Answers to Q8 to Q11 are elaborating on the effort of parents, teachers and friends to ensure children’s safety. Results go from 63% to 73%. It is not bad, but it could be better.

Q12 deals with rules set by teachers, what can and cannot be done on the school’s Internet. The average findings are at 40%, and it is again lower in the lower grades (from 10% to 28%), and it indicates that primary school teachers lack knowledge of the safety on the Internet and need further education in order to be able to act responsibly.

Q13 offered four options and gives us information how much parents invest in the technical protection of their children from dangers of the Internet (protective software and/or filters). Average result is at the modest 38%. It is very low, especially in light of public campaigns to protect children from dangers in cyber space.

The last question Q14 answers how engaged parents are in the protection of their children. Findings in this segment are quite modest (21%-43%), reasons could be parents’ negligence or lack of knowledge. Outcome should be better, especially because it requires only time spent with children and not any financial investments.

C) Students’ understanding of the elements of cyber bullying and their response to the unwanted harassment

Third group of questions relates to the knowledge of cyber bullying. As in the second group of questions, questions that were posed in 2008 and in 2011 (Q1-Q5) are picked out as well as those posed in 2015 (Q7-Q15).

The questions were: Q1 – What bothers you the most on the Internet: a) Security – identity theft (a0); b) Advertisement – commercials (a1); c) Pornography (a2); Bad manners of the members of the Internet communities, such as insults, swearing etc (a3); Q2 – Have you ever felt bad for experiencing one the following things on the Internet a) seen photos of violence (a4); b) been insulted (a5); c) been threatened (a6); Q3 – Has anybody posted your photos or video clips with your images to someone without your permission? Q4 – Has anybody used your e-mail with your permission? Q5 – Has anybody used any part of your Internet identity without your permission?; Q5 – Has anybody posted your photo without your permission?: Q7 – Have you ever looked for new friends on the Internet? Q8 – Have you added a new friend to your friend’s list or on your contact list without meeting him in the real life?: Q9 – Have you ever sent your personal data to somebody you never met outside of the cyber space?: Q10 – Have you ever sent your photos or video clips with your images to someone you have never met outside of the cyber space?: Q11 – Have you ever contacted somebody online that you first met outside of the cyber space?: Q12 – Have you ever went to meet a person you met online?: Q13 – Sometime kids tell or do things that can bother you or the others, offend you, hurt you or make you or the others feel uncomfortable. Has anybody treated you that way on the Internet within the last 12 months?: Q14 – Harm, hurt, assault, anxiety or humiliation can be the outcome of the sexual images or messages of the other person on the Internet – Has anybody hurt you in that way within the last 12 months?

Findings are shown in Tables IV (Q1-Q5) and V (Q7-Q13)

First question (Q1) was testing students’ sensibility to disturbing contents that may be received via e-mail or could come across on the Internet. Findings show that students have low understanding of the potential dangers. While low percentage of students in the lower grades is reasonably expected (they are still little and don’t understand terminology), results for the group of students from the 5th through the 8th grade raise concern

Individual percentages go up to 40%-50%, but that is comparatively low, knowing what kind of situations they may come across. Parents and teachers share the responsibility for the situation.

Next question (Q2) relates to the potentially harmful experiences students’ came across. There is low percentage of such experiences, up to 20%, but that is, never the less, raising concern. It is important to educate children – students. When teachers or parents don’t understand dangers that ICT users can face, let them learn about it by themselves, or help them take a course.

Following three questions (Q3-Q5) relate to identity theft or fake user’s profiles. Students need to be aware how to protect their e-identity. Again, percentages are not high, they go up to 30%, but that is more than enough to raise concern.

Following six questions (Q7-Q12) tested students’ behavior in terms of safety. Although activities can be well intended (to make friends), caution is always recommended, as activities are occurring in the electronic media environment. This is primarily parents/teachers domain, as they need to educate children/students how to safely use the ICT and avoid potential dangers. Risky behavior in some elements is alarming, as it goes up to 30%.

The last two questions (Q13 and Q14) deal with the exposure to cyber bullying. Questions pertained not to the potential dangers, but to the actual bullying that occurred (or students experienced them as such). Average of 16% is very high as it targets the most vulnerable children/students.

Due to the limited space, this research is presenting some 20% of the obtained data. The article aims to raise awareness among professionals and parents about dangers that anyone can face, and especially to educate children how to avoid unwanted harassment on the Internet.

More information about the research and findings in Croatia, can be obtained from the first author, and for the findings of the EU survey, on the official web site of the project [11].

IV. CONCLUSION

The study describes findings of the survey that was conducted over the period of eight years. The survey focused on children’s safety on Internet, use of the ICT and its trends. Students from the 1st to 8th grade of elementary school participated in the survey. Findings were summarized in three groups: a) ICT use among students, b) Parent/Teacher cooperation and provision of support to Children/Students in regard to cyber bullying, and c) Students’ understanding of what constitutes cyber bullying and their response to unwanted harassment. Obtained data were compared to the findings of a similar survey “EU Kids Online”, conducted in 25 EU countries.

Obtained data show that students start using ICT at younger age than before, they use it more frequently and for longer periods of time, while still having low informational literacy from the aspect of safety. Parents need to invest more effort in learning advantages and dangers of using ICT in order to support and encourage children to use ICT and, on the other hand, to protect them from cyber bullying. Teachers need to invest more time and effort in teaching children the elements of cyber bullying and its prevention, even when school curriculum does not require them to do it.

Implementacija G Suite alata u nastavu stručnih predmeta iz područja računalstva

Lovro Šverko, prof., Mario Martinović prof.
Srednja škola za elektrotehniku i računalstvo, Rijeka, Hrvatska,
lovro.sverko@sser.hr, mario.martinovic2@sser.hr

Sažetak - U ovom radu predstavit će se pilot projekt „Implementacija Google Suite alata u nastavu stručnih predmeta iz područja računalstva“ Srednje škole za elektrotehniku i računalstvo Rijeka, problemi prilikom implementacije i načini na koje se ti problemi mogu izbjeći ili riješiti, prednosti i nedostatci korištenja G Suite za obrazovanje te rezultati istraživanja provedenog među učenicima i nastavnicima koji sudjeluju u projektu. Ovo istraživanje imalo je za svrhu istražiti stavove učenika i nastavnika o utjecaju G Suite alata za obrazovanje na kvalitetu nastave, rad na zadatcima, komunikaciju između učenika i nastavnika te mogućnost djeljenja nastavnih materijala u digitalnom obliku. Istraživanjem je obuhvaćen uzorak od 105 učenika upisanih u smjer tehničar za računalstvo – novi kurikulum i 8 nastavnika stručnih predmeta iz područja računalstva. Cilj rada je opisati proces implementacije G Suite alata u rad škole te prikazati prikupljene podatke istraživanja, a kao zaključak rada prikazane su prednosti i nedostatci uvođenja G Suite alata u nastavu.

I. UVOD
Nakon što je predstavljen u svibnju 2014. godine, projekt “Google aplikacije za obrazovanje” (današnji naziv “G Suite za obrazovanje”) uspješno je okončao pilot fazu. Ovaj online paket alata integrira Google Učionica, Disk, Dokumente i Gmail kako bi potaknuo učitelje da ih koriste za dodjeljivanje i prikupljanje zadaća online, kao i za poboljšanje komunikacije s učenicima. Google Učionica se besplatno nudi korisnicima paketa G Suite za obrazovanje. Dostupna je na 42 jezika, među kojima je i hrvatski (Google Učionica).

Rezultate istraživanja o utjecaju G Suite alata na obrazovanje, na uzorku od u 880 000 učenika, u 6 država, Google je objavio na ovoj adresi[1].

Prvi korisnici G Suite za obrazovanje u Srednjoj školi za elektrotehniku i računalstvo, učenici 3.d razreda, koji se obrazuju po novom strukovnom kurikulumu, smjer tehničar za računalstvo (25 učenika) i jedan nastavnik stručnih predmeta iz područja računalstva, počeli su koristiti G Suite s ciljem testiranja rada u nastavi s navedenim alatima. Danas je na školskoj domeni prijavljeno 45 nastavnika, 1 administrator, 2 testna korisnika i 201 učenik.

II. IMPLEMENTACIJA ALATA U RAD ŠKOLE
A. Pilot projekt
Srednja škola za elektrotehniku i računalstvo u Rijeci je u školskoj godini 2016./2017. počela sa provedbom
projekta “Implementacija alata Google aplikacije za obrazovanje”. Pilot projekt je posljedica sve konfliktnijeg stanja između, s jedne strane kompetencija koje bi učenici trebali usvojiti i s druge strane klasičnog oblika nastavnih sredstava i pomagala te metoda poučavanja (udžbenici, ploča i kreda, projektor…). Konflikt je posebno izražen u sektorima strukovnog obrazovanja poput elektrotehnike i računalstva.

Pojednostavljeno rečeno, u odnosu suprotnosti stoji sadržaj koji se kontinuirano i sve brže mijenja i udžbenici koji po svojoj prirodi ne mogu pratiti te promjene, a u nekim slučajevima ih i nema.

Kao logično i provjereno rješenje nude se neki od IKT alata poput onih objedinjena u G Suite. Za primjer korisnici – učenici kao alat za vježbe ustreza je rješenje s kojim se komunicira s one strane suprotnosti novim” materijala i kodova za primjenu offline u digitalnom obliku. Nakon testiranja Moodle i Edmodo alata, na red je došao Google Disk kao alat za dijeljenje materijala i Gmail kao alat za komuniciranje s učenicima (većina učenika je imala privatni Google račun). Vrlo brzo se pojavilo problem s organizacijom dokumenata, objavljivanjem obavijesti putem e-pošte te pregledavanja nepregledne liste e-pošte s učeničkim odgovorima, upitima i predanim zadacima. Kao naručena, Google Učionica je u tom razdoblju postala dostupna za obrazovne institucije i u Hrvatskoj.

**a) Dinamika**

Budući da je korištenje G Suite kolekcije alata bilo dobro prihvaćeno od strane učenika, a uvelike je olakšavalo svakodnevan nastavnički rad, prvi nacrt pilot projekta predstavljen je na Stručnom vijetu nastavnika...

b) Sudionici

Prije no što učenici i nastavnici mogu započeti s korištenjem G Suite-a, administrator mora izraditi njihove školske Google račune. Školski Google račun izrađen je za sve nastavnike, učenike koji se obrazuju po novom strukovnom kurikulumu, smjer tehničar za računalstvo, koji aktivno koriste Učionicu te za sve učenike završnih razreda sa svrhom prijave završnih radova putem Google Obrazaca. U izradi školskog kurikuluma sudjelovali su svi nastavnici, a Učionicu koriste nastavnici stručnih predmeta iz područja računalstva te mali broj nastavnika iz ostalih predmeta (poput Fizike, Engleskog jezika, Vjeronauka i sl.).

B. Google Suite za obrazovanje

a) Google Učionica

Google Učionica je dostupna samo učenicima i nastavnicima sa školskim računom Google Suite-a za obrazovanje. Ovaj alat nastavnicima stići vrijeme, pojednostavljuje organiziranje predmeta i unaprijeđuje komunikaciju s učenicima i kolegama. Osmišljen je kao pomoć nastavnicima pri izradi i prikupljanju zadataka bez upotrebe papira, s mogućnosti automatske izrade zadatka i stvaranja kopije dokumenta za svakog učenika. Na Slici 1 prikazan je izgled početne stranice Učionice s prikazom izrađenih predmeta.

Mobilna aplikacija za Android učenicima i nastavnicima omogućuje prikaz predmeta i komuniciranje u stvarnom vremenu. Učenici mogu otvoriti svoje zadatake i raditi na njima izravno na mobitelu ili tabletu, a nastavnici mogu pratiti tko je predao rad i pregledati zadatak – u školi ili u pokretu.

b) Google Disk i Dokumenti

Google Disk (engl. Google Drive) je online servis za pohranu podataka „u oblaku“. Koristi se za izradu, sinkronizaciju, dijeljenje i izmjenu dokumenata između korisnika. Google Dokumenti omogućavaju izradu, dijeljenje i izmjenu tekstualnih dokumenata, tablica i prezentacije unutar preglednika. Na jednom dokumentu može raditi više korisnika istovremeno, a svaka promjena se automatski sprema.

c) Gmail

Gmail je sustav za e-poštu koji je intuitivan, ima odličnu antivirusnu zaštitu i zaštitu od neželjene pošte, integriranu pretragu i kalendar. Za korisnike paketa za obrazovanje ne sadrži oglase.

d) Kalendar

Google Kalendar je aplikacija za jednostavnu izradu, dijeljenje i organiziranje rasporeda koja je integrirana s ostalim aplikacijama poput Učionice, Diska, Kontakata i Gmaila.

e) Hangouts

Google Hangouts je jednostavna aplikacija za videokonferencije i razmjenu poruka.

f) Ostali alati i aplikacije

Postoje mnoge aplikacije koje su integrirane sa G Suite alatima. Neke od tih aplikacija su: GeoGebra (graafički kalkulator za funkcije, geometriju, algebru, analizu, statistiku i 3D geometriju), LucidCharts (alat za izradu dijagrama), LucidPress (alat za dizajn tiskanih i digitalnih publikacija), DuoLingo (platforma za učenje jezika), AutoDesk Project Ignite (platforma za dizajn 3D projekata), WeVideo (alat za obradu videa), i još mnoge druge.

C. Primjeri primjene G Suite u radu škole

b) Primjeri iz nastave

Jedna od prednosti korištenja Učionice u nastavi je jednostavna izrada zadatka. Umjesto klasične izrade radnih listova na papiru, dovoljno je izraditi željeni dokument u Google Dokumentima te ga u formi zadatka predati učenicima na Učionici. Svaki učenik može dobiti svoju kopiju radnog lista koji, nakon izvršenog zadatka, jednostavno predaje u zadatak na Učionici.

Slika 3 – Evidencija izrade zadataka u predmetu
Tako predani radni listovi se automatski spremaju u mapu s nazivom zadatka na Disku, a dostupni su za pregled i u izrađenom zadatku u Učionici (Slika 2). Nastavnici mogu pratiti predavanje zadataka u stvarnom vremenu ili podacima o vremenu predaje zadatka mogu pristupiti kasnije. Također, nastavnici se obavještavaju kada učenik predaje zadatak nakon zadanog roka.

Sljedeća prednost korištenja G Suite-a je mogućnost davanja povratnih informacija učenicima. Učenici mogu poslati svoj prijedlog ili pitanje kao javni ili privatni komentar u zadatku na Učionici. Javni komentar zadatka vide nastavnik i svi učenici na predmetu, dok privatni komentar vide samo nastavnik i učenik koji ga je postavio te su izvrstan način davanja povratne informacije samo jednom učeniku.

Učionica također automatski izrađuje evidenciju zadataka za svaki predmet (Slika 3). Podatci se sprema na pregled na Google Tablicu kojoj se već jednostavno pristupa iz Učionice, tako da je nastavnicima olakšano praćenje rada učenika kroz cijelu godinu.

Integracija Učionice s Kalendarom i Gmail-om omogućuje automatsko slanje obavijesti o nadolazećim rokovima, novim zadaćima, objavama i komentarima te mogućnost slanja tjednih izvješća o radu učenika roditeljima ili skrbnicima, ukoliko ih se pozove u Učionici. Roditelji ili skrbnici koji prihvataju poziv imaju pravo po Java aplikaciji Google-ovih dokumenata pomoću Google Obrascima. Radi donošenja kvalitetnijih zaključaka uspoređivali smo podatke po više kriterija:

- odgovore učenika i profesora na ista pitanja,
- podatke dobivene statistikom Google Suite-a i
- podatke dobivene anketama.

B. Statistički podaci Google Suite-a

a) Broj sudionika

b) Datoteko objavljene na Google Disku

Pregled broja datoteka pohranjenih na Disku izličen na Slici 5 pokazuje da je broj objavljenih datoteka na Disku višestruko porastao, ali je uočljeno da je istovremeno rastao broj Google-ovih dokumenata pomoću Google Obrascima. Naknadno smo ovu činjenicu povezali s nekim mišljenjima učenika i nastavnika.

Kao posebno važan podatak ističemo da su učenici viših razreda „računalstva“ u prosjeku objavili više od 57 datoteka po učeniku.

c) Aktivnosti na Google Učionici

U razdoblju od listopada 2016. godine do siječnja 2017. godine minimalan broj objava u dvotjednim razdobljima u svim razredima nije padao ispod 19, a maksimalan je bio 33. Broj objava ima rasti trend, a udio učeničkih objava trostruko je porastao.

d) Komunikacija putem e-pošte

Kao što je prikazano na Slici 6, u ovakvom načinu rada, komunikacija putem e-pošte pokazala se nepogodnom.

C. Ankete učenika i nastavnika

Anketirani su učenici razreda novih strukovnih kurikuluma (pet razreda) te kolege SV računalstva. Većina sudionika slaže se da je prihvatljiviji sadržaj u elektroničkom obliku (učenici 83%, nastavnici 75%), ali

a) Važnost različitih oblika digitalnih sadržaja i komunikacije

Učenici i nastavnici se dobrim dijelom slažu u pogledu značaja različitih usluga na Google Disk-u i Učionici. Grafikon na Slici 7 prikazuje prosječne ocjene koje su sudionici dali pojedinim oblicima sadržaja.

Učenici i nastavnici najkorisnijim smatraju objavljivanje digitalnih sadržaja u okviru Google Učionice (zadatci, dokumenti, prezentacije i ostali multimedijski dokumenti), a jedino veće odstupanje vidi se kod ocjenjivanja (što je, vjerojatno, većim dijelom sociološki problem).

U istom smjeru idu učenički odgovori na pitanje koji digitalni sadržaj im nedostaje, prikazani na Slici 8 (najtraženiji su zadatci i pitanja te multimedijalni sadržaj).

b) Mišljenja učenika i nastavnika

Za kraj smo ostavili nekoliko primjedbi nastavnika i učenika koje svakako treba uzeti u obzir.

