporary education requires changes to traditional educational system, thus it is also essential to enable conditions for active learning and adequate improvement of teachers.

The main aim of the research presented in this article is establishing the frequency of pupil’s computer use, both at home and in school, and the main objective of that use. The second aim was to research into the rate of Internet use, and checking for possible differences in its’ frequency based on pupils gender, age, and place of residence.

This article uses results from a survey conducted among pupils of elementary schools in Vojvodina, in order to check what differences in use of computers and Internet exist among them. It is interesting to notice that schools usually do not allow Internet use during breaks, which has the largest effect on the differences of Internet use at home and in schools. As might be expected, the most often use of Internet is connected with social networks and game playing, easily pointing to lack of time for personal contact. Another straightforward conclusion is that excessive use of Internet and computers influences psychomotor and cognitive development of pupils [1]. More or less direct consequences of such a behavior by pupils are the lack of:

- capacity to find needed information,
- ability to quickly solve given problem,
- development of abstract and logical thinking,
- increase of knowledge and experience in synthesis of gathered data, and
- progress in reading and writing skills and understanding of read material,

which all certainly influence pupils motivation for learning. It is also noticeable that through Internet use, pupils acquire new knowledge in their own time, usually connected with their age and needs.

II RELATED WORK

Article [2] elaborates on the results of a survey in which 291 parents of an urban elementary school (K-6) participated. Parents reported on their computer equipment at home, the type and frequency of their children's educational software and Internet use, and shared their ideas how better connections between computer use at home and school might be created. The results indicate that most of students’ computer use was dedicated to game playing followed by various other software activities. Students reported more limited Internet activities. While home computer ownership is not necessarily contingent upon gender, some software and Internet use tended to be gender specific activities.

One of the common conclusions [3] is that girls tend to use computers less frequently than boys also, boys tend to represent the vast majority of video game players, as can be proved by observations of school behavior and research into video game playing at home, so the results presented are not unexpected. The results showed that the video games have a both positive and negative aspects. In order to maximize the good aspects of video games, parents should learn about and set rules and guidelines regarding the games their children play and how often they play them and also consider engaging in games with their children in order to better understand the games as well as promote the positive aspects of gaming. Video also games have the potential to be used as powerful teaching tools. On the negative side, use of violent video games is associated with increased aggressive behaviors. Additionally, time spent playing video games can crowd out time spent in more healthy activities, such as exercise, reading or school work.

Internet addiction and behavior concerning Internet among pupils was examined in [4]. It is recognized that the persons’ manners and activities on the Internet, closely reflect their conducts in a real, everyday social life. Mentioned paper deals with the use of Internet in

MIPRO 2017/CE
performing mainly illegal activities, such as molestation and abuse of other Internet users, giving false statements on behalf of others, or illegal gambling. The paper also investigates the amount of time users spend on the Internet. Difficult consequences of Internet addiction were research topic in [5]. Within this research, it has been established that the students in the USA are spending more than 25 hours per week on the Internet, or more than 5 hours per day, either using the computers, tablets or mobile phones. The paper focuses on three facts distinguishing factors of Internet usage, Internet activities, and consequences of Internet use. Achieved results show that the Internet overuse comes from various reasons. Students are not using Internet only for studying purposes, but also a lot of time they spend within social networks, searching the data, or playing games.

In study presented in [6], conclusions can be found about children in Hong Kong schools. On the daily average, children spend their time with Internet and electronic screen devices as follows (numbers go over 100%, because multiple answers were allowed):

- 44.2% for the use of TV,
- 31.6% for the use Tablet PC, and
- 31.8% for the computer usage.

Considering the average amount of time a day spent on electronic screen devices and Internet, this research shows that 70.9 % spends less than 1 hour, 22.6% between 1-3 hours, additional 3.3 % spend more than 3 hours, while the data for the rest of 3.2% is not available. Article [7] shows analysis of the children from “European union Online”, a 25-country survey regarding excessive use of the Internet by children. Children were most likely to report that they spend their time surfing (about 42% of the children), or that they had gone “without eating or sleeping” because of the Internet (about 17% of them). Without Internet about 67% of the children are bored! This paper also shows that there were significant differences between boys and girls, between young people from different age groups, and between children from households where parents had mutually diverse education.

The trends considering Internet usage by students and pupils today were examined in [8]. Paper shows that there exists a large growth of use of Internet and digital media in general, including computers, mobile phones, tablets, and video-games. Article shows that children start using in an extremely early age, at the preschool institutions. Overuse of these digital media can have very negative effect on children at such an early age, but also later, and can influence psycho-physical development, unless it is aimed to train and educate children to a proper use of those media.

In [9] authors showed the results about students Facebook users. The results show that over 90 percent of pupils were already existing Facebook users. Approximately 58 percent of the respondents were below the age of 25 and used Internet for various reasons on a daily basis. A further 10 percentage used the Internet at least once per week. 65 percentage of the pupils have access to the Internet at home and a good news is that 75 percentage of pupils had a personal computer with Internet access.

Finally, we found a paper [10] that show that the most frequent activity was playing computer games (64% responses), then working on the internet (27% responses), writing (26% responses) and others. The results showed too that boys preferred playing games whereas girls preferred writing. The use of internet was similar between two sexes. Computers at homes were used mainly for computer games, while prevalent activities in schools were related with searching for information from the internet and using e-mail. This means that the use of PCs in the school was very consistent, but the use of e-mail and information from the internet at home was quite different than the use of PC for games or MS Word.

### III DATA AND METHODS

The dataset used in this paper was derived from a research carried out in 66 elementary schools across Autonomous Province of Vojvodina, Republic of Serbia. It included N=7007 elementary school students who filled in the questionnaires. The sample was formed from students attending higher grades (VII and VIII) of elementary school. The surveyed students attend monolingual, bilingual, or trilingual schools. The main aim of exploring and expanding the national community lies in the fact that Vojvodina is an intensely multiethnic community. This way, we were able to focus on general, overall state in the elementary schools in Vojvodina when it comes to ICT integration.

The survey consisted of questions regarding demographic characteristics, frequency of using computer and Internet at school and at home, purposes of using ICT, integration of ICT in the classrooms, as well as students perception of ICT integration for learning purposes.

Data were analyzed using descriptive statistics, nonparametric statistical methods, and binary logistic regression. Summary statistics are presented by percentages for categorical variables. Crosstab procedure and chi square test of independence were used to examine differences in characteristics between groups for nominal variables. Binary logistic regression was employed to model outcomes of dependent variable with only two categories. It was used to assess the factors influencing excessive Internet use among elementary school pupils. Pupils covered by the research were divided into two focus groups:

- students with excessive Internet use, and
- with non-excessive, “normal/usual” Internet use.

The student was considered to use Internet excessively of he/she spent more than 25 hours/week on the Internet. The dependent variable was coded according to this classification: students were assigned the value 1 if they use Internet excessively and the value 0 otherwise. Total of 8 predictors entered the model, and all variables were categorical. Performances of the model were tested using Omnibus Tests of Model Coefficients. Model with all independent variables against a constant-only models was statistically significant (chi square= 626.389, p=.000).
This result indicated that the set of chosen variables makes reliable distinguishing between mentioned two groups of students. The regression results are presented as odds ratios. Odds ratios above 1 stand for positive associations between independent and dependent variables, while odds ratios below 1 and above 0 stand for negative associations. The level of significance in all conducted tests was 0.05.

### IV RESULTS

The survey sample offers a balance across the gender and the grade of the students. The results are given in Table 1.

#### TABLE I. BASIC CHARACTERISTICS OF STUDENTS

<table>
<thead>
<tr>

Further, we have investigated whether there are any significant differences between mentioned purposes of Internet use, and gender and/or place of residence. The statistical analysis revealed that there is a statistical significant difference between gender and use of Internet for study purposes (chi square = 7.011, p=.008). According to the results we reached, male are using Internet more for study related activities than females (61%). There is also a statistically significant difference between place of residence and Internet use for study purposes (chi square = 21.844, p=.000). Students from cities are using Internet more for study purposes (63%). There were no statistical significant differences between gender and place of residence and Internet use for socializing and fun. Differences in a sense of Internet use for reading news were only significant considering the place of residence (chi square = 41.592, p=.000). Students from cities use Internet more for reading news (66%). There is a statistically significant difference between gender and Internet use for games (chi square = 14.154, p=.000). As expected, and proved in many research papers, males are using Internet more for playing games (61%). Females are using Internet primarily for communication with other students, more than males (53%), and that difference is significant (x2= 27.874, p=.000).

#### TABLE IV. COMPUTER AND INTERNET USAGE IN SCHOOLS

*denotes significant variables
Older students have higher odds to be in the group of students who excessively use Internet, than younger students. The results also show that girls are more prone to use Internet excessively, than boys. Finally, students from smaller places of residence are more likely to use Internet excessively, compared to students living in bigger cities. Still, there is a negative association of Internet use for study purposes, and excessive use of Internet. On the other hand, there is positive association of excessive Internet use for socializing and fun, for reading news, for games and for communication with other students. The results confirmed our main hypothesis that students who use Internet for non-study related purposes are more likely to be Internet addicted.

V CONCLUSIONS

To give a verbal explanation and discussion of presented results, we can induce the following. Based on the presented results, we can conclude that the students of 7th and 8th grade of elementary schools in Vojvodina have a rather high rate of Internet use, sometimes very extensive. Comparison also shows that Internet is used more among students of the 7th grade, compared to the students of the 8th grade (70%).

In addition, surveyed data show that boys tend to use Internet more at home (54%) than in schools. This result can be expected since, as we already mentioned, Internet use in schools is usually forbidden during breaks. As both common sense and research show, game playing is one of the most popular ways of computer use. Our research confirm to that, showing that about 86% of surveyed students mention this activity as one of their main methods of computer use. Following this activity, on the list of the most popular methods of computer use are “gaining new information” for about 71% of students, “doing their homework” for 57% of pupils, and “expanding their existing knowledge” for about 31% of pupils. Significant and rather expected is the result showing that students living in bigger cities have better access, and use Internet more often (62.5%).

Abstract: E-learning System has become a common constituent unit of web page of any higher education institution. At the Polytechnic Nikola Tesla in Gospić Loomen is established since 2010, a system that is designed in a role of teaching repository for students and for preparation of e-courses for the teachers and students. The aim of this paper is by using descriptive and inferential statistics, and based on a survey conducted among students, examine how, and to what purpose and how often students used Loomen E-learning System.

Keywords: e-learning system, Loomen, higher education, statistical methods.

I. E-learning and Learning Management System
The concept of E-learning can be defined in various ways. One of definitions can be E-learning is learning with the help of ICT technologies. For example, Zhang and others (2004.) defined e-learning as technology-based learning in which learning materials are delivered electronically to remote learners via computer network.

E-learning has following forms of teaching [3]:
- teaching in which the application of ICT technologies is exclusively as a supplement to traditional teaching (face-to-face, f2f),
- teaching in which you can combine traditional forms of teaching supported by ICT technology. This form of teaching is called Hybrid Learning i.e. learning mix mode. Hybrid learning uses the system for learning on distance (Learning Management System, LMS) and videoconference,
- exclusively online teaching without face to face contact.

However, the use of ICT technologies in the educational process requires some technical, and also pedagogical and organizational skills of the authors of the online content. The digital teaching content requires from author a special approach in understanding the design process of online content. In the process of creating and designing online content, it is important to follow certain pedagogical and didactic rules.

Due to development of e-learning technologies we can talk about three generations [4]:
- e-learning 1.0,
- e-learning 1.3,
- e-learning 2.0.

According to Kljakić (2007.), [5] the third generation of e-learning (e-learning 2.0) takes advantage of Web 2.0 technology in which the emphasis is on collaboration, knowledge creation, virtual communities, and for the first time students can participate in developing teaching materials. The advantage of e-learning 3.0 is in enabling to achieve 95% of success (as shown in Table 1).

Table 1. Achieving success in learning.

<td>70%</td>
</tr>
<tr>
<td>Of what we experience</td>
<td>80%</td>
</tr>
<tr>
<td>Of what we teach others</td>
<td>95%</td>
</tr>
</tbody>
</table>

The potentials of e-learning 2.0 are reflected in the following [6]:
- unlimited possibilities for creating, distributing, publishing, commenting of the content using Internet,
- easier use of e-learning solutions based on Web 2.0 technologies,
- focusing on students,
- the learning process becomes creation of a network.

Regardless of the generation of e-learning, all e-learning systems can complement each other, depending on the needs of the educational context and can be independently applied.
A. Learning Management System (LMS)

Development of systems for distance learning began in 1996 as a part of the www internet service. Using the LMS system is reflected in the technological advancement of the teaching, but maintaining the support of the classical model of learning (f2f). The advantages of using LMS are the grouping of students, starting learning at the same time, periodic distribution of new materials and expectations of the end of the learning at the same time. Today there are numerous LMS systems on the market that differ in the way how they save teaching materials and other information required in the process of learning and teaching. The main features of all LMS systems can be divided into two basic groups [7]:

- administrated group of functions,
- teaching group of functions.

Administrator functions enable the monitoring and adjustment of functions that are not related to the transfer of knowledge (of system functions). Systemic functions are related to the following processes (examples):

- creating user accounts,
- creating access permissions,
- creating user groups,
- various forms of reporting, analysis, process monitoring,
- support in the development of teaching materials,
- connectivity with other systems within the organization,
- adjustment of the system to the various program platforms,
- other system features.

Teaching functions are extremely important because the final result in learning and teaching process depends on them. If there is not enough functional support, that will be reflected in the final learning outcomes (quality) in the use of LMS by students, and teachers. Some of the most important teaching functions of the LMS system are: [8]

- the content of teaching (lessons, modules),
- navigation (management) through the elements of the system,
- self-evaluation of participants (students),
- communication between teacher and students,
- additional authoring tools for creating additional content (eg. tests, discussions, etc.).

II. Learning Management System Loomen at Polytechnic Nikola Tesla in Gospić

Loomen is a software tool used for the creation of online educational contents and teaching at distance. Loomen is an open source software, licenced as a free making it extremely popular in the implementation of the processes of education supported by ICT technologies. The Loomen system is based on Moodle [9] (Modular Object-Oriented Dynamic Learning Environment) within CARNet service designed for creating digital learning content. From the security and authentication point of view, system is enabled through an electronic identity in the AAI@EduHR system.

The Loomen system on Polytechnic Nikola Tesla in Gospić is used since 2012. In the initial period the most of the courses were introduced from all three studies (Professional Study of Road Transport, Professional Study of Economics of Entrepreneurship and Professional Administrative study) and a brief training of employees and students was carried out. The system is used primarily as a teacher repository system and for forwarding information to students in the current academic year. Over the coming years the system was updated, and became one of the primary sources of information and preparations of the exams. The next step in upgrading the Loomen system is the introduction of e-courses.

Loomen is the application for creating and maintaining online courses based on the GNU GPL2 (GPL - General Public License) license. Originally, Loomen is written in the PHP program language and supports multiple types of databases (eg. MySQL). Also, language interface has been translated into several languages, and many users of open-source software were involved in the creation of new functionality as well as those existing, and made a new modules and test existing one and provide a customer support. Table 2 shows the basic features of the Loomen LMS system.

| Table 2. Basic features of the Loomen LMS system. |

2 GPL licence preserves the freedom of users of softwares: the right for use, the right form making copies and the right to modify and redistribute of the modified program. GNU GPL is copyleft licence. Software that may arise as a modification of the existing software guarantees the same freedom (ie. to be distributed under the same licence).

### III. Theoretical background: about survey in Šibenik

Perišić, Goleš and Devčić (2012) conducted a research about e-learning system at the Polytechnic in Šibenik. In their study they used methods of descriptive and inferential statistics: graphical and numerical methods, estimations of the parameters and hypothesis testing procedures (χ² test). The level of use and students' satisfaction with e-learning system and other forms of online information and relation between using e-learning system and students’ success were analyzed. The study was conducted at the Polytechnic in Šibenik on three departments: the Department of Management (professional study of Management and specialist professional graduate study of Management), Department of Administration (professional study of Administration) and Department of Transport (professional study of Transport). Analysis was based on 304 respondents. The level of use of online information sources, and especially e-learning system and the quality of existing online information sources was examined. The analysis showed that students of the Polytechnic in Šibenik in a great extent use e-learning system. Authors showed that there is statistically significant difference in the use of e-learning system between students with different study success. Students with better study success used e-learning system in a greater extent than those with lower study success. Students are mainly satisfied with the coverage of the courses with e-learning system.

### IV. Sample and Questionnaire

The study was conducted on a sample of 71 students of professional studies Economics of Entrepreneurship (56% of respondents) and Road Transport (44% of respondents) at the Polytechnic of Nikola Tesla in Gospic. The average age of respondents was 20.4 years. Among the respondents was 42.3% of male and 57.7% of female respondents. 38% of respondents were the first, 18% the second, and 44% third year of the study. Mostly, full-time students were tested (90% of respondents), and only 10% of respondents were part-time students. 84% of respondents had average success E or D or C, and 16% of respondents had average success B or A. Data were collected using a questionnaire on a random sample of students of the Polytechnic. The survey was conducted in November 2016. The questionnaire contained six questions related to the demographic characteristics of respondents (age, gender, year of study, mode of study, average success and professional study) and 9 questions that gave information about forms of sources of information used, with an emphasis on the Loomen.

### V. Empirical Results

Students can look for information on different ways: standard (bulletin board, Registry of Polytechnic, consultations, phone calls) or online forms of getting information (website, Loomen, social networks). According to conducted research 4% of respondents used standard forms, 59% of respondents online forms of information, and 37% both. 45% of respondents believed that the standard forms of information were sufficient to obtain information on time, and 55% think that were not sufficient. 82% of respondents believed that online sources of information are sufficient to obtain information on time, and 18% think that they are not enough. Students used online forms of information: website (37%), Loomen (22%), social networks (7%) and all of the above (34%).

![Figure 3. Online forms of informing.](http://www.ssmb.hr/libraries/0000/2796/e_learning_LMS.pdf)
Students used Loomen never (4% of respondents), sometimes (72% of respondents), often (24% of respondents).

</tbody>
</table>

Figure 4. Frequency of using Loomen Source: authors' calculation.

The purpose in which students most commonly used Loomen is literature and teaching materials (28% of respondents), exam results (30% of respondents), professor’s notices (8% of respondents), examples of the old exams (9% of respondents), all of the above (25% of respondents).

<table>
<thead>
<tr>
<th>The purpose of using Loomen</th>
</tr>
</thead>
<tbody>
<tr>
<td>literature and teaching materials</td>
</tr>
<tr>
<td>10</td>
</tr>
</tbody>
</table>

Figure 5. The purpose of using Loomen Source: authors' calculation.

86% of respondents believed that Loomen help them while studying, and 14% think that it didn’t. 46% of respondents believed that there is room for improvement of Loomen, and 54% believed that there isn’t. Students gave some recommendations for improving the Loomen and the most common recommendations we can extract creating and implementing the application and implementing all courses on Loomen.

The obtained data showed that there is no statistically significant relationship between year of study and frequency of using Loomen ($\chi^2 = 6.294$, $p = 0.178$), nor between the year of study and online forms of informing that students use ($\chi^2 = 6.908$, $p = 0.329$), nor between the year of study and the purpose of which students most commonly used Loomen ($\chi^2 = 13.52$, $p = 0.095$). Furthermore, there is no statistically significant relationship between the modes of study and online forms of informing that students use ($\chi^2 = 1.609$, $p = 0.6573$), nor between modes of study and frequency of using Loomen ($\chi^2 = 0.291686$, $p = 0.8643$), nor between modes of study and the purpose of which students most commonly used Loomen ($\chi^2 = 0.2608$, $p = 0.992$).

The results indicated that there is a habit among students to use online sources of information, such as Loomen. Unfortunately, so far it has not been proved that the use of the Loomen can help students achieve better results. Management of the Polytechnic should have to make further efforts to facilities at Loomen do more help in preparing exams, which would then have a positive impact on the success of students.

In subsequent studies we should try to include more part-time students to give their answers in questionnaires.

VI. Conclusion

In today’s online environment, each higher education institution must take into account the availability of information, teaching materials, literature, professors’ notifications, exam results etc. via online forms of informing such as web pages, Loomen or other E-learning systems, social networks and more.

Loomen e-learning system is one of the ways how teaching materials and information can be available for students and without requiring physical presence at the university/college. In this paper, the study about frequency and purposes of using Loomen was conducted on the random sample of students of the Polytechnic Nikola Tesla in Gospic. Analysis of the results showed that the students of the Polytechnic have the habit of using online forms of information (mostly Polytechnic’s website and then Loomen), that students use Loomen sometimes (72% of students) and often (24% of students). The purpose in which students most commonly used Loomen is literature and teaching materials (28% of respondents), exam results (30% of respondents), professor’s notices (8% of respondents), examples of the old exams (9% of respondents), all of the above (25% of respondents).

There was no statistically significant relationship between the frequency and purpose of using Loomen system and characteristics of students (year of study, student status, success of studying). In the future Polytechnic should enrich the content of the Loomen in terms of introducing new courses on Loomen (which was the proposal for the
improvement of a number of students) and in the future should certainly consider the introduction of e-courses which would be an additional step in raising the quality of teaching and quality of entire contents that Polytechnic is offering to its students.

If we compare the obtained results with a similar survey about using e-learning system that was conducted in 2012 by Perišić, Goleš and Devčić we can notice certain similarities, and differences also. Thus, it was shown that, which is the case in Šibenik also, that students developed the habit of using online sources of information; 59% of students used only online sources of informing, and 37% of students used online and standard sources of informing (in Šibenik 45% of students used only online, and 47% of students both forms).

However, 24% of students used Loomen often, and 72% of students sometimes (in Šibenik 71% of students often, and 24% sometimes). In this study, as well as in Šibenik, the relationship between frequency of using Loomen and student’s status was statistically insignificant. Furthermore, the relationship between frequency of using Loomen and Department of the Polytechnic was statistically insignificant, while in Šibenik this relationship appeared to be statistically significant. Unlike the students in Gospić, the relationship between the frequency of using Loomen and average student’s success measured by average score in Šibenik showed statistically significant.

Determination of time criteria for assessment in Learning Management Systems

Trpimir Alajbeg, Mladen Sokele, Vladimir Šimović
Zagreb University of Applied Sciences, Department of Electrical Engineering, Zagreb, Croatia
trpimir@tvz.hr, msokele@tvz.hr, vsimovic@tvz.hr

Abstract - Today’s Learning Management Systems, in conjunction with knowledge and skill acquisition modules, offer the possibility for automated assessment of the aforementioned knowledge and skills. Their implementation in teaching offers a wide range of advantages: reducing teacher administrative work, reducing the possibility of errors concerning preparation, execution and evaluation of exams; elimination of teacher’s subjectivity during the evaluation phase; lessening of inappropriate student actions during exams etc. A majority of tests that are done through LMS have a time limit, which opens up a problem of determining the optimal time parameters for a specific exam. The paper includes a statistical data analysis that was collected during five years via LMS Moodle on the Personal Computer Applications (PCA) course in professional study of electrical engineering at the Zagreb University of Applied Sciences. Through analysis and modelling the results of the statistical data processing, guidelines for time criteria for future tests were made.

I. INTRODUCTION

The advantages of using a Learning Management Systems (LMS) are significant. For students: the ability to prepare themselves for classes, laboratory and construction exercises with the emphasis on the ease of access to all course material, computer applications and tasks for individual preparation and work.

LMS systems are also beneficial for lecturers. They help to reduce the time spent in preparation and execution of exams, as well as to minimise errors in their evaluation and grading, especially when quick grading is required. Additionally, they considerably reduce the administrative tasks (e.g. class attendance tracking system for obligatory laboratory exercises, benefits of centralized grade database). Also, the automated knowledge and skill tests eliminate the teacher’s subjectivity during the evaluation phase of the exam [1]. Another benefit is the possibility for the student to check the results of the exams in real time i.e. immediately after its end. [2]. By using the application Net Support School that is installed on all of the computers used for LMS, a reduction of inappropriate student actions during exams is achieved.

The results of automated knowledge and skills exams can be used to assess the existence of questions or tasks that are either too easy or too complex. Consequently, the questions or tasks can be then reformulated or replaced with new ones without altering the structure of the existing test. With all that in mind, setting of time criteria for assessment in LMS is challenge. The adjustment of time criteria is in direct correlation with the number and complexity of tasks in each individual exam. The basis for it are the log data that was collected during five years of usage LMS Moodle for the Personal Computer Applications (PCA) course in professional study of electrical engineering at the Zagreb University of Applied Sciences.

The paper examines possible directions of LMS time criteria determination and/or optimization. Primarily, the optimization is not focused on saving the time (i.e. overall test duration) but on the adequate number of tasks increase in existing time period framework. The increase in the number of tasks ensures better class material coverage, enables implementation of more specific tasks as well as improvements in cognitive linkage of knowledge and skills. Therefore, the leading idea is to examine how possible time reduction and/or number of tasks increase reflects on overall successful attempts as well as identification and differentiation of better and barely enough prepared students. In order to achieve proposed idea, analysis and modelling of the results of the statistical data processing and the procedures for time criteria determination were made. The results of the aforementioned analysis and modelling could be used for developing of time criteria guidelines, noting that each test must be adapted to the specific requirements of particular lesson.

In Section II., explanatory parameters describing test solving dynamics are defined. In Section III. explanatory parameters are applied on results of attempts separated according to achieved scores as well as possible effect of test duration reduction is investigated by analysis of test solving dynamics slope near the test completion time. Based on analogy of test solving dynamics with diffusion process, in Section IV. the new model, named Declining Bass Model (DBM) is introduced. Finally, in Section V. the new model is applied in improved form (doubled DBM) that shows differentiation of better and barely enough prepared students. In addition, it is shown that new model enables determining of intensity of test solving that clearly identifies above mentioned differentiation.

II. INPUT DATA AND ITS REPRESENTATION

Automated knowledge and skills exams are used to assess acquired skills in case of laboratory exercises and acquired knowledge in case of theoretical course parts (i.e. midterm exams and final exam). Initially, the duration of the exams was determined by having the teaching staff of
the course solving exams and obtained average measured time were tripled for students.

Automated knowledge and skills exams via LMS Moodle have been used for nine years. Data for the first four years are not analysed because the tests were in constant improvement: the question database was constantly expanded and altered to optimally adapt to the course needs (Single or Multiple Choice; Short Textual or Numerical Answer, Matching, etc.). In the last five years, when automated knowledge and skills exams are in enable phase, analyses and modelling of the gathered data is reasonable.

Analysis of test solving dynamics is obtained through tests’ logs processing. According to the graphical representation (see Fig. 1 – case of Image processing test, all attempts: passed and failed), the following explanatory parameters can be identified and defined:

- number of students solving test \( M \) [\#] (in presented case \( M = 755 \))
- defined level for characteristic duration of test \( v \) [%] (in presented case \( v \) is set to 90%)
- characteristic duration of test \( \Delta t \) [s] i.e. time needed for \( v \) [%] of students to finish test (in presented case for \( v = 90\% \), \( \Delta t \) is 1191 s: from \( t_e - \Delta t = 609 \text{ s} \) to \( t_e = 1800 \text{ s} \))
- overall test duration \( t_e \) [s], after the expiration of the time \( t_e \) the test is locked (in presented case \( t_e = 1800 \text{ s} \))

Fig. 1 Example of test solving dynamics (case: Image processing test), \( M \) – number of students solving test, \( v \) – defined level for characteristic duration of test, \( \Delta t \) – characteristic duration of test, \( t_e \) – overall test duration

The main idea is to get quantification of test completion slope. In the case of Image processing test, the slope is moderate: within the first 34% of available time 10% of students submitted exam, and during the remaining part of \( \Delta t / t_e = 66\% \) of total time 90% students submitted exam. Therefore, dimensionless parameter defined as:

\[
g = 1 - \frac{\Delta t}{t_e}
\]  

with predefined level for characteristic duration \( v \) can be used for quantification of test completion slope gradient or in other words for the level of rush at the end of test solving. Parameter \( g \) is in range \([0,1]\) so it can be represented as percentage, where higher percentage means higher slope gradient.

Values for abovementioned parameters for all encompassed tests (all attempts, passed and failed) are given in Table 1.

### III. ANALYSIS OF SUCCESSFUL ATTEMPTS

Previous example illustrates statistics for all student attempts: passed and failed scores together. For proper determination of time criteria for test duration, data should be separated according to achieved scores. Intervals of scores 0%-33%, 34%-67% and 68%-100% are used for representation on Fig. 2, noting that first interval means that a student failed the test.

Values of parameter \( g \) (test completion slope gradient) from Table 2 shows that the better prepared students that
achieved higher scores are under lower time pressure (lower parameter \( g \)).

Table 2. Number of students that finished exam within the first and the remaining interval divided according the final scores (case: Image processing test)

</tbody>
</table>

* the first time interval is defined through level for characteristic duration of test \( v = 90% \)

Detailed analysis of the test solving dynamics slope near the test completion time can be obtained by its first derivative in the point \( (t_e, 0) \). Obtained gradient gives the ratio of decrease in the number of successful attempts depending on the reduction in the duration of the test. With that idea in mind, Fig. 3 shows the possible effect of overall test duration reduction on successful attempts, all percentage wise.

![Possible effect of test duration reduction on successful attempts](image)

Fig. 3 Gradient of test solving dynamics in point \((t_e,0)\) for cases: Image processing test and Spreadsheet test

With appropriate scaling of the abovementioned results, the actual amount of reduction in the number of successfully completed tests can be obtained, which is the goal of future authors' research. However, in this paper is an opportunity to show that for some tests this dependence is more strongly expressed. As it is shown on Fig 3, in case of Image processing test 10% reduction of overall test duration results in possible reduction of successful attempts of 11 %, and even 48% in case of Spreadsheet test.

![Declining Bass Model (DBM)](image)

Fig. 4 The Declining Bass model (DBM): dependence on the coefficient of imitation \( q \) and coefficient of innovation \( p \) 

\[ B(t; M, p, q, t_e) = M \frac{1 - e^{-(p+q)(t \geq t_e)}}{1 + \frac{q}{p}} \]  \hspace{1cm} (2)

The model \( B(t) \) introduces the effect of innovators via coefficient of innovation \( p \) which corrected deficiency of simple logistic growth, i.e. considers a population of \( M \) adopters who are both innovators (with a constant propensity to adopt service) and imitators (whose propensity to adopt service is influenced by the amount of previous adoption). To emphasize model dependence of its parameters, it is convenient to indicate the model as \( B(t; M, p, q, t_e) \), \( t \geq t_e \).

The Bass model describes growth with positive gradient. On contrary, test solving dynamics has negative gradient i.e. it declines. Therefore, prior to use the Bass model needs to be modified in declining Bass model. Declining growth is accomplished by mirroring of time variable axis, \( t \rightarrow -t \) (Fig. 4).

The new model, named Declining Bass Model (DBM) has the following form:

\[ DB(t; M, p, q, t_e) = M \frac{1 - e^{-(p+q)(t \geq t_e)}}{1 + \frac{q}{p}} \]  \hspace{1cm} (3)

Similar to (2), the DBM (3) is defined by four parameters: \( M \) – starting amount of customers; \( p \) – coefficient of innovation, \( p > 0 \); \( q \) – coefficient of imitation, \( q \geq 0 \) and \( t_e \) – time when service decease, \( B(t \geq t_e) = 0 \). Higher coefficient of innovation \( p \), \( p > q \)

IV. INTRODUCTION OF THE DECLINING BASS MODEL (DBM)

By analysing the graphical representation of test solving dynamics on Fig. 1 it can be concluded that in the sense of time series methods resembles to a declining growth model [3]. More precisely, customers (students) are leaving service (test solving) and after overall test duration \( (t_e) \) there is no customers left on market (knowledge assessment).

The best known model for a full description of the genesis of the new service adoption is the Bass model [4]. The Bass diffusion model (2) is defined by four parameters: \( M \) – market capacity, \( M = B(t \rightarrow \infty) \); \( p \) – coefficient of innovation, \( p > 0 \); \( q \) – coefficient of imitation, \( q \geq 0 \) and \( t_e \) – time when service is introduced, \( B(t \leq t_e) = 0 \):

The model \( B(t) \) introduces the effect of innovators via coefficient of innovation \( p \) which corrected deficiency of simple logistic growth, i.e. considers a population of \( M \) adopters who are both innovators (with a constant propensity to adopt service) and imitators (whose propensity to adopt service is influenced by the amount of previous adoption). To emphasize model dependence of its parameters, it is convenient to indicate the model as \( B(t; M, p, q, t_e) \), \( t \geq t_e \).

The Bass model describes growth with positive gradient. On contrary, test solving dynamics has negative gradient i.e. it declines. Therefore, prior to use the Bass model needs to be modified in declining Bass model. Declining growth is accomplished by mirroring of time variable axis, \( t \rightarrow -t \) (Fig. 4).
contributes to a steep disappearance of the service from market, and higher coefficient of imitation \( q \), \( q > p \) smooth disappearance of the service from market.

Due to fact that \( M \) is the asymptote of DBM, i.e. model (3) obtains value \( M \) only for \( t \rightarrow \infty \), characteristic duration \( \Delta t \) should be defined through certain level smaller than \( M \). (see description of \( v \) [%] in Section II – explanatory parameters definitions).

V. TEST SOLVING DYNAMICS MODELLING

For better understanding dynamics of test solving for successful attempts, data is modelled with DBM as time series.

The first step was fitting with single DBM where \( M \) (number of students solving test) and \( t_e \) (overall test duration) were fixed, i.e. values for them are taken directly from sample. The remaining parameters \( p \) and \( q \) are obtained by ordinary least squared method.

For case Image processing test - successful attempts, results are as follows (Fig. 5):

\[
M = 619 \text{ students} \\
t_e = 1800 \text{ s} \\
p = 3.38 \text{E-04} \\
q = 3.48 \text{E-04}
\]

Achieved correlation coefficient is \( r = 0.9980 \), and root-mean-square error is \( \text{RMSE} = 11.511 \).

\[
DDB(t) = DB(M_1, p_1, q_1, t_1; t) = DB(M - M_1, p_2, q_2, t_2; t)
\]

\[
= M_1 \frac{1 - e^{-(q + p)M_1t}}{1 + \frac{M}{p_1} e^{-(q + p)M_1t}} + (M - M_1) \frac{1 - e^{-p_1t}}{1 + \frac{M}{p_1} e^{-p_1t}}
\]

The idea is to identify two groups of students – one better prepared that will successfully finish test in the first wave (parameters indexed with 1) and other one that will finish test in the second wave (parameters indexed with 2). According to that assumption, parameters of model (4) are prepared as follows:

\[
t_1 < t_e \\
M_1 < M \\
DDB(t \rightarrow \infty) = M \\
DB_1(t \geq t_1) = 0 \\
DB_2(t \geq t_2) = 0
\]

In the first step single DBM has 2 free parameters \( p \) and \( q \), and doubled DBM has 6 \( (M_1, p_1, q_1, t_1, p_2, q_2) \) which are obtained by ordinary least squared method, too.

For case Image processing test – successful attempts, result are as follows (Fig. 6):

\[
M_1 = 284 \text{ students} \\
t_1 = 1300 \text{ s} \\
p_1 = 9.20 \text{E-04} \\
q_1 = 4.05 \text{E-03} \\
M - M_1 = 335 \text{ students} \\
t_e = 1800 \text{ s} \\
p_2 = 9.55 \text{E-04} \\
q_2 = 2.93 \text{E-03}
\]

Achieved correlation coefficient is \( r = 0.9995 \), and root-mean-square error is \( \text{RMSE} = 5.797 \).

Following the abovementioned assumption, in the next step data is modelled with doubled DBM (4):

Students take the tests with different levels of preparation. Even when the analysis is done on the successful attempts only, the graph on Fig. 5 shows discontinuities in smoothness of experimental data. It can be assumed that this is result of inhomogeneous sample, i.e. a group of students is consisted of a better prepared ones and others. It is worth mentioning that unprepared students are not included (only successful attempts are analysed).

Now when model that identifies groups of students according to their knowledge/skills is founded and it provides good fitting results, it is possible to determine intensity of test solving \( l(t) \). The intensity of test solving is a rate of test solved with respect to the change of the time variable. It can be calculated as a negative derivative in time of doubled DBM’s components (5):
Intensity of test solving $I(t)$ for each separate group is graphically shown on Fig. 7 for case: Image processing test – successful attempts. Differentiation between groups are especially visible through different peak times of their intensity functions. Numerical results are as follows:

- Maximal intensity of solving for the first wave is achieved around $t_{m1} = 1005$ s, and for second wave around $t_{m2} = 1515$ s,
- Maximal values of $I(t)$ for both waves are almost equal $I_1(t_{m1}) \equiv I_2(t_{m2}) = 0.433$.

From Fig. 7, it is evident that success of better prepared students will not be affected with appropriate test time reduction and/or number of tasks increase as it will affect the other ones.

**VI. CONCLUSION**

On account of the nine-years usage of the LMS Moodle on courses in professional study of electrical engineering at the Zagreb University of Applied Sciences it has been possible to perform a detailed and reliable processing of the acquired statistical data.

The data was analysed as a time series and explanatory parameters that are extension of the simple overall test duration parameter are defined: characteristic test duration, test completion slope gradient and peak of test solving intensity. These parameters are determined and evaluated for different knowledge and skills exams and could be used as time criteria optimization guidelines for similar LMS provided tests.

Based on the similarities with diffusion models, a new model named Declining Bass Model, is developed. If new model is applied in improved form (doubled DBM), the differentiation of better and barely enough prepared students can be obtained.

Further research will be focused on the quantifying abovementioned indicators for their practical applications in support of LMS Moodle usage for other courses, too.

Abstract – This paper discusses the possibilities of employing the process of the blended learning of professional English through the Moodle platform. It discusses different theoretical approaches to language learning implemented within the Moodle platform and the associated cognitive domains according to Bloom’s taxonomy. The paper focuses on examining the Moodle activities within the language learning framework along with the levels of each activity within the cognitive domain. These activities are implemented at the University North within a wide range of courses covering English for Professional Purposes aimed at the engineering education. The paper can serve as a framework for the possible applications of different Moodle elements in the teaching of English for Professional Purposes.

I. INTRODUCTION

Rapid advances in technology and computer-aided teaching have offered new opportunities and enforced the application of new tools, methodologies, approaches and frameworks to promote active foreign language teaching and learning. English, as a global language, is probably the most commonly spoken language in the world when combining the native and non-native speakers, and currently the language most often taught as a foreign language in the Croatian higher education.

Creating a successful language learning environment within the higher education environment is becoming ever more complex. Information behavior and information preferences of students are also constantly changing and should be regularly examined. Faced with the new Web 2.0 services that include both the technological side by introducing new technologies and the new patterns of information behavior geared towards a more participative and socially oriented environment, new approaches based on individualization or autonomy are constantly examined.

In order to fulfill its mission of educating competent professional personnel for the needs of the real economy, University North implemented Moodle, an open-source Learning Management System (LMS), one of the currently fastest growing successful e-learning systems in the higher education environment, used in 231 countries and with nearly 100 million users worldwide [1].

In that context, Moodle has been receiving more and more popularity in higher education in the recent years, especially in the learning-teaching process applied in the English courses, offering a wide range of courses covering English for Professional Purposes. Teaching foreign languages for professional purposes is considered to be a priority in the updating of engineering education, and the ability to communicate in other languages is becoming an integral part of the professional competence of any specialist.

II. MOODLE AND LANGUAGE LEARNING APPROACHES

From the perspective of language learning approaches, Moodle implements two main approaches: the blended learning approach and the communicative approach.

The term blended learning originated around the year 2000 in the business world in connection to corporate training, followed by higher education, and finally it appeared in the world of language teaching and learning [2]. Blended language learning (i.e. integrating the use of technology into the classroom-based learning and teaching) is still a relatively new concept, but recent research appears to indicate that when “appropriately” implemented, blended learning can significantly improve the learning experience [3].

The communicative approach to language learning allows language teachers to follow the goal of making “the student the center of the learning experience wherever possible.” Moodle supports the key features of Communicative Language Learning, some of which are learner autonomy, the social nature of learning, curricular integration, focus on meaning, diversity, alternative assessment, the role of teachers as co-learners, etc. [3].

While the blended learning approach provides the environmental setting within the Moodle platform, the communicative approach focuses on the roles of students and teachers. The connecting point between those two approaches, namely the learner and the environment, is the learning activity. For this reason, the design of blended learning needs to be centered on the activity design [4].

MIPRO 2017/CE
Along with the two approaches discussed, it is important to indicate and categorize the activities based on their learning outcomes. One of the most widely applied taxonomies of learning outcomes is Bloom’s taxonomy that identifies six levels within the cognitive domain, from the simple recall or recognition of facts as the lowest level, through the increasingly more complex and abstract mental levels, to the highest order which is classified as evaluation [5]:

1. **Knowledge**: define, list, name, order, recognize, relate, recall, repeat,
2. **Comprehension**: classify, discuss, explain, identify, indicate, report, review, select,
3. **Application**: apply, choose, demonstrate, sketch, solve, use, write,
4. **Analysis**: analyze, calculate, compare, contrast, discriminate, examine, experiment,
5. **Synthesis**: assemble, construct, create, design, develop, formulate, prepare, propose, write,
6. **Evaluation**: assess, attach, choose, compare, predict, rate, select, evaluate.

In order to select the best approach in EPP teaching (using the most appropriate activities within the Moodle platform to develop targeted outcomes), it is necessary to examine the Moodle activities within the language learning framework along with the levels of each activity within the cognitive domain.

### III. MOODLE ACTIVITIES IN EPP TEACHING

In the last few years, while trying to improve the management of the English language course at the University North, Moodle has emerged as an invaluable asset of that process. Considering the fact that the course is aimed at teaching a foreign language for professional purposes, a certain level of autonomy is required from students, and that is seen as an additional means of developing the students’ skills needed in the professional environment. Students who participate in Moodle-based courses not only gain knowledge in the areas stipulated by the curriculum, but they also develop practical skills such as decision-making, applying critical evaluation, and problem solving [6]. As a learning platform that allows students to access the contents of the course 24/7, students are given a certain amount of autonomy in their learning process. They can access the lectures and assignments at any time and it is up to them to decide when and how fast they want to go through the course and cover the discussed topics [7]. In lieu of being pressured into learning in a traditional class environment only, they exercise individual control over the speed of their work by being given the option to learn and revise any material that they have missed or insufficiently acquired during the face-to-face lectures.

Moreover, Moodle offers a wide range of activities that can be used to improve the learning of a language. The activities and their advantages in EPP language teaching are presented and discussed in the next section.

**Chat** - Students can get together for a chat session which allows them to enter into dialogue with each other. By discussing a certain topic with each other and the teacher, they practice the use of the language and they draw each other’s attention to the possible errors they might have overlooked, or they give each other additional ideas for the solving of the given task. However, it is important for the teacher to offer guidance when needed and to steer the wheel if the students go off track [8]. Levels of activity within the cognitive domain: Comprehension; Application; Synthesis; Evaluation.