Primjedbe nastavnika:

- „Vremenska zahtjevnost kod pripreme materijala koji se ne sastoji samo od slova i znamenki, nego ima grčka slova kao simbole, uključuje razlomke, ekspONENTE, potencije.“
- „Trebam cijelu koncepciju rada koju sam već napravila sada opet prepisivati u Google i to prilagođavati novom mediju, jednostavno dodatni posao ako već imaš sve razrađeno.“
- „Volio bih vidjeti bolji sustav za sprječavanje eventualnog prepisivanja.“

Neki odgovori učenika na pitanje „Ako bi se Google aplikacije prestale koristiti u nastavi, kako bi to utjecalo na tebe?“ bili su:

- „Donekle nam to spremi na redirect i učenje, ali ne zadovoljavaju ili miru učenje.“
- „Miss to Google aplikacije učenja, ali to je uskoro.“
- „Ako će se Google aplikacije prestale koristiti, armi će se sa svim ovim.“

Metodologija

Učenicima i učenici koriste pojedini oblici sadržaja?

Slika 6 – Dnevni prosjek poslane e-pošte

Slika 7 – Koliko učenicima koriste pojedini oblici sadržaja?

Valja uzeti u obzir i razvoj Google-ovih alata koji je bio osjetan i u kratkom periodu od tri mjeseca (čak i na naš prijedlog).

S druge strane, moramo imati na umu koliki posao stoji pred nastavnikom koji predaje četiri predmeta u sedam razreda te da je pisanje u bilježnicu i čitanje iz knjige u nekim slučajevima puno efektnije. Dakle, svjesni smo da se, bez obzira na sofisticiranost radi samo o alatu koji u nekim slučajevima ne može, niti smije zamijeniti “živu riječ predavača”.

Raptor  
-intrepreter dijagraama tijeka

Vilim Jurković, prof.
Tehnička škola Zagreb
vilim.jurkovic@skole.hr

I. UVOD

Poučavanje programiranja zahtjevan je posao pogotovo kada ga treba prezentirati apsolutnim početnicima. Edukator mora imati puno umješnosti kako približiti, vizualizirati logiku upravljanja radom računala. Tada se najčešće kreće sa crtanjem dijagraama tijeka, posve isto kao u vrijeme kada se programiranje poučavalo i bez računala u učionici – na papiru. Iako postoji cijeli niz alata za crtanje dijagraama tijeka računalnog programa, postoji jedan koji je mnogo više od toga. Iza ikone izumrlog reptila i naziva RAPTOR (Rapid Algorithmic Prototyping Tool for Ordered Reasoning) skriva se razvojno okruženje za programiranje bazirano na dijagramu tijeka. Radi se o besplatnom softverskom razvijenom na US Air Force Academy, Department od Computer Science. Raptor doista može pomoći u počecima učenja programiranja kada pažnju učenika želimo usmjeriti prema analizi problema, razlučivanju zadatka na manje segmente, razvoju logike i ispravne semantike, a pri tome se što manje opterećivati sintaksom. Dijagram tijeka koji se crta olovkom oduvijek je bio na tom tragu, ali sada, zahvaljujući Raptoru, on može postati i pravo programersko razvojno okruženje. To je krucenje idealno i za samostalni rad učenika kod kuće, jer se u njemu svaka ideja vrlo jednostavno može „oživjeti“ i testirati.

II. MOGUĆNOSTI RAPTORA

Crtajući dijagram tijeka u Raptoru učenici „oživljavaju“ nacrtani algoritam, vide njegovo izvršavanje i kroz interpretaciju lako uočavaju vlastite pogreške. Alat je izuzetno jednostavan i njime se može ovladati vrlo brzo, jer nije potrebno poznavanje složene sintakse. Sadrži tek mali set dobro poznatih simbola za crtanje dijagraama tijeka: ulaz, izlaz, dodjela vrijednosti, odluka, petlja i poziv procedure (Slika 1.). Doista, u Raptoru program jednostavno razlučimo na manje cjeline, procedure, te ih onda pozivamo u glavni program (main), pritom njihovo pozivanje i izvršavanje. Svaka se procedura kreira u zasebnoj novoj kartici razvojnog okruženja. Svoj dijagram tijeka jednostavno slažemo povlačenjem simbola na odgovarajuće mjesto prema osmišljenome algoritmu. Za pokretanje programa i upravljanje njegovim izvršavanjem koristimo tipke Play, Stop, Pause, Step to Next Shape, a po želji podesimo i brzinu izvršavanja. U vrijeme izvršavanja, po lijevoj strani u realnom vremenu, imamo pregled vrijednosti svih varijabli, a po završetku izlaz nam se ispišu u glavnoj konzoli (Master Console). Na raspolaganju nam je upravljanje brojčanim i znakovnim vrijednostima koje možemo smještati i u polja.

Slika 1. Sučelje Raptora
U Raptor su ugrađene sve standardne matematičke operacije, trigonometrijske funkcije kao i funkcije zaokruživanja i slučajnih brojeva. Naravno, kako bismo ostvarili sve programske funkcionalnosti nužni su nam još i standardni relacijski i logički operatori koje Raptor također pozna. Raptor ima ugrađenu pomoć i uredno će prijavljivati sintaksne pogreške, a za svaki će simbol otvoriti prozor pomoći. Zaljubljujući se u pratnju, funkcionalnostima razvojnog okruženja učenik se minimalnom opterećuje sintaksom i najveći dio svoje pažnje može usmjeriti na logiku programiranja. U tome mu jednostavno kroz primjere možemo pomoći i komentiranjem – uz svaki simbol dijagrama jednostavno možemo postaviti „balon“ sa tekstom komentara. Kada dijagram želimo ispisati možemo ga podesiti skaliranjem i pogledati pregled prije ispisa. Važna je i funkcija Print to Clipboard koja nam osigurava jednostavan izvoz crteža u neku drugu aplikaciju za obradu teksta ili slike (Slika 2.).

III. PRIMJENJIVOST RAPTORA U NASTAVI

Raptor ima i svoje naprednije mogućnosti. Iz dijagrama tijeka moguće je generirati kod u nekom od programskih jezika (C#, C++, Java, …), ali tako generirani kod uvijek zahtijeva intervencije i ispravke. Druga napredna mogućnost je objektno-orijentirani način rada (object-oriented mode) u kojem možemo koristiti i UML. Međutim, prva primjenjivost Raptora u nastavi pronalazi se u njegovoj jednostavnosti i mogućnosti da već prvi školski sat programiranja učenici – programiraju i uvidjuju rezultate svake svoje osmišljene aktivnosti kroz interpretaciju dijagrama tijeka. Sa programiranjem se na neki način susreće velika većina učenika i Raptor može poslužiti da se za algoritamski način razmišljanja pobudi dalje veći interes. Mnogi učenici nikad neće postići visoku razinu vještina i znanja o pisanju učinkovitog koda u nekom programskom jeziku, ali će uporabom alata, kao što je Raptor, sigurno unaprijediti svoj analitički način razmišljanja. Sa druge strane, motivirani i za programiranje zainteresirani učenici nakon Raptora znatno brže napreduju u učenju programiranja u nekom od programskih jezika (Python, C++, …).

IV. ISKUSTVA PRIMJENE RAPTORA

Iskustva poučavanja programiranja u više od 20 godina rada sa učenicima jako su određena populacijom učenika, motiviranosti učenika i usmjerenjem. S obzirom da programiranje poučavam u različitim usmjerenjima, od gimnazijskih do trogodišnjih i četverogodišnjih strukovnih, različita su i iskustva. Pa i iskustva primjene Raptora u nastavi programiranja. Učenici tehničke gimnazije, iako motivirani i sa visokim očekivanjima u učenju programiranja, rado prihvaćaju Raptor kao uvod u programiranje u Pythonu. Rješavajući zadatke u Raptoru vizualiziraju tijek izvršavanja programa, grade dobre temelje razumijevanja osnovnih algoritamskih struktura (slijeda, grananja, ponavljanja), a i nekih složenijih kao što je petlja u petlji. Kada iste te zadatke krenu rješavati u Pythonu često se prisjećaju svojih dijagramskih rješenja u Raptoru i kao da im u mislima ostaje dio te vizualizacije. Gimnazijalci u nekoliko sati programiranja u Raptoru sposobni su kreirati već i složenije algoritme npr. sa primjenom polja. Na nastavu programiranja u srednjoj školi ne gledam kao na početak stvaranja budućih programera, iako je ugodno iskustvo kada neki od učenika vide sebe na tom putu. Većina učenika neće nikad postati programeri, a programiranje bi im ipak trebalo biti korisno u izgradnji analitičkog razmišljanja, logičkog zaključivanja i realizaciji cijelog niza drugih funkcionalnih i odgojnih ciljeva nastave. Poučavanje programiranja u strukovnim zanimanjima najčešće zahtijeva ulaganje puno truda u motiviranje učenika. Tako već sam početak učenja programiranja u C++ svojom strogom sintaksom odvlači pažnju učenicima i oni najčešće izuzetno malo razmišljaju, a rješenja pokušavaju pronaći „modifikacijama“ nekih prijašnjih rješenja.
Programiranjem u Raptoru učenici pred sobom vide svaki korak izvršavanja svojeg algoritamskog rješenja, tijek, vrijednosti svih varijabli, rezultate pa i vlastite pogreške. Tada su okrenuti razmišljanju i traženju rješenja, početak programiranja im je zanimljiviji što jako utječe i na motiviranost. I prelazak na programiranje u C++ učenicima izgleda kao nešto već videno te „poznatoj“ priči dodaju sintaksu novog programskog jezika. Ponekad je dobra praksa rješavanje problema najprije u Raptoru, a zatim pisanje koda u C++ ili Pythonu. Želimo li učenicima osigurati napredovanje u učenju programiranja moraju im do kraja biti jasne sve algoritamske strukture, elementarni tipovi podataka, funkcioniranje varijabli, … Već nakon nekoliko sati bavljenja Raptorom napredniji učenici su sposobni napraviti program u kojem se pogađa slučajno generirani broj, a stvarno učenje doživljavaju kao dobru zabavu.

V. ZAKLJUČAK

Raptor je izvrstan besplatni programski alat kojim se u nastavi programiranja kroz „živu“ interpretaciju dijagrama tijeka daleko učinkovitije mogu ostvariti ciljevi u počecima učenja programiranja, od razvijanja analitičkog načina razmišljanja do usvajanja konkretnih programerskih vještina. Raptor učenicima, zbog svoje jednostavnosti i transparentnosti, olakšava usvajanje temeljnih pojmova i postupaka nužnih za razumijevanje programiranja. Posebnu vrijednost Raptora vidim u tome što potiče na razmišljanje i traženje rješenja u vrijeme kad učenike kroz obrazovanje želimo što više usmjeravati prema razvoju kreativnosti, logike i stvaralaštva.

LITERATURA

Virtualno putovanje Europom – primjena informacijsko-komunikacijske tehnologije u nastavi

Nataša Boj*
*III. osnovna škola Čakovec, Čakovec, Republika Hrvatska
natasa.boj@skole.hr

Sažetak - Učenicima osmih razreda ponuđena je tema za razredni projekt „Virtualno putovanje Europom“. Formirani su razredni timovi osmislili putovanje u zamišljenome vremenu, gdje se posjetilo pet gradova po izboru u jednoj ili više europskih država. Zadatak je bio napraviti detaljan plan puta koji ubraja organizaciju prijevoza, pronalazak smještaja, prehranu, kupnju ulaznica za muzeje i galerije te posjećivanje odabranih povijesnih i kulturnih odredišta. Maksimalni mogući troškovi putovanja bili su unaprijed određeni. Po završetku rada učenici su svoje putovanje izložili pred razredom te se osvrnuli na radom stečene dojmove. U ovome su se projektu učenici iskazali znanjem i vještinama iz različitih predmeta: geografije, povijesti, likovne i glazbene kulture, stranog jezika, hrvatskog jezika, matematike i informatike. Informatička znanja i vještine odnosile su se na raznovrsna područja koja su učenici savladali tijekom dosadašnjeg obrazovanja: pretraživanje interneta, procjenu kvalitete web stranica, uporabu različitih web alata, korištenje programa za pisanje i uređivanje teksta, izradu tabličnih proračuna i prezentacija, dijeljenje dokumenata, korištenje obrazovne društvene mreže „Edmodo“, poznavanje autorskih prava. Nakon izlaganja rezultata ovoga virtualnoga projekta, doznaje se da su učenici zadatak ocijenili kao prilično zahtjevan, ali jednako zanimljiv te životno koristan i primjenjiv.

I. UVOD

Nastavni plan i program informatike za osme razrede, koji obuhvaća nastavnu cjelinu „Internet“, ostavlja prostora za planiranje teme „Školski internetski projekti“ u trajanju od osam sati. Osnovni cilj „Školskih internetskih projekata“ ponavljanje je i povezivanje sadržaja različitih školskih predmeta te učenje uz primjenu informacijsko-komunikacijske tehnologije i različitih internetskih alata i usluga. Ovakav način rada očituje primjenu stečenih znanja u problemskim situacijama iz svakodnevnoga života.

Učenje se ostvaruje radom na školskom projektu kojeg nastavnik detaljno planira, prati i ocjenjuje. U procesu planiranja definiraju se ključne...
točke i način vrednovanja individualnog učeničkog napretka i sudjelovanja u projektu. Mogućnost učeničkog samoocjenjivanja u ovome je slučaju uspješno iskorištena. Nastavnica je ocjene učenika, bazirane na osnovi prethodno definiranih kriterija, procijenila realističnima i pažljivo danima.

II. GLAVNI DIO

Ideja učeničkoga projekta „Virtualno putovanje Europom“ pokrenuta je na razini razreda. Formirani su razredni timovi od tri ili četiri učenika, što se smatra optimalnom veličinom, kako se veće skupine često teže organiziraju po pitanju učinkovitosti. Naime, svrha je stvorenih timova ujedno suradničko združivanje znanja i vještina pri rješavanju problema, kao i vježbanje vlastitog umijeća planiranja, pronalaska informacija te kreativnog razmišljanja. Timski je zadatak bio osmisliti putovanje Europom u određenome zamišljenom vremenu te u okviru toga posjetiti pet gradova po svome izboru u jednoj ili više zemalja. Cilj je suradnja u timovima u izradi detaljnog plana putovanja u Europu, pronalazačenje smještaja, načina prehrane, kupnje ili rezervacije ulaznica za muzeje i galerije te opskrbe ostalih potrepština. U skladu s tim, djece su formirane skupine od tri ili četiri člana, kojima je zadaća izraditi detaljan plan putovanja u Europu u određenom razdoblju.

Izvedba projektnog zadatka

Faze izvedbe:

1. Podjela učenika u timove (3-4 učenika)
2. Podjela zadataka (svaki tim dobiva iste zadatke)
3. Detaljno objašnjenje zadatka:
4. Planiranje virtualnog putovanja Europom u trajanju od najviše sedam dana
6. Posjetiti pet gradova u Europi, u istoj ili različitim državama
7. U svakome gradu posjetiti najmanje dva kulturno-povijesna i turistička odredišta
8. Vrsta prijevoza, smještaja i prehrane pod oznakom za želj
9. Dozvoljeni troškovi: 10.000, 00 kn po osobi
10. Udruga po izboru kojoj bi se donirao eventualni ostatak novca
11. Pretpostavka: osobe koje putuju punoljetne su i imaju status studenata (bitno zbog cijena određenih ulaznica jer studenti imaju popust)
12. Način određivanja novca: dozvoljeni troškovi
13. Pretpostavka: osobe koje putuju punoljetne su i imaju status studenata (bitno zbog cijena određenih ulaznica jer studenti imaju popust)
14. Napraviti sljedeće dokumente:
   1. Plan puta (Ms Word)
   2. Troškovi_putovanja (Ms Excel)
   3. Naše_virtualno_putovanje (Ms PowerPoint)

Dokument Plan puta (Ms Word) treba sadržavati sljedeće:

- Imena članova putujuće grupe
- Datum početka putovanja
- Datum završetka putovanja
- Polazno i završno odredište
- Rutu putovanja, tj. relacije gradova
- Naziv osiguravajuće kuće zbog osiguranja za vrijeme putovanja i iznos troškova osiguranja

Dokument Troškovi_putovanja (Ms Excel) treba sadržavati sljedeće:

- Učenstvo
- Datum
- Pretpostavke
- Naziv osiguravajuće kuće
- Smještaja, smještaja u hotelu, posjete i razgledavanja znamenitosti, ručak i/ili večera, odjava iz hotela i dr.)
- Naziv osiguravajuće kuće zbog osiguranja za vrijeme putovanja i iznos troškova osiguranja
- Sve poveznice do pronadenih informacija i podataka (prijevoz, smještaj, cijene)

Dokument Naše_virtualno_putovanje (Ms PowerPoint) treba sadržavati sljedeće:

1. Radni list 1 – Troškovi putovanja
2. Radni list 2 – Smještaja, smještaja u hotelu
3. Radni list 3 – Ukupni troškovi

Radni list 1 treba sadržavati sljedeće:

- Za putovanje automobilom:
- Sve poveznice do pronadenih informacija i podataka (prijevoz, smještaj, cijene)
Datum početka putovanja
Vrijeme putovanja (sati)
Prosječnu potrošnju goriva odabranog automobila
Broj prijeđenih kilometara automobilom
Cijenu goriva po litri
Novčani iznos potrošenog goriva za automobil
Novčani iznos potrošen za autocestu
Ukupni novčani iznos potrošen za put na jednoj relaciji

Za putovanje avionom, vlakom ili autobusom:
    Datum putovanja
    Relaciju putovanja
    Način prijevoza
    Vrijeme početka prijevoza
    Vrijeme završetka prijevoza
    Novčani iznosi putnih karata po osobi
    Ukupne troškove za sve osobe po jednoj i svim relacijama
    Ukupne troškove za sve osobe na svim relacijama

Radni list 2 treba sadržavati slijedeće:
    Vrijeme provedeno u gradu
    Naziv grada
    Kulturno-povijesne znamenitosti i turistička odredišta
    Cijenu ulaznice po osobi
    Cijenu ulaznica za sve osobe
    Vrstu smještaja i kontakt osobe koja nudi smještaj
    Ukupnu cijenu smještaja za sve osobe
    Približne troškove hrane u jednom gradu
    Približne troškove hrane za sve osobe u jednom gradu
    Ukupne dodatne troškove (autobus, podzemna željeznica, parking...) u jednome gradu
    Ukupne troškove smještaja, ulaznica, hrane i dodatnih troškova u svim gradovima

Radni list 3 treba sadržavati sveukupne troškove:
    prijevoza
    smještaja, ulaznica, hrane
    dodatnih troškova
    troškova osiguranja putovanja