**Database** - With the help of the Database module, teachers can help students build vocabulary lists through which students master a specific professional matter introduced during the lecture. The database can function as a personal glossary which students can consult when they revise for the exam. Levels of activity within the cognitive domain: Knowledge, Application, Analysis, Synthesis, Evaluation.

**Forum** - Forum is an activity that allows a group of Moodle users to ask and answer questions [8]. Students can ask the teacher and each other for help by asking questions, and at the same time help others by answering their questions and giving their input on a certain matter. Moreover, students can subscribe to a certain forum and receive an e-mail when someone offers a new answer to the posed question. As with the Chat module, it is important to give students a certain level of autonomy, i.e. to make them feel as if they were in charge and thus give them the option to express their views and opinions more freely, without the sense that they are being “monitored”. Levels of activity within the cognitive domain: Comprehension, Analysis, Synthesis, Evaluation.

**Hot Potatoes** - This module is defined as a free, easy-to-use quiz-making program ideal for setting up quick quizzes to review or test students [8]. This module can cover the testing of basically all main elements of a

</table>
language, from grammar and vocabulary to reading and listening. Cloze tests, crosswords, matching exercises and multiple-choice are the most common types of Hot Potatoes tests [3]. They are quite attractive for students because they require their full attention when eliminating the incorrect answers, but also because they are allowed to use the “back” button, which in a way allows them to “cheat” and improve their results. Levels of activity within the cognitive domain: Knowledge, Comprehension, Application, Analysis, Synthesis.

Journal - This module allows students to keep a diary where they can reflect on their learning process and discuss the matters that they did not manage to master during class and have thus been left unclear. There they can also write drafts of their writing assignments. Considering the fact that it is only the student and the teacher who have access to this module, they can ask the teacher questions about a certain lecture or matter that they do not feel comfortable enough to ask in the Forum. They can then correct their assignments in accordance with the teacher’s comments [7]. Levels of activity within the cognitive domain: Comprehension; Analysis.

Lesson/Lecture - The Lesson/Lecture module requires a lot of patience from teachers because it is quite complicated to set up, but at the same time it is very rewarding as it allows them to progress step by step through a lesson. For example, students are given a certain text to read, and then they are given a question accompanying that text. If they answer the question correctly, they move on to the next page where a new question or assignment awaits them. On the other hand, if they answer the question incorrectly, they can either take the question again or choose to go to an easier one. This module can be used for the presentation of cultural information, teaching grammar, reading professional texts, listening, etc. [7]. Levels of activity within the cognitive domain: Knowledge, Comprehension, Application, Analysis, Synthesis, Evaluation.

Questionnaire - The Questionnaire module is a customizable survey which can be very useful for getting feedbacks or opinions of various aspects of the course, or for getting students to write their own surveys and practice asking questions [8]. Moreover, by asking them questions about a certain text that they had to go through, the teacher can get a solid evaluation of the students’ preferences and on the basis of the results, work on the improvement of the materials. Levels of activity within the cognitive domain: Analysis, Synthesis.

Dictionary - This module serves a similar purpose as the Database module. Students make vocabulary lists to which they add definitions, and that can help them master a particular matter in a more concrete, substantial way. It also allows them to find in one place the vocabulary they need in order to pass the course and that potentially shortens the time they would usually need to prepare for the exam. Levels of activity within the cognitive domain: Analysis, Synthesis.

SCORM – The abbreviation stands for Shareable Content Object Reference Model. Teachers can save Hot Potatoes quizzes as a SCORM file, which bundles all the files in the activity and teachers can then import the SCORM file directly into the course home page [8]. SCORM files enable a more synoptic reading of the data due to the fact that what SCORM does for the programs is equal to what PDFs do for documents. [8] Levels of activity within the cognitive domain: Application.

Survey - A Survey is comprised of questions with slightly different answers, which then allows the teacher to collect the answers in the form of a percentage and thus get a better view of the students’ opinion on a certain topic. Teachers are yet again given the opportunity to get an insight into the students’ opinion of the course and on the basis of that they can implement certain changes and improve the course. Levels of activity within the cognitive domain: Analysis, Evaluation.

Test - This module allows teachers to conduct continuous assessment and/or final assessment via Moodle. Teachers can create a number of questions for the evaluation, limit the time the students have for solving the questions, and based on their performance, and decide on the final grade. Levels of activity within the cognitive domain: Knowledge, Comprehension, Application, Analysis, Synthesis, Evaluation.

Wiki - As the name discloses, this module functions as the Wikipedia webpage, meaning that its content can be edited by all users, i.e. course participants. This module is good for collaborative work such as joint writing projects and task planning [8]. This module enforces the sense of team work, while at the same time it allows the students to keep a certain level of autonomy. Levels of activity within the cognitive domain: Application, Analysis, Synthesis, Evaluation.

Assignment - The teacher gives out an Assignment and posts the instructions in the activity description. Students have to respect the deadline when they submit their Assignment as an attachment. The Assignment is then reviewed and assessed by the teacher, who is the only one who can see the submitted file. This module often goes hand in hand with the Test module in the sense that it plays a crucial role in the final assessment. Levels of activity within the cognitive domain: Comprehension, Application, Analysis, Synthesis, Evaluation.

Workshop - Workshop is similar to the Assignment module, the only difference being that as opposed to the Assignment module, it can be peer-reviewed before the file is submitted, meaning that it is not only accessible to the teacher, but also to other
students who can write their own comments and contribute to the final version. Levels of activity within the cognitive domain: Application, Analysis, Synthesis, Evaluation.

As we can see, Moodle offers a wide range of learning activities that can be implemented in the EPP teaching. The activities are imbued with a number of advantages, both for the students and the teachers. Firstly, the students are given a much higher level of autonomy not only on the basis of source availability, but also on the basis of modules such as Chat and Forum, where they can ask both the teacher and their colleagues questions that can help them in mastering the course. As it is often the case, some students might find it easier to ask a question via an online platform than during a face-to-face lecture where they feel more exposed to the reaction of their environment. Such modules increase the level of student activity and investment. Moreover, students of technical studies often shift their focus away from foreign language courses towards their main interest, the technical courses [4]. Under such circumstances, it is necessary to spark their interest by engaging them in cloze tests, multiple-choice exercises, crosswords, and matching exercises offered by the Hot Potatoes module. One additional advantage offered by Moodle through the Hot Potatoes module is the involvement of multimedia tools [7]. The Hot Potatoes module not only makes language learning more interesting to students by employing a variety of game-like teaching possibilities, but it also enhances their ability to focus on particular information and it develops their skills of information processing [9]. Moreover, what is one of the most important features of Moodle is the development of student autonomy, which stays with the individual far beyond the completion of the EPP course. Throughout the years, it has been observed at the University North that with the blended learning method that is implemented in the EPP course, students have become more active and interested in the lectures, and with each assignment, the number of students who fulfill all the requirements introduced at the beginning of the course is growing.

IV. THE TEACHER’S ROLE

As is the case with face-to-face lectures, the role of the teacher is indispensable in the blended learning method. Firstly, teachers should always be on the alert when it comes to their professional expertise due to the fact that the area of ICT advances rapidly and if they wish to offer their students the best possible working environment, they have to follow all the novelties that are constantly being introduced. Teachers have for a very long time been blending face-to-face lectures with various kinds of technology-assisted methods [8]. However, with the upsurge of Web 2.0, teachers have been given a very powerful tool which can help them with the advances in the foreign language teaching. Hence, it is crucial that they be methodologically careful when choosing the materials for their students and the means through which they will implement them. Back in 1999, Egbert and Hanson-Smith suggested eight “optimal” conditions for learning a foreign language, and one of them stresses the importance of learner autonomy [10]. Much of the learner autonomy lies in the hands of the teacher. It is on the teacher to encourage students to actively participate in the discussions, but yet again, they should not be too overwhelming in doing so [8]. One of the best modules that plays a significant role in the development of student autonomy is the Forum, which empowers and encourages class members to give answers to their classmates’ questions, which not only supports camaraderie, but also gives students the sense of “being in charge”, whereas the teacher is no longer seen as the only source of knowledge [8]. The students then not only feel autonomous, but they also become more motivated. However, autonomy aside, it is of extreme importance to set boundaries. Naturally, the whole point of the blended learning method is to allow students to decide by themselves when they want to study, but it is up to the teacher to ensure that they have indeed met all the requirements by the end of the course. Therefore, it is important to clearly state and explain the goals and objectives of the course and set the necessary deadlines when it comes to the enforcement of modules. Through the implementation of rules, certain managerial skills that they will need in their future professional life are developed.

Last but not least, feedback. When it comes to all types of learning, but especially language learning, it is very important for students to receive feedback as a confirmation that their learning style and strategies have been successful, or as an input on what should be modified or additionally worked on in order to reach the desired level.

V. CONCLUSION AND FUTURE WORK

The role of the blended learning method has in the last couple of years become increasingly popular, especially when it comes to the teaching of foreign languages. Moodle, an open-source learning management system, was introduced at the University North as a supplement to face-to-face lectures and it has proved to be of vital importance in the EPP teaching. Employing a variety of Moodle modules, the EPP course has progressively been working on the development of student autonomy and achieving the optimal conditions for learning a foreign language. Even though there is still room for improvement in the use of the modules, the blended learning method has been recognized as a tremendous asset in the EPP teaching, as it gives an exceptional opportunity to integrate the information advances with the advances of students both in their studies and their future professional life.

In this light, this paper can serve as a framework for the possible applications of different Moodle elements in the teaching of English for Professional Purposes. Future work in the field should be aimed at carrying out case studies of applying different Moodle activities based on
the proposed theoretical framework and measuring the student competence and satisfaction level within the blended learning approach.

brijana.juricic@fpz.hr
bruno.antulov@fpz.hr

Abstract - Air traffic controllers are responsible for guiding aircraft through the airspace and for ensuring timely, safe and expeditious flow of air traffic. Throughout the whole education and later work, air traffic controllers undergo extensive training that is divided into three phases – initial training (basic and rating training), unit training (transitional, pre-on-the-job and on-the-job training) and continuation training (conversion and refresher training). In all three phases of the training, the focus is placed on practical training exercises performed on computer based simulation devices. This paper focuses on basic part of the initial training and gives an overview of practical training exercises performed on a particular computer based simulation device. It also provides an insight into challenges the candidates are faced with while mastering the techniques of performance based training.

I. INTRODUCTION

Air traffic controllers are responsible for safe and expeditious flow of air traffic. Their main task is to provide separation between aircraft. They perform a complex task of guiding aircraft through the airspace safely and efficiently. The goal of Air Traffic Control (ATC) is to minimize the risk of aircraft collisions while maximizing the number of aircraft that can fly safely in an airspace at the same time. To be able to perform all the mentioned duties, air traffic controller candidates have to undergo extensive training and skill acquisition process. During the training, air traffic controller candidates acquire knowledge on procedures, learn about characteristics of a certain airspace, master how to detect and solve potential conflicts between aircraft, learn how to use equipment on their working positions, etc. This paper focuses on basic part of the initial training and gives an overview of practical training exercises performed on computer based simulation devices. It is divided into five sections: 1. Introduction, 2. Air Traffic Controller's Training, 3. Air Traffic Controller's Basic Training, 4. The Simulator - BEST Simulation System, and 5. Conclusion.

II. AIR TRAFFIC CONTROLLER’S TRAINING

Since air traffic control is a highly regulated sector, air traffic controller's (ATCO) training is defined by thorough regulations that prescribe minimum training requirements. In the EU ATCO training has to comply with and meet the requirements laid down in the Commission Regulation (EU) 2015/340 that enables overall standardization of training.

Standardization of training and required competences should also reduce fragmentation and differences in licensing process and enable mutual recognition of licenses among different countries [1].

The training is divided into three phases – initial training, unit training and continuation training that are shown on Figure 1.

Figure 1. Progression of ATCO training [2].

Initial training consists of basic training and rating training. Basic training is defined as theoretical and practical training designed to impart fundamental knowledge and practical skills related to basic operational procedures [2].

Basic Training provides theoretical knowledge and practical skills to enable an ab initio candidate to progress to more specialized Rating Training. The Rating Training provides knowledge and skills related to a job category and appropriate to the discipline to be pursued in the ATS environment [2]. It consists of theoretical subjects and practical exercises. After successful completion of initial training candidates are awarded Student ATCO License. This license is a prerequisite for starting the following phase of training.

The Unit Training leads to the issue of an Air Traffic Controller License that enables ATCOs to work with live traffic. It is subdivided into three parts: Transitional Training, Pre-On-the-Job Training and On-the-Job Training.

Transitional Training is designed primarily to impart knowledge and understanding of site-specific operational procedures and task-specific aspects. It ensures the
development of skills through the use of site-specific simulations and training [3].

Pre-On-the-Job Training (Pre-OJT) is locally based training during which extensive use of simulation using site-specific facilities will enhance the development of previously acquired routines and abilities to an exceptionally high level of achievement [2].

On-the-Job Training - OJT is the final phase of unit training during which previously acquired job-related routines and skills are integrated in practice under the supervision of a qualified on-the-job training instructor in a live traffic situation. [2].

Continuation Training is training for ATCOs with valid license that enables an upgrade or improvement of existing knowledge and skills and includes refresher and conversion training.

Refresher training is designed to review, reinforce or enhance the existing knowledge and skills of air traffic controllers to provide a safe, orderly and expeditious flow of air traffic. Conversion Training is designed to provide knowledge and skills appropriate to a change in the operational environment [2].

All the phases of training consist of theoretical and practical training. Practical training is performed on computer based simulation device, so called synthetic training device (STD). There are two different types of STDs - simulators and part-task trainers. Simulators are computer based devices that simulate important functions of the real situation of ATCO working positions, airspace, procedures, flight trajectories etc. Part-task trainers are computer based devices that enable simulation of partial ATCO functions. Both STDs are used to train candidates in gaining practical skills. Candidates take part in different practical exercises created for each segment of the training according to prescribed requirements. Each certified ATCO training organization defines the number of practical exercises to be performed for different phases of ATCO training in accordance with international standards.

III. AIR TRAFFIC CONTROLLER’S BASIC TRAINING

As previously mentioned, Basic Training is a part of Initial Training. Basic training can be provided as separate course or integrated with rating training. Basic Training is designed in a way that candidates (ab initios) acquire fundamental knowledge and practical skills related to basic operational procedures. The goal of the course is to teach candidates basic theory needed for future work and for rating training. Basic Training is developed and provided by licensed ATCO training organizations and approved by the competent authority.

In Croatia there is only one training organization approved for provision of ATCO basic training and that is Croatian Air Traffic Control Training Centre (HUSK).

HUSK is a unit established at the Faculty of Transport and Traffic Sciences of the University of Zagreb that is certified to provide basic training. HUSK provides two different basic training plans and programs: integrated program of training provided through undergraduate study of aeronautics, air traffic control module, and a separate basic training course [4].

The training program integrated in the undergraduate study of Aeronautics lasts 6 semesters. After the completion of the program, candidates are awarded bachelor’s degree (bacc.ing.aeronaut.) and a Certificate on successful completion of Basic Air Traffic Controller Training [5]. The other training program is organized as a separate course lasting from 16 to 24 weeks depending on tender requirements. After the completion of the course, candidates are also awarded Certificate on successful completion of Basic Air Traffic Controller Training [6].

Both HUSK programs are compliant and harmonized with requirements of the EU REG 2015/340 and of EUROCONTROL’s Specifications on the ATCO Common Core Content Initial Training.

During the basic training candidates are obliged to take lessons and successfully fulfill courses’ requirements. Theoretical trainings are comprised of the following subjects as prescribed by EU REG 2015/340: Introduction to the Course, Aviation Law, Air Traffic Management, Meteorology, Navigation, Aircraft, Human Factors, Equipment and Systems and Professional Environment.

According to the EU REG 2015/340 practical training is provided within Air Traffic Management subject. During the provision of practical training on simulator, candidates develop skills of maintaining aircraft separation, monitoring aircraft movement through airspace and communicating with pilots. Candidates have to incorporate acquired theoretical knowledge into practical training skills for all three types of air traffic control (aerodrome, approach and area control).

IV. THE SIMULATOR - BEST SIMULATION SYSTEM

There are a few companies in the world involved in the development and production of ATC simulators that provide a realistic simulation of aircraft flight and human-in-the-loop real time simulation of air traffic controller’s work. All simulation systems used by ATCO training organizations should be certified and approved by competent authorities for the usage in practical training. A simulation system that is very often used by ATCO training organizations in Europe is called BEST (Beginning to End for Simulation and Training) Simulator produced by Micro Nav Ltd. According to HUSK internal survey and according to the research Comparison of Radar Simulator for Air Traffic Control [7], BEST simulator is rated as the best solution to be used in ATCO training.

BEST simulator covers all levels and types of training:
• basic (ab initio)
• rating
• validation
• on-job-training support
• conversion
• refresher
• competency checks
• handling emergencies and unusual situations
• approach control – radar and non-radar
• tower control
• ground and ramp control
• tower data assistant working
• civil and military [8].

BEST is constructed in such a way that it gives a very realistic simulation of the real traffic situations. The following section describes the system functionality and the minimum hardware requirements, software information and additional system and support information.

A. Hardware Requirements

BEST runs on commercial standard PCs, networking and peripherals. The minimum hardware specifications are Pentium 4 dual core processor 2.8GHz or equivalent, 2GB RAM, 40GB hard disk drive (workstation position) or 80GB hard disk drive (system manager position), CD-ROM drive (required at the system manager position only), 100Mbps/1Gbps network capability and operating system Windows 7 Professional (workstation position or stand-alone system) and Windows 2003 Server (networked System Manager) [8].

B. BEST Software Development Platform

The BEST software is written in C++ using the Borland C++ Builder development environment and it uses Windows operating systems and networking. BEST simulation system comprises of the following ATC radar simulation and training facilities:

• ATC radar controller/student facilities
• Supervisor facilities
• Pilot facilities
• Simulation facilities for driving real radar workstations
• System manager facilities
• Data preparation facilities
• Self-teach facilities
• Voice recognition & output facilities
• Simulated audio communications facilities
• Scripting facilities
• Networking facilities
• Data management facilities [8].

C. BEST simulation system at the Faculty of Transport and Traffic Sciences

As it was mentioned earlier, HUSK is an approved ATCO training organization that is certified for provision of basic training and is a part of the Faculty of Transport and Traffic Sciences. From 2013 the Faculty owns BEST Radar Simulator that is situated in The Laboratory for Control of Air Navigation at the Department of Aeronautics and used by HUSK. It has two ATCO working stations, one pseudo-pilot working station and one supervisor working station which is also used as a pseudo-pilot working station. The user interface is similar to the real ATC workstations. As it can be seen on Figure 2, the ATCO working station consists of a radar screen, an auxiliary screen, a voice communication interface screen, a keyboard, a mouse, two sets of headphones and some communication switches.

Standard operating system has recording and playback system, which allows a recorded exercise to be played back. A replay may be paused at any time and candidates may be faced with their performance.

Figure 2. The ATCO working stations of the BEST Radar Simulator at the Faculty of Transport and Traffic Sciences

Process of training and roles of all persons involved as well as their interactions can be seen on Figure 3.

Figure 3. Simulation process during ATCO practical training.

As it can be seen, there are constant MMI (Man–Machine Interface) interactions in three processes: ATC Simulator–ATCO candidate, ATC Simulator -pseudo-pilot and ATCO candidates and pseudo-pilots when using radio communication. Practical instructor supervises the work of ATCO candidate. Roles and functions of all participants are explained in further text.

D. The ATCO working station

The ATCO working station enables the ATCO candidate to monitor the air traffic situation on the radar screen and to pass instructions through a set of headphones to a pseudo-pilot. The candidate has to perform a complex task of monitoring all the aircraft through the delegated airspace.

At the same time the candidate has to take into consideration the simulated traffic situation, decide what instruction to issue to the pilot, inform the pilot through a
voice channel on the actions to be taken, observe if the pilot follows the instructions, record all the changes in the system, make an update of the current traffic situation and be familiar with the all equipment. The candidate continuously observes the simulated traffic situation on the radar screen that shows the current traffic situation. The standard radar screen display is shown on Figure 4. The position of an aircraft is marked with an * sign and accompanied with the label that mandatory contains aircraft’s call sign some additional information regarding aircraft type, speed and attitude.

Figure 4. The standard radar screen display.

The display controls are located on the toolbar at the top of the display. Different characteristics of the radar display can be altered by selection of an appropriate tool such as:

- display manipulation tools (zoom facility, centre, drag facility, map layer selection, display range, range rings, compass rose, and text size)
- target display options (history trail, predict vector, track label position, target filters route and trail length)
- information display (exercise time and status (active/frozen), QNH and ATIS identifier)
- target symbols: primary cover only, secondary cover only, combined cover, forced onto display, filtered by height or SSR code), etc. [8].

E. Pseudo-pilot working stations

The BEST pseudo-pilot working station facilities are user-friendly. The pseudo-pilot working station consists of a radar screen, an auxiliary screen, a voice communication interface screen, a keyboard, a mouse, a set of headphones and communication switches. The pseudo-pilot facilities allow the pilot to make changes in flight’s behavior as instructed by the controller or instructor. This is achieved via Pilot MMI that is shown on Figure 5.

Figure 5. The Pilot Man–Machine Interface [8].

The BEST pilot interface uses standard Windows input methods working with a keyboard or a mouse, or with a combination of both. This allows complex, chained commands to be entered easily. All the inputs are optimized for fast keyboard entry [8].

All aircraft under pilot’s control are listed in the Call sign List. The target aircraft can be selected with the keyboard or with the mouse by selecting from the radar display or the Call sign List.

Using Pilot MMI, the pseudo-pilot can enter a command for the currently selected aircraft or can select another aircraft and make necessary changes. When the keyboard is used to select an aircraft, pressing the letter key displayed in the first column of the Call sign List will display the Pilot MMI for the associated aircraft [8].

F. Practical Instructor role in simulation process

Practical instructor is instructor authorized to train candidates during practical exercises. Practical instructor sits next to the ATCO candidate. He/she instructs the candidate, provides advice and tuition, observes how a candidate interacts with the equipment, pays attention to candidate’s behavior and attitude, monitors if a candidate takes appropriate actions and issues correct clearances. After each exercise, the instructor fills in Daily performance lists for each of the candidates giving his/her opinion on the candidate’s performance.

Practical instructor can communicate with the ATCO candidate and with the pseudo-pilot (without the controller’s knowledge) via voice communication facilities. The voice communication facilities support simulated radio transmissions between the candidate and pseudo-pilot, communication between the instructor and the candidate and pseudo-pilot for teaching purposes, simulated intercom communications between positions and simulated telephone communications.

G. Supervisor working stations

Supervisor working station is the central part of the complete simulation system. A supervisor has the access to the pseudo-pilot working station facilities and to the majority of functions of student-controller facilities. The supervisor is in charge of managing an exercise – he/she starts the exercise, restarts the paused exercise, changes the traffic situation adding additional flights, removes flights, saves a text file of all script commands run during the course of the exercise and edits the script files associated with the airspace, exercise and/or weather set etc. When the simulator is ready to run, the Supervisor Controls dialog is presented on the screen at the supervisor position.

H. Provision of Basic Training at HUSK

As it was said earlier HUSK uses BEST Radar Simulator for the provision of practical exercises during basic training. When the program integrated through undergraduate study of aeronautics is used, candidates do seven exercises of Aerodrome Control, seven of Approach Control and seven of Area Control. Each candidate does altogether 21 exercises (seven for each type of control) and
spends 21 hours training on BEST radar simulator individually.

Exercises of each type of control differ in traffic, number of aircraft involved, number of conflicts, different traffic flows and in performance objectives that candidates need to fulfill. Before the beginning of practical training for each type of control, the candidates are introduced to the simulator equipment and its functionalities. Provision of every exercise is conducted in accordance to the activities given in Figure 6.

Every practical exercise on the simulator starts with group briefing. It is an introduction to the exercise where candidates are introduced with the performance objectives, particular characteristics of the exercise, separation methods and radio-telephony communication. It is provided in the classroom. Group briefing is followed by individual briefing when instructor leads candidate through an exercise, explains the goals of the exercise and emphasizes the important segments, shows flight plans. Individual briefing is as done one-on-one and provided at the BEST simulator.

The candidate does the exercise run on his/her own.

![Diagram](image-url)

**Figure 6. Activities in practical exercise provision**

Exercise run lasts approximately 45 min. During the exercise run, instructors train and monitor candidate’s work on BEST radar simulator. The instructor observes candidate’s performance and provides guidance, if necessary. They use Daily performance lists to track and evaluate candidate’s progress or do the final assessment of the candidate’s performance using Simulator Assessment List in the case of the last exercise.

After the completion of the exercise run, the instructor does the individual debriefing and evaluates the candidate’s work according to the set objectives of the exercise, points out candidate’s strengths and weaknesses and gives the recommendations for the subsequent exercises. Individual debriefing is provided while the candidate is still at the simulator.

As it is said, the instructor uses Simulator Assessment List to make final assessment and evaluation of the candidate’s knowledge, performance and attitude. A candidate needs to achieve at least 75% on the final assessment to pass.

For each of the exercises, each candidate is awarded the following performance indicators:

- Excellent (90-100%) - the candidate has reached the highest passable standard; the performance was excellent but with a few minor errors.
- Very good (85-89%) - the candidate has reached higher passable standard; the performance was very good but with more minor errors.
- Good (80-84%) - the candidate has reached passable standard; the performance was good but with errors.
- Sufficient (75-79%) - the candidate has reached the lowest passable standard; the performance was acceptable but with major errors.
- Insufficient (74 % and bellow) - the candidate has failed to reach a passable standard; the performance was less than acceptable and/or erratic [9].

The last segment of each exercise is group debriefing. When all candidates finish the same exercise, a group debriefing is held. It is review of the exercise run and discussion of the outcome of the exercise and candidates’ achievements and gives the recommendations for the subsequent exercises.

The instructors repeat the objectives of the exercise, summarize the key points, emphasize well-performed elements, discuss the most frequent mistakes and provide advice for the future.

After completion of the Basic Training simulation exercises on BEST radar simulator the candidate can perform the following performance objectives [3]:

- checking and using the working position equipment
- developing and maintaining situational awareness by
- monitoring traffic and identifying aircraft when applicable
- monitoring and updating flight data display(s)
- maintaining a continuous listening watch on the appropriate frequency
- issuing appropriate clearances, instructions and information to traffic
- using approved phraseology
- communicating effectively
- applying separation
- applying coordination as necessary
- applying the prescribed procedures for the simulated airspace
- detecting potential conflicts between aircraft
- appreciating priority of actions
- choosing appropriate separation methods.

I. Example of area control exercises at HUSK training organisation

To achieve smooth and performance based training process at HUSK, all candidates undergo through the set of exercises specifically designed for basic training. All exercises are designed with the assistance of certified
practical instructors and are carefully constructed to achieve candidate's continuous progression in skills and are in accordance with performance objectives. As it was said earlier candidates attend three types of simulator exercises, aerodrome, area and approach control exercises and are trained and supervised by certified practical instructors.

To show progress and differences in the exercises during basic training at HUSK, exercises for area control will be explained in more detail in the terms of ATCO workload, number of aircraft and traffic complexity.

Exercise number one is the first exercise for area control. Before the beginning of this exercise, instructors introduce and demonstrate the functionalities of the computer based training device – BEST simulator. All its segments needed for performance of area control exercises are explained in detail and shown to candidates. The objectives of exercise number one are familiarization with the equipment, introduction of generic airspace and basic scenario with low complexity traffic and low ATCO workload requiring heading change. The number of aircraft in the first exercise is four.

In the second exercise, candidates work in the same generic airspace, but are faced with slightly higher workload and traffic complexity in basic scenario. The number of aircraft is increased to ten.

Croatian upper control area is simulated in exercise number three. Candidates go through scenario with overflying traffic and intermediate complexity and ATCO workload requiring heading, level, speed and frequency changes. There are eight to nine aircraft in this exercise.

The fourth exercise is similar to the third exercise, but with slightly higher workload. The scenario includes converging traffic. The complexity is intermediate requiring again some heading, level, speed and frequency changes. The number of aircraft is nine.

Exercise number five is the same as the fourth exercise. Complexity and ATCO workload are the same as in the fourth exercise, only the number of aircraft is increased to ten. This exercise enables candidate’s consolidation in progress. Exercise number six is the last one before the final assessment exercise where candidates deal with the highest traffic load on crossing and opposite tracks resolving conflicts by level change or by vectoring. This is the most complex exercise with the highest ATCO workload. The number of aircraft in this exercise is twelve.

Exercise number seven is the last exercise and also the assessment exercise. The final assessment and evaluation are carried out during this exercise according to the criteria said in the part H of this paper. In the course of this exercise, the candidates should show what skills and competence they have gained during the practical training. After the completion of practical exercises a candidate shall reliably and consistently apply standard coordination, approved radiotelephony, vertical, longitudinal and radar separation and control techniques [10].

If we compare candidates’ behavior and attitude during the performance of exercises, it can be concluded that during the first two exercises candidates have difficulties with the adaptation to the computer based simulation device and familiarization with its functions. With the progression of exercises it is expected that candidates are adopted and familiarised with the system and that they are capable of coping with higher number of aircraft, higher ATCO workload and traffic complexity.

V. CONCLUSION

Air traffic control candidates undergo extensive training. Their training consists of three phases and incorporates theoretical and practical parts. Theoretical training includes all the subjects and topics needed to perform complex ATCO work. Practical training is provided on computer based simulation device where candidates gain practical skills in maintaining aircraft separation and guiding aircraft through airspace. HUSK, as well as every other air traffic control training organization, is obliged to use an adequate computer based simulation device in provision of practical training. BEST radar simulator used by HUSK training organization meets all the objectives and requirements prescribed for the provision of basic ATCO training.

The perspective of use of digital libraries in era of e-learning

Radovan Vrana
Department for information and communication sciences,
Faculty of humanities and social sciences, University of Zagreb, Zagreb, Croatia
rvrana@ffzg.hr

Abstract – The aim of this paper is to review digital libraries’ role in supporting e-learning. Digital libraries offer technology based information resources and services to enable learners to access relevant knowledge anywhere anytime. As such, digital libraries are inseparable from the learning process because they made e-learning possible. Though highly relevant for e-learning, digital libraries haven’t been used in education to their full capabilities due to their unequal development worldwide, legal and technical barriers and the fact that the industrial sector (commercial publishers) still manages access to digital content used in education on commercial basis (making it inaccessible to wide audience without paying a fee). The paper also present results from the research of digital libraries and their capabilities for inclusion in education.

I. INTRODUCTION

During centuries, libraries have been the guardians and distributors of “books, journals, maps and other materials that are used by students in the learning process” [1]. Today, they are concerned about their sometimes diminished role in society and this role relies increasingly on information and communication technology which gradually leaves behind traditional information institutions including libraries and printed resources for learning used so far. The response of libraries to the current challenges was development of new digital information resources supplemented by new content delivery services. Presently, libraries worldwide display successfully both their traditional and digital faces and efficiently serve different purposes and different audiences. One such purpose in which libraries participate successfully is e-learning. Libraries have already been introduced to the scene of computer-based learning in the mid-20th century and they are now connected in the unity of libraries and e-learning [2]. They “serve as specific media to implement the learning process” [3]. Libraries support e-learning by offering carefully selected information resources and a variety of ICT supported services to facilitate access to their holdings which include learning material as well [4]. These services include: online bibliographic instructions, computerized library catalogs, digital libraries, distance learning services, e-databases, instant messaging services, inter library loan and document services, ready references, virtual classrooms, virtual references etc. [5]. In the era of ubiquitous learning in which learners of all age use electronic devices on daily basis to access learning material on local computer network as well as on the internet, libraries are expected to make an extra effort to adapt and prepare content in their existing digital collections and their online library services supported by rapidly changing information and communication technologies. Research [2] confirmed existence of such a trend in which students of today have closely embraced modern technologies to enhance their learning, and libraries have become their partners in role of knowledge organizer offering various services that are ICT incorporated. Having this in mind, this paper will discuss the role and perspective of use of digital libraries in today’s evolving e-learning environment.

II. LIBRARIES IN THE DIGITAL ERA AND E-LEARNING

Libraries were among pioneering institutions which introduced computer technology in their daily operations in the middle of 20th century and they continued to introduce new technological successes throughout the rest of the century to improve access to and use of library holdings. Major step forward in library development happened in the beginning of the 1990s when digital libraries were introduced. The concept of digital libraries was a major success from its very start as “it came out of closed walls of library and reached users in their home, workplace and even while traveling, with the help of laptops” [6]. Digital libraries “have emerged as a leading edge technological solution to the persistent problem of enhancing access, process of archiving and expanding the dissemination of information” [7]. Digital libraries generally speaking “consist of digital contents (which are sometimes but not necessarily text-based), interconnections (which may be simple links or complex metadata or query-based relationships), and software (which may be simple pages in HTML or complex database management systems)” [8]. More specifically, digital libraries offer “online catalogue, databases, multimedia, online journals, digital repositories, electronic books, electronic archives and online / electronic services” [9]. Digital libraries have brought digital revolution which has affected almost every aspect of library services „from the automation of internal recordkeeping systems to the digitization of physical collections, and from the acquisition of new „born-digital” works of art or library publications, to the use of technology to present collections and engage audiences” [10]. The engagement of audiences of different types proved to be crucial for the
development of digital libraries because libraries have formed their services according to information needs and requests of different audiences including students and educators.

In spite of the engagement of different audiences including students [11] digital libraries didn’t have any substantial role to play in the learning sector because in some cases they were not included fully in the learning process in favor of the industrial sector (mostly commercial publishers) which controls digital information resources. They suggested that digital libraries had (and still have) a great potential in learning due to the nature of resources they bring together and that can be used “to illustrate a variety of educational topics in practically all areas of knowledge, or to support individual learning” [11]. Digital libraries are indispensable for education because the offer up to date material, immediate access to a wide range of sources which do not exist physically, provide resources via an internet connection each moment from each place and because of these advantages, in digital libraries learning is independent process [12]. The role of digital libraries is clear: they function as „digital schools that offer formal packaging for specific skills and topics as well as general browsing for creative discovery and self-guided, informal learning” [13]. Same authors [13] suggested that digital libraries serve at least three roles in learning: they serve a practical role in sharing expensive resources including physical and digital resources, equipment, human resources – librarians who serve to allow instructors and students to share expensive materials and expertise; they serve a cultural role in preserving and organizing artifacts and ideas as well as ensuring access to materials through indexes, catalogs, and other aids that allow learners to locate items appropriate to their needs; and finally, they serve social and intellectual roles by bringing together people and ideas with formal, informal, and professional learning missions. Libraries “both traditional and digital one have three roles in education: place for sharing reach information, maintaining ideas, and give awareness to bring together individual with learning aims” [12]. Tanner and Deegan [14] analyzed values and benefits of use of digitized resources in teaching and learning and concluded that “The increasing availability of digitized resources allows educational institutions to provide students with more varied, more accessible and richer teaching materials than ever before. This encourages a more exploratory, research based approach to teaching and learning. Entirely new kinds of topics and courses can be studied, new modes of assessment are possible, and students are given a richer educational experience”. Abbott and Cohen [15] investigated possibilities of use of large digital collections (in libraries) in education and found out that students (as library users) face a challenge when they try to find and access primary documents in digital libraries because documents (digital resources) can be found in any number of digital libraries on the internet and this presents a problem. The solution to this problem would be better integration of information about digital resources and networked systems on global level so they could be more easily located and used.

The relationship between digital libraries and e-learning is quite straightforward. Digital libraries as networked information systems are already part of the learning process [2]. The need for digital libraries in e-learning could be also found in the very definition of e-learning: „E-learning could be interpreted as electronic learning; the learning that involves the Internet; learning from a distance via the aid of the internet and, or other electronic gadgets“ [2]. E-learning includes „all forms of electronic supported learning and teaching, which are procedural in character and aim to effect the construction of knowledge with reference to individual experience, practice and knowledge of the learner“ [3]. E-learning is not possible without the learning material and that is where digital libraries as the aid come in convenient. The existing experiences, practices and knowledge of the student become more rich as they gain access to the quality information resources in digital libraries which have become an important stakeholder in the learning process in the last two decades. Pavani [1] analyzed whether digital libraries are suitable for inclusion in the learning process and found out the following reasons for doing so: documents in all formats are managed in a unified way: texts, animations, interactive exercises, audio files, video streams, e-books, e-journals and online tests can be stored, described and distributed through computers and networks; access control: contents can be assigned different types of access according to the classes of users that are entitled to them; content sharing: authors can make their contents available for other faculty to aggregate into their courseware; interactivity: contents stored in digital libraries can be interactive and based on multimedia; customization: some users may require special characteristics of the contents and the system; reuse: courseware can be developed with a granularity that makes it flexible to combine and support multiple syllabus; cross-institution cooperation: digital libraries are networked information resources and this allows that contents can be used from different cooperating institutions; any place and any time learning: students study in different hours of the day any day of the week. Wangila [16] shares similar thoughts: digital libraries were developed to enable higher education (and other educational) institutions provide library services to all its students and other stakeholders in and off campus to facilitate access to digital library resources from any location or work station making it easy to share digital information as well as available to everyone at any time. Huang [17] analyzed the concept of library 2.0 (best of libraries to date with community support and ICT support) and its relationship with e-learning. The author offered the following characteristics that would make stronger mutualism of libraries and e-learning: library is everywhere; no barriers (library is accessible and age-friendly and it provides access to the library’s resources); library is individualized (actively providing readers with diversified content according to their needs); library is inviting participation; library promotes flexibility and best-of-breed systems (support for the e-learning to make them customized and flexible according to the needs of different subjects). Finally, digital libraries also facilitate knowledge sharing between the stakeholders in the learning process and encourage them “to work together,
develop their skills, and form strong and trusting relationships” (Dhiman, 2010).

For students, digital libraries provide technology based information and services to enable them “to access relevant information and services anywhere anytime, as well as provide empowerment for innovative and life-long learning” [3]. A document “Digital libraries in education” [18] suggested existence of three chains of support for students in digital libraries. First, if a digital library provides users with profiles, they are able to form learning communities. Second, content supported by metadata enables the formation of customizable collections of educational objects and learning materials. Third, tools supported by common protocols or standards enable the development of varied application services that enhance the value of the library’s content for the learner.

Librarian’s job has also changed as it began to depend more intensively on information and communication technology. According to Sreenivasulu [19], the librarian’s role is now oriented towards “consultancy to the users and providing digital reference services, electronic information services, navigating, searching and retrieval of digitized information through web documents that pan the universal digital library or the global digital library”. For Ashikuzzaman [20], librarians must assert themselves as key players in the learning process, thereby changing their roles from the information providers to educators, they should become information gateways and advocates the librarian’s involvement in teaching communities so as to meet information needs of the students. For Hernosa and Anday [4] librarians transformed their jobs into virtual or digital environments, while customizing their services and resources for e-learners (they provide remote access to, and electronic delivery of, library resources, and are using communication technologies to deliver electronic reference services and instructional support).

III. DIGITAL LIBRARY SERVICES FOR E-LEARNING

Digital libraries are opened to the wide public and as such they offer many possibilities of inclusion of their content in formal and informal learning. Calhoun [21] investigated social roles of digital libraries which also include teaching, learning and the advancement of knowledge. For formal education, digital libraries can offer the following services: specialized educational digital libraries, portals for teachers or students, integration with learning management systems and access to primary sources [21].

For progress of knowledge digital libraries offer the following services: self-archiving, deposit incentives; mandatory deposit, open access journals. libraries as publishers, digital libraries of theses and dissertations, cross-repository services, object reuse and exchange services, workflow-based content creation and management, data curation and researcher profiling services [21], digital information resources usable on different electronic devices, library services for information discovery, course materials, exhibits, workshops etc. Wangila [16] pointed out that “the integration of the digital library technology with the educational enterprise has come at a similar time when the student requirements for access to library resources also heightened”. The same author suggests the need for policies, guidelines and standards to ensure professional efficiency and quality of information service delivery in digital library.

In spite of wealth of materials and services, all digital libraries are not equal. Their differences define their possible use. This part of the paper will present digital libraries which offer support for the learning process. The focus will be on the most famous world digital libraries as there is no one global register which would list all existing digital libraries offering educational resources. Since each digital library (and institution behind digital library) has its own approach to presenting learning and teaching materials, it is rather difficult to compare them against a fixed set of criteria.

The purpose of the research is to identify major digital libraries which offer educational information resources and services as part of their Web site. The research aims to provide answers to two questions: 1) do researched digital libraries have a section with educational content as an integral part of their Web sites that can be clearly and undoubtedly identified; 2) is such educational section of a digital library clearly structures as to offer learning material, teacher support, lesson plans, and other aid necessary for teaching and learning? The following section of the paper will present digital libraries which have educational section.

The British Library

The British library at http://www.bl.uk [22] offers online resources, visits and workshops and teaching resources in the “Learning” section of its Web site. The teaching section presents teaching resources divided into sections „By subject”, „By age”, „By resource”. Each of these sections is further divided into subsections „Language”, „Curriculum”, „Subject” and „Themes” with ready-made teaching material. The online resources section of the British Library Website offers items and expert commentary related to History, English and Citizenship with complete insight into topics in the enumerated categories.

Fig. The British Library teaching resources
The Library of Congress

The Library of Congress at https://www.loc.gov/education/ [23] offers classroom materials and professional development to help teachers use primary sources from the Library's vast digital collections* (Library of Congress). The Library of Congress Web site for education is divided into two big categories „For Students & Lifelong Learners” and „For Teachers”. The first category offers materials for advancement of reading, poems for high schools, American history for elementary and middle school students, fun science facts from the Library of Congress and highlights from the Library's online collections. In category for teachers, the Library of Congress offers blog with posts about use of primary sources and tools and techniques to use them, free resources to help teachers effectively use primary sources from the Library's digital collections in their teaching, teacher-created lesson plans using Library of Congress primary sources, sets of primary source on frequently taught topics and primary source-based, ready-to-use resources for teachers and facilitators. This Website offers one of the most thoroughly prepared content among the researched libraries.

Fig 2. The Library of Congress education resources

Europeana Space

Europeana Space at http://www.europeana-space.eu/education/ [24],is an EU funded project focused on the creative re-use of available digital cultural content* (Europeana Space: About). The Web site offers 5 examples of Educational Demonstrators, a MOOC (Massive Open Online Course), dissemination events and collection of resources and best practices as well as 6 thematic Pilots. Europeana Space targets users from primary school to universities and engaging them with digital cultural heritage.

Fig 3. Europeana Space

Historiana

Historiana at http://historiana.eu/ [25] The EUROCLIO programme is an „on-line educational multimedia tool that offers students multi-perspective, cross-border and comparative historical sources to supplement their national history textbooks” (Historiana). Historiana offers three categories that can be used in teaching and learning: „Historical thinking” which introduces and individual to historical interpretation of facts, analysis of historical sources etc.; „Teaching methods” with instructions on how to teach history and „Teaching challenges” that offer content on how to improve history teaching.