Napomena: svi novčani iznosi izražavaju se u kunama i eurima (koristi se srednji tečaj HNB-a)
Dokument „Naše virtualno putovanje“ (Ms PowerPoint) treba sadržavati slijedeće:
    naslovni slajd
    sadržaj
    osnovne informacije o putovanju
    kartu s označenom rutom putovanja
    putovanje po danima: relacija, vrijeme
    polaska, vrsta prijevoza, cijene prijevoza
    zanimljivosti o posjećenim gradovima
    poveznicu na službenu web stranicu grada
    fotografije grada, muzeja, galerija i dr.
    tablicu sa sveukupnim troškovima putovanja
    zaključak i dojmove

4. Podjela zadataka u samome timu
5. Izvedba zadataka
6. Prezentacija rješenja
7. Pitanja i odgovori
8. Ocjenjivanje i samoocjenjivanje
9. Obrazlaganje ocjene za pojedini rad te
    uspoređivanje pozitivnih i negativnih dijelova
    izrađenog projektnog zadatka
10. Uspoređivanje različitih izvedbi istoga zadatka
11. Zaključak

B. Rezultati rada na projektu

Rezultati projektnoga rada očekivano su različiti,
ocjena pretežito dobar i vrlo dobar, a ističe se rad tima
koji je prema ocjeni nastavnice i učenika ocijenjen kao
izvrstan.
Slijede neki od primjera preuzetih iz dokumenata koji
su nastali kroz rad na projektu spomenutog najboljeg
ima (ojena: izvrstan, 100% bodova)

Ms Word dokument – Plan puta

Imena članica turističke grupe: Nola Barila, Laura
Levačić, Laura Vinković
Datum početka putovanja: 02.01.2017.
Polazno i završno odredište: Čakovec
Ruta putovanja:
    Čakovec–Zagreb
    Zagreb–Brussels
    Brussels–Rotterdam
    Rotterdam–Amsterdam
    Amsterdam–Dublin
    Dublin–Manchester
    Manchester–Zagreb
    Zagreb–Čakovec

Korišteni načini prijevoza: automobil, avion
Marka automobila: Ford Focus
Nazivi zrakoplovnih kompanija: Croatia Airlines, Bruxelles Airlines
Detaljan plan puta za 1. dan
Datum: 02.01.2017.
04:30 h – polazak iz Čakovca prema Zračnoj luci Zagreb osobnim automobilom
06:20 h – polazak iz Zagreba u Bruxelles zrakoplovom, cijena karata za tri osobe: 4.951,80 kn
08:45 h – dolazak u Bruxelles, razgledavanje grada: Manneken Pis, Atomium, Mini Europe, cijena ulaznica za tri osobe: 765,00 kn
16:00 h – Ručak u restoranu Chez Léon, cijena: 97,13 kn, šetnja i razgledavanje grada
19:00 h – dolazak u hotel Des Colonies, večera, noćenje, cijena noćenja i doručka za tri osobe: 554,00 kn

C. Evaluacija radova učenika
Od strane učiteljice definirani su slijedeći elementi ocjenjivanja i bodovi a koji su osnova za samoocjenjivanje od strane učenika.

Sadržaj prezentacije – 38 bodova
- Sadržaj - 1 bod
- Zaključak – 1 bod
- Karta (ruta puta) – 1 bod
- 5 gradova – 10 bodova
- Poveznice do službenih stranica posjećenih gradova – 2 posjeta po gradu – 10 bodova
- Zanimljivosti o gradovima i/ili posjećenim mjestima – 5 bodova
- Excel tablica s pojedinačnim i ukupnim troškovima – 5 bodova

Maksimalni broj bodova: 62

Elementi koji doprinose ostvarenju bodova vezanih za sadržaj prezentacije su:
- Sadržaj - 1 bod
- Zaključak – 1 bod
- Karta (ruta puta) – 1 bod
- 5 gradova – 10 bodova
- Poveznice do službenih stranica posjećenih gradova – 2 posjeta po gradu – 10 bodova
- Zanimljivosti o gradovima i/ili posjećenim mjestima – 5 bodova
- Excel tablica s pojedinačnim i ukupnim troškovima – 5 bodova

Elementi koji doprinose ostvarenju bodova vezanih za izgled prezentacije su:

Grad: Rotterdam
Dan: 03.01.2017.
Rotterdam Zoo: 60 € (40,00 kn)
Witte de With Center for Contemporary Art: 9 € (67,50 kn)
Nederlands Photo Museum + Multimedia tour: 67,50 € (506,25 kn)
- Naslovn slajd
- Pozdravni slajd
- Autori prezentacije
- Naziv škole
- Datum izrade prezentacije
- Dizajn – dobar odnos boja pozadine i teksta
- Dobar raspored sadržaja i slika
- Ispod slike piše što slika prikazuje
- Postojanje prijelaza između slajdova
- Postojanje animacija
Svaki element se boduje a 1 bodom što je ukupno 10 bodova.

Elementi koji doprinose ostvarenju bodova vezanih za izlaganje prezentacije su:
- Pozdrav – 1 bod
- Predstavljanje tima – 1 bod
- Najava što će se izlagati – 1 bod
- Kontakt s razredom (publikom) – 5 bodova
- Samo čitanje sa slajdova – 1 bod
- Uz postojeći tekst na slajdovima učenici dodaju neke novu činjenicu – 5 bodova
- Hvala na pažnji, imate li pitanja – 1 bod

Evaluaciju rade učenici na osnovu prije spomenutih elemenata ocjenjivanja, učiteljica radi analizu tih ocjena i po potrebi korekciju u suradnji s timom. Svaki tim ocjenjuje svoj rad. Realizirano je i ocjenjeno od strane učenika 12 projekata. 9 projekata ocijenjeno je ocjenom dobar (62% - 79%), 2 projekta ocjenom vrlo dobar (80% - 90%) i samo jedan projekt dobiva ocjenu odličan (sa maksimalnim brojem bodova). Učenici su realni u ocjenjivanju s obzirom da su elementi jasno definirani unaprijed.

III. ZAKLJUČAK
Način na koji učenici uče moguće da je i važniji od samoga čina učenja. Radeći na projektu učenici primjenjuju različita znanja i vještine stečene tijekom osnovnoškolskog obrazovanja. Povezuju se znanja iz slijedećih nastavnih predmeta: matematike, hrvatskog jezika, engleskog i njemačkog jezika, povijesti, geografije, likovne i glazbene kulture te informatike. Primijenjena informatička znanja jesu: pisanje i oblikovanje teksta, izrada proračunskih tablica, izrada prezentacija i izlaganje, napredno pretraživanje interneta, kritičko korištenje pronadjenih informacija na internetu, poznavanje autorskih prava tj. korištenje fotografija s dozvoljenih web stranica, korištenje različitih alata i servisa.

Uz primjenu informatičko-komunikacijske tehnologije, učenicima su omogućeni: timski rad, planiranje, istraživanje, kritičko razmišljanje te odlučivanje i po završetku zadatka i vježbanje javnog nastupa. Nadalje, učenici su se po prvi puta bavili smocjenjivanjem vlastitog rada i stekli uvid u složenost takvoga posla.
Može se zaključiti kako su učenici cjelokupni rad na projektu procijenili izuzetno zahtjevnim ali ujedno i izazovnim te vrlo koristan za svakodnevno snalaženje u životu.

Tablica 1. Prikaz izračuna troškova ulaznica - Rotterdam

<table>
<thead>

</table>

Zahtjevnost se odnosi prije svega na opsežnost projekta ali i na organizaciju rada na projektu. Zato je trebalo napraviti dobru podjelu poslova među članovima tima. Veliki izazov je bio usklađenje sadržaja prezentacije s nastalim troškovima, poveznicama do stranicama s cijenama ulaznica, letova i dr. Većini timova to nije bilo usklađeno ili troškovi nisu bili ni prikazani. Najbolji tim je izrazio želju i nadu za stvarnom potrebom rješavanja takvog izazova u nadolazećem vremenu, možda tijekom srednjoškolskog obrazovanja. Nastavnica je zadovoljna postignutim učeničkim rezultatima, posebno tima koji se najbolje istaknuo kvalitetom rada, jednako kao i izlaganja.

IV. POPIS LITERATURE

Aktivnosti transnacionalne suradnje u jačanju digitalne kompetencije u obrazovanju i osposobljavanju

Marina Mirković
Tehnička škola, Požega, Republika Hrvatska
marina.mirkovic@po.t-com.hr

Sažetak

Posljednjih godina, koncept ključnih kompetencija postao je važan u europskim obrazovnim sustavima. Digitalna kompetencija je jedna od osam temeljnih kompetencija za cjeloživotno učenje. Uključuje samouvjereno, kritičko i kreativno korištenje digitalnih tehnologija na poslu, u slobodno vrijeme i komunikaciji. Aktivnosti transnacionalne suradnje (Transnational Cooperation Activities - TCA) uključuju niz aktivnosti poput radionica, treninga, seminara, aktivnosti jačanja partnerstva u okviru tema relevantnih za Erasmus+ program. Sudjelovanje u TCA-u znači stvaranje i širenje mreže kontakata i suradnju s organizacijama iz sličnog ili različitog područja djelovanja iz cijele Europe kao i stjecanje znanja i praktičnih vještina u temama relevantnim za program Erasmus+ te stjecanje podrške za projektne ideje.

Autorica rada sudjelovala je na dva TCA kontakna seminara – u Estoniji i Malti. Na seminarima je uspostavljena suradnja s europskim kolegama kroz komunikaciju i razmjenu ideja u stvaranju projektnih ideja. Slijedeći trendove novih tehnologija, nastavnici trebaju u skladu sa stvarnošću prilagoditi se promjenama kako bi stvorili učinkovite modele nastavnog procesa koji će poboljšati sudjelovanje učenika u aktivnostima nastave kao i procesu učenja. Putem TCA seminara edukatori u strukovnom obrazovanju i osposobljavanju uče kako osigurati učenicima dinamično i praktično iskustvo učenja u struci s naglaskom na praćenje razvoja tehnologije u danom polju.

I. UVOD

Digitalna kompetencija mora se razvijati u sustavu obrazovanja. Primjena informacijsko-komunikacijske tehnologije (IKT) u obrazovanju pomaže u promicanju kritičkog mišljenja, komunikacije, suradnji i kreativnosti. Učenici otkrivaju učinkovitu uporabu informacijsko-komunikacijske tehnologije u nastavi i učenju. Jedna od glavnih prepreka za znatan razvoj digitalne kompetencije kroz nastavu je nedovoljna obuka nastavnika. Oni moraju biti sustavno i strukturirano upoznati sa novim tehnologijama i metodama učenja. Ova kompetencija se odnosi na logično i kritičko razmišljanje, visoku razinu vještine upravljanja informacijama i dobro razvijene komunikacijske vještine.

II. DIGITALNA KOMPETENCIJA

Jaz u digitalnim vještinama i dalje je prisutan u trenutku kada je potrebno više nego prije stručnjaka u području informacijskih i komunikacijskih tehnologija. Računala, mobiteli i digitalne tehnologije su središnji dio našeg svakodnevnog života i mogu nam pomoći u rješavanju mnogih izazova s kojima se suočavamo, od sigurnosti na cestama i zdravog starenja do bolje javne usluge i održivog okoliša.

U posljednjih nekoliko godina, koncept ključnih kompetencija dobiva način da se na važnosti u europskim obrazovnim sustavima. Većina europskih zemalja postigla je značajan napredak u uključivanju ključnih kompetencija u nacionalne kurikulume i druge normativne dokumente. Digitalna kompetencija je jedna od osam temeljnih kompetencija za cjeloživotno učenje. Ona odbija samopouzdanje i kritičko korištenje elektronskih medija. Digitalne tehnologije su ključni pokretači inovacija, rasta i otvaranja novih radnih mjesta u globalnom svijetu.

Nažalost, nemaju svi znanja, vještine i stavove kako bi

1088
mogli koristiti digitalne tehnologije na kritičan, suradnički i kreativan način. Nedostatak digitalne kompetencije velikog dijela stanovništva EU-a ima dramaticne posljedice na njihovu perspektivu zapošljavanja. Ljudi bez osnovnih računalnih vještina su neaktivni na tržištu rada. Digitalna kompetencija postaje potrebna za zaposljivost i aktivno građanstvo, pogotovo jer se očekuje da će 90% radnih mjesta u skoroj budućnosti zahtijevati određene razine IKT vještina.

Digitalna kompetencija odnosi se na sposobnost uporabe digitalne tehnologije. Osnovne vještine uporabe IKT-a podrazumijevaju: pronalaženje, procjenu, pohranjivanje, stvaranje, prezentiranje i razmjenu informacija te komuniciranje i sudjelovanje u suradničkim mrežama putem interneta.

Portaal kroz pet online tečajeva osposobljava nastavnike da pouzdano i kritički koriste informacijsko-komunikacijske tehnologije u nastavi, surađuju i komuniciraju pomoću IKT-a, te koriste alate za stvaranje e-sadržaja. Uz procjenu znanja na kraju svakog tečaja, uveden je i sustav stručnog ocjenjivanja završnog rada sudionika tečaja (peer review).

III. TCA

Jedan od glavnih izazova u obrazovnom sektoru je pripremiti stanovništvo za kontinuirano ažuriranje digitalne kompetencije kako bi se lakše prilagodili tehnološki raznolikom okruženju. Transnacionalna suradnja i razmjena inovativnih ideja između europskih obrazovnih institucija kroz Erasmus+ program je prilika za rješavanje tih problema.

Aktivnosti transnacionalne suradnje (Transnational Cooperation Activities - TCA) nacionalnim agencijama (NA) za program Erasmus+ omogučuju poboljšanje kvalitete i učinka samog programa putem treninga i aktivnosti umrežavanja u području mladih, ali i u području obrazovanja – općeg, strukovnog, visokog te obrazovanja odraslih.

TCA obuhvaća niz događanja, seminara i radionica, koje omogućuju Erasmus+ nacionalne agencije kako bi surađivali i dijelili primjere najbolje prakse u cijeloj Europi. Opći je cilj aktivnosti poboljšanje kvalitete i utjecaja Erasmus+ programa na nivou sustava. Prilikom planiranja TCA, Nacionalne agencije usklađuju potrebe s ciljevima utvrđenim u strateškim dokumentima kao što su Europa 2020. i Strategije za mlade u Europskoj uniji.

TCA je uglavnom usmjeren na mlade te obrazovanje i osposobljavanje, uključujući:

- pojedine i organizacije koje djeluju u području mladih;
- strukovno obrazovanje i osposobljavanje (VET) i ustanove za obrazovanje odraslih;
- javna tijela na lokalnoj, regionalnoj ili nacionalnoj razini koja su odgovorna za obrazovanje i politiku za mlade.

TCA uključuje niz aktivnosti poput radionica, treninga, seminara, aktivnosti jačanja partnerstva u okviru tema relevantnih za Erasmus+ program uključujući:

- alate za unaprjeđenje kvalitete međunarodnog rada s mladima;
- socijalnu uključenost, kulturalnu raznolikost i interkulturalne kompetencije;
- aktivno europsko građanstvo;
- zaposljivost i socijalno poduzetništvo;
- osnovne vještine u obrazovanju odraslih i naukovanje.

Sudjelovanje u TCA-u znači:

- stvaranje i/ili širenje mreže kontakata i suradnja s organizacijama iz sličnog ili različitog područja djelovanja iz cijele Europe;
- stjecanje znanja i praktičnih vještina u temama relevantnima za program Erasmus+ te stjecanje podrške za projektnu ideje;
diseminacija projektnih rezultata na europskoj razini.

Agencija koja organizira aktivnosti transnacionalne suradnje objavljuje poziv za sudjelovanje u aktivnostima. Prijave (slika 1.) se uglavnom podnose online putem Agencije za mobilnost i programe Europske unije (AMPEU) [5] ili putem stranice Salto-youth.net. SALTO (Support, Advanced Learning and Training Opportunities) je mreža osam resursnih centara koji rade na europskim prioritetnim područjima unutar područja mladih putem platforme Salto-youth.net [6].

Agencija za mobilnost i programe Europske unije odabire kandidate iz Hrvatske na osnovi relevantnosti i kvalitete prijave, uzimajući u obzir sljedeće:

- ravnoteža među odabranim sudionicima po regijama iz kojih dolaze i spolu ako razlika u kvaliteti prijave nije presudna
- najviše jedna osoba po organizaciji može biti odabrana za određenu aktivnost, osim ako u pozivu nije naznačeno drukčije
- prednost pri odabiru imat će osobe i organizacije koje u tekućoj godini još nisu sudjelovale ni u jednoj aktivnosti u okviru aktivnosti transnacionalne suradnje, osim ako se aktivnost za koju se prijavljuju ne nastavlja na prethodnu ili mogu pokazati relevantnost svih aktivnosti za svoj svakodnevni rad s mladima.

Prijava se ocjenjuje prema sljedećim kriterijima:

- Prijavitelj je predstavnik organizacije koja je prihvatljiva za sudjelovanja u TCA-u i navedena je u prijavi
- Relevatnost i iskustvo prijavitelja i organizacije u odnosu na temu i ciljanu skupinu sudionika propisane pozivom;
- Način na koji prijavitelj planira iskorištiti i diseminirati novostečene vještine i rezultate aktivnosti u svom svakodnevnom radu, te planirane follow-up aktivnosti;
- Dobrobiti koje sudionik, njegova organizacija i ostali dionici dobijaju sudjelovanjem na aktivnosti;
- Dobrobiti sudjelovanja na aktivnosti u pogledu privatnog i profesionalnog razvoja;
- Planira li prijavitelj iskorištiti iskustvo i novostečena znanja za prijavu projekta u okviru Erasmus+ programa [7].

IV. TCA SEMINAR U ESTONJI

Svrha je ovog seminara da sudionici pronađu partnere sa sličnim interesima i razviju projektno ideje za nova KA2 strateška partnerstva na temu IKT-a i digitalnih vještina. Seminar je također pružio priliku za razmijenu iskustava, upoznavanje novih pristupa u tom području i mogućnost stvaranja novih međusektorskih i transverzalnih suradnji.

Ciljna skupina kontakt seminara bili su predstavnici škola i organizacija za obrazovanje odraslih, kao i ostalih organizacija relevantnih za područja školskog i obrazovanja odraslih, a koji su zainteresirani za temu seminara te namjeravaju razviti i prijaviti Erasmus+ KA2 strateško partnerstvo.