Fig 4. Historiana

National library of Australia

National library of Australila at http://www.nla.gov.au/using-the-library/learning [26] offers the learning section at its Website. The section is further divided into learning program and school and teacher program. The learning program includes learning sessions to help users use library collections for research, work and study and topics like getting started at the Library, using microform readers, academic eResources and Trove, online resources from Australian libraries. Additional topics include resources for family history research like searching passenger lists, finding
newspapers, findmypast.com and ancestry.com and Trove for family history. The schol and teacher program include library exhibitions, collections and reading rooms for students to find out more about Australian history and culture. They critically interpret texts and learn search methods to understand historical and contemporary events and issues.

In theory, digital libraries have great potential and predispositions for support to the learning process. In practice, digital libraries are usually part of national libraries which are more frequently oriented towards preservation of national heritage and less to support of schools and universities. While the first part of the paper straightforwardly explained reasons for better inclusion of digital libraries in education and the second part demonstrated lack of actual sections of digital libraries prepared for inclusion in the learning process by offering review of very few digital libraries equipped for participation in education. Answers to research question would be: 1.) there are few digital libraries that clearly offer a section with educational content as an integral part of their Web sites that can be clearly and undoubtedly identified; 2.) these sections a digital library frequently (but not generally) have structures as to offer learning material, teacher support, lesson plans, and other aid necessary for teaching and learning. One could argue that all library holdings are to be used in the learning process and that might be true to some extent. However, education is well defined activity which relies heavily on national educational standards and pedagogical frameworks and procedures and require clearly defined approach of use of any material in the learning process. As a result, national libraries must prepare the neccesary library material together with instructions for teachers and students to become fully recognized as educational aids by those for whom they are built.

FIG 5. NATIONAL LIBRARY OF AUSTRALIA

Gallica

Gallica at http://gallica.bnf.fr [27 ] is the digital library of Bibliotheque nationale de France which provides free online access to millions of documents of all types (books, magazines, images, videos, partitions, maps, manuscripts, etc.). At http://gallica.bnf.fr/blog/28112016/75-epub-gallica-selectionnes-par-le-ministere-de-education-nationale it offers selected books from the national literature history for use in education. Actually, all Gallica is intended for research and learning but it doesn't offer a specialized section of its Website with support to teachers and students. Bibliotheque nationale de France offers a number of services to students but does not single out special collections for education.

FIG 6. GALICA DIGITAL LIBRARY

IV. CONCLUSION

One could argue that those for whom they are built

ArTeFact – Digitization of Archives of Technical Faculty from the Period 1919 – 1956

Marko Tucaković, Jadranka Lisek
University of Zagreb, Faculty of Electrical Engineering and Computing
(Central Library)
Unska 3, 10000 Zagreb, Croatia
E-mail: marko.tucakovic@fer.hr, jadranka.lisek@fer.hr

Abstract – The purpose of this article is to present the process of creating a future portal of digitized archival collections of council minutes (records from council meetings) of the High Technical School – Technical Faculty between 1919 and 1956, a project funded by the Faculty of Electrical Engineering and Computing of the University of Zagreb. The project aims at using metadata and available contemporary technology tools (scanning, Indigo, server space etc.) to enable to potential users the access to trustworthy data on historical facts about the development of STEM subjects within the University of Zagreb as well as in the rest of the country.

The Central Library of the Faculty of Electrical Engineering and Computing aims at promoting the idea of creating a virtual technical library based on digitized historic heritage.

I. INTRODUCTION

Royal High Technical School in Zagreb was established in 1918; its faculty members were appointed during the course of 1919 and the classes started on 1st October 1919, but a brief overview of its history shows that its creation started much sooner and that it was a slow process, hindered by many problems.¹

The School became a part of the University of Zagreb in 1926 under the name Technical Faculty [1]. Technical Faculty offered the first university study programme of technical studies in Croatian language in the region. It was active until 1956, when it divided into a number of technical faculties within the University of Zagreb, such as Faculty of Electrical Engineering (which changed the name in 1995 to Faculty of Electrical Engineering and Computing), Faculty of Architecture, Faculty of Civil Engineering and Faculty of Mechanical Engineering and Naval Architecture [2]. This information points to the significance of the Technical Faculty, not only in the history of the University of Zagreb, but also in the general development of technical sciences in Croatia. Technical Faculty Archival documentation is kept at the Faculty of Civil Engineering in Zagreb, and consists of Technical Faculty Council minutes. This documentation consists of more than 4000 bound pages of text, partly written by hand and partly written with typewriter. The records represent a valuable source of information on the formation of the Technical Faculty, as well as the records on the formation of individual laboratories, the decisions about the activities of the Faculty, decisions about curriculum, lists of scientific and teaching staff, records on the former Library of the Technical Faculty and the literature used etc. The documents also demonstrate the high level of activity and involvement that the Faculty had in the scientific and educational life of the University of Zagreb, but also in the wider community. This means that this archival documentation makes an essential starting point for any research on the development of technical sciences in the region.

Institutions in general digitize documents for several reasons: to preserve the original, to make the documents more accessible, to create a new service, to add new documents to the fund or on demand [3]. There are several reasons why The Central Library of the Faculty of Electrical Engineering and Computing decided to start the digitization process of the Technical Faculty Archives. Since these documents represent the only source of information for research of the development of scientific and educational activities in the field of technical sciences in the region, their content is of great historical importance for all the technical faculties which now operate as parts of the University of Zagreb, but

¹ The Society of Engineers and Architects of Croatia and Slavonia, at their Annual Assembly held on 21st February 1989, unanimously and enthusiastically accepted the proposal of its members, Mr. Lenucije Milan and Engr. Ursinije Mihaio, to establish in Zagreb High Technical School, i.e. Technical Faculty, but for the next ten years it all remained just an idea. The topic again became relevant in 1903, during the 25th Anniversary of The Society of Engineers and Architects of Croatia: Mr. Sanisavljević Julije, the author of the Commemorative Book, finished his historical overview of the Society with the following words: “There is no doubt that the High Technical School will be established in Zagreb in the near future, thus
also beyond, because the influence of the Faculty can also be seen in the neighboring countries. For our Library, the archives are additionally important because they mention the former Faculty Library, which was a predecessor to modern libraries which now work as integral parts of technical faculties. For these reasons, the first and most important goal was, as it usually is in the digitization projects, to make the content of the documents available to all interested users and researchers. The original documents are kept at the Faculty of Civil Engineering and in order to access them, it is necessary to make a formal request to the Faculty. Even then, they can only be used within the Faculty and only at the designated hours. In addition, there is no way to search the documents, since they have not been indexed. That makes any research difficult, given that the documents contain more than 4000 pages. It is a problem that our Library had in the past, when we often couldn’t give precise answers to user’s queries, since it was not possible to search several thousands of pages in a short time. Because of that, content analysis and metadata allocation to the individual documents, which will make them searchable and automatically more accessible, is an important goal of the project.

The second reason is the protection of the original documents. As was mentioned earlier, some of these documents are almost a hundred years old, which means that they are extremely sensitive and fragile. That makes handling them very difficult, and copying them causes damage which could lead to their permanent loss. Digitization will enable access to the information without the need to handle the originals, which contributes significantly to their protection, and provides some form of backup in the event of damage to the original.

The third goal was inspired by the desire to give our users new services and new possibilities, but also to contribute to the Croatian Cultural Heritage program, which collects and presents digital collections of Croatian cultural heritage on its Internet portal. We are convinced that this project will result in new research and academic papers, and we hope to use all the experiences and knowledge gained in this project, as well as user feedback, in the future. Our final goal is to make these documents just the first content on the portal and to continuously add new material in the future in order to create the Virtual Library of technical fields at the University of Zagreb. Here we see a great potential for cooperation with other technical faculties.

**SELECTION FOR DIGITIZING:**

**A Decision-Making Matrix**

```
| Does the material have sufficient intrinsic value to ensure interest in a digital product? | yes/no stop |
| Will digitization significantly enhance access? Incentive use by an identifiable constituency? | yes/no stop |
| What goals might be met by digitizing? |
| Preservation (creation of faithful reproductions to replace deteriorating materials or to reduce handling of fragile and/or valuable materials) |
| Improved intellectual control (e.g., creation of an electronic finding aid linked to digital images; creation of digitized tables of contents and indexes linked to bibliographic records) |
| Added functionality (e.g., ability to distribute widely, to search and manipulate text, to study disparate materials in context) |
| Cost savings (e.g., creation of virtual collections with costs and responsibilities shared by multiple institutions) |
| Does a product exist that meets identified needs? |
| Are rights and permissions for electronic distribution secured or secureable? | yes/no stop |
| Does current technology yield image quality adequate to meet stated goals (e.g., accurate OCR, creation of high quality copies)? |
| Does technology allow for adequate digital capture from a photo intermediate? | yes/no stop |
| Are the costs of scanning and post-scan processing supportable? Does the institution have the necessary expertise and resources to plan and implement the project? Is there sufficient organizational and technical infrastructure to curate, manage, and deliver digital products? |
| Can the project be redefined to narrow scope or recall objectives? Can infrastructure needs be addressed? | yes/no stop |

Proceed to plan, implement, and evaluate project
```

*Image 1. A Decision-Making Matrix [12]*
II. PROJECT

Every digitization project requires careful planning of every aspect of the procedure, in order to carry out each step of the process as effectively as possible – document selection, scanning, editing and quality control, protection, storage and transfer, presentation, usage and maintenance of digital material [4]. For that purpose, in this project we used the guidelines of the project Croatian Cultural Heritage [5], while libraries can also use IFLA Guidelines for Digitization Projects [6] and, as was the case in our project, IFLA Guidelines for Planning the Digitization of Rare Book and Manuscript Collections [7]. Once institutions decide on a material to digitize, it is necessary to plan costs, define technical demands and procedures (method of digitization according to the material, metadata allocation and creation and maintenance of the interface) and check the legal aspects. In the project, the library must also make a plan for staff management, especially if it possesses the necessary equipment for digitization and plans to do it alone.

Before the start of our digitization process, we requested and received permission from the holder of the document. Since the documents were bound in several volumes, it was necessary to scan them with a special scanner for bound material. Some documents were bounded in such a way that a few centimeters of text were covered; in those cases, the documents were unbound before scanning, and afterwards returned into the original state. In doing so, special attention had to be paid to the preservation of documents, which are in a very fragile state due to their age and storage conditions.

In every digitization project, an institution must decide whether to carry it out within or to hire an outside service provider, i.e. digitization studio. Both approaches have their advantages and disadvantages, and the decision on which one to take depends on several factors. Stančić states that the benefits of digitization within an institution are a higher degree of control over the process, variety of activities that can be done, effectiveness and efficiency. Preconditions for such digitization projects include qualified staff or resources to educate the staff for work on digitization, and the necessary equipment. On the other hand, according to Stančić, digitization outside of an institution has advantages from technical and financial point of view, which means that in this case a library is not required to provide the space for scanning, does not have to worry about the equipment (which is expensive and relatively rapidly becomes obsolete), does not have to manage staff and is not responsible for solving problems that may occur in such projects, such as system crashes, errors and delays [8].

Central Library of Faculty of Electrical Engineering and Computing at the moment does not possess the necessary equipment nor the adequate number of qualified staff to carry out this project alone. For this reason, the Faculty of Electrical Engineering and Computing, as the sponsor of the project, entrusted this job to the company named ArhivPRO as an external associate. ArhivPRO is a company specialized in digitization projects and for this purpose it developed a system called Indigo, by which academic institutions can build their repositories, and which is used by many institutions in Croatia. Part of Indigo which deals with search and morphology was developed in cooperation with Text Analysis and Knowledge Engineering Lab, based in the Faculty of Electrical Engineering and Computing.

Indigo is a software platform that gives the archives, libraries, museums, galleries and other institutions that have digitized material the ability to create and publish digital collections on the Internet in accordance with the standards (the system is compatible with the international standards and protocols such as OAIPMH, Z39.50, EDM, CIDOC-CRM, LIDO, UNIMARC and MARC21). The system can retrieve the data from the catalog by using the Z39.50 protocol, and it allows integration with any system that supports the standardized methods of data exchange. Every institution that has a license to use the system can independently store digitized data on the Internet, add metadata and search documents, and after the material had been edited and stored, it becomes visible to users. The system can store text, image, audio, video and 3D material. Stored and edited data can be searched by metadata or full text, and the system uses facets to make the screening of material easier, while users can also have semantically related items displayed to them. The system is built for usage in Internet cloud, and does not require installation on computer, just a web browser and Internet access.

File formats created after digitization and processing were image and text. Supplied image formats were master files in an uncompressed TIFF format and JPG image derivatives in decreased dimensions. Supplied text files were PDF-s consisting of a text used for search and indexing, with an image above it.

Digitization was followed by file editing. It entailed cropping images to the size and format which will be used in the browser and page alignment for pages that were slanted during binding. It should be noted that the result of scanning a textual document is a digital image of the document, and not an actual electronic text document which can later be edited on a computer. That means that it is impossible to search a scanned image of a text without additional editing. In order to automatically create a text document out of a scanned image (in contrast to simple manual transcription), it is necessary to use Optical Character Recognition (OCR) programs. OCR is defined as “a process by which a digital image, which contains characters, letters or numbers written by hand, typewriter or printed on paper, is converted into a digital format such as text files. OCR systems are analytical artificial intelligence systems that take into account individual characters, rather than whole words or phrases” [9]. In other words, OCR programs analyze images and try to determine which letters are in those images and, based on that, they create text files. The efficiency and accuracy of this process depends mostly on the quality of the source material and the quality of the scanned image (sharpness and resolution). Therefore, before the beginning of the scanning, it is necessary to determine the resolution, i.e. the number of dots-per-inch – dpi, and how much information will each dot
contain. Currently, there is no OCR program that works with 100% accuracy, even in ideal conditions; rather, their recognition accuracy is on average 99.95%, which is considered to be the lower limit of acceptability, since even with this level of accuracy it is still necessary to manually correct one to two errors per page. The problem with OCR is in the fact that increasing the accuracy from 99.95% to 99.99% doubles the cost of the process because of the need to increase scanning resolution, which also slows the whole process [8]. In order to increase recognition precision, texts intended for OCR analysis are usually not scanned in color, but rather as black and white documents. This helps to achieve the best contrast between lighter background and darker letters [8]. In our project, it was important to preserve and present the original look of the documents; therefore, they were scanned in color, and later transferred into a black and white (achromatic) images for the OCR analysis.

Indexing and metadata allocation are a part of the project which are the most time and energy consuming. Every scanned image has an OCR generated text in the background, but due to the nature of the original documents, especially older ones (archaic vocabulary, parts of the text were written by hand, and those written by typewriter are often not clear enough), it was impossible to get a satisfying accuracy. That means that, even though it is already possible to make full text search of those images, the accuracy of the search is low. To make the search as precise and relevant as possible, those generated texts that are of low quality are being manually transcribed into Indigo (for high quality OCR generated texts only small corrections are needed), and synonyms are being added for the archaic terms. The procedure demands great care and precision and is therefore slow and time consuming.

After this process is completed, every document will be allocated metadata according to the scheme which will be determined in the future, taking into account types of documents and user needs. In general, “metadata describes various attributes of information objects and provide information on their meaning, context and organization. Theory and practice of descriptive metadata is very familiar to librarians because its roots are in the cataloging of printed publications. In the digital environment, additional categories of metadata enable navigation and records management” [10]. For scanned documents, metadata generally consists of technical metadata automatically made by the digitization devices for each file (such as the date of digitization and the equipment used, its technical characteristics and settings used for digitization); metadata that refers to the content of the digital records and metadata added for the purpose of unambiguous identification of the individual records in a digital archive [8].

Stančić states that the problem of storage and transfer of digital data, i.e. the browsing mode and data usage should be considered together, since the aim of digitization in institutions is ensuring the availability of the material. That is why the issue of storage of digitized data is at the same time the issue of transfer of stored data, because storage determines the method and speed of access to the data. Browsing mode depends on whether the data will be accessed via Internet or locally and what options for usage will the users have. Criteria for the selection of quality systems for storage of digital resources in the longer term are the media longevity and durability, high capacity, low cost, wide acceptance and directness (on-line) or semi-directness (near-line).[8] Since our digitized materials are meant to be accessible on-line, it will have to have built-in links which will enable quick and simple navigation through the document, and this will be enabled by Indigo.

III. FUTURE PLANS – VIRTUAL LIBRARY

The digitization of Technical Faculty Archives is just a first step in creation of the Internet portal of The Central Library of the Faculty of Electrical Engineering and Computing, where the Library will offer access to its digitized data. The aim of the Library is to use modern technologies in order to enable its users the best possible service. We hope that the Portal will be used as a foundation for the creation of the Virtual Library of Technical Faculties, in which we plan to cooperate with other technical faculties and give our users a unified digital library. The benefits of virtual libraries, compared to the classic ones, are numerous (constant availability of material, access from anywhere in the world, unlimited number of copies….) and therefore we believe that the creation of such library would complement the work of currently existing conventional and hybrid academic libraries and provide users with a new service, along with the already existing ones. Computers have long been an integral part of library profession and the creation of the Virtual Library is a logical next step in the continuous development of services of the Central Library of the Faculty of Electrical Engineering and Computing.

Introductory Physics Course for ICT Students: Computer-Programming Oriented Approach

Vladimir Krstić
College for Information Technologies, Zagreb, Croatia
vladimir.krstic@vsite.hr

Abstract - Physics is an important subject and it is good that introductory physics courses are obligatory subjects in many, if not all, ICT colleges and universities in Croatia. However, these courses often cover too many different areas of physics and are presented in a traditional way – lectures / solving problems on paper / laboratories. We think that the introductory physics courses for ICT students should be more oriented towards computer programming and solving physics problems using computers. In this work we show how we plan to use SageMath, a free open-source mathematics software system licensed under the GPL, to boost students’ understanding of the electric potential and the electric field.

I. INTRODUCTION

Numerical computations followed by visualizations allow students to study and explore non-trivial physical models, develop and test their intuition and physical reasoning better than the standard paper-and-pencil approach [1, 2]. Hence, we at the College for Information Technology in Zagreb are currently in the process of restructuring our physics curriculum. The main goal of this process is to incorporate numerical computations to the current curriculum.

This structural change in the curriculum implies changes in the type and amount of educational materials that can be covered in one semester introductory physics course. Some materials in the current curriculum are more suitable to be included in the new curriculum and some must be left out because numerical computations occupy a substantial part of the course in the new curriculum [2].

In this article we present a part of our modified lesson plan on the subject of electric field and electric potential. Some of the goals of the lesson are the development of students’ understanding of superposition principle and integral calculus. All programs given in this article have been written in SageMath 7.4 [3].

II. PROBLEM DESCRIPTION AND ALGORITHM

A. Physical Problem

A straight wire of length \( L = 1.0 \, \text{m} \) is uniformly charged and the total charge on the wire equals \( Q = 1.0 \, \text{nC} \) (Fig. 1). Find the electric potential and the electric field everywhere in space [4].

![Figure 1. Graphical representation of the problem.](image)

B. Coordinate System: Which one to choose?

Ideally, students have to decide what coordinate system best suits the problem and where to position the wire in the chosen coordinate system. We use the Cartesian coordinate system and position the wire in such a way that we can easily exploit the symmetry of the problem (Fig. 1). Because of one of the symmetries of the problem (the problem is invariant with respect to the rotation around the \( x \)-axis), it is enough to find the solution of the problem in the \( x-y \) plane.

C. Algorithm

The wire is divided into \( N \) segments of equal length: \( \Delta x = \frac{L}{N} \). Since the wire is uniformly charged, the electric charge of each segment equals \( \Delta Q = \frac{Q}{N} \). The electric potential and the electric field vector at the point \( \vec{r} = (x, y) \) is a sum of contributions of each segment:

\[
\varphi(x, y) = \sum_{i=1}^{N} \Delta \varphi_i \approx \sum_{i=1}^{N} k \frac{\Delta Q}{|\vec{r} - \vec{r}_i|},
\]

(1)

\[
\vec{E}(x, y) = \sum_{i=1}^{N} \Delta \vec{E}_i \approx \sum_{i=1}^{N} k \frac{\Delta Q}{|\vec{r} - \vec{r}_i|^2} \frac{\vec{r} - \vec{r}_i}{|\vec{r} - \vec{r}_i|},
\]

(2)

where \( k = 9.0 \cdot 10^9 \, \text{Nm}^2/\text{C}^2 \) and \( \vec{r}_i \) is a position vector of an arbitrary point within the \( i \)-th segment. In our realization of the algorithm, we will take the point in the middle of the segment.
III. WRITE THE PROGRAM AND TEST IT

It is straightforward to translate the electric potential function \( \psi(x, y) \) into Python function \( \text{potential}(x, y) \) in SageMath. Here we use SageMath function \( \text{vector} \) to create vector objects so we can employ methods associated with vector objects to write more readable code. In our case we use only vector subtraction and the \( \text{norm()} \) method to calculate the norm of a vector.