Iz Republike Hrvatske, uz profesoricu Mirković, na seminaru su sudjelovali Elvira Vučković (Osnovna škola „Petar Zoranić“, Nin) i Josip Sobin (Učilište Jantar, Split).

Na seminaru je sudjelovalo 70 sudionika iz 21 europske zemlje. Održana su predavanja i radionice o digitalnoj kompetenciji, te predstavljen Erasmus+ program. Posebno su bili korisni primjeri dobre prakse KA2 projekata. Sudionici su imali priliku aktivno participirati u svim sadržajima. Za istaknuti je pozitivne primjere direktnih i neposrednih suradnji na radionicama, a kako i sudionici surađivali te kroz komunikaciju i
Jedan od zadataka za polaznike bio je izraziti pojam/riječ karakterističan za primjenu IKT-a u obrazovanju u razdoblju sljedećih pet godina. Polaznici su predložili: izazov, eksplozija, sloboda, održivost, uzbudljivost, timski rad, mogućnosti, različitost, online obrazovanje, brzina, dostupnost, kreativnost, inovacija, raznolikost, interakcija čovjeka i računala, razvoj, otvoreni um, učinkovitost, digitalizacija, zabava, osnaživanje, zbrka, bezgraničnost, suradnja (slika 2.).

Sudionici su prema interesima u grupama (slika 3.) raspravljali o temama:

- Razvijanje digitalne kompetencije nastavnika - povećanje kontinuiranog profesionalnog razvoja nastavnika i programa stručnog usavršavanja
- Kreativna upotreba digitalne tehnologije - korištenje IKT metoda i alata za matematiku i prirodne znanosti
- Kreativna upotreba digitalne tehnologije - korištenje IKT metoda i alata u humanističkim i društvenim znanostima
- Rješavanje mogućih problema i rizika pri korištenju digitalne tehnologije - kao što su ovisnosti o računala, rizici od rizika računala, zastojivanja elektronskih alata, privlasti podataka, itd.
- Nastava programiranja i robotika u školama

Kroz promišljanja o mogućim projektnim idejama, polaznici su analizirali razne situacije i mogućnosti primjene IKT-a u aktivnostima međunarodne suradnje. Najizazovniji zadatak je izgraditi sustav obuke i razvoja IKT vještina u školi - sustavno uključiti sve nastavnike u svim stručnim područjima kako bi se razvijao i usavršavao. Time će se postići podsticanje za učenje i nastavu u kojoj učenici od pasivnog promatrača postaju aktivni sudionici u okruženju za učenje. Time će se postići podsticanje za učenje i nastavu u kojoj učenici od pasivnog promatrača postaju aktivni sudionici u okruženju za učenje. Ideje za pojedine projekte razrađene su i postavljene na online zid putem Padlet alata (slika 4.).

V. TCA SEMINAR NA MALTI

U razdoblju od 22. do 24. studenog 2016. godine u Rabatu (Malta) održan je TCA kontaktni seminar pod nazivom „Iskustvo iz prve ruke za nastavnike strukovnog obrazovanja i osposobljavanja“ u organizaciji Agencije za mobilnost i programe EU. Prema prihvaćenoj prijavi, na seminaru je kao predstavnica nastavnika Republike Hrvatske sudjelovala profesorica savjetnica računalstva Marina Mirković iz Tehničke škole u Požegi.

Svrha je ovoga kontaktnog seminara bila naučiti edukatore u strukovnom obrazovanju i osposobljavanju kako osigurati učenicima dinamično i praktično iskustvo učenja u struci s naglaskom na praćenje razvoja tehnologije u danom polju, bolje se upoznati s mogućnostima koje program Erasmus+ nudi edukatorima u strukovnom obrazovanju kako bi prethodno navedeno postigli, razvijati projektno ideje na temu seminara te olakšati sudionicima pronalazak potencijalnih partnera za provođenje osmišljenih projekata.

Na seminaru je sudjelovalo 32 sudionika iz 15 europskih zemalja. Održana su predavanja i radionice o uvođenju i primjeni e-ucenja u strukovnom obrazovanju i osposobljavanju.

Radionice (slika 5) u kojima su sudionici raspravljali o svojim promišljanjima o uvođenju e-ucenja u strukovnom obrazovanju imale su zadane teme/pitanja:

- Pogledi na kvalitetu i vrednovanje tečaja e-ucenja
- Koliko je važan izbor platforme (LMS) e-ucenja? Koe ključne značajke očekujete od nje?
- Koje podatke uspješnosti razmatrate kod izbora e-ucenja ili mješovitog e-ucenja?
- Da li su nastavnici običniji za efikasnu uporabu sustava e-ucenja? Što smatrate efikasnim programom obuke nastavnika za e-ucenje?
- Da li su nastavni planovi i programi, propisi, sustavi upravljanja školom pripremljeni za e-ucenje? Što je potrebno izmjeniti?

Slika 4. Prikaz dijela online zida s idejama međunarodnih projekata

E-ucenje potiče promicanje digitalne pismenosti, unapređenje alata i metodologija u aktivnostima digitalnog ucenja. Integracija informacijsko-komunikacijske tehnologije u obrazovanju je potuga za promjenu i priliku za povećanje kvaliteta, raznolikosti i učinkovitosti u europskim sustavima obrazovanja i osposobljavanja. Cilj je iskoristiti potencijal e-ucenja promicanjem inovacija u metodama poučavanja s ciljem poboljšanja kvaliteta procesa ucenja i njegovanja autonomije učenika, paralelno s razvojem socijalnih i komunikacijskih vještina učenika suradnjom i interakcijom učenika.

Važno je pokrenuti online tečajeve za profesionalne razvoj širokog raspona nastavnika u određenim područjima, kao što su matematika, znanost, tehnologija, obrazovanje u području ekologije, korištenje mobilnih uređaja u školskoj praksi. Povećanje svijesti nastavnika u izgradnji poticajnog okruženja za učenje pruža im dodatnu vrijednost i saznanje kako koristi IKT za podršku individualiziranom učenju, suradničkom učenju, učenju temeljenom na projektima, formativnom ocjenjivanju i kreativnoj primjeni digitalne tehnologije.

Uz predavanja o e-ucenju na seminaru je predstavljena tvrtka SGM iz Berlina kojoj je osnovna djelatnost pomoć u oblikovanju obrazovanja. Zalažu se za stvaranje novih načina učenja. Tvrtka se specijalizirala za nova i rastuća tržišta obrazovanja od školske razine preko stručnog osposobljavanja do sveučilišta.
Od individualnog učenja do korporativnih obuka za tvrtke, isporučuju kontinuirani profesionalni razvoj u različitim i uglednim tržištima sa svojim stručnjacima brojnih disciplina/područja koji prepoznaju izazove i zahtjeve scenarija učenja u različitim vrstama učenja i obrazovnim kontekstima.

Pomažu trenerima, sudcima i igračima svih uzrasta iz cijelog svijeta da razvaju bolje razumijevanje uloge i prirode njihovog sporta. SGM Sport omogućuje korisnicima da nauče sve, od osnovnih temelja do napredne taktike svog sporta kroz specijalizirani online trening. SGM Zdravstvena zaštitna specijalizirala se je u pružanju tečaja e-učenja za nastavak profesionalnog razvoja zdravstvenih djelatnika. SGM InZenjering stvara optimalne stručne ili akademske programe obuke pomoću referentnih standarda za procjenu u kombinaciji s ispitima poduzeća i industrije. Prilagođeni programi e-učenja izrađuju se po sadržaju i satima, ovisno o individualnim potrebama pojedine tvrtke [8].

Sudionici seminara posjetili su Institut za izučavanje turizma (ITS) i Koležd za umjetnost, znanost i tehnologiju (MCAST) na Malti.

VI. ZAKLJUČAK

U skladu s ključnim kompetencijama EU za cjeloživotno učenje nužno je povećanje digitalne pismenosti nastavnika, poboljšati vještine u primjeni IKT-a te ih potaknuti da koriste računalo kao pedagoški alat u nastavi. Time će se unaprijediti IKT vještine među učenicima uz integriranje u svim obrazovnim aktivnostima. Nastavnici će sve više koristiti digitalne medije, web sredstva i načine komunikacije koje obično koriste djeca i mladi, te primjenjivati razne korisne programe, alate i digitalne nastavne materijale. Dublji i širši utjecaj omogućit će suradnja nastavnika u međunarodnim projektima i oblici stručnog usavršavanja.

Aktivnosti transnacionalne suradnje kroz radionice, treninge i seminare omogućuju nastavnicima suradnju s europskim kolegama uz komunikaciju i razmjenu ideja u stvaranju projektnih ideja. Slijedeći trendove novih tehnologija, nastavnici trebaju u skladu sa stvarnošću prilagoditi se promjenama kako bi stvorili učinkovite usluge na projektima međunarodnog stručnog usavršavanja. Nastavnici će postati svjesni različitih novih i inovativnih alata za suradnju, komunikaciju i kulturno razumijevanje te razvijati globalnu svijest za potporu učenicima u tim područjima. Povezivanje europskih škola svim sudionicima projekta omogućuje bolje shvaćanje i poimanje europske vrijednosti i dimenzije. Neposredna suradnja daje osjećaj pripadnosti europskoj zajednici škole.

Kritička i etička uporaba IKT-a otvara nove oblike učenja i suradnje za potporu različitim stilovima učenja. Učenici će doživjeti radost, zadovoljstvo, uspjeh u njihovom obrazovanju i cjeloživotnom učenju. Omogućeno je aktivno sudjelovanje u učenju - unutar i izvan škole. Nastavnici korištenjem IKT-a omogućuju svojim učenicima da rade na rješavanju složenih problema iz stvarnog života u suradničkim aktivnostima učenja na projektima međunarodne suradnje. Povezuju se različita predmetna područja kroz suradnju više nastavnika škole.

Nastavnici su stalni promotori inovacija u školama. Diseminacija rezultata TCA seminara pružiti će ostalim nastavnicima saznanja o ovoj mogućnosti međunarodnog stručnog usavršavanja te potaknuti želju da se uključe u slijedeće prijave. Učinkovitost stručnog usavršavanja nastavnog osoblja će biti poboljšana. Brojni projekti vezani za strukovno obrazovanje omogućuju obuke nastavnika i jaču povezanost učenika sa svijetom rada.

Međunarodni projekti obogaćuju nastavni rad, rad škole, prepoznatljivost, donose razne koriste učenicima, učiteljima i zajednici. Na osobnoj razini pruža učenicima strogo i održavaju, uz integriranje u svim obrazovnim aktivnostima. Nastavnici će sve više koristiti IKT u aktivnosti. Time će se unaprijediti IKT vještine među učenicima uz integranje u svim obrazovnim aktivnostima. Nastavnici su stalni promotori inovacija u školama.

LITERATURA

Sažetak - Programski jezik Python već je neko vrijeme zastupljen u obrazovnim programima srednjih škola u Republici Hrvatskoj, a počeo se uvoditi i u osnovne škole, zasad u sklopu predmetne nastave informatike.

Pored nesumnjivih prednosti, programski jezik Python ima svojih nedostataka, posebice u segmentu jezička poteškoća koja po svojim nedostacima, posljedica je svojih pojava u svladavanju same po sebi zahtjevne vještine programiranja.

Kako bi se učenicima olakšalo svladavanje sintaktičkih pravila i omogućila veća umjerenost na primjeru programiranja u rješavanju problema, razvili smo programski paket Poskok. Sastoji se od osam metoda programiranja u rješavanju problema, razvili smo pravila i omogućavamo pravilnu interpretaciju koda.

Programski paket Poskok dostupan je mrežno (online), za njegovo izvršavanje nisu potrebni dodaci, a izvodi se u bilo kojem mrežnom pregledniku koji podržava standard HTML5.

Ključne riječi: programski jezik Python, programski paket Poskok, programiranje, metodika poučavanja programiranja.

I. UVOD

Unazad nekoliko godina u obrazovne programe naših srednjih škola počeo se uvoditi programski jezik Python. Budući da se često ističe kako se radi o programskom jeziku opće namjene, koji ima široku primjenu u praktici, ideja da ga se koristi u cjelokupnoj "obrazovnoj vertikali", od primarnog do terciarnog obrazovanja inicirala je njegova uvodenje i u nastavne programe osnovnih škola u sklopu predmetne nastave informatike (izborni predmet od 5. do 8. razređa).

Uvođenje Pythona u nastavne programe osnovnih škola (ponovo) otvara stare dileme:

- Treba li poučavati programiranje u osnovnim školama?
- Koji programski jezik je primjeren za početnike?
- Treba li poučavati programski kôd ili je važnije učenike naučiti rješavati probleme?

Ova otvorena pitanja aktualna su u stručnim krugovima ne samo u nas, nego i u svijetu. Ovdje ćemo se usredotočiti samo na pitanje odabira programskog jezika za početnike.

 Mnogi fakulteti već dulje vrijeme imaju Python u svojim nastavnim programima. Stoga ne čudi da je Python 2014. godine pretekao Javu i postao najpopularniji programski jezik u uvodnim silabusima programiranja na najprestižnijim sveučilištima u SAD [1].

Trend uvođenja Pythona u sekundarno obrazovanje također je zamjetan na svjetskoj razini. Kada govorimo o sekundarnom, a posebice primarnom obrazovanju, u promišljanju i/ili procjeni primjene programskog jezika u nastavni proces svakako moraju biti uključeni i pedagoški aspekti. Provedeno je mnogo usporednih analiza Pythona u odnosu na ostale programske jezike, ali je prema nama raspoloživim podacima i smerima istraživanja koja se bave pedagoškim aspektima njegova uvođenja u nastavne sadržaje primarnog obrazovanja.

Tijekom odabira programskog jezika za početnike potrebno je uzeti u obzir nekoliko čimbenika. Prvi programski jezik utječe na uspjeh učenika u korištenju i kreiranju algoritama te na rješavanje problema pomoću programiranja općenito [2]. Uspjeh nekog programskog jezika u profesionalnom okruženju nije ujedno prediktor uspjeha u učenju [3]. Također, neki autori upozoravaju da rezultati koje učenici postižu na predmetima programiranja ne koreliraju visoko s njihovim ostalim akademskim postignućima [4].

Nesumnjivo, programski jezik Python ima svojih prednosti. Primjerice, jednostavna i fleksibilna sintaksa, neposredna povratna interpretacija koda, jednostavna uporaba modula itd. Na osnovu toga neki istraživači zaključuju da Python olakšava kako poučavanje tako i učenje [5].

U tablici 1. naveden je jedan trivijalan poređenje primjeri jednostavnosti Pythonove sintakse u odnosu na programski jezik Java i C.
Tablica 1. Poredbeni primer sintakse u Pythonu, Javi i C-u