If possible, students should write their own program, but providing them with one is quite acceptable due to the fact that some students might have no previous programming experience. However, we think that it is very important to encourage students to extensively test the program on their own. In order to test the program, they should start thinking about the physics of the problem to determine which properties the solution of the problem must have:

1. As we move away from the wire, the shape and size of the wire become less and less important, and the approximation of the wire with the point charge becomes more and more acceptable. In terms of equipotential lines: the shape of the equipotential lines should be symmetric with respect to the axis:

   \[ \psi(x, y) = \psi(-x, y). \]  

2. Because of the symmetries of the problem, the electric potential function (the solution of the problem) is symmetric with respect to the \( x \)-axis and the \( y \)-axis:

   \[ \psi(x, y) = \psi(x, -y), \]

   \[ \psi(x, y) = \psi(-x, y). \]  

3. Sometimes, often because of the symmetries of the problem, it is not too difficult to calculate the analytical solution of the problem or to find the analytical solution on the Internet. Students should use the analytical solution to test the numerical solution. For example, in our problem the electric potential function on the \( y \)-axis is easy to calculate or find:

\[
\psi(0, y) = k \frac{Q}{L \ln \left( \frac{L}{2} + \sqrt{\left( \frac{L}{2} \right)^2 + y^2} \right)}
\]

Equipotential lines can be calculated and plotted in SageMath using the \( \text{contour_plot} \) function. You can evaluate \( \text{contour_cell?} \) in the SageMath cell to find out details about its parameters and usage. The number of parameters for this function is huge but some parameters are more important than the others: the most important is to provide the function we are examining, region where to search for equipotential lines and value of the electric potential for each equipotential line. We have calculated and plotted several equipotential lines (Fig.2). As expected, their shapes are more circular as we move away from the charge distribution. The straight line in Fig.2 represents the straight wire. Notice in our SageMath program how we combined two graphics objects \( \text{contour_plot} \) graphics and one of the SageMath graphics primitives, \( \text{line} \) with the use of the \( + \) operator. Axes labels are added to the combined graphics; labels are typesetted in LaTeX if given within two $ signs and LaTeX commands escaped with an extra slash.

The second property of the solution implies that equipotential lines should be symmetric with respect to the \( x \)-axis and \( y \)-axis and it seems that our solution has this property (Fig.2). Students should check this property by calling the function \( \text{potential} \) for several points in the \( x \) – \( y \) plane.
Student programming in the introductory physics courses can be placed at the angle where the electric field and students can test this claim by actually computing solutions and extensively test their programs.

By modifying the existing SageMath programs, analyze or sketch an algorithm and the problem and predict the solution of the problem, then write or sketch an algorithm and numerically solve the problem by modifying the existing SageMath programs, analyze solutions and extensively test their programs.

The electric field vector is normal to the equipotential line and students can test this claim by actually computing the electric field for a given charge distribution and plot it.

### IV. IT IS TIME FOR PRACTICE

There are many problems that students should now be able to analyze and solve. For example:

- A wire can be placed along the y-axis.
- A wire can be placed at the angle $\pi/4$ with respect to the x-axis.
- Two parallel wires with the same type of charge or with the opposite types of charges.
- Two short wires with the opposite charges placed along the x-axis.

Student should be encouraged first to analyze the problem and predict the solution of the problem, then write or sketch an algorithm and numerically solve the problem by modifying the existing SageMath programs, analyze solutions and extensively test their programs.

### V. CONCLUSION

SageMath is a great free and open-source alternative to Mathematica and Matlab. SageMath uses Python as its main language. Python is usually the first computer language that many students meet because teachers often use this language in their introductory computer programming courses. This opens an opportunity to modify our introductory physics courses for ICT students. We can now use physics to support programming courses and make physics more suitable and usable for this specific group of students. In this article, we have shown how one can use SageMath to work with students on their understanding of the electric potential and the electric field.

Advocacy of born-digital materials: an ESP course example

Darija Pešut,
Visoka škola za informacijske tehnologije, Zagreb, Croatia
dpesut@vsite.hr

Abstract - The coexistence of print and electronic format brings forth a great variety in the choice of most suitable literature for students. If the choice is electronic, it is important to distinguish between digitized materials and the ones that originated in digital format. The author attempts to advocate the creation and usage of born-digital materials by presenting a published electronic handbook created for an ESP course for ICT students at the College for Information Technologies in Croatia. In addition to presenting the software used for the creation of the electronic handbook, the methods of using the electronic handbook in the classroom are also given.

I. INTRODUCTION

Nowadays, we witness the existence of two literature formats which are interchangeably used in academic environment: print and electronic.

The introduction of the electronic format has triggered the undertaking of numerous studies about student format preferences. Recent studies have shown the general preference towards the print format [2], although the use of electronic literature has been signified for specific use as reference literature [3].

An ESP (English for Specific Purposes) course specially designed for ICT students at the College for Information Technologies uses a traditional coursebook as obligatory literature. The approach to learning in this course is blended, meaning that the lecturer integrates technology with traditional teaching methods.

Being that electronic literature is mostly used by students as reference literature; the lecturer of the ESP course has written and published an electronic handbook as supplementary literature for the students of this course. This article presents the contents, the software used for creation and the methods of using the handbook as a teaching and study tool.

II. ELECTRONIC LITERATURE

As the term itself suggests, electronic literature is a collection of writings which are read/displayed on an electronic device. Depending on the electronic format, the devices can be various: smartphones, tablets, PCs, notebooks, PDAs, etc.

When defining electronic literature, it is important to distinguish between digitized print literature and literature which originated in electronic form or born-digital literature.

Today, works are written and prepared for print with the use of ICT technology, but born-digital literature is a collection of writings which cannot exist without electronic devices [4].

One of the most important differences between the digitized and the born-digital, which is also the reason for the author’s advocacy of born-digital literature, is found in multimedia features. Digitized print literature most often takes the form of a PDF document which usually does not have any multimedia features like audio, video and interactivity.

Born-digital literature can offer much more than the printed word by combining multimedia with standard text and providing interaction with the reader. The type of multimedia and interaction used should depend on the purpose of the text written. The purpose of the electronic handbook, presented under the following heading, is educational and should be used as supplementary literature.

III. THE ELECTRONIC HANDBOOK

The electronic handbook “IT English – Language work (student’s handbook)” was created to be used as supplementary literature for the ESP course English for IT specialists. The handbook deals with specific language work which is covered by this course. The language work covered in the handbook comprises verb tenses, articles, adjectives, adverbs, the passive, modals, phrasal verbs, infinitive and participles, linking words and phrases, sentence clauses, and word building.

A. Contents

The language work is demonstrated through 47 sections, out of which 25 are chapters which present definitions, rules and examples while the other 22 are quizzes. The navigation between chapters and quizzes is user friendly allowing the user to jump from one to the other.

Chapters deal with specific language work which is presented in a simple form as if it were a summary of main rules written on a whiteboard (Fig 1). The simple form organized as guidelines guarantees that the students can easily use this handbook as supplementary literature.
The quizzes are mainly composed of cloze exercises with multiple choice answers or questions with multiple choice answers. After choosing their answers, the users are then given the possibility to check them (Fig 2).

B. Software

Depending on the desired functionalities of the electronic publication, the author can choose between numerous commercial and free applications. The author of the electronic handbook presented in this article has chosen to use Libar – an application of the Croatian Academic and Research Network - CARNet.

Libar was created for two purposes; as a web application and a mobile application [1]. The web application is intended for designing/creating electronic educational materials, while the mobile application is intended for the usage of these materials.

Libar was selected by the author for three reasons:

1. It is a free service for the members of the Croatian Academic and Research Society.
2. Libar is very simple to use and it doesn’t require any technical or programming knowledge. Functions are similar to word processing programs (Fig 3.).
3. The mobile application allows students to view and use the electronic handbook on their smartphones without any specific device.

The electronic materials created in Libar can be saved and published in the PDF or EPUB format. They can also be connected to an LMS system using SCORM. The author is allowed to choose the rights of access. The use of materials can be restricted or they can be published in the mobile application as OER (Open Educational Resources) using one of the Creative Commons licences.

The electronic handbook presented in this article has been published in PDF and EPUB format in the mobile application as an OER under the Creative Commons licence “Attribution-NonCommercial-NoDerivs CC BY-NC-ND”. The PDF file allows the users to read the electronic handbook but they cannot interactively solve the quizzes. The EPUB file enables the users to solve the quizzes and to check the answers.

The mobile application does have a temporary restriction where the EPUB format is only supported for the Android and iOS smartphones, while the Windows phone only allows reading the PDF format.

C. The methods

The electronic handbook was designed to have two purposes. The first purpose is supplementary literature and the second is teaching material.

As supplementary literature, the students can use it as a revision tool for the main topics of language work for their ESP course. As a teaching material, both students and the teacher can use it, even in class.

The teacher can use the electronic handbook instead of Power Point presentations or writing on the whiteboard by displaying the selected chapter using a laptop and projector. The students can also simultaneously view the chapter on their laptops or smartphones. If the teacher needs an extra exercise to do in class, he/she can use the quizzes from the handbook.

The students of this ESP course use a laptop in class and have viewed the handbook during lessons. Some of them have also used their smartphones. During class, students have reported the handbook to be quite useful as they do not need to copy from the whiteboard and they have easy access to it from their smartphones.
IV. CONCLUSION

The presented electronic handbook has been used for the first time in the fall semester of the academic year 2016/2017. The author is prepared to collect experiences from students and on the basis of the findings expand the handbook with more theory, practice or multimedia in the new edition.

The handbook has shown to be of use to the students of the ESP course and they mainly used it for revising and practicing language work before exams. In addition to being supplementary literature, the electronic handbook has shown to have an additional value. The added value is that it can be used by the teacher as projected materials during lessons.

The biggest value of born-digital materials is the presence of multimedia and interactive features. The presented electronic handbook does not include many of these features; nevertheless, it can be seen as a prototype of an electronic textbook for the mentioned ESP course which is planned for publication in the near future.

Theoretical and practical challenges of using three ammeter or tree voltmeter methods in teaching

Vladimir Šimović, Trpimir Alajbeg, Josip Ćurković
Department of Electrical Engineering
Zagreb University of Applied Sciences
vsimovic@tvz.hr, trpimir.alajbeg@tvz.hr, jcurkovic@tvz.hr

Abstract - The three ammeter method and the three voltmeter method are used for measurements of power. More specifically, they are used to calculate the power factor of a specific load. Both methods are used on the „Fundamentals of electrical engineering” course in professional study of electrical engineering at the Zagreb University of Applied Sciences as an introduction to measurements of power and phasor arithmetic. Both methods are susceptible to accuracy problems caused by small errors in measuring devices. These accuracy problems in specific scenarios that were used during the course presented an opportunity to educate students on the difference of theory and its practical application. This paper examines our solution to the perceived accuracy problems and discusses the changes that were made in course material and teaching methods to highlight the difference between theory and practice.

I. INTRODUCTION

As an integral part of the Fundamentals of electrical engineering, course students must attend and earn a passing grade in five laboratory exercises. The exercises are used as a tool to educate students on the process of conducting experiments, interpretation and discussion of results and applying theoretical knowledge from course classes. For many of the students, the laboratory exercises present the first real opportunity to handle instruments specific to electrical engineering.

Among the five laboratory exercises, one deals in measurements of power, specifically with the measuring and calculating the power factor (cos φ) of a specific load (Z_t) in a simple AC circuit. This is done by using two methods; three ammeter and the three voltmeter method.

II. THE METHODS

A. Three voltmeter method

The three voltmeter is used in an inductive circuit to measure the value of the power factor. As seen on Figure 1, one voltmeter is used to measure the voltage of the circuit (U_i), the second one measures the voltage on the non-inductive resistance (U_R) that is connected in the series with the load branch and the third voltmeter is used to measure the voltage of the load (U_t).

The power (P) consumed by the load can be determined as the product of the voltage and current of the load (U_tI_t) and the cosine of the phase angle between these two (the power factor).

\[ P = U_t I_t \cos \phi \] (1)

Using the law of cosines, the power factor (cos φ) can be calculated.

\[ \cos \phi = \frac{U_i^2 - U_R^2 - U_t^2}{2 U_R U_t} \] (2)

For optimal accuracy, the non-inductive resistance should be large enough so that the voltmeter (or multimeter) can measure it with satisfactory accuracy, but not too large, otherwise the voltage available to the load would be too small. Ideally, it should be close or equal to load impedance.

B. Three ammeter method

The three ammeter is also used in an inductive circuit to measure the value of the power factor, independent of source frequency and waveforms. In this method, as seen on Figure 2, across the inductive circuit load in which the power factor is to be determined, a non-inductive resistance is connected parallel with the load branch. One ammeter is used to measure total current of the circuit, the second one measures current going through the non-inductive resistance and the third ammeter measures the current of the load branch.

Current through the resistive branch (I_R) is in phase with source voltage while the current of the load (I_t) has
its own phase, which will affect the power factor (cos φ). Total current (I_i) is a vector sum of the other two currents. Using the law of cosines, the power factor can be calculated.

\[
\cos \phi = \frac{(I_i^2 - I_R^2 - I_t^2)}{(2 I_R I_t)}
\] (3)

For optimal accuracy, ideally, the non-inductive resistance should be close or equal to load impedance as it should be for the three voltmeter method.

III. METHOD IMPLEMENTATION

A. The actual configuration

In these experiments for measuring the power factor in both three ammeter and three voltmeter methods the AC source is set to 7.5 V RMS (Root-Mean-Square), with the frequency set at 50 Hz. The voltmeter that is connected in parallel to the source, as seen on Figures 1 and 2, is used to set its output voltage. For both methods, the same electrical circuit elements were used; a non-inductive resistance value of 680 Ω and a load phase that consisted of a variable resistor of 100 Ω and a capacitor of 10µF.

Three Digital Multimeters PeakTech 2010 were used to measure current or voltage, depending on the method. The used elements were connected as seen on Figures 1 and 2. For the three ammeter method a fourth Digital Multimeters PeakTech 2010 was used to set the voltage of the source.

B. Occurring problem

One of the problems that affected the results of both methods was the fact that in the original configuration the measurement devices that were used were all analog. This was mostly due to the fact that students were divided in six pairs that did the laboratory exercise simultaneously. This meant that at any given time during the class, at least eighteen instruments were needed. Since analog meters use a needle and scale to indicate values, the accuracy of the results is also affected by the operator’s ability to read the readout on the meter, as seen on Figure 3.

There is also the problem of the meter’s impedance. Digital voltmeters have significantly higher impedance than their analog counterparts do; they are more accurate when measuring voltage.

It is well documented [7][8][9] that for optimal accuracy the methods require that the non-inductive resistance should be close or equal to load impedance.

In the original configuration of the laboratory exercise, an adjustable resistor (rheostat to be specific) was used in the two-part load impedance. As a wire-wound resistor, a rheostat has a large inductance at higher frequencies, which affects the impedance of the load and its power factor, which would translate into further deviation from the theoretical one. Since the used frequency is 50 Hz, the effect is negligible.

There is also the matter of internal impedance of circular wires that for most low-frequency applications has no effect on the circuit or the results of the experiment and therefore can be ignored.

C. Presented opportunity

The noted problems presented an opportunity to further educate the students on the disparity between the practical and theoretical. To be more specific, to educate them about:

- risks of misreading analog instruments
- effects of measurement devices on the measurements themselves
IV. CHANGE IN TEACHING METHODS

In the process of tackling the occurring problems different angles had to be considered. In the end, changes were made in all stages of this specific laboratory exercise and even some other exercises.

A. Pre-experiment

As part of the preparation for the laboratory exercise, students are assigned problems to solve to better prepare themselves for the exercise itself. With effects of measurement devices on the measurements themselves in mind, a specific circuit, similar to the one in the experiments, was assigned. Students were instructed to calculate the deviation in measurement devices readouts between two cases; when the instruments were ideal (no internal impedance) and when they were real (internal impedance was given). The assignments were done for a specific frequency, but can be altered and expanded for calculation for a wide range of frequencies using Microsoft Excel or some other spreadsheet program (Open Office Calc comes to mind as an open source alternative). This approach requires some knowledge of using functions in a spreadsheet program, which makes it an ideal task for a different course called Personal Computer Applications that is also taught as a part of professional study of Electrical engineering at the Zagreb University of Applied Sciences.

B. During the experiment

For the laboratory experiment itself, few key elements were changed.

Since uncertainty of reading analog instruments or human error is not a part of the intended lesson, nor the curriculum of Fundamentals of electrical engineering, analog instruments were swapped with their digital counterparts. These subjects are a part of a different course; Electrical Measurements, and therefore, because of the change, teaching materials have been altered for a different laboratory exercise on that course to educate the students on accuracy problems related to reading of analog instruments.

The most important change is the change in load

Figure 4. The actual configuration of the experiment with the three ammeter method used as described

Figure 5. Updated experiment using the three ammeter method
impedance. Instead of the wire-wound resistor (rheostat), a typical carbon composition resistor was used. This lessened the effect of the rheostat’s large inductance on the impedance of the load and its power factor but more importantly, because of its small size, the swap enabled us to construct eight different load phase impedances that were placed in 3D printed black boxes. This was done to insure that all students will have different measurement results which among other things would reduce cheating. The changes are noted on Figures 5 and 6.

In addition, an oscilloscope was added to the experiment with one channel connected to the AC source and the other channel to the load phase. The oscilloscope is used for both methods but is crucial to the three voltmeter method where it is used to teach students about phase shifts. The students are instructed to compare the value calculated from the power factor and the value of the phase shift that can be read from the oscilloscope. By doing so, they can determine the nature of the load, more specifically whether it is inductive or capacitive in nature. With the usage of a digital oscilloscope, the readout can be stored for analysis on the computer at home.

C. Post-experiment

As a tool for further education of the students on all of the above-mentioned topics, an EDA (Electronic Design Automation) program is used post-experiment. The Proteus ISIS (Intelligent Schematic Input System) package is the EDA program of choice. Students can freely and legally download a demonstration version of the program. Among several other restrictions, the main restriction, in comparison to a full version, is that the project cannot be saved or stored digitally in any way, but the readouts can be manually noted in the post-experiment documentation. These can be used later for comparison with the results of the pre-experiment assignment and the experiment itself.

The Proteus ISIS package, as seen on Figure 7, enables further education post-experiment in a way that could not be realised during the laboratory exercise because of time constraints. With Proteus, the student can simulate the behaviour of the circuit and its elements on a wider frequency spectrum without the need for additional physical circuit elements. To execute that in a laboratory exercise environment, an addition of a signal generator would be needed and perhaps even a data acquisition module. This would further complicate the exercise itself for both the student and the educator.

Changing the values of electric circuit elements is an easy task in Proteus and that helps to evaluate both
methods in sub-optimal configurations, specifically, when the non-inductive resistance is not close or equal to load impedance. In addition, changing the load impedance in Proteus, as with any other element in the circuit, results in an instant change of instrument readouts. This is something that yet again, is not so easy to accomplish in the laboratory environment. Not only because of time constrictions, but because it is not practical to have so many circuit elements at student’s disposal. So, instead of having multiple sets of capacitors, inductors and resistors, physically available, to evaluate the behaviour of the method when the non-inductive resistance is not close or equal to load impedance, this can be achieved by simply adjusting the elements in Proteus with a few clicks of the mouse.

V. CONCLUSION

Although power factor meters exist, even today, the tree ammeter method and the three voltmeter method are commonly used for calculation of the power factor of a specific load, both in practice and as a teaching tool. Both methods have practical and theoretical downsides and limitations, those same downsides and limitations can be used as a part of the teaching process in educating students on the divergence of the practical from the theoretical.

The addition of an EDA program proved to be an invaluable asset and a teaching tool even for a „Fundamentals of electrical engineering” course in professional study of electrical engineering at the Zagreb University of Applied Sciences, where up until recently, the usage of computers, for this specific course, was a rarity. Given the methods susceptibility to accuracy problems outside specific conditions described in section II, and physical and time constraints of working with students in a laboratory setting, the addition of an EDA program after the exercise helped us immensely to further educate the students about the problems when the mentioned methods were applied in sub ideal conditions.

Given the satisfaction with the involvement of computer usage in the education process in the mention course, further developments and EDA program inclusions are planned.

BIBLIOGRAPHY

National Competition of Photography as Visual Art in Croatian Primary Schools, High Schools and Schools of Applied Arts

zvjezdana.prohaska@azoo.hr, zdenko.prohaska@ri.t-com.hr, ivan.uroda@gmail.com

Abstract - Photography as a visual art is studied in subjects in Croatian primary schools, high schools and schools of applied arts and design.

In this article the preparation of a national competition in using photography and computers in Croatian schools at three levels mentioned above, will be presented, discussed and evaluated.

For evaluation of the photos a special and original computer program, called Photobox, was developed. It is actually a database in graphic format, where all photos can be stored, viewed and comments added.

For grading, scoring and ranking of the participants a main Excel spreadsheet with two additional Excel spreadsheets, which represent input databases, where also carefully elaborated.

I. INTRODUCTION

Under the auspices by the Ministry of Science and Education (Ministry), the Education and Teacher Training Agency (Agency) and one of the selected secondary or primary schools organize every school year, a competition - exhibition of pupils of primary and secondary schools in the field of visual arts and design called - LIK.

The competition includes three target groups: pupils from fifth to eighth grade of primary schools in the field of art, pupils from first to fourth grade in high schools, art schools in the field of visual arts, art history and theory of fine arts and pupils from first to fourth grade in secondary schools who are educated in the field of visual and applied art and design in a variety of programs and fields of fine art.

This competition - exhibition LIK has a 19 years tradition and represents the visual range of the pupils in the performance of artworks on a given topic and different art techniques (traditional and modern). Artworks by pupils selected at the three levels and assessed by a commission, at the school, county and national levels.

The artworks are selected and evaluated based on the criteria set up by the State Commission (Commission). This Commission is composed of professors from art academies, study of design and architecture, history, fine arts, and teachers of primary schools and secondary schools in the field of fine art.

The Commission prepares and creates the tasks for all three target groups of primary and secondary schools. Members of the Commission are appointed by the director of the Agency with the prior approval of the Ministry of Science and Education. From the members of the State Commission three committees in charge of the selection and evaluation of artworks (photographs) of the three above-mentioned groups of primary and secondary schools are appointed.

High-quality and objective evaluation of artworks and photos provided by the criteria for the assessment of individual elements that apply to all three levels of competition: school, county and national levels. All the artworks are coded and the results made public (e.g. the results of the national level will be published on the website of the Agency).

The most successful artworks of pupils at all three levels will be presented to the public at exhibitions.

The exhibitions are regularly well-attended at schools and in public cultural and art institutions, i.e. museums and galleries (e.g. at the national level in the Mestrović Gallery in Split, the Amphitheatre in Pula, etc.).

Details of the competition - exhibition LIK are integrated in the Guidelines published on the website of the Agency. There is the data related to the organization of all three levels of competition, time schedule, category, method of rewarding pupils, a list of members of the Commission as well as a list of tasks that it performs.

Together with the instructions of the competition - exhibition LIK three documents on the tasks of the above mentioned three target groups of pupils are published. Art tasks are made at the school level with the expert assistance of teachers or teachers who are mentors of pupils. At the county level artworks are selected, and the most successful are sent to a higher level, i.e. the state level, for a new selection.
II. THE ORGANIZATION OF THE COMPETITION - GENERAL VIEW

The competition-exhibition of pupils of primary and secondary schools in the field of visual arts and design - LIK 2017 (main technique: photography) organized by the Ministry and the Agency has the following time schedule and levels: [2]

School competition-exhibition:
30th January 2017 (Monday)

County / inter-county competition-exhibition:
27th February 2017 (Monday)
Submission of the artworks by 10th February 2017

National competition-exhibition:
26th to 28th April 2017 (Wednesday, Thursday and Friday)
Submission of (all) artworks to by 10th March 2017

Note: Pupils from first to fourth grade of secondary schools and schools of fine and applied arts and design have just the school and state level.

Main topic and categories of the Competition - Exhibition are:

**Topic - incentive of the competition:** Sound image

**Categories**

1. Pupils from 5th to 8th year of primary schools / ART CULTURE
   A - competition-exhibition of artworks on the theme - incentive
   B - competition-exhibition of artworks on the set theme and visual problem

2. Pupils from 1st to 4th year high school / FINE ART (subjects: fine art, history of art and theory of design)
   A - competition-exhibition on the theme - incentive realized artistic expression based on research work
   B - competition essay on a given topic - incentive

3. Pupils from 1st to 4th year schools of applied arts and design and schools implementing programs of fine art and design
   A - competition-exhibition of artworks on the theme - incentive
   B - competition-exhibition of artworks set on the theme and visual problem

**School competition**
The state commission prepares the Tasks for the school competitions. The school committee is appointed by the school director.

Primary schools - visual arts category 1A can send from the school to the county level no more than 10 artworks.
Secondary schools-character visual art (general education subject) in the category 2A can send from the school to the county / inter-county level maximum 2 artworks.
Secondary school of fine and applied arts and design and the schools that educate pupils in programs of fine and applied arts and design (verified learning programs by the Ministry of Science, and Education / Curricula and framework programs for secondary schools of fine arts and applied arts and design, 2001) in category 3A.

School committees (1A and 2A category) must prepare a list of selected pupils in Excel tables downloaded from the website of the Agency / Competitions and festivals and forward to the county level committees (except 3A category directly to the state level).

**After the school competition** has finished, the schools have to forward electronically to the upper levels (inter-county or the county commission in addition to 3A category directly to the State Commission, i.e. the secretary of the State commission. Tables must be sent by e-mail. The organizer of each level of competition is required to consolidate the pupils registered in one table (spreadsheet), what should be done by copy and paste technique. All artworks should be evaluated according to prescribed propositions and criteria.

**County competition**
County commissions are appointed by the county offices. County offices determine the place and the host school, which will organize and carry out the selection of the best artworks of the competition-exhibition. It is desirable to set up an exhibition in a museum or a gallery and to prepare a simple and adequate catalog.

**National competition**
The State Commission has a president, secretary and members. They are appointed by the director of the Agency with the prior approval of the Ministry of Science and Education. The Evaluation committee (selected among the members of the State Commission) is split up by categories. Each category is coordinated by one of the members. The artworks in each category are evaluated by three members. The members of the evaluation committees at the national level cannot be mentors to pupils who are participating in the competition.

The evaluation committees choose up to 13 artworks of pupils in category 1A, 2A and 3A, which will participate in the exhibition (up to 39 pupils). At the state level, pupils are also invited to compete in the category 1B, 2B and 3B.

Pupils who win the first three places in these competitions will receive a special recognition. To the competitions and festivals on the state level, pupils will be invited according to their results in competitions held on the county level, what has to be confirmed by the Commission.

***III. COMPETITION AT DIFFERENT LEVELS***

In this chapter details of the competitions at different levels will be elaborated.

A. **Primary schools competition**
The tasks for pupils at the primary school level are defined below:
The task for pupils from 5th to 8th grade of primary schools, 1A category - ART CULTURE
A - competition-exhibition of artworks on the theme - incentive

**Sub-theme-stimulus:** Rhythm of light, the rhythm of colors

**Teaching area:** Flatbed design / 2D
Artistic techniques: traditional photography, digital photo. (photos must be in color /C/)

Size: size of photography should be prepared for print 30x40 or 30x45 cm (depending on the extent of filmed) and 300 dpi resolution. The artworks at the school, county and national level are reviewed and evaluated in a digital format and in printed form size 13x18 cm

Key concepts: photo, color, light, rhythm, contrast, composition, framing

Goals: Pupils will observe, learn about and evaluate the role of color, light, rhythm, contrast, composition and framing to create images on the sub-theme-stimulus rhythm lights, the rhythm of colors. Pupils will explore, express and evaluate different kinds of rhythms in their own work.

Task: Pupils will:
- explore art / visual elements and key concepts for subtopic-stimulus rhythm lights, the rhythm of colors (separating bit of artwork pupils): photo, color, light rhythm, contrast, composition, framing
- express own idea in the medium of photography
- apply photographic procedures in making photographs (classical and digital, the ability of computer processing to the extent that does not distort and does not alter the basic meaning of the recording)
- evaluate role of color, light, rhythm, contrast, composition and framing

Evaluation:
Works will be evaluated according to the following criteria:
- divergent opinion
- art problem / key concepts: photo, color, light, rhythm, contrast, composition, framing
- understanding and creative application of art techniques and resources: the classic photography, digital photography
- connecting / interdisciplinary and correlated access

Primary schools:
Photo:
Pupils take photos by their camera or mobile phone (without limitation). Captured images can be processed in programs for photo editing to the extent that does not distort and does not alter the basic meaning of the recorded contents. Photographs must be in color /C/. Permitted file extension is JPG maximum size of 5 MB.

B. High schools competition

The tasks for pupils at the high school level are defined below:
The task for the pupils from first to fourth grade of high schools (subjects: Fine arts, art history and theory of design), 2A category - FINE ART
A - Competition - Exhibition of artworks on the theme incentive realized by artistic expression - based on research
Key concepts: photography, composition, rhythm, framing, light, contrast, composition - re-composition, definition - re-definition, recycling, texture, structure
Intersubject correlation: musical art, computer science, mathematics, Croatian language and literature and physics

Goals: The aim of the competition is to accomplish a picture using photography as a medium, taking into account its historical significance, technological capabilities, functions and aspects of photography. Selected access to traditional and contemporary photography pupils will be able to interpret the artistic manipulation of a photograph through the history of the connotation of the stylistic periods and artistic direction 20th century. Research activities will encourage the realization of artistic creations, develop creativity, the ability of divergent and convergent thinking and independence in planning and realizing the artistic task.

[6], [8]

Task:
Pupils will:
- Pupils prepare exclusively a collage of photos that are individually recorded. It can be done in digital or analog (classical) paper collage of printed photos. In the collage, with elements of photography, can use a collage of colored paper, can be used as a newspaper article, but not in terms of content, but in terms of its graphism.

Assignments:
Pupils will:
- apply photographic procedures in making photographs (classical and digital, the ability of computer processing to the extent that does not distort and does not alter the basic meaning of the recording)
- formulate a picture as a matrix for further consideration of the techniques of collage
- devise a collage as a redefinition, recomposition, confrontation and recycling questioning tone, rhythm, composition, structure, texture, schematisation, variation, modularity, multiplication and fragmentation
- realize their own idea as a piece of artwork in the medium of photography and in the technique of collage and photo collage
- evaluate the role of composition, rhythm, framing, light, contrast, texture, structure, chiaroscuro
- conclude intermediate, multimedia, interdisciplinary, correlation creating new compositions photography

Artistic techniques: traditional photography, digital photography (photos may be color /C/, Monochrome /M/ or black and white /BW/), a collage and photo collage

Format: Minimum dimensions of the artwork is 15x15 cm, and the maximum 50x50 cm and all possible formats between the smallest and the largest dimension are allowed (e.g. 15x50, 30 x 50, etc.)

Evaluation:
The artworks will be evaluated according to the following criteria:
- visibility and correlation interdisciplinary approach to research and artistic expression and study forms of communication in different areas of art
- creative self-expression and world view and appreciation of ethical and aesthetic values in the artistic creations
- creativity and expression in artistic expression

Each criterion can be evaluated with a maximum of twenty points and the total sum amounts to sixty points.
Fine art:
Photo collage:
Pupils create exclusively collage of photos that are individually recorded. They can do digital or analog (classical) collage of photos and print them. In the collage, beside photo elements, paper and newspaper articles can be used, not in content but in terms of its graphism. Permitted file extension is JPG maximum size of 5 MB.

C. Schools of applied arts and design competition
The tasks for pupils at the level of schools of applied art and design are defined below:
The task for the pupils from first to fourth year high school, 3A category - ART AND APPLIED ART AND DESIGN
A - competition-exhibition of artworks on the theme incentive
Topic-incentive: sound image / incentive: intermediality / Multimedia sound track

Intermediality - multimedia sound track:
- Intermediality defined as the process by which structures and materials are typical from one medium transferred to another; one of these media usually is artistic
- Multimedia is manifested in art as the expression of different art forms in one integrated medium.
A related concept is the transmediality - an area in which identity and subjectivity changes and transforms using other media.

Note to teachers:
Research and creativity of pupils through the medium of photography and multimedia has numerous possibilities, which can easily seduce the naive observer, therefore it is necessary to explain the basic concepts of the media to the pupils.

Task:
ARTICULATION DESIGN FEATURES - intermediality - multimedia sound track
Pupils need to formulate and define systems within the composition on the concept of intermediality - multimedia sound track and show the symbolism of cooperation each element.

Goals: The pupil will be able to observe, explore and make an artistic technique / technology of his choice (in accordance with the curriculum at the department and school) on the subject of incentive-Sound Image / intermediality / Multimedia intermediality - multimedia audio clip.
During the realization of tasks pupils will be introduced to photography as a medium of expression, historical and artistic development of the same, and the role and importance throughout the 20th century. [3]
They will investigate the possibilities of photography, the achievements of modern technical / technological capabilities and to traditional or contemporary processes reinterpret obtained record (procedures redefinition / recomposition create new visual facts). [5]

Evaluation:
The artworks will be evaluated according to following criteria:
- interdisciplinary and correlated approach to research and artistic expression
- unifying themes as incentives (research access to forms of communication) and skills development in the material / medium
- the relationship of form and ideas

Each criterion can be evaluated with a maximum of twenty points and the total sum amounts to sixty points.
Artworks that have less than fifty percent of the points (less than thirty points) cannot go to a higher level (state).

Schools of applied arts and design:
Pupils can realize their ideas as: photogram, chemo-gram, collage (analog and digital), photography, photomontage, photo story, photo albums, photo books, photo object, photos in textile design, jewelry, photo graphic design, photo design furniture (pupil artworks in 3D simulation), photos in interior design (pupil artworks in 3D simulation) and as a video clip, no longer than 3 minutes.
Two-dimensional artworks may have a minimum size of 10x10 cm and a maximum size of 70x70 cm and all derivative formats, both small and great.
Three-dimensional artworks may have minimum size dimensions of 15x15x15 cm and 50x50x50 cm as maximum, as well as all derivative formats, from small to the greatest format.

IV. PROGRAM PHOTOBOX AND EXCEL SPREADSHEETS
For evaluation of the photos at all three levels a special computer program called PhotoBox, actually a database in graphic format, was developed and programmed in Visual Basic for Windows. [1], [4], [7]
In this software all photos of the participants or pupils can be stored, viewed and notes could be made. Similar computer programs were already presented by the authors in articles at two earlier MIPRO Conferences. [9], [10]
The first screen of the program PhotoBox with the main menu, where photos can be loaded, saved, printed and pasted from the clipboard and to the clipboard, is shown in (Fig. 1) below.

![PhotoBox](image)

Figure 1. Program PhotoBox

For the scoring and ranking of the photos or pupils in the competition, a special Excel spreadsheet was developed, to get not only the results, but also a basic statistical analysis of the artworks submitted to this competition. (Fig. 2)
V. INSTALLATION OF PROGRAM PHOTOBBOX AND EXCEL SPREADSHEETS

The computer program PhotoBox consists only of two application files, i.e. the PhotoBox program file (photobox.exe) and the Visual Basic runtime module (vbrunxxx.dll). To install the program PhotoBox it is necessary to copy both files to a directory on the hard disk of a PC (for example C:\PhotoBox) and to start the program by clicking the program file or icon (photobox.exe) with a Microsoft compatible mouse.

Concerning the installation of the three Excel spreadsheets presented above, it is necessary to copy these files in the working directory of the PC where Microsoft Excel program can access them.

VI. CONCLUSION

In this article the preparation of the national competition of photography in Croatian primary schools, high schools and schools of applied arts and design was elaborated. A special computer program, PhotoBox, for viewing and sorting of the photos was developed, as well as a main Excel spreadsheet for grading, scoring and ranking of the participants and two additional Excel spreadsheets as input databases for the main spreadsheet were programmed.

Generating large random test data table for SQL training

U. Sterle*
* Šolski center Kranj/Srednja tehniška šola, Kranj, Slovenia
uros.sterle@sckr.si

Abstract - For a quality SQL training we need many different exercises and many different tables. There are many databases along with the exercises in English. In Slovenian and other languages we have a lack of them. The idea was to create a random table from existing data. On the web we find a lot of data in our own language. When we assemble these data according to some random logic, we can obtain a large table, which is needed for practising SQL language.

We've compiled a table of people which includes the following information: name, sex, place of residence, birth date and time, the profession and a popular place. From the Web we obtained information about the most common first names by gender, family names, places in Slovenia and the professions. Birthdays were generated randomly, so that a person's age is between eighteen and eighty years. Popular places were also randomly generated as a geolocation in Slovenia.

We could easily use any other data to generate random tables.

Table was used in exercises of the module entitled "Advanced usage of databases" in the third year of secondary school program of Computer Technician.

I. INTRODUCTION

These instructions give you guidelines for creating your own large random test data table for SQL training.

All you need is find your own data, create your own tables and adjust SQL code to fit your data.

We compiled a table of people with basic information such as name, sex, place of residence, birth date and time, the profession and a popular place.

We could easily use any other data to generate random tables. This is the main advantage of this method, because it is not dependent on data we used. Disadvantage is that you need to know SQL to use this method. There is idea for web application, which would create table itself, when we choose CSV file for importing and this is the next step of development.

We used MySQL database management system (DBMS), but the code can be easily adjusted to any other DBMS such as SQL Server, Oracle, PostgreSQL etc.

II. GETTING DATA FROM THE WEB

A. First names and family names

From the web page of The Statistical Office of the Republic of Slovenia [1] we obtained data for first names and family names. Together we downloaded six csv files. One file for male first names, one for female first names and four files for family names. We adjusted files for importing in MySQL tables. We excluded the first names that appear less than five times, and so we get 3595 men and 3871 women's names. Similarly, we have done with family names and we get 28369 different family names.

B. Places of residence, settlements

We took data from another subpage of The Statistical Office of the Republic of Slovenia [2]. We downloaded one file. There are 6037 settlements from Slovenia together with number of households in individual settlements.

C. Professions

Webpage mojaizbira.si [3] contains a list of 496 professions and we used them for our database.

III. PREPARING DATABASE

After we retrieved data from web, we had to prepare out database for generating random data. We created several tables:

A. Table for first names

First we created a table named first_names with columns for name, number of names and gender. Here is the MySQL code for creating this table:

``` mysql
CREATE TABLE first_names ( 
  first_name VARCHAR(20), 
  number INT, 
  gender CHAR 
) DEFAULT CHARSET='utf8' 
ENGINE=MyISAM; 
```

1060 MIPRO 2017/CE
We used LOAD DATA INFILE sentence to import data from file to database table.

LOAD DATA INFILE 'first_names.csv'
INTO TABLE first_names
CHARACTER SET 'utf8'
FIELDS TERMINATED BY ';'
LINES TERMINATED BY '\r\n'
IGNORE 1 LINES;

We see some imported data in Table I.

B. Table for family names
Second table was named family_names with columns for family name and number of them. Here is the MySQL code for creating this table:

```sql
CREATE TABLE family_names (
    family_name VARCHAR(20),
    number INT
)
DEFAULT CHARSET='utf8'
ENGINE=MyISAM;
```

We used LOAD DATA INFILE sentence to import data from file to database table.

LOAD DATA INFILE 'family_names.csv'
INTO TABLE family_names
CHARACTER SET 'utf8'
FIELDS TERMINATED BY ';'
LINES TERMINATED BY '\r\n'
IGNORE 1 LINES;

We see some imported data in Table II.

C. Table for settlements
Settlements table contains code, name of settlement type (settlement or municipality) and the number of households. Here is the MySQL code for creating this table:

```sql
CREATE TABLE settlements (
    code varchar(6),
    name VARCHAR(35),
    type VARCHAR(10),
    households INT
)
DEFAULT CHARSET='utf8'
ENGINE=MyISAM;
```

We used LOAD DATA INFILE sentence to import data from file to database table.

LOAD DATA INFILE settlements.csv'
INTO TABLE settlements
CHARACTER SET 'utf8'
FIELDS TERMINATED BY ';'
LINES TERMINATED BY '\r\n'
IGNORE 1 LINES;

We see some imported data in Table III.

D. Table for professions
Next table was named professions with columns for id and name of profession. Here is the MySQL code for creating this table:

```sql
CREATE TABLE professions (
    ID INT,
    profession VARCHAR(120)
)
DEFAULT CHARSET='utf8'
ENGINE=MyISAM;
```
TABLE IV. SOME DATA FROM TABLE PROFESSIONS

<table>
<thead>
<tr>
<th>id</th>
<th>poklic</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>administrator</td>
</tr>
<tr>
<td>2</td>
<td>agronom</td>
</tr>
<tr>
<td>3</td>
<td>agronom za sadjarstvo</td>
</tr>
<tr>
<td>4</td>
<td>aktuar</td>
</tr>
</tbody>
</table>

Data from professions.csv file:

id;poklic
1;administrator
2;agronom
3;agronom za sadjarstvo
4;aktuar

We used LOAD DATA INFILE sentence to import data from file to database table.

LOAD DATA INFILE 'professions.csv'
INTO TABLE professions
CHARACTER SET 'utf8'
FIELDS TERMINATED BY ';'
LINES TERMINATED BY '\r\n'
IGNORE 1 LINES;

Table IV represents imported data for professions.

E. Table for random generated names

Last table was named persons with columns for first name, family name, settlement, profession, birthday and gender. Here is the MySQL code for creating this table:

CREATE TABLE persons (first_name VARCHAR(20), family_name VARCHAR(20), settlement VARCHAR(35), profession VARCHAR(120), birthday DATETIME, gender CHAR)
)
DEFAULT CHARSET='utf8'
ENGINE=MyISAM;

IV. GENERATING RANDOM DATA

We created following procedure to create random person from previously generated tables.

DELIMITER //
CREATE PROCEDURE generate_random_names (n INT, year1 INT, year2 INT)
BEGIN
DECLARE fi, fa, s, g VARCHAR(40)
CHARACTER SET utf8;
DECLARE id_p INT;
DECLARE b DATETIME;
WHILE n > 0 DO
SELECT first_name, gender
INTO fi, g
FROM names
ORDER BY -LOG(RAND())/number
LIMIT 1;
SELECT family_name
INTO fa
FROM family_names
ORDER BY RAND()
LIMIT 1;
SELECT id
INTO id_p
FROM professions
ORDER BY RAND()
LIMIT 1;
SELECT CURDATE() - INTERVAL (FLOOR(RAND()*(year2-year1+1)*365)+year1*365) DAY - INTERVAL (FLOOR(RAND()*24*60)) MINUTE
INTO b;
SET n = n - 1;
INSERT INTO persons(first_name, family_name, settlement, profession, birthday, gender)
VALUES (fi, fa, s, id_p, b, g);
END WHILE;
END//
DELIMITER ;

Finally we run the procedure:

CALL generate_random_names(10000, 18, 80);

The meaning of the last sentence is that we generate 10000 persons whose age is between 18 and 80 years.

V. APPLICATION IN TEACHING PROCESS

We will show you just three examples of question and answers during our classes.

- Question 1: Write a query to display the names (first_name, family_name) and birthday for all people who were born in Ljubljana.
- Answer:

  SELECT first_name, family_name, birthday
  FROM persons
  WHERE settlement = 'Ljubljana';

- Question 2: How many female persons were born in 60's?
- Question 3: Write a query to display the number of people living in Ljubljana.
Answer:
SELECT COUNT(*)
FROM persons
WHERE GENDER = 'Ž' AND
YEAR(birthday) BETWEEN 1960
AND 1969;

- Question 3: List all data for persons who were
  born on Friday the 13th in alphabetical order.