<table>
<thead>
<tr>
<th>Python</th>
<th>Java</th>
<th>C</th>
</tr>
</thead>
</table>
| ```python
print('Hello World')
``` | ```java
class HelloWorld {
    public static void main(String[] args) {
        System.out.println("Hello World");
    }
}
``` | ```c
#include<stdio.h>
int main(int argc, char** argv) {
    printf("Hello World");
}
``` |

Unatoč nabojeanim prednostima, Python ima i svoje nedostatke. Ovdje se nećemo upuštati u njihovo šire opisivanje, nego ćemo spomenuti neke koje po našem mišljenju početnicima zadaju najviše poteskoća.

Input je inicijalno tekstnog tipa (string) što zahtijeva, želimo li u varijablu pohraniti broj, dodatno komplikiranje mišljenju po decimalnim brojem. Primjerice:

- Vjerojatno ni prihvatljiv, ishod nekih operacija s zasigurno spadaju me trivijalna i, vjerojatno, konkretni uzrok pogreške, iako je pogreška relativno Pythonov interpreter javit programerima, a kamo li po...

Programerima koji nisu upoznati s problemom poničevanja sintaktičkih pogrešaka Python ponekad vraća poruke koje su teže razumijevanje i iskusnim programerima, a kamo li početnicima u programiranju. Primjerice, upišimo li u IDLE naredbu:
- >>> a = input('upiši broj ')
- >>> a
- '5'

u varijablu a pohranili string '5', unatoč tomu što je unesena vrijednost po svojoj prirodi bila broj.

Tijekom detektiranja sintaktičkih pogrešaka Python ponekad vraća poruke koje su teže razumijevanje i iskusnim programerima, a kamo li početnicima u programiranju. Primjerice, upišimo li u IDLE naredbu:
- >>> print('zbroj je')

Pythonov interpreter javit će poruku:
- SyntaxError: EOL while scanning string literal

što nije nimalo intuitivno, u smislu da ne upućuje na konkretn uzrok pogreške, iako je pogreška relativno trivijalna i, vjerojatno, česta.

Programerima koji nisu upoznati s problemom pomičnog zaleđa u računalu, a učenici u osnovnoj školi zasigurno spadaju među njih, neće biti razumljiv, a vjerojatno ni prihvatljiv, ishod nekih operacija s decimalnim brojem. Primjerice:
- >>> a = 4.55 - 4
- >>> a
- 0.5499999999999998

Istraživanja autora koji su se bavili pitanjem odabira prvog programskog jezika za početnike ukazuju da programski jezik Python ima svojstva kojih su posebice problematična početnicima, čak i u srednjoj školi: uvlačenje programskog koda udesno (indent), asimetrični raspon (range), uporaba dvotočke, kompleksije s inputom, nužnost uporabe modula, odnosno biblioteka za tole složenije radnje, posebice u grafici [3]. Isti autori ističu problem da iako se Python proglasa programskim jezikom opće namjene koji se koristi u stvarnim, konkretnim primjerima, učenici malo od toga mogu vidjeti na razini početničke uporabe/primjene Pythona.

Osim toga, podsjetimo da učenici imaju teškoća u manipuliranju apstraktnim konceptima, čak i ako je sintaksa za njihovu provedbu jednostavna [5].

Suočeni s nabojeanim nedostacima programskog jezika Python i ponukani neizbježnim procesom njegovog uvodenja u nastavne programe naših osnovnih škola, odlučili smo se osmisliati aplikaciju koja će učiteljima i učenicima olakšati poučavanje i učenje Pythona. Budući da se (pred)znanje učenika mijenja tijekom učenja i da se kulminiranjem nastavnih sadržaja metodika poučavanja treba tome prilagodavati, došli smo do zaključka da će biti učinkovitije ako svladavanje osnovnog programskog jezika Pythona realiziramo kroz više jednostavnih, metodički postupnih aplikacija. Postupnost se ogleda u tome što u početnim aplikacijama učenik ne mora poznavati niti se mora obzirati na sintaktička pravila da bi nešto isprogramirao, tj. da bi riješio problem programiranjem. U kasnijim aplikacijama sve više dolazi do izražaja stečen jednostavnih i njegova primjena.

Nastali skup aplikacija nazvali smo paket Poskok i ovdje ga po prvi puta predstavljamo široj stručnoj javnosti.

II. OPIS PAKETA POSKOK

U uvodnom dijelu opisa predstavljene su neke od zajedničkih značajki aplikacija sadržanih u paketu.

Paket Poskok sastoji se od osam aplikacija kojima se učenik upoznaje s osnovnim mehanizmom programiranja – ulaz (formiranje varijabli i unos podataka), obrada podataka i izlaz (ispis rezultata obrade).

Osim izvođenja aritmetičkih operacija i pridruživanja vrijednosti varijablama, u obradi podataka postupno se uvodi koncept donošenja odluka, odnosno odlučivanja o daljnjem tijeku izvođenja programa (do složene naredbe if) te koncept ponavljanja naredbi (petlje for i while).

Tijekom usložnjavanja programskih sadržaja, naglasak je na metodičkoj postupnosti. U početnim aplikacijama od učenika se ne zahtijeva poznavanje sintakte programskog jezika Python jer je sučelje tako koncipirano da traži samo upis vrijednosti varijabli, odnosno tekstla ulazne i/ili izlazne poruke, a aplikacija sama generira programski kod. To učeniku omogućava fokusiranje na problemski sadržaj, a ne na sintaktička pravila. Kasnije se taj omjer postupno mijenja pa se od učenika sve više traži samostalno upisivanje i izvođenje naredaba.

Kako bi se učeniku olakšalo razumijevanje koncepta varijable i pridruživanje vrijednosti istoj, aplikacije sadrže okvir Varijable u kojem se prikazuju trenutačne vrijednosti formiranih varijabli. U svrhu veće zornosti, brojčane varijable (i njihove vrijednosti) ispisuju se crvenom bojom, dočim se tekstovne (string) varijable prikazuju plavom bojom.

Primjerice, sljedeći programski kod u Pythonovom IDE-u nema vidljivi izlaz:
Tijekom izvođenja ova tri programska retka učenik nema uvid što se događa s varijablama, odnosno sa sadržajem njihovih memorijačkih lokacija. Nasuprot tomu, u Poskoku učenik stalno ima pregled nad vrijednostima varijabli. Na slici 1. prikazano je stanje varijabli nakon izvođenja gore spomenutog koda.

Slika 1. U okviru Varijable prikazuju se trenutačne vrijednosti varijabli i vrsta podataka

Posebnu pozornost posvetili smo obradi i interpretaciji pogrešaka. Budući da se u početku od učenika ne zahtijeva poznavanje sintakse, Pythonovo interpretiranje pogrešaka morali smo zamijeniti vlastitim sustavom pomoći. To je zahtijevalo drugačiji način parsiranja Pythonovog programskog koda i detektiranja sintaktičkih pogrešaka. Tako smo dobili sustav interpretacije vlastitih pogrešaka. Tamo gdje je to bilo moguće, obuhvatili smo i (neke) pogreške u semantici. Vlastiti parser i interpreter omogućili su nam kreiranje preciznih povratnih informacija. Tako smo dobili sustav interpretacije pogrešaka koji ne samo što je na hrvatskom jeziku, nego ima i upotrebljivu didaktičku vrijednost.

Kao primjer, navest ćemo pogrešno napisan programski kôd (nedostaje jedna zatvorena zagrada):

```python
>>> a = int(input('zbroj je ')
```

Dok će u Pythonu interpreter javiti poruku:

```
SyntaxError: invalid syntax
```

u Poskoku učenik dobije znatno precizniju poruku, odnosno uputu:

```
Nedostaje zatvorena zagrada funkcije int
```

Tijekom razvoja povratnih poruka o učinjenim pogreškama zatipali smo se koliko sustav koji toliko pomaže, zapravo odmaže učeniku (u smislu umanjanja potrebe da sam istražuje uzroke svojih pogrešaka i tako empirijski stiže nova znanja). Budući da je to područje koje tek treba istražiti, u postavkama aplikacije ugradili smo mogućnost da korisnik sam odabere koju razinu informacija, odnosno pomoći želi. Primjerice, ako korisnik odabere malu razinu pomoći, u gore spomenutom primjeru pogrešno napisanog programskog kôda dobit će samo kratku poruku:

```
Pogreška!
```

Time smo omogućili učenicima koji to žele da sami analiziraju svoj kôd i pronalaze uzroke svojih pogreški.

Nakon zajedničkog predstavljanja, ukratko ćemo opisati namjenu i funkcionalnost pojedinih aplikacija iz paketa Poskok.

A. Poskok 1

Prva aplikacija po mnogočemu se razlikuje od ostalih aplikacija u paketu. Namijenjena je početnicima najmlađe dobi koji još nisu potpunosti svladali pisanje na računalu, a temelji se na kornjačini grafici ugrađenoj u Python. Zašto smo za početnike odabrali baš kornjačnu grafiku?

Prema Piagetu, djeca u dobi od 7 do 11 godina funkcioniraju na stupnju konkretnih operacija, pa apstraktno mišljenje još nije razvijeno [6]. Sukladno tomu, učenici u nižim razredima nisu na takvom stupnju kognitivnog razvoja da bi mogli uspješno (samostalno) upotrebljavati apstraktni programski jezik za rješavanje konkretnih problema. Seymour Papert, idejni začetnik programskog jezika Logo, pokazao je da se uporabom računala i robotske kornjače upravljane programskim jezikom Logo Piagetovi razvojni stupnjevi mogu djelomice nadvladati [7], tj. da se pomoću primjerenih računalne tehnologije može ubrzati razvoj razumijevanja apstraktnih pojmov.

Problem svladavanja formalnih sintaktičkih pravila programskog jezika u aplikaciji Poskok 1 sveden je na minimum na taj način što su umjesto standardnih programskih naredaba uvedene „programske akcije“. Time je izbjegnuto pisanje uobičajenog programskog kôda – učenik ne upisuje naredbe, nego se one zadaju klikanjem mišem na odgovarajuće gumb, tj. akciji naredbu, a ponegdje se traži i upisivanje argumenta naredbe (slika 2.).

Klikom na tipku pokreće se odgovarajuća akcija kornjače, a ujedno se genera i zapis naredbe (u okviru Naredbe), kao što se vidi na slici 3. Kako bismo početnicima omogućili intuitivno povezivanje guma s pravilima uporabili apstraktni programski jezik Logo, pokazali je da se uporabom kornjačkih naredbi uvrštenje guma u pravilo može ubrzati razvoj razumijevanja apstraktnih pojmov.

Slika 2. Naredbene, tj. akcijske tipke

Klikom na tipku pokreće se odgovarajuća akcija kornjače, a ujedno se genera i zapis naredbe (u okviru Naredbe), kao što se vidi na slici 3. Kako bismo početnicima omogućili intuitivno povezivanje guma s generiranom naredbom, vodili smo računa da, svugdje gdje je to moguće, naziv gumba i naziv naredbe bude identičan i na hrvatskom jeziku.

U svrhu poticanja učenja originalnih "kornjačinih" naredaba iz Pythonova modula Tkinter, editor naredbi sadrži tipku u obliku engleske zastave kojom se akcije naredbenih tipki prevode u originalne Pythonove naredbe.

Slika 3. Sučelje aplikacije Poskok 1
Osim što se u editoru naredbi ispisuju naredbe generirane nakon izvođenja akcijskih tipki, naredbe se mogu uređivati (dopisivati, brisati, mijenjati i sl.) i izvršavati. Takav dualni način upravljanja korjačom (pomoću naredbenih tipki i izvršavanjem naredaba u editoru naredbi) osmišljen je radi prilagodbe razvojnim sposobnostima i stupnju predznanja učenika.

Jedan od češćih uzroka pogrešaka i nedoumica tijekom programiranja u korjačnoj grafici jest status pera korjača. Primjerice, ako je pero podignuto, naredbe kretanja nemaju vidljiv učinak – korjača ne crta, tj. ne ostavlja trag. Kako bismo učenicima olakšali uvid u stanje korjačina pera, načinili smo panel Pero (slika 4.) s posebnim naredbenim tipkama koje sadrže grafički indikator statusa, tj. svojstva pera – pero spušteno ili dignuto, boja i širina pera.

Aplikacija Poskok 1 pokriva programski sadržaj od desetak osnovnih korjačnih naredaba do programskke petlje, što osigurava crtanje i nešto složenijih likova.

B. Poskok 2

Od ove aplikacije nadalje upotrebljavaju se standardne naredbe programskog jezika Python za ulaz, pridruživanje vrijednosti i izlaz. Posebnost aplikacije Poskok 2 i Poskok 3 jest u tome što učenik ne piše naredbe, nego iz glavnog izbornika bira što želi inicirati (input, pridruživanje ili print) pa popunjava unaprijed zadane kontrole vrijednostima ili željenim porukama.

U funkcionalnom smislu, Poskok 2 je simulacija Pythonovog IDLE-a, samo što je grafički drugačije struktuirana (slika 5.).

U okviru Naredbe, koje nije editabilno, ispisuju se naredbe odabrane u glavnom izborniku za naredbe (slika 5, gore lijevo). U središtu je već prije opisani okvir Varijable, a desno je žuti okvir Izvršavanje u kojem se izvode input i print naredbe.

Naredbe iz okvira Naredbe mogu se izvršiti odjednom (gumb Izvrši) ili postupno (gumb Postupno). Nakon klika na potonji gumb, prikažu se dva dodatna gumba: zelenim gumbom izvršava se naredba po naredbi, a crveni gumb služi za izlazak iz postupnog načina izvršavanja.

Posebnost aplikacije je automatsko iscrtavanje dijagrama toka. Dok se naredbe izvode u postupnom načinu, trenutačna naredba u okviru Naredbe ispisuje se na crvenoj podlozi, a u dijagramu toka trenutačni blok iscrtava se crvenom bojom i crvenim strelicama toka kako bi učenik lakše pratio slijed izvođenja naredaba.
D. Poskok 4

U četvrtoj po redu aplikaciji po prvi puta se uvodi upisivanje naredaba iz naredbenog retka (dakle, bez posredovanja izbornika za naredbe). Svi ostali elementi sučelja poznati su od prije, tako da se učenik osjeća u već poznatom okruženju (slika 8.).

Kao značajna novost, u okviru Naredbe dodana je mogućnost uređivanja naredaba. Poskok 4 je prva aplikacija u paketu koja od učenika zahtijeva poznavanje sintakse programskog jezika Python (za naredbe input, pridruživanje vrijednosti i print) i prva koja učeniku omogućava slobodno upisivanje i uređivanje naredaba pa predstavlja veliki skok u metodicičkom smislu. Zato je ovaj interpreter naredaba dodatno nadograđen kako bi učeniku ne samo prijavljivao pogreške, nego ga upućivao što treba ispraviti.

E. Poskok 5

Ova je aplikacija namijenjena obradi naredbe if. Zbog njene složenosti i zahtjevnih sintaktičkih pravila, ponovo je uveden izbornik za naredbe kako bi se učeniku olakšalo usvajanje primjene logičkih uvjeta koje naredba if sadrži (slika 9.).

Korištenjem izbornika za naredbe učenik ne mora razmišljati o pravilnom uvaženju naredbenog retka udesno niti o uporabi dvotočke jer se o tome brine aplikacija. To mu omogućava da se fokusira na pravilno kombiniranje, odnosno sastavljanje logičkih uvjeta kako bi riješio postavljen problem.

Ovdje nije omogućeno uređivanje naredaba jer pretpostavljamo da je učenicima potrebno određeno vrijeme dok usvoje zahtjevnu sintaksu naredbe if. Budući da sama aplikacija generira programski kód, time je učenicima ipak omogućeno da rješavaju probleme logičkog odlučivanja i grananja programa.

F. Poskok 6

U aplikacijama Poskok 6, Poskok 7 i Poskok 8 više se ne koristi forma izbornika za naredbe, nego učenik slobodno unosit će prikazivanje vrijednosti i print) i prva koja učeniku omogućava slobodno upisivanje i uređivanje naredaba pa predstavlja veliki skok u metodicičkom smislu. Zato je ovaj interpreter naredaba dodatno nadograđen kako bi učeniku ne samo prijavljivao pogreške, nego ga upućivao što treba ispraviti.

Kao značajna novost, u okviru Naredbe dodana je mogućnost uređivanja naredaba. Poskok 4 je prva aplikacija u paketu koja od učenika zahtijeva poznavanje sintakse programskog jezika Python (za naredbe input, pridruživanje vrijednosti i print) i prva koja učeniku omogućava slobodno upisivanje i uređivanje naredaba pa predstavlja veliki skok u metodicičkom smislu. Zato je ovaj interpreter naredaba dodatno nadograđen kako bi učeniku ne samo prijavljivao pogreške, nego ga upućivao što treba ispraviti.

Zato je ovaj interpreter naredaba dodatno nadograđen kako bi učeniku ne samo prijavljivao pogreške, nego ga upućivao što treba ispraviti.

Zbog složenosti naredaba koje obradjuju (naredbe if, for i while), ove tri aplikacije imaju okvir Diagram toka u kojem se automatski iscrta dijagram toka. Mišljenje smo da vizualna prezentacija programskog koda pomaže učenicima u razumijevanju njegova izvođenja, što posebice dolazi do izražaja tijekom postupnog izvođenja složenih naredaba kao što su logički uvjeti i programske petlje.

Zbog složenosti naredaba koje obradjuju (naredbe if, for i while), ove tri aplikacije imaju okvir Diagram toka u kojem se automatski iscrta dijagram toka. Mišljenje smo da vizualna prezentacija programskog koda pomaže učenicima u razumijevanju njegova izvođenja, što posebice dolazi do izražaja tijekom postupnog izvođenja složenih naredaba kao što su logički uvjeti i programske petlje.

Slično kao netom opisana aplikacija Poskok 5, i aplikacija Poskok 6 sadržajno obrađuje naredbu if, ali na metodicički drugačiji način, odnosno kroz drugačije koncipirano korisničko sučelje (slika 11.). Učenik ovde više nema pomoć izbornika za naredbe koji bi generirao programski kód, nego ga mora sam upisati, što pretpostavlja da je već svladao sintaksu naredbe if.

Korištenjem izbornika za naredbe učenik ne mora razmišljati o pravilnom uvaženju naredbenog retka udesno niti o uporabi dvotočke jer se o tome brine aplikacija. To mu omogućava da se fokusira na pravilno kombiniranje, odnosno sastavljanje logičkih uvjeta kako bi riješio postavljen problem.

Pokazuimo na primjeru koliko korisna može biti uporaba dijagrama toka za razumijevanje programskog koda. Kód koji slijedi ispod (isti je i na slici 11.) sadrži uglaženu naredbu if, odnosno složenu strukturu if-else-else:

```python
if a > b:
    print('a > b')
else:
    if a < b:
        print('a < b')
    else:
```

Slika 8. Sučelje aplikacije Poskok 4

Slika 9. Sučelje aplikacije Poskok 5

Slika 10. Spremanje i učitavanje programskog koda

Slika 11. Sučelje aplikacije Poskok 6

Pokažimo na primjeru koliko korisna može biti uporaba dijagrama toka za razumijevanje programskog koda. Kód koji slijedi ispod (isti je i na slici 11.) sadrži uglaženu naredbu if, odnosno složenu strukturu if-else-else:
print('a = b')

Pripadajući dijagram toka prikazan je na slici 11. Ako gornji primjer transformiramo u if-elif-else strukturu:

```python
if a > b:
    print('a > b')
elif a < b:
    print('a < b')
else:
    print('a = b')
```
dobije se identičan dijagram toka. Na taj način učenicima se zorno pojasni što je else, logička struktura znakovita za programski jezik Python.

G. Poskok 7 i Poskok 8

Zadnje dvije aplikacije paketa Poskok obraduju programske petlje, pa ćemo ih opisati zajedno, budući da imaju slično korisničko sučelje i gotovo jednak programsku funkcionalnost.

Aplikacija Poskok 7 namijenjena je usvajanju programske petlje for (slika 12.) a aplikacija Poskok 8 obraduje programsku petlju while (slika 12.). Obje aplikacije sadrži iste elemente sučelja kao aplikacija Poskok 6.

Uvidem u dijagram toka na slici 12. primjetno je da svaka naredba ima svoj grafički blok. Naime, namjerno je izbjegnuto združivanje istovrsnih naredaba u jedan blok, što često možemo vidjeti u stručnog literaturi. Smatramo da je s metodičkog motrišta ovakvo združivanje u blokove pogrešno, a za početnike i vrlo zbunjujuće. Osim toga, združivanjem naredaba u jedan blok onemogućilo bi se pravilno izvođenje postupnog načina izvršavanja programskog koda.

Tijekom izvođenja programske petlje u postupnom načinu (tipka Postupno) do punog izražaja dolazi okvir Variable u kojem učenik prati promjene vrijednosti brojača petlje ili vrijednosti varijabli koje se izračunavaju u tijelu petlje. Na taj način učenik dobiva dubinski uvid u funkcioniranje petlje i može pratiti ispunjene logičkih uvjeta za izlazak iz petlje.

III. ZAKLJUČAK

Opisani paket aplikacija Poskok zamišljen je kao pomoć u poučavanju i učenju programskog jezika Python u sklopu nastave informatike u našim osnovnim školama. Paket je još u fazi razvoja i traženja optimalnih pedagoških i metodičkih rješenja, pa ga stoga još nismo sustavno evaluirati.

U izvedbenom smislu, realiziran je kao skup online aplikacija napisanih u JavaScriptu i jQueriju pa se može izvoditi u bilo kojem web- pregledniku koji podržava standard HTML5. Aplikacije su međusobno neovisne što osigurava da ih se koristi zasebno, bez unaprijed zadanog (predviđenog) redoslijeda, čime je omogućena fleksibilnost primjene u nastavi.

Budući da nismo raspolagali objektivnim i provjerениm smjernicama za uvođenje programskog jezika Python u nastavne sadržaje primarnog obrazovanja, u kreiranju paketa Poskok rukovodili smo se općim spoznajama o Pythonovim prednostima i nedostacima te vlastitim promišljanjem i iskustvom. To je ujedno i jedan od glavnih nedostataka ovog paketa pa njegovu uporabnu vrijednost u nastavi tek treba istražiti.

Trenutačno postoji niz otvorenih pitanja na koja ćemo pokušati pronaći odgovor u idućoj fazi razvoja i primjene Poskoka u nastavi. U svrhu daljnjeg razvoja, odnosno dorade paketa planiramo istražiti nekoliko problemskih segmenta:

- za koje dobne skupine učenika je pojedina aplikacija iz paketa (metodički) primjerena,
- da li programski strukturirana pomoć u svladavanju sintakske zapravo odmaže učeniku u stjecanju trajnih kompetencija,
- može li se učenje potaknuti/ubrzati ugradnjom sustava kontekstualnih uputa koje bi precizno, u odnosu na kontekst, upućivale na određene dijelove grada.
LITERATURA

Sažetak – Sve što postoji u stvarnom životu nastojimo digitalizirati. Možemo li obrnuti postupak, nečemu digitalnom dati fizički oblik?
Odgovor je DA. Upravo 3D printerom i njegovom tehnologijom možemo premostiti jaz između digitalne i fizičke stvarnosti. Uz eLearning podučavanja počinje i era eMaking stvaranja. Uvođenje 3D print tehnologije čini nastavu dinamičnijom, ohrabruje učenike da pronalaze kreativna rješenja, da opipom istraže i dožive stvarnost i da na kraju svoga obrazovanja uđu spremniji na tržište rada. Godine nisu ograničavajući faktor. Čak i djeca mogu početi s izradom popularnih likova iz omiljenih crtanih filmova. Učenici mogu izraditi objekte za potrebe nastave. 3D printom koriste se ljudi iz struke, inženjeri, znanstvenici, dizajneri, arhitekti, doktori, hobisti, robotičari pa čak i oni kojima to predstavlja čistu zabavu. Isprintani predmeti mogu služiti kao pomagala u radionicama ili domaćinstvima, predstavljati realizaciju nekog dizajnerskog modela ili prototipove. Iako ima različitih tipova printera, najzastupljeniji su printeri koji koriste FDM tehnologiju s PLA ili ABS plastičnim materijalima.

Razvoj 3D tehnologije napreduje brzo i širi se u svim segmentima ljudskog djelovanja. Ograničavajući faktori su brzina i prostor printanja. 3D print tehnologija ovisi o vrsti materijala (ABS, PLA, PVC, PUR, keramika čelik, aluminij) i tehnologiji slaganja. FDM tehnologija podrazumijeva polurastopljenog plastičnog materijala ili filamenta na podlogu (vidi sliku 1), sloj po sloj gradeći tako konturu nacrtanog modela prema naredbama generiranog G-koda (strojni jezik kojim su definirane kretnje, brzina i putanja pomičnog dijela stroja).

1. UVOD

III. FDM TEHNOLOGIJA

FDM tehnologija podrazumijeva polurastopljenog plastičnog materijala ili filamenta na podlogu (vidi sliku 1), sloj po sloj građenje tako konturu nacrtanog modela prema naredbama generiranog G-koda (strojni jezik kojim su definirane kretanje, brzina i putanja pomičnog dijela stroja).

Slika 1: Prikaz FDM tehnologije.

veličini. Nakon što je tijelo stavljeno u ispravni položaj i izabrana prava veličina, slijedi virtualno rezanje na slojeve, podešavanje temperature ekstrudera (dio glave printera kroz koji prolazi filament i istiskuje ga), priprema materijala za početak printanja (uvlačenje filamenta u ekstruder) i po potrebi biranje gustoće ispune ili brzine printanja, postavljanje potporne strukture ili načina priječavanja za podlogu.

Program (Slic3r ili CuraEngine) raste priprema slojeva, podešavanje temperature ekstrudera (dio glave printera kroz koji prolazi filament i istiskuje ga), pristup materialima za početak printanja (uvlačenje filamenta u ekstruder) i po potrebi biranje gustoće ispune ili brzine printanja, postavljanje potporne strukture ili načina priječavanja za podlogu.

Program (Slic3r ili CuraEngine) reže model u slojeve i pritom stvara G-kod, koji se može pokrenuti s računala. Postoje besplatni programi, i odgovaraju nažalost, no neki su zahtjevni za instalaciju. Najbolji izbor je Autodesk Fusion 360, koji se također koristi za dizajniranje rudera i mašina. OpenSCAD je jedan od odraslih korisnika, koji može experimentirati s dizajnom ili materijalom, tu su programi Blender i Meshmixer. Za one koji još nemaju vještine dizajniranja, mogu pronaći gotove modele na mrežnim stranicama kao što su Thingiverse, Pinshape ili Shapeways.

II. JESMO LI SPREMNI ZA 3D PRINT TEHNOLOGIJU U OBRAZOVANJU?

Ako pogledate danas učenike kako pristupaju tehnologiji, primijetiti ćete da je za njih razgovor telefonom ili čitanje e-maila nešto starijeg, teško je da se o njihovo raditi. Mladim ljudima pametni telefoni služe kako bi se beskonačno pisali poruke, tijekom čitanja informacija na internetu, fotografirali se u svakoj prilici ili snimali videozapise. Istovremeno mogu raditi više stvari odjednom: slušati glazbu, učiti geografiju i pisati poruke.

Od tehnologije posjeduju i služe se računalima, pametnim telefonom, tabletima, prate serije po sezonama na android televizorima, a vrijeme provedeno na tim uređajima mjeri se u satima. Tehnologija je sastavni dio života mladih ljudi, tehnologiji posjeduju i služe se računalima, pametnim telefonima, tabletima, televizorima, a vrijeme provedeno na tim uređajima mjeri se u satima. Tehnologija je sastavni dio života mladih ljudi, tehnologiji posjeduju i služe se računalima, pametnim telefonom, tabletima, prate serije po sezonama na android televizorima, a vrijeme provedeno na tim uređajima mjeri se u satima.

Konstrukcija, hobi ili dizajn kroz tečajeve oglašavane rashodim za vijekovima, koji žele svoje vrijeme iskoristiti za konstruiranje, hobi ili dizajn proti tečajeve oglašavane putem javnih glasila.

III. 3D MODELI

Pristupom 3D tehnologiji u drugim osnovnim i srednjim školama ili udrugama, pružiti satove iz osnova modeliranja onim korisnicima koji žele svoje vrijeme iskoristiti za konstruiranje, hobi ili dizajn proti tečajeve oglašavane putem javnih glasila.

III. 3D MODELI

printanje, a sama konstrukcija prepušta se 3D printeru.

Početak 3D printanja u razredu zahtijeva vremena i prostora. Razlikujemo 3 vrste aktivnosti koje je moguće ostvariti u razredu:

- rad pojedinca, učenik radi sam na projektu, razred nije uključen;
- timski rad, grupa učenika radi na svom projektu, rade samo oni zainteresirani;
- rad cijelog razreda, svi u razredu printaju, obično neki mali predmet.

Najčešći oblik aktivnosti je individualni rad na 3D printeru, npr. izrada završnog rada. Zatim slijedi rad u grupama, npr. kontinuirano okupljanje tijekom cijele godine kroz neku slobodnu aktivnost. Najrjeđe i najteže je uključiti cijeli razred, ali i to je ponekad moguće. Takav oblik aktivnosti proveli smo u svim prvim razredima naše škole kroz razredni predmet Računalstvo. Obradili smo nastavni sat pod nazivom Izlazne jedinice što je uključivalo prezentaciju rada 3D printera i sudjelovanje cijelog razreda te dva nastavnika.

Najčešći oblik aktivnosti je individualni rad na 3D printeru, npr. izrada završnog rada. Zatim slijedi rad u grupama, npr. kontinuirano okupljanje tijekom cijele godine kroz neku slobodnu aktivnost. Najrjeđe i najteže je uključiti cijeli razred, ali i to je ponekad moguće. Takav oblik aktivnosti proveli smo u svim prvim razredima naše škole kroz razredni predmet Računalstvo. Obradili smo nastavni sat pod nazivom Izlazne jedinice što je uključivalo prezentaciju rada 3D printera i sudjelovanje cijelog razreda te dva nastavnika.

**V. ZAKLJUČAK**

Primjena novih tehnologija pa tako i uporaba 3D print tehnologije u obrazovanju omogućuje lakše učenje, potiče kreativnost, znatiželju, unaprjeđuje znanje. Korisno je za cijelu školu i lokalnu zajednicu. Cijena printera nije više nedostupna. Zbog brojnih mogućnosti i funkcionalnosti 3D printera moguće je proizvesti sve što mašta može zamisliti. Tehnologija 3D printera razvija se svakodnevno i za očekivati je da će na tržištu doći noviji i moderniji modeli. 3D printeri ulaze u firme, škole, domove pa će tako uskoro postati normalni standard u kućanstvima.

Nastavnici u ICT području o mogućnostima za svoje stručno usavršavanje

K. Blažeka, Tehnička škola Čakovec, Čakovec, Hrvatska
kristinka.blazeka@skole.hr

Sažetak - Poboljšanje nastavnih prakse i obrazovnih postignuća učenika dokazano se ostvaruje kroz rast stručnih kompetencija (znanja i vještina) nastavnika. Zbog toga obrazovni sustav treba potporu u stručnom usavršavanju nastavnika koje je sustavno, kontinuirano i kvalitetno te usmjeren na važan sadržaj, ali i prilagođeno za daljnje kontinuirano cjeholjudstveno obrazovanje i rad. Nastavnici trebaju usvajati nova znanja u područjima koja predaju i nove načine poučavanja, trebaju razumjeti proces učenja i pedagogiju, odgovarati na potrebe učenika i na potrebe podrudnje, te moraju biti sposobni razviti jaku povezanost između očekivanja učenika i ciljeva kurikuluma. Ovaj tekst je pristupaj i sa kojim se škola istraženo je kako nastavnici podrazumijevaju koncept obrazovanja sa najvećim utjecajem na vještine obrazovanja. Upotrebom stručnog usavršavanja te identificira skup principa svih učenika. Uspješna karijera nastavnika objedinjuje njihove gledište vezano uz potporu učenja i pedagogiju, odgovarati na potrebe u područjima koje prenose i oblikuju okruženje za učenje. Njihovo znanje, vještine, stavovi i sklonosti imaju izravne i ozbiljne implikacije na uspjeh učenika i njihov profesionalni uspjeh učenika. U procesu obrazovanja od nastavnika se očekuje posjedovanje predmetnog i pedagoškog znanja, a njihova karijera treba pokazivati kako njihov profesionalni razvoj nije stao u trenutku stjecanja osnovne i kvalifikacija. Zato je njihovo profesionalno usavršavanje njihova obaveza s ciljem poboljšanja individualnog učenika i njihovog rada u učionici.

Nastavnici trebaju ovladati učinkovitim strategijama učenja kako bi učinkovito projekcijama učenja i učenje učenika koje su učenici osećali s ciljem poboljšanja individualnog učenika i njihovog rada u učionici.

I. UVOD

Iako dobro pripremljeni u disciplini ili predmetnom podrudju, nastavnici se, posebno u ovim godinama, zaštita, sučeljaju sa stvarnom složenosti rada u učionici: baza njihovog znanja u sadržajima koje predaju obično nije dovoljna kako bi učinkovito bilo usavršavanja te identificira skup principa njihove gledište vezano uz potporu učenja. Uspješna karijera nastavnika objedinjuje njihove gledište vezano uz potporu učenja i pedagogiju, odgovarati na potrebe u područjima koje prenose i oblikuju okruženje za učenje. Njihovo znanje, vještine, stavovi i sklonosti imaju izravne i ozbiljne implikacije na uspjeh učenika koje poučavaju i zato profesionalno usavršavanje nastavnika predstavlja ogromnu investiciju u razvoj profesionalnog kapitala usmjerenog u osiguravanje sva znanja i vještina i učinkovitosti učenja i poučavanja u našim školama [1]. Uvriježen je konsenzus kako je glavni element u procesu obrazovanja i učenja u našim školama [1].

U tom smislu, profesionalni razvoj nastavnika uključuje procesi kojima se obrazovanje učenika s ciljem da nastavnici omogućuju usavršavanje i produbljivanje njihovih znanja, vještina i predanosti s ciljem učinkovitog izvođenja njihovih radnih uloga (Schwille i Dembele, 2007).

II. PROFESIONALNI RAZVOJ NASTAVNIKA

Profesionalni razvoj nastavnika definira se kao promjena u izvedbi, znanju, stavovima i percepcijama nastavnika. To su te promjene značajnije, jače su izražene pozitivne promjene u rezultatima učenja učenika.

1. Konkretno i učioničko.
2. Unosi izvanškolsku vještine.
3. Uključuje nastavnike u izbor područja koje će razvijati i aktivnosti koje će poduzimati.
4. Omogućuje nastavnicima suradnički rad sa kolegama.
5. Osigurava mogućnosti za mentoriranje.
6. Kontinuirano je u vremenu.
7. Podržano je od strane učinkovitog školskog rukovodstva.

U tom smislu, profesionalni razvoj nastavnika uključuje procesi kojima se obrazovanje učenika s ciljem da nastavnici omogućuju usavršavanje i produbljivanje njihovih znanja, vještina i predanosti s ciljem učinkovitog izvođenja njihovih radnih uloga (Schwille i Dembele, 2007).
Precizno, ono što se očekuje od pojedinaca-nastavnika da znaju i budu sposobni raditi, treba biti definirano standardima koji stvaraju okvir za odlučivanja o certifikacijama, licenciranju, promoviranju i naknadama za rad. Također, standardi mogu definirati uvjete za provoditelje i programe usavršavanja nudići okvir i za odluke o njihovoj akreditaciji, dozvoli i prepoznavanju.

Uvidom u npr. standarde u SAD može se primijetiti da oni obuhvaćaju: znanje o predmetnim sadržajima, znanje razvoju i učenju djece, poznавањe različitih stilova učenja i nastavnih strategija, znanja o okolinama učenja, komunikaciji i i planiranju nastave, znanja o ocjenjivanju, znanja o profesionalnom razvoju, suradnji i odnosima. U Egiptu, primjerice, standardi za nastavnike obuhvaćaju između ostalog: znanje određivanja obrazovnih potreba učenika, planiranje globalnih ciljeva, oblikovanje odgovarajućih obrazovnih aktivnosti, korištenje strategija učenja odgovarajuće potrebama učenika, uključivanje učenika u rješavanje problema, kritičko i stvaralačko razmišljanje, osiguravanje okoline koja jamči pravnicu, učinkovito upravljanje vremenom za učenje i ograničavanje izgubljenog vremena. Nadalje, nastavnici bi trebali potpuno biti svjesni temelja i prirode predmeta koji predjaju, potpuno poznavati metode istraživanja u tom predmetu, biti sposobni taj predmet integrirati sa drugim predmetima te biti sposobni proizvoditi znanje. Osim toga moraju biti sposobljeni za samoevaluaciju, evaluaciju učenika i ostvarivanja povratne veze, te u konačnici ostvarivati profesionalnu etiku i profesionalni razvoj. U Pakistanu, npr. nastavnici trebaju imati znanje predmeta koji predjaju, znanja o humanom razvoju i rastu, poznавање islamskih vrijednosti, znanja o planiranju nastave i nastavnim strategijama, ocjenjivanju, okolinama učenja, komunikaciji, suradnji i partnerstvu, profesionalnom razvoju i posjedovati i ICT znanja [3]. Dodatno, standardi se mogu iskorištiti za definiranje, ocjenjivanje i pomoć u razvoju kvalitete profesionalnih razvojnih programa.

III. PROFESSIONALNO USAVRŠAVANJE NASTAVNIKA U NEKIM SPECIFIČNIM KONTEKSTIMA

A. Usavršavanje nastavnika u ICT podrucju

Povećanjem investicija u obrazovne tehnologije, ICT nastavnici dodatno igraju važnu ulogu u uspješnoj integraciji tehnologije u nastavne procese. U devedesetim godinama prošlog stoljeća, o računalima se pohvaćalo u okviru zasebnih nastavnih predmeta u mnogim europskim državama. U novije vrijeme, žarište integracije tehnologije pomiće se sa učenja o ICT na učenje sa (kroz) ICT (npr. kako koristiti Internet ili obrazovni softver za rješavanje različitih problema). U razvijenim državama (zapadna Europa ili Amerika) ICT kompetencije općenito se usavršavaju kroz sadržaje učenja i aktivnosti drugih predmeta, no ponegdje se (npr. Engleska, Grčka, Bugarska) ICT vještine i dalje poučavaju kao odvojeni predmet, pa nastavnici trebaju posjedovati i stručnost u predmetima koji pokrivaju sadržaje vezane uz programiranje računala, umrežavanje, razvoj softvera i druge. Ovo je posebno karakteristično za strukovne škole. Od ICT nastavnika zahtijeva se da u svom području uvijek imaju aktualizirana znanja, ali i da njihovo usavršavanje i profesionalni rast budu dovoljno učinkoviti kako bi ovladali odgovornošću da kod svojih učenika osiguraju razvoj vještina kritičkog razmišljanja.