Answer:
SELECT *
FROM persons
WHERE DAYNAME(birthday)='Friday' AND

VI. CONCLUSION

Table was used in exercises of the module entitled
"Advanced usage of databases" in the third year of
secondary school program of Computer Technician. The
responses of students and other teacher were excellent.

We conducted a short survey at the end. Previously
our exercises were based on English tables so students
were very satisfied with data in their own language. They
would also like to have more exercises with data in their
own language.

I also introduced this method to two other database
teachers and they find it very useful and included method
in their own curriculum.

Programming Lego Mindstorms for First Lego League Robot Game and Technical interview

Barbara Strnad
Gimnazija Novo mesto, Novo mesto, Slovenia
Društvo Čarunalnik društvo za napredno uporabo računalnikov Novo mesto, Slovenia
barbara.strnad@gmail.com

Abstract - It is of great importance in the information age to equip children with the capacity to independently navigate in the flood of all available data and be responsible towards acquiring knowledge. We must provide a learning environment, where children can be enhanced to think creatively and develop innovative solutions. The article further presents the robotic part (a robot game with a technical interview) that is half of the multidisciplinary program First® Lego® League, which was brought to Slovenia by Super Glavce, the Institute for the Promotion of Knowledge. There is an overview of several months’ work and the preparation for the robotic part of the competition, where children have to build and programme an autonomous robot that can complete as many tasks on the competition mat as possible in a limited amount of time. During this process a technical portfolio is made, where children record the progress, the problems and describe ways of solving the problem, explain strategies and present innovative solutions. The technical portfolio is the basis for the technical interview. The ways of working with lego robots in preparation for the First® Lego® League competition can be successfully replicated in class with the topic of algorithmic ways of thinking and programming.

I. INTRODUCTION

In this article, we want to show that Lego robots are a very effective learning tool, which facilitates the development of logical thinking, creativity, and greatly increases children's interest in learning programming. Children's participation in the preparations for the robot game in the context of a multidisciplinary program First® LEGO® League (FLL) encourages the search for creative and innovative design and software solutions. The working methods of the FLL program, where the activity focuses on children, who learn through their own work and creation, can be replicated in class.

II. FLL PROGRAM

Since we live in an age of high technology and we are entering the era of robots, we started with robotic activities in classroom three years ago. Lego robots allow students to learn how robots work and how we can manage robots in a fun way. Likewise, we have in mind the finding [4] that on average Slovenian children do not want to learn science and technology topics, the same is true in developed countries [3].

Because children are highly motivated if they have their goals in mind, we joined the FLL program, because of the robot game and technical interview. Also, studies have shown that the FLL program increases children's interest in science and technology.

FLL is an international, multidisciplinary research program for children from 9 to 16 years old. Program promotes curiosity, creativity, collaborative learning, and teamwork. Because of a thoughtful, efficient and attractive concept young people learn about the concept of STE(A)M (science, technology, engineering, (art) and math) in a different way than what we are used to in regular classes. With the help of attractive robotics challenges, children get enthusiastic about science and technology, through the game they develop and strengthen their logical and technical way of thinking.

For the robotic part of FLL, teams plan, construct, programme and test an autonomous robot so that it can carry out a range of missions in the 2.5 minute long match on the FLL mat. Tasks on the mat represent the most typical problems of the current FLL challenge: the 2014 season was themed World’s Class, in the 2015 season it was themed Trash Trek, and in the 2016 season, Animal Allies (Fig. 1).

III. PREPARING FOR THE COMPETITION

Preparations for the regional, national competition and later international, are very intense. Only in the third season did we first encounter a child who has already had some experience with Lego robots. The vast majority of children have no experience with programming, only a few have some experience with programming in Scratch.

Work starts in early September when teams receive bricks to assemble models to FLL mat. Students must follow building instructions very carefully, as imprecisely built models can influence the choice of strategies and can impair the robot’s performance.

Figure 1: FLL mat from 2014, 2015 and 2016
When constructing models (Fig. 2) children can get a lot of knowledge and ideas associated with mechanical devices and mechanisms. The models include many basic mechanical principles that can be found in advanced mechanical devices, mechanisms, and structures of real life.

Students can explore the gear mechanisms when constructing models. When the FLL mat is ready, a detailed review of the missions must be done, including precise and repetitive reading instructions and watching videos with a description of the requirements. Students then determine a strategy and make a detailed plan route. (Fig. 3). It is important to indicate the points of assurance, sensors may also be used.

We can now start building the base (Fig. 4) of the robot from the Mindstorms EV3 robotic kit. When constructing the base, it is very important to pay attention to the size and weight, to select the most appropriate tires, to plan the use of sensors and their positions, to think where the robotic arm will be located, etc. A lot of attention must be paid to whether the robot is well balanced and whether the center of gravity is in the right place. Improper weight distribution may cause the robot to behave erratically, for instance undesirable turning, so the location of the brick is very important. We should also not ignore the weight of the attachments and connections, which can increase the uncertainty of the robot.

When choosing tires it is necessary to carry out several test runs. Larger wheels may be faster, but less precise, with smaller wheels, the robot is slower, but you can achieve greater accuracy. Harder rubber is less deformed and less likely to withdraw from the rim. The rear wheels or sliders should move in all directions and be of the same height as the front wheels.

We can use four large motors or three large and one middle motor. The base of the robot usually has two to three light sensors, a gyro sensor, possibly a touch sensor. We want to construct the most solid and compact base with straight sides. When driving along the wall you might find a small side wheels come in handy. Changing attachments on the robot has to be as sleek, fast, and efficient as possible, even with shaky hands during the competition. The base must allows free access to the battery charging input and USB port.

Parallel to the construction of the base we start learning how to programme. We find knowledge in books and on the internet, where there is a real treasure trove of ideas and tools for learning. We begin with a variety of challenges: driving straight is required, especially when you want to drive fast, maintain the direction of the gyro sensor, tracking lines (Fig. 5).

When we are satisfied with the base of the robot, which is agile, and how it moves around the mat with appropriate speed and power, we can start with the construction of attachments.

Older children who have already participated in the program can transfer their experience and knowledge: their younger colleagues can learn the basics from them and get information about the barriers and traps which can occur in the competition. With peer involvement in all phases and areas of work, a positive climate can be felt in the team. Children learn from each other through conversation, discovery, research, and debate. We're trying to create a learning environment that encourages students to be more active, with more effective learning, commitment to the quality knowledge and taking responsibility for it.

Initially fun and very comfortable work with robots brings children new challenges in mechanics and programming. Usually it turns out that some children are best constructors, others are better programmers, and few are very good at both. To effectively solve tasks and eliminate problems in the robotic table, good cooperation of both constructors and programmers is crucial. Both carefully observe what is happening with the robot, analyze its mission, try to determine the cause of unwanted behavior of the robot, and remove it. Slow-motion video of the robot can be very helpful. Each ride has to be tried out as often as possible, in different conditions, in different racing fields and this way we can gain as much experience as possible to foresee several possible mistakes. We want to ensure maximum accuracy in the performance of all tasks, so we try to prevent mistakes either with the design of the robot or with programming.

That children do not lose motivation, training matches are organized in early November. Training matches are usually a new momentum for a team, because new ideas are born and usually we realize there is still quite some
work to be done. The training is excellent preparation for the competition (Fig. 6).

While working on a robot, teams need to write a robot diary, where the process of construction and the programming process is well described and documented. A technical map is divided into three parts, three skill areas. One chapter is dedicated to mechanical design, where teams put evidence of structural integrity: durability, mechanical efficiency, and mechanical equipment of the robot. The robot must be able to withstand the rigors of competition. The second chapter is dedicated to programming (Fig. 7): the quality and efficiency of programming. To visualize the programming process and the steps in improving programs (use of loops, my blocks, math, and comments). The third chapter is devoted to strategy and innovation. Here we present a complete cycle of improvement, the process development and interpretation of improvements, modifications, advantages and disadvantages of our solutions, the possible errors ... Here teams should clearly define a strategy to tackle all tasks and specifically highlight innovation and the basic features of the robot, which add a lot of value.

Robotic diary serves as a basis for the preparation for a technical interview with judges where students have to present the process of building a robot, attachments and programming. During the interview there should be a demonstration of the drive of the robot we are most proud of, and to answer the judges' questions.

The main competencies that students acquire are the development of imagination and spatial performance, conquering mathematical and technological skills, learning programming, and learning a variety of computer technology while cooperating with each other and with experts. It is experiential learning, developing creativity and innovative problem solving. Creativity is creating new connections, which can happen only when the mind is enabled to do flexible and adaptive functioning. FLL allows and encourages all this.

IV. CONCLUSION

Participating in the FLL has had a great influence on author of this paper. As a teacher, the author has changed his way of teaching a lot. Children now have a much more active role in the learning process. As a teacher, the author of this paper is usually their supervisor, assistant, and sometimes even the mediator. Teacher directs students to reflect on the achievements, thereby increasing their involvement in monitoring their own learning process and, consequently, their responsibility for their own work and performance quality.

Children who had participated and still participate in the program obtain a wide range of skills. Computer logic allows them to understand and program the robot; their technical knowledge comes in handy when they are constructing machines, because working with motors, sensors, levers, and gears do not pose any major problems. They must also be able to cooperate with other members of their group and add their piece to the mosaic.

This type of work is quite different from everyday school life because it requires a different type of work from the students, which allows them to become more independent, and the quality of their knowledge in combination with experience is sharply increased.

Abstract - The article provides results of a research study on safety of children on the Internet, and on use of the information-telecommunication technology (ICT) from the aspect of safety. The study was conducted on the elementary school children using paper or web-based questionnaires. It involved 1,232 students from grades one through eight of elementary school (approximately 400 students per survey), ages 7-15. The study was conducted over a period of eight years on three occasions (2008, 2011, and 2015) in elementary school Kastanjer, in Pula, Croatia. Based on the questions and answers, the findings are separated into groups: a) use of ICT among students; b) parents/teachers cooperation and provision of support to children/students in regard to cyber bullying; and c) students’ understanding of what constitutes cyber bullying and their response towards unwanted harassment. The results show poor informational literacy of students in terms of safety. Parents need to invest much more effort in recognition of predation and dangers of the ICT use in order to protect their children, and teachers should spend more time and more educational contents related to the elements of cyber bullying and their prevention in order to teach their students.

I. INTRODUCTION

Use of computers, smart phones, and other devices that can connect to the Internet is spreading fast, in business and education as well as in a family circle. In families, the most frequent users of the information-telecommunication technology (ICT) are children. Most children have access to technologies with the Internet access, and learn in fun ways how to use ICT. At the same time, development of technology, its interactivity and increasing possibilities of communication represent a risk for all users, particularly children.

Today, parents are often facing the fact that their children know more than they do, and that children are growing up in a virtual world that is significantly different from the world the parents know. Therefore, parental home-upbringing becomes more complex and presents ever increasing challenges in providing support and safety for their children. Parents’ worry is warranted because there are real dangers, and the worry is increased by parents’ lack of understanding of dangers brought in by the technology. On one hand, parents do not want to stop progress of their children since the ICT bring many benefits, while on the other hand they do not know enough, which represents potential danger.

Most youth and children, while playing online video games, watching videos clips, or socializing on social networks, develop their digital competences [1]. Through playing video games, whether online or not, a child develops, because video games stimulate thinking processes, associative thinking, support intuition and hypothetical thinking, improve coordination of movements, and represent unbiased teachers with unlimited patience [2]. A child releases emotions while playing video games, and video games can be useful tools in learning because they provide instantaneous reward.

European Parliament and the Council of the European Union in their recommendations on key competences for lifelong learning state that digital competency is a tool every person should have, in order to adapt to the fast-changing world [3]. The key elements of digital competency are the basic ICT skills: use of computers for exploration/browsing, assessment, storage, creation, presentation, and exchange of information, as well as creation of networks of cooperation through the Internet [4].

Children who had earlier exposure to the Internet and who grew up in that world show better knowledge and skill in computer use, mathematics, and reading, as well as in the general educational achievements. Research conducted in Australia, intended to establish the vocabulary development in children between four and eight years of age, on a sample of more than 9,000 children who had access to the Internet, has shown a developed vocabulary and well-developed verbal abilities. The exception observed by this research was in a negative relationship between use of game consoles and vocabulary development. Children-users that used only game consoles had lower linguistic abilities than other children [1]. It is important to understand the relevance of digital technology as an integrated tool for learning, which – when used reasonably – promotes linguistic, cognitive, and social development of youth and children.

The conclusion that arises is that children should be encouraged to use ICT, while it is exceptionally important to teach them how to use such devices in the correct and appropriate ways [5].
However, the fact remains that is not possible to control the contents other users will publish over the Internet, which brings into focus the other aspect of the ICT use, which is safety of children on the Internet and their exposure to disturbing contents. Children and youth are facing media challenges, primarily cyber bullying, as well as potential sexual harassment through social networks [6].

Results of the EU Kids Online survey conducted in 2010 in 25 EU countries indicates that it is necessary to continuously teach children and youth regarding safety standards and contents to ensure that all children have a minimal basic safety knowledge. Such an approach would prevent children from being digitally isolated and unqualified [7], [8], [9] and digitally illiterate. To be literate in a digital age involves more elements, one of which is the skill for responsible use of technology.

In the upbringing and education of children, from the point of the ICT use, teachers and parents have equal roles, teachers in school, and parents at home.

Review of the existing curriculum for elementary school [10] clearly shows that none of them require teachers to cover areas of safety of students on the Internet in any of the subjects. While use of computers, the Internet, and ICT is used in many subjects (with specific goals and tasks), from Croatian language, nature and social sciences, technical culture, music and arts, foreign language, extracurricular activities of the information-communication technology (which is a part of the teaching process only in a very small number of elementary schools outside of the regular curriculum – in Pula, for example, only in one of 10 schools) and the elective subject of informatics (taught only to those students who choose this subject), at the same time, there is only one mention of the acceptable use of e-mail (Theme 13. Acceptable behavior when using e-mail. Educational goals: communicating over the Internet in an acceptable mode). Since this educational content is mostly not presented in schools, most students have no chance to hear it, and it all depends on their teachers of Informatics science (for students who elected the subject) who may choose, but are not required to talk about safety of students on the Internet while working on some other subject. The same is true for other subjects, where the situation is even worse since teachers of other subjects have no obligation to mention the issue, and have poor understanding of ICT.

II. SAMPLES AND RESEARCH METHODOLOGY

This article describes the findings of the survey conducted in the Elementary school “Kastanjer” in Pula, with participation of students from the first to the eighth grade. The survey was conducted on three occasions over the period of eight years (2008, 2011 and 2015). Elementary school students participated in the survey by manually filling in paper forms or, alternatively, by filling in web forms. Survey questions and findings are divided into three groups: a) Use of ICT among students, b) Parents/Teachers cooperation and provision of support to Children/Students in regard to cyber bullying, c) Students’ understanding of what constitutes cyber bullying and their response towards unwanted harassment.

The survey involved 1232 students with valid answers (403 students in 2008, 362 in 2011 and 467 students in 2015). Participants were students from the 1st to 8th grade of the elementary school, 7-15 years of age and gender-wise, with slightly higher participation of boys (645) than girls (587).

In the first survey, students from 2nd to 8th grade manually filled in the paper forms. The second survey applied the same method of data collection and students from the 2nd to 7th grade participated in the survey. In the third survey, students from the 1st to 4th grade manually completed paper questionnaires and from the 6th to 8th grade, students completed web questionnaires. Questionnaires were, on all three occasions, completed anonymously and teachers assisted younger students when they came across new words or phrases. First and second survey had the same questionnaire (21 questions, 19 of the closed type and 2 of the open type), while the third was more extensive (81 questions, all of them of the closed type) and was consistent with the questionnaire used in the survey “EU Kids Online”.

III. QUESTIONNAIRE, FINDINGS AND ANALYSIS

The questionnaire contained three groups of questions. The first group contained questions about ICT use among students, the second group dealt with cooperation of parents/teachers and provided support to children/students from the aspect of cyber bullying and the third group of questions was about students’ knowledge of the elements of cyber bullying and their response to the unwanted harassment. All answers were grouped by grades: 1st and 2nd, 3rd and 4th, 5th and 6th, and last, but not least, 7th and 8th. The reason for such combination is that there are minor differences in students’ age. Distinctions are also made in terms of the gender of participants and the year the surveys were conducted.

A) ICT use among students

Findings on the ICT use among students are shown in Table I (Findings of the posed questions). Questions are as follows: Q1 – How many times a day do you use the Internet?; What do you do most often on the Internet? Options provided were: Q2 – Play online games; Q3 – I am exploring data and school curriculum; Q4 – Use E-mail; Q5 – Watch movies and listen (and download) music; Q6 – Chat with friends; Q7 - Read news.

In the first question (Q1 – “How much time students spend on the Internet”), it is indicative that, as expected, older the students, the more time they spend on the Internet.
It was also expected to find that boys spend more time on the Internet than girls. In 2015 there is a significant increase of time spent on the Internet among all age groups. At average, boys spend 238 minutes per day on the Internet and girls, 175 minutes per day. This finding cause concern in light of the fact that many students answered that they spend approximately 6-10 hours per day on the Internet.

Q2-Q7 was focused on the answers of students’ activities on the Internet. Findings show that top four activities are Q2, Q3, Q5 and Q4: Playing online games, exploring educational contents, watching (and downloading) movies/listening (and downloading) music and reading news and entertaining contents. They spend less time using e-mail and chat services. Most of boys (2/3 in 2015) spend the majority of time playing online games (Q2) and exploring educational contents, while girls (also 2/3 of them) spent the majority of time playing online games. In 2008, the findings were different: 45% of boys used the Internet most often to explore educational contents and girls (50%) to play online games. Findings of the survey conducted in 2011 are quite consistent with the findings of the 2008’s survey.

It is also expected to find that boys spend more time on the Internet than girls. In 2015 there is a significant increase of time spent on the Internet among all age groups. At average, boys spend 238 minutes per day on the Internet and girls, 175 minutes per day. This finding cause concern in light of the fact that many students answered that they spend approximately 6-10 hours per day on the Internet.

The second group identified four questions (Q1-Q4) that were posed in 2008 and 2011 and 10 questions (Q5-Q14) that were posed in 2015.

The questions were: Q1 – Do your parents check the Internet sites you visit?; Q2 – Have your parents talked to you about dangers on the Internet?; Q3 – Have you talked to your parents about the Internet content that bothers you?; Q4 – In the near future, the school will give a lecture for parents about the Dangers of the Internet. What do you think, are your parents going to attend it?; Q5 – Do your parents encourage you to explore the Internet and learn online on your own?; Q6 – Do you have some shared online activities with your parents?; Q7 – Have you ever talked to your teacher about your online activities?; Q8 – Have you ever received any help from your parents, teachers or friends when you couldn’t do or find something on the Internet?; Q9 – Have your parents, teachers or friends ever explained to you why some sites are good or bad?; Q10 – Have your parents, teachers or friends ever suggested how to safely use the Internet?; Q11 – Have your parents, teachers or friends helped you when something bothered you on the Internet?; Q12 – Have your teachers set rules of what you do or find something on the Internet?; Q13 – Have your parents, teachers or friends ever suggested how to safely use the Internet?; Q14 – Do your parents sometimes check what web sites you are visiting?; Q15 – Do your parents sometimes check a) what web sites you are visiting? (13a); b) software for parental control or other tracking tools of the visited web sites? (13b); c) program, service or contract that limits your time spent on the Internet? (13c); d) software that prevents spam or junk messages and viruses? (13d); Q14 – Do your parents sometimes check a) what web sites you are visiting? (14a); b) your e-mail messages or instant messages? (14b); c) your profile on social networks or online communities? (14c); d) friends or contacts you are adding to your social profile / instant messages account? (14d).

Although it is not shown in the Table II, almost all students started using ICT before they started going to school: Average age when boys started using ICT was 5.6 years and 6 years of age for girls.

Findings of the first four questions are shown in the Table II, and the others in the Table III.

Based on the answers to the first question (Q1) parents, in general, insufficiently control online activities of their children. Among younger students, it is at around 50% (which is not so bad), among older students, from the
Findings from the survey conducted in 2015 are quite satisfying (over 90%), in comparison to the earlier years when percentage of parents talking to their children about the dangers were at around 10%. This data primarily relates to the students from the 1st to the 4th grades.

The last question in this group was “In the near future, the school will give a lecture for parents about the Dangers of the Internet. What do you think, are your parents going to attend it?” Findings are diverse and they go from 30% to 90%. Lower percentage is in the lower grades and significantly higher, in the higher grades. This question was not posed in the survey conducted in 2015, therefore, comparative analysis could not be completed.

It is very important to encourage children to use the Internet (Q5), as it brings many comparative advantages. When the answer to the Q6 is positive (Do you have some shared online activities with your parents?), it means that children have parental support. Sadly, only 29%-59% of parents understand advantages of such support and encourage children to use the Internet or share activities with their children on the Internet. This will become a problem when children will have questions and won’t ask parents to help them, and would instead ask either a friend or, more often, try to find answers on the Internet. It is also very important that teachers show interest and concern (Q7) for students’ activities on the Internet. Findings show that at average 40% of students interacted with their teachers and got a positive response. In lower grades, the average responses were 17% and 25%, and in higher grades, the percentage was slightly higher. It is possible that teachers lack practical knowledge in this area, but it is always positive to show concern.