B. Usavršavanje nastavnika u srednjoškolskom kontekstu

Niz je važnih razlika između osnovnih i srednjih škola sa potencijalnim utjecajem na vrste profesionalnog usavršavanja nastavnika koje bi imale pozitivan utjecaj na rezultate učenika. Srednje škole su često veće, učenici su stariji, kurikularni sadržaji su sofisticiraniji. Nastavnici su specijalizirani za predmete koje poučavaju, znanja su im više usmjerenja na specijalistička i sadržajna, manje na pedagoška. Kaže se kako 'Secondary school teachers teach subjects, but primary teachers teach students.’

Usprkos tim razlikama, obično nema značajnih razлиka u aktivnostima, procesu učenja, trajanju ili učestalosti stručnog usavršavanja, a niti o mjestu niti davanju usluge. Čak su i vrste podrucja učenja slične iako se pružaju različitim rastvorima.

IV. KAKO PROFESSIONALNO USAVRŠAVANJE NASTAVNIKA UČINITI UČINKOVITIM?

Istraživanja u SAD [5] pokazala su kako je bar pet ključnih značajki koje čine profesionalno usavršavanje učinkovitim u procesu poboljšanja učenja i poučavanja: (1) usredotočenost aktivnosti na sadržaj predmeta i na to kako učenici uče taj sadržaj; (2) aktivno učenje kod kojeg nastavnici promatraju, dobivaju povratne informacije, analiziraju rad učenika i prezentiraju; (3) usklađenost sadržaja, ciljeva i aktivnosti sa školskim kurikulumom i ciljevima, znanjem i uvjerenjima nastavnika, potrebama učenika, škole, područja, državnih reformi i politika; (4) kontinuirano trajanje tijekom školske godine najmanje 20 sati neposrednog kontaktta i (5) zajedničko sudjelovanje gруpe nastavnika istog razreda, predmeta ili škole koji sudjeluju u aktivnostima usavršavanja stvarajući interaktivnu zajednicu učenja. No, u obzir treba uzeti i specifičnosti kao što su: nastavnici se razlikuju u reakcijama na isto stručno usavršavanje, zatim stručno usavršavanje je uspješnije ako je eksplicitno vezano uz razvoj učenika. Srednje škole su često veće, učenici su stariji, kurikularni sadržaji su sofisticiraniji. Nastavnici su specijalizirani za predmete koje poučavaju, znanja su im više usmjerenja na specijalistička i sadržajna, manje na pedagoška.
samo profesionalni razvoj sa predonim utjecajem (potrebno je imati mogućnost ocjenjivanja aktivnosti profesionalnog usavršavanja).

U Italiji je u periodu od 1998-2000 odlučeno je da se u procesu reformi priznaju ograničenja dominantne paradigme i napusti tradicionalni model profesionalnog usavršavanja nastavnika. Novi pristup utemeljuje se, između ostalog, na:

a. Novoj viziji – stručno usavršavanje nastavnika znači da oni predviđaju i vode svoj proces usavršavanja, a ne da su njime vođeni:

• Svaki nastavnik ima svoju osobnu profesionalnu biografiju; svaki nastavnik treba imati vlastiti personalizirani razvojni plan.
• Tijekom svoje karijere nastavnici prolaze profesionalne cikluse i slijed iskustva učenja. Profesionalni učitelj nije samo kompetentan i stručan, nego i profesionalac kontinuirano naučenog znanja.
• Nastavnici su reflektivni profesionalci; razvoj implicira kontinuiranu refleksiju iskustva smišljanja novih obrazaca djelovanja, svjesnijih i učinkovitijih.
• Profesionalni razvoj nastavnika pomaže u poboljšanju učenja i postignuća učenika.

b. Novoj politici

• Razvoj koherentne politike za profesionalni razvoj nastavnika.

• Zahtjev za kvalitetom (definirani standardi za organizaciju i financiranje sustava, aktivnosti pružanja, plan povećanja vještina voditelja projekta).

• Svakom je nastavniku omogućeno da na aktivnostima usavršavanja sudjeluje 5 dana godišnje.

• Pojedinačno su školama dani resursi za njihove razvojne planove i profesionalno usavršavanje nastavnika.

• Financijski resursi dolaze iz drugih područja javnih aktivnosti (zdravstvenog, socijalnog...).

• Mnoge aktivnosti koje se izvode na školskoj razini imaju izravan utjecaj na profesionalni razvoj i pomažu smanjiti troškove treninga (kolegijalno obrazovanje, kooperativni projekti, razvojni projekti, grupe za samopomoć...).

• Novi pristupi (ICT, mješoviti sustavi financiranja projekata kroz javno i privatno investiranje).

• Oblikuje se lista akreditiranih davatelja usluga (institucija i agencija) treninga nastavnika čime se povećava kvaliteta i osigurava njihova pouzdanost. Poseban položaj prepoznat je za strukovna udruženja nastavnika i znanstvene zajednice otvorene nastavnicima.

• Novim modelima

• Nugoročni cilj predstavlja postepena izgradnja integriranih okolina učenja za profesionalni razvoj nastavnika: obećavajuće rješenje su sponzorirane i podržane mreže nastavnika koje rade na razvoju kurikuluma u kooperaciji sa školama, profesionalnim udruženjima i školskom administracijom.

• Na inovativne se načine ostvaruje partnerstvo sa sveučilištima.
• Razvijaju se i implementiraju pilot sheme za financiranje istraživačkih projekata nastavnika.
• Tečajevi se nude preko TV satelitskih kanala, ostvarena je pilot shema za video on demand (preko 2000 uglavnom 10minutnih programa) preko Interneta.
• U skupu profesionalnih usluga koje mogu aktivirati, nastavnici mogu koristiti i druge stručnjake i profesionalce (npr. profesionalna pomoć i mentoriranje za početnike).
• Motivaciju nastavnika može povećati, te osigurati novi uvid u specifična interesna područja, dotijac sa drugim organizacijskim okolinama: razvija se poseban program u kojem se nastavnicima nudi desetodnevna scena u različitim potencijalnim okolinama učenja (agencija za komunikaciju, moderna biblioteka...).

• Naglašava se lokalno bazirane mogućnosti profesionalnog razvoja: centri nastavnika i usluge nastavnicima na lokalnoj razini dio nacionalne politike. U zajedništvu sa lokalnim upravama, muzejima, umjetničkim galerijama, javnim knjižnicama nastavnicima se nude različiti skupovi inicijativa.

• Za interakciju između davatelja usluga i korisnika razvija se web site na kojem nastavnici mogu naći informacije o mogućnostima profesionalnog razvoja.

Poduzimaju se individualne mjere, naglašava se profesionalna autonomija nastavnika, škole trebaju podržavati planove individualnog stručnog usavršavanja nastavnika, financijska sredstva za istraživanje daju se individualnim nastavnicima. Nema nužnog podrazumijevanja uniformnog pristupa za sve. Holistički pristup profesionalnom usavršavanju nastavnika traži politiku diverzifikacije mogućnosti i personalizaciju profesionalnog rasta. Manje tečajeva, ali više kvalitete, fokusirane i specifične inicijative koje u obzir uzimaju potrebe, profesionalne i životne cikluse, trajanje karijere i konstruktivistički pristup. Nove strukture baziraju se na kooperativnim shemama, dijeljenoj viziji i zajedničkom radu na projektima. Visokokvalitetni sustav profesionalnog usavršavanja nastavnika traži jaku vezu sa istraživačkim zajednicom.

U Engleskoj raste broj škola koje imaju za kontinuirano profesionalno usavršavanje po dva sata svaka dva tjedna, uz pet standardnih dana za usavršavanje, što daje godišnje najmanje 63 sata profesionalnog razvoja. U tih 19 dvostrutih sesija godišnje, stručni aktivi mogu se fokusirati na svoje razvojne prioritete, a nastavnici mogu zajednički planirati lekcije i raditi na njihovom nastavnom radu. Kako bi se omogućilo više rada na profesionalnom razvoju, prilagođen je školski raspored, a rezultati su se, usmjeravanjem na suštinu, znacajno povećali.

Sesije se temelje na predmetnim područjima, uključuju zajednički sat, gledanje i debatiranje sa kolegama primjera (vlastite) prakse na videu o aspektima i poteškoćama i podržavaju mreže nastavnika koje rade na razvoju. Zajednički sat, gledanje i debatiranje sa kolegama primjera (vlastite) prakse na videu o aspektima i poteškoćama i podržavaju mreže nastavnika koje rade na razvoju. Tijekom svoje karijere nastavnici prolaze profesionalne cikluse i slijed iskustva učenja. Profesionalni učitelj nije samo kompetentan i stručan, nego i profesionalac kontinuirano naučenog znanja. Profesionalni razvoj nastavnika pomaže u poboljšanju učenja i postignuća učenika.
područja pri poučavanju. Tako se ostvaruje mogućnost poboljšavanja prakse na mikro-razini (pokreti, upiti, suputine tehnike upravljanja razredom) i pristup koji povezuje poučavanje sa rezultatima učenika. Identificiranjem i odabirom manjeg broja razvojnih prioriteta stručnih aktivta oigurava se visoka razina usklađenosti između upravljanja uspješnošću, razvoja predmeta, individualnog razvoja i cjelokupnog razvoja škole. [4].

Tablica u nastavku iznosi usporedbu sustava profesionalnog usavršavanja u različitim državama:

V. ISTRAŽIVANJE

**Svrha**

Nastavnici pokazuju više motivacije za usvajanje novih znanja i njihovu implementaciju u praksi ako profesionalno usavršavanje kojem pristupaju ispunjava njihova očekivanja, odnosno ako to usavršavanje nudi sadržaje relevantne njihovim stvarnim zadacima u učionicama i ako je vezano uz njihove specifične potrebe za učenjem.

Istraživanjem se željelo ispitati i dobiti odgovore na specifična pitanja vezano uz percepciju nastavnika o postojećem konceptu stručnog usavršavanja, o načinima njegovog ostvarivanja i o ograničenjima sa kojima se nastavnici suočavaju:

1. Opseg, mogućnosti i učestalost sudjelovanja nastavnika na različitim oblicima stručnog usavršavanja
2. Raznovrsnost i upotrebljivost stručnog usavršavanja u različitim područjima
3. Potrebe za usavršavanjem u različitim područjima iz okruženja svakodnevnog rada nastavnika

**Metodologija i instrumenti**

**Uzorak**

Sudjelovalo je, odnosno prikupljeni su odgovori ukupno 55 nastavnika osnovnih i srednjih škola, 21 muškog i 34 ženskog spola. Podaci su analizirani prema temama razvijenim u odnosu na specifična pitanja kojima je vodeno istraživanje. Upitnik su ispunjavaли sudionici međuzupanijskog stručnog skupa EU projekti u školama, održanom u siječnju 2017. godine. Na skupu su većinom sudjelovali nastavnici s područja Međimurske i Varaždinske županije. 25 nastavnika zaposleno je u srednjim školama, a 30 u osnovnim.

**Rezultati**

Slike 1. i 2. prikazuju demografske karakteristike ispitanika:

**Slika 1.** Demografske karakteristike ispitanika prema dobi

**Slika 2.** Demografske karakteristike prema radnom iskustvu ispitanih nastavnika
Slika 3. Postotak potvrđnih odgovora na pitanja postavljena u anketi (N=55)
Iz grafičkog prikaza (slika 3.) vidljivo je kako je najveći postotak nastavnika (preko 98%) potvrdno odgovorio na pitanje: „Da li biste bili zainteresirani za plaćeno višednevno stručno usavršavanje izvan uobičajenog radnog vremena?“, što navodi na isticanje značaja koje stručno usavršavanje ima za nastavnike.

Iz prikaza se, nadalje, s obzirom na visok postotak potvrdnih odgovora, očuva kako je velika većina nastavnika u proteklih godinu dana sudjelovala u organiziranim oblicima stručnog usavršavanja (radionice, seminarji, konferencije...) i kako nastavnici u gotovo 78% slučajeva nemaju poteškoća prilikom odlaska na stručno usavršavanje organizirano tijekom radnih dana, te da im škole u gotovo istom postotku osiguravaju zamjene.

Postotak potvrdnih odgovora smanjuje se prilikom odgovora na pitanja o upotrebljivosti mogućnosti za stručno usavršavanje u različitim područjima: od 47% do 58% nastavnika smatra da su organizirane mogućnosti nedovoljno upotrebljive.

Vrlo niski postotci potvrđenih odgovora uslijedili su na pitanja o količini ponuđenih mogućnosti za stručno usavršavanje u različitim područjima: tek 14,6% ispitanih nastavnika misli da je bilo dovoljno mogućnosti za usavršavanje o poučavanju učenika s posebnim potrebama, a u području discipline i upravljanja razredom tek 18,2% ispitanih nastavnika misli da je tih mogućnosti bilo dovoljno.

S obzirom na niz ometajućih, ali učenicima zanimljivih faktora za vrijeme nastave o ICT-u (igre, chat, pregled web-a i dr.), nastavnicima u području ICT tehnologija izazov je osigurati učinkovito upravljanje razredom i usmjeriti pažnju učenika na nastavu.
sposobnosti. Sustavi sa visokim postignućima (Singapur) snažno investiraju u učenje i profesionalni razvoj svojih nastavnika.

Mnogo nas je koji smo inspirirani i kojima je pomogao sjajan nastavnik. Žato ja važno da nastavnici imaju pogodnost profesionalnog učenja kojeg trebaju i zaslужuju. U školama je potrebno stvarati kulturu povjerenja (i izazova) koja će poticati razvoj profesionalnog učenja nastavnika. U najuspješnijim školama osigurava se usmjeravanje i podrška, povjerenje u nastavnike, ohrabruje kreativnost, inovativnost i određena količina uzimanja rizika.

Možda bi trebali poduzeti neke odlučne korake u cilju poboljšanja profesionalnog učenja za nastavnike – čak i smanjenjem vremena koje očekujemo da će provesti u učionici ‘‘teach less, and teach better’’, odnosno ‘‘Our greatest resource is our teachers and their most precious resource is their time; it is common sense, then, that we must give our greatest resource the time to learn to become even better teachers.’’ [4]

S obzirom na rapidan rast tehnologije i njezinu neophodnost u obrazovanju, nastavnicima u ICT području trebali bi biti osigurani redoviti i kontinuirani treninzi kako bi njihova znanja u svakom trenutku bila relevantna. To bi bilo moguće postići ponudom ažuriranih programa profesionalnog usavršavanja na godišnjoj bazi.

LITERATURA

Primjena novih informacijsko komunikacijskih tehnologija u projektnoj nastavi

Ivana Ružić
I. osnovna škola Čakovec,
Ulica kralja Tomislava 43, Čakovec, Hrvatska
ivana.ruzych@skole.hr

U obrazovanju gotovo svakodnevno spominjemo projektne nastave kao oblik nastave pogodan za usvajanje novih znanja i vještina, razvoja stavova učenika, ostvarivanje različitih oblika suradnje i osobnog i profesionalnog rasta pojedinca kao pripremi za buduću zanimanja i razvoj kompetencija za cjeloživotno učenje. Ovakav oblik nastave omogućuje potpunu usmjerenost učitelja prema učeniku, razvija i osnažuje timski rad i suradnički odnos svih sudionika projekta, omogućuju razvoj istraživačkih, organizacijskih, komunikacijskih i kritičkih vještina učenika, te usvajanje metodologije znanstveno istraživačkog rada.Projektna je nastava važan način učenja u suvremenim obrazovnim sustavima, jer je primijenjivanja u svim vrstama nastave, osobito pri učenju interdisciplinarnih tema i sadržaja, u izvannastavnim aktivnostima, a neizostavna je u radu s nadarenim projektnim ciljevima. Informacijsko komunikacijska tehnologija u ovom kontekstu je alat koji doprinosi ostvarivanju motivacije svih sudionika u projektu.

I. UVOD

U današnje doba svaka organizacija nastoji ostvariti što bolju stratešku prednost kako bi postala prepoznatljiva i uspješnije funkcionirala. U obrazovnim ustanovama u nastavu se sve više uvodi projektni način rada njezinoj timski duh među učenicima i učiteljima te priprema učenika za budućnost tj. kako bi osvarili što veću konkurentnost na tržištu rada te se adekvatno pripremili za buduće karijere i vlastiti poslovni i osobni razvoj, razvili sposobnosti u četiri podložna razina motivacije svih sudionika u projektu.

II. ULOGA SUDIONIKA U PROJEKTNOJ NASTAVI

U svakom obrazovnom procesu najvažnija je uloga učitelja koji planira, motivira, provodi i vrednuje ishode obrazovnog procesa.

Projektna nastava traži veći angažman učitelja koji:
-postavlja ciljeve i zadatke odabrane teme,
-poštive učenike na stvaralačko istraživanje,
-pomaže učenicima u izradi projekta,
-vodi proces planiranja,
-predlaže suvremene i aktualne sadržaje i metode,
-poštive socijalizaciju učenika i zajedno s njima kritički vrednuje rezultate.

Uloga učenika u u projektnoj nastavi sastoji se u tome da učenici:
-daju inicijativu za rad sukladno njihovom interesu i sposobnostima,
-aktivno planiraju sve etape i tijek rada,
-traže rješenja problema,
-sudjeluju u samoocjenjivanju i vrednovanju rezultata rada.

Prednosti projektne nastave:
- veća je aktivnost učenika, veća sloboda komuniciranja među članovima skupine; učenici se međusobno nadopunjuju, podsjećaju na prijašnje gradivo i zajedno dolaze do rezultata.

- uspostavlja se kvalitetnija veza: učenik-član, učenik-nečlan, učenik-nastavnik

- primjenom projektne nastave učenici uče socijalizacijske vještine, razvijaju komunikaciju, toleranciju i smanjuju različite predarsude

- jačanje samopoštovanje i samopouzdanje učenika

- povećanje motivacije (ukidanje klasične provijere znanja) učenika za rad i učenje

- znanja i metode koje usvajaju su dugotrajne, a vještine i navike koje steknu primjenjive su u svakodnevnom životu.

III. PRIMJER PROVEDENIH PROJEKATA

Erasmus+ KA2 Keep Invest Donate Spend (KIDS) je međunarodni projekt financiran sredstvima Europske komisije. Provodio se dvije godine u pet partnerskih škola s područja EU. Cilj projekta je razvijati financijsku pismenost djece, roditelja i učitelja podizanjem svijesti o važnosti vlastitog ponašanja i raspolaženja dobrima, omogućuje djeci da stječu naviku štednje, osmisle, predlažu i provode kampanju podizanja svijesti u svojoj školi, susjedstvu i širokoj zajednici, koristeći crtež, plakate, računalne igre i obrazovne programe, video i druge sadržaje i aktivnosti kroz koje će prenijeti snažne poruke na temu financijske pismenosti. Ovaj program prate i obrazovni materijali prilagođeni za djecu i mlade prema dobim skupinama, obrazovni materijali za učitelje i roditelje.

Erasmus+ KA2 European Goodwill Cup je međunarodni projekat u kojem je sudjelovalo 8 škola širom Europe. Cilj ovog projekta je pokazati učenicima da živeći u ovom tehnološki napređenom društvu uz množstvo informacija i manjka slobodnog vremena ne izgube najvažnije ljudske i društvene vrijednosti poput senzibiliziranja za potrebe i probleme ljudi i životinja, a naročito onih nemoćnih, starih i najpotrebnijih ljubavi i brige. Cilj je i potaknuti ih na svakodnevnu čitanje knjiga, pravilnu i zdravu prehranu te pozitivan odnos prema školi. Cilj projekta je i međusobno povezati učenike te ih ohrabriti da čine društveno korisne stvari poput besplatnog volontiranja potrebitim i da o takvim i sličnim društveno korisnim aktivnostima obavještavaju jedni druge preko mrežne komunikacije (chat, Skype, video-konferencije...) i time građe prijateljstva s ostalim učenicima/sudionicima projekta diljem Europe. Želimo učenicima pokazati poveznice između škole i pravog života te da je korijenje engleskog jezika neophodno za medukulturalnu komunikaciju, ali i da je znanje stranog jezika jedna od najvažnijih kompetencija za zaposlenje.

Ovaj projekt stvorio je multinacionalnu vezu za desetke učitelja, stotine učenika i njihovih obitelji iz različitih dijelova Europe te nam proširio vidike, znanja, vrline i učinio nas boljim građanima ovog Europejskog društva.

Safety and mobility for all je međunarodni obrazovni program usmjeren na podizanje svijesti o sigurnosti u prometu među mladima. Program okuplja više od 15 milijuna učenika u 35 zemalja sa ciljem poticanja, razvijanja i jačanja podučavanja i učenja o sigurnosti na cesti i održive mobilnosti. Učenike usmjerava prema promatranju različitih situacija u prometu, razumijevanju svijeta oko sebe i razmišljaju o značenju i utjecaju njihovog kretanja. Podizanje svijesti na taj način omogućuje mladim ljudima da osmisle, predlažu i provode kampanju podizanja svijesti u svojoj školi, susjedstvu i širokoj zajednici, koristeći crtež, plakate, video i druge sadržaje i aktivnosti kroz koje će prenijeti snažne poruke na temu sigurnosti na cestama i održivu mobilnost za sve.

IV. ULOGA INFORMACIJSKO KOMUNIKacijsKE TEHNOLOGIJE U PROJEKTNOJ NASTAVI

Učenici su uz potporu učitelja, samostalno vodeći se vlastitim interesima i sklonostima osmisli i proveli niz aktivnosti za ostvarenje postavljenih ciljeva projekta.

IKT nastoji se smisleno i sa svrhom koristiti u svakoj projektnoj aktivnosti, razvijajući digitalne kompetencije i digitalnu inteligenciju učenika. Dok digitalne tehnologije postupno obuhvaćaju sve dijelove svakodnevnog života, 60% učenika nikada ne koriste digitalnu opremu u svom razredu. Puni potencijal za poboljšanje obrazovanja kroz IKT-a u Europi i dalje tek treba otkriti, a to je razlog zašto je Europska komisija razvija politiku i potporu istraživanja kako bi učenici odgovaraj za život u 21. stoljeću i rad [1].

Aktivnosti učenika:

- aktivno korištenje online platformi za komunikaciju i suradnju (eTwinning, Google docs),
- izrada i oblikovanje vlastitog loga programa,
- oblikovanje 3D modela i ispis na 3D pisanjima,
- izrada mrežnih stranica projekta koristeći CMS sustav Joomla,

Slika 2. Prikaz mrežnih stranica

- izrada obrazovnih računalnih igara koristeći alate Game Maker, Scratch, Alice, Blender i Construct, a koje se mogu koristiti na osobnim računalima, tabletima i pametnim telefonima na operacijskim sustavima Windows, Android i iOS,
- izrada kalkulatora sa osnovnim matematičkim operacijama u alatu Visual Basic 2015., a koji se može koristiti na osobnim računalima, tabletima i pametnim telefonima na operacijskim sustavima Windows, Android i iOS,

- izrada elektroničke knjige, videa, kvizova i drugih multimedijskih obrazovnih sadržaja.

Na taj način učenje postaje usmjereno prema učeniku, njegovim interesima i sposobnostima. Učenjem razvijamo kreativnost, inovativnost učenika, suradničko učenje, pozitivan odnos prema radu i učenju.

Posebna pažnja posvećena je programiranju kao pismenosti 21. stoljeća. Programiranje pojačava kreativnost, uči ljude da surađuju, da rade zajedno bez obzira na fizička ograničenja i zemljopisne granice, ono je univerzalni jezik koji nam omogućuje komunikaciju. Tehnologija je dio našeg života, a programiranje nas povezuje i zbližuje[3]!

Navedene aktivnosti provodile su se kao niz radionica na nastavi i u sklopu izvannastavnih aktivnosti te kao radionice u vrijeme odmora za učenike. U dijelu radionica...
sudjelovali su i članovi Društva distrofičara i cerebralne paralize iz Čakovca sa ciljem aktivnog sudjelovanja u projektnim aktivnostima svih članova lokalne zajednice, razvijanja empatije i suradnje kod učenika škole. Humanitarnom prodajom radova, prikupljena su sredstva koja su donirana socijalnoj samoposluzi u Vukovaru te kao pomoć za liječenje učenika naše škole koji boluju od teško izliječivih i rijetkih bolest.

V. ZAKLJUČAK

Međunarodni projekti obogaćuju cjelokupan nastavni proces te omogućuju razvoj obrazovnih sadržaja, razmjenu iskustava i primjera dobre prakse među partnerima. Odabirom projekta teme, ciljeva, sadržaja i aktivnosti, omogućuju upotpunjavanje školskih kurikulum, nastavnih planova i programa temama koje koje budućim generacijama doprinose cjelokupan razvoj u profesionalnom i privatnom smislu. Informacijsko komunikacijska tehnologija kod učenika dodatno razvija interes i motivaciju za rad, a omogućuje uvođenje inovativnosti u obrazovnom procesu.

LITERATURA

Robotika – učenje stvaranjem

Loredana Zima Krnelić, prof.pedagogije i informatike
OŠ Vežica, Rijeka, Hrvatska
loredana.zima@me.com

Do sada su naučili programirati robota tako da može svijetiti u različitim bojama, odsvirati različite animacije, interakcije i računalne igrice. Zalijepujući mBot robotu, po prvi puta ono što isprogramiraju mogu testirati uživo, točnije na robotu. Tako isti program na svakom robotu radi drugače, ovo je izvrstan način kako motivirati djecu za programiranje. Naime, točnost izvršavanja programa ovisi i o automatiji. Iako isti program na svakom robotu radi drugače, to uvjetuje neprestano testiranje i usavršavanje programa.

I. UVOD

II. SCRATCH

III. PRVE ROBOT „IGRAČKE“

Ovakva nastava izazvala je veliki interes učenika, te se već u idućoj školskoj godini (2016./2017.) za nju prijavilo 30 učenika, i to najviše učenika petih, šestih i sedmih razreda. Vrlo brzo uvidjela sam da je 5 robota premalo jer svako dijete želi imati svoj robot i suočiti se s novim alatom i elektronike koja nam je potrebna.

Slika 2. mBlock program za programiranje mBot robota

Iako isti program na svakom robotu radi drugače, to uvjetuje neprestano testiranje i usavršavanje programa. Dostupnost hardvera danas, potrebno je iskoristiti za rad na projektima koji postoji mobilna verzija zahvaljujući kojoj učenici mogu upravljati robotom putem tableta ili mobilnog telefona.

Slika 1. mBot robot

No kako bih „začinila“ nastavu na način da potaknem poduzetnost, istraživanje, timski rad i svakako kreativnost i inovativnost, zadala sam učenicima sljedeće: 1. podijelite se u grupe / timove, 2. pronađite robota kojeg želite složiti 3. istražite potrebne dijelove (naziv, cijenu te gdje ih potaknem djecu za programiranje. Vrlo brzo sam dobila povratnu informaciju kako može svijetiti u različitim bojama, odsvirati različite animacije, interakcije i računalne igrice. Zalijepujući mBot robotu, po prvi puta ono što isprogramiraju mogu testirati uživo, točnije na robotu. No kako bih „začinila“ nastavu na način da potaknem poduzetnost, istraživanje, timski rad i svakako kreativnost i inovativnost, zadala sam učenicima sljedeće: 1. podijelite se u grupe / timove, 2. pronađite robota kojeg želite složiti 3. istražite potrebne dijelove (naziv, cijenu te gdje ih možemo naručiti) i javite učiteljici što vam nedostaje. Obzirom da su na nastavi Robotike učenici od 5. do 8. razreda naša komunikacija odvijala se putem viber grupe. Vrlo brzo sam dobila povratnu informaciju što im sve treba i krenula u nabavku. Osim toga krenula sam u kupovinu dječjeg alata i elektronike koja nam je potrebna.

Ovakva nastava izazvala je veliki interes učenika, te se već u idućoj školskoj godini (2016./2017.) za nju prijavilo 30 učenika, i to najviše učenika petih, šestih i sedmih razreda. Vrlo brzo uvidjela sam da je 5 robota premalo jer svako dijete želi imati svoj robot i suočiti se s novim alatom i elektronike koja nam je potrebna.

No kako bih „začinila“ nastavu na način da potaknem poduzetnost, istraživanje, timski rad i svakako kreativnost i inovativnost, zadala sam učenicima sljedeće: 1. podijelite se u grupe / timove, 2. pronađite robota kojeg želite složiti 3. istražite potrebne dijelove (naziv, cijenu te gdje ih možemo naručiti) i javite učiteljici što vam nedostaje. Obzirom da su na nastavi Robotike učenici od 5. do 8. razreda naša komunikacija odvijala se putem viber grupe. Vrlo brzo sam dobila povratnu informaciju što im sve treba i krenula u nabavku. Osim toga krenula sam u kupovinu dječjeg alata i elektronike koja nam je potrebna.
Ukupan trošak za dječji alat bio je 500 kuna, a za elektroniku 700 kuna. Iako je u planiranju troškova potrebno voditi računa o dodatnim troškovima za koje trenutno tražimo donacije, a to su: dodatni namještaj kao na primjer: radne površine, ormari, police, plastični spremnici, zatim više kompleta dječjeg alata jer jedan nije dovoljan te svakako više kompleta elektronike kako bi sva djeca istovremeno mogla raditi na različitim projektima.

Za izradu naših prvih robot "igračaka" iskoristili smo elektronski otpad i dijelove starih dječjih igračaka.

A. Auto na daljinski
Naš prvi auto na daljinski sastoji se od dva motora od 3V, starog USB kabela, dvije baterije od 1,5V te dva prekidača.

Slika 3. Auto na daljinski, naša prva robot igračka

B. Mini buba
Mini buba sastoji se od dvije ledice, baterije, motora koji vibrira iz starog mobitela i prekidača koji pokreće simulaciju kretanja.

Slika 4. Mini buba, naša druga robot igračka

U izradi robot „igračaka“ naučili smo istraživati, surađivati, testirati, biti strpljivi kad nam ne ide, prepoznati svoje sposobnosti, podijeliti posao, zapravo naučili smo promišljati, razmišljati, analizirati i zaključivati, a sve kroz igru, zabavu i druženje bez straha od neuspjeha.

IV. ARDUINO PLOČICA
Ideja o slaganju robota te uopće robotikom nema smisla bez programa točnije programiranja istog. Iz tog razloga naš sljedeći korak bio je složiti robota kojem je osnova Arduino pločica zahvaljujući kojoj možemo povezati softver i hardver. To je ujedno izvrstan način kako motivirati djecu za učenje programiranja.

Naš prvi robot je preslika mBot robota s novim imenom dakako. A osim elektronike i programa koji njime upravlja, učenici su dijelove robota izradili uz pomoć 3D printera i na taj način proširili znanje u radu s novim tehnologijama.

Slika 5. Naš prvi robot, preslika mBota koji se bazira na Arduino pločici. Robot se samostalno kreće, prepoznaje prepreke te ih izbjegava

Arduino pločicu iskoristiti ćemo za nove projekte u kojima će učenici na zabavan način učiti programirati svijet oko sebe te biti kreativni i inovativni.

V. ZAKLJUČAK
Činjenicu da je hardver postao dostupan svima potrebno je iskoristiti za učenje i to već u najranijoj dobi učenika, usudila bih se reći već od 3. razreda osnovne škole. Inovativnost i kreativnost su ključne kompetencije učenika koje treba razvijati, a ovo je izvrstan način kako to ćiniti. Tehnologija je neizostavan dio budućih zanimanja i svijeta uopće. Ovakav način učenja razvija ključne kompetencije učenika za budućnost, priprema ga za cijeloživotno učenje i ono najvažnije osnažuje ga u realizaciji ideja kroz iskustveno učenje ili učenje stvaranjem.

LITERATURA
Upravljanje znanjem kao ključna tržišna prednost intelektualnih radnika

Tihana Babić*, Andrej Lacković * i Manuela Babić**

Sažetak - Upravljanje znanjem počelo je davno i nije suvremena inovacija informacijske tehnologije, ali s evolucijom ekonomije iz upravljanje prema poduzetničkoj ekonomiji, nazivanoj i ekonomija temeljena na znanju, upravljanje znanjem postaje jedan od temeljnih resursa na koji se temelji efikasnost i efektivnost modernoga poduzeća te čini okocinu njegovih sržnih kompetencija. Znanje postaje najvažniji izvor konkurentne prednosti na tržištu, te uz informaciju i informacijsku infrastrukturu postaje glavna pretpostavka koja intelektualni kapital stavlja u poziciju da stvara vrijednost. Znanja, vještine i kompetencije zaposlenika u organizaciji zapravo su kapital s obzirom da utječu na kompetitivnost te organizacije i ne stavlja u poziciju da stvara vrijednost. Novo znanje postaje glavna pretpostavka koja intelektualni kapital temelji efikasnost i efektivnost modernoga poduzeća, te uz informaciju i informacijsku infrastrukturu postaje glavna pretpostavka koja intelektualni kapital stavlja u poziciju da stvara vrijednost. Znanja, vještine i kompetencije zaposlenika u organizaciji zapravo su kapital s obzirom da utječu na kompetitivnost te organizacije i ne stavlja u poziciju da stvara vrijednost. Novo znanje postaje glavna pretpostavka koja intelektualni kapital temelji efikasnost i efektivnost modernoga poduzeća, te uz informaciju i informacijsku infrastrukturu postaje glava
Znanje, prema tome, postaje najvažniji izvor konkurentne prednosti na tržištu te je uz informaciju i informacijsku infrastrukturu, pretpostavka koja intelektualni kapital stavlja u poziciju da stvara vrijednost. Program upravljanja znanjem neke organizacije i/ili poduzeća, trebao bi uključivati sve 3 dimenzije: 

- ljude: stvaraju i koriste znanje kao temelj za donošenje ispravnih odluka;
- sadržaj: podaci, informacije i znanja važna za organizaciju, uključujući procese i procedure;
- tehnologije: tehnička infrastruktura i alati koji omogućuju zapisivanje, spremanje i isporuku sadržaja znanja onima koji ga trebaju, onda kada ga trebaju[9].

Tek kad su uključene sve tri dimenzije, organizacija može stvarati dodanu vrijednost i jačati konkurentnu prednost na tržištu, a mjerljivost stvaranja vrijednosti može stvarati dodanu vrijednost i jačati konkurentnu

B. Znanje kao kapital organizacije

Organizacije nastoje znanje pretvoriti u kapital transformiranjem iz apstraktnih kategorije u konkretnu, mjerljivu vrijednost, pri čemu se vrlo često okreću prema 24/7 poslovnom modelu, u kojem je glavna zadaća pretvoriti znanje u dinamički resurs koji se neprekidno koristi u takvom non-stop poslovnom okruženju. Razloga je mnogo: tržište postaje globalno, stopa inovacija raste, sve su složeniji proizvodi i usluge, rokovi za raspoloživost znanja su sve kraći, smanjenje broja zaposlenika postaje opći trend, dolazi do gubitka ljudi i rotacije radnih mjesta. Također, javlja se problem neraspoloživosti znanja kada su potrebna jer su često nedostupna, nekompletna i/ili razdijeljena po organizacijskim segmentima. Osnovni cilj organizacije stoga postaje pretvaranje osobnih znanja koja posjeduju pojedinci u organizacijski kodificirana znanja kao što su standardi, procedure i upute[10].

Dvije su vrste znanja: tacitno znanje koje je teško artikulirati i eksplicitno koje se može izraziti riječima i brojkama te se lako komunicira, procesi i alatima. Tacitno znanje je uvijek jezgara i sredstva za izravnu komunikaciju, dok je eksplicitno znanje objektivnije i lako komunicabilno. Tacitno znanje može biti složenije, a eksplicitno znanje može biti lako razumljivo i razumljivo.

Tek kad su uključene sve tri dimenzije, organizacija može stvarati dodanu vrijednost i jačati konkurentnu prednost na tržištu, a mjerljivost stvaranja vrijednosti može stvarati dodanu vrijednost i jačati konkurentnu

B. Znanje kao kapital organizacije

Organizacije nastoje znanje pretvoriti u kapital transformiranjem iz apstraktnih kategorije u konkretnu, mjerljivu vrijednost, pri čemu se vrlo često okreću prema 24/7 poslovnom modelu, u kojem je glavna zadaća pretvoriti znanje u dinamički resurs koji se neprekidno koristi u takvom non-stop poslovnom okruženju. Razloga je mnogo: tržište postaje globalno, stopa inovacija raste, sve su složeniji proizvodi i usluge, rokovi za raspoloživost znanja su sve kraći, smanjenje broja zaposlenika postaje opći trend, dolazi do gubitka ljudi i rotacije radnih mjesta. Također, javlja se problem neraspoloživosti znanja kada su potrebna jer su često nedostupna, nekompletna i/ili razdijeljena po organizacijskim segmentima. Osnovni cilj organizacije stoga postaje pretvaranje osobnih znanja koja posjeduju pojedinci u organizacijski kodificirana znanja kao što su standardi, procedure i upute[10].

Dvije su vrste znanja: tacitno znanje koje je teško artikulirati i eksplicitno koje se može izraziti riječima i brojkama te se lako komunicira, procesi i alatima. Tacitno znanje je uvijek jezgara i sredstva za izravnu komunikaciju, dok je eksplicitno znanje objektivnije i lako komunicabilno. Tacitno znanje može biti složenije, a eksplicitno znanje može biti lako razumljivo i razumljivo.
b) rotacije radnih mjesta i otkazi ne narušavaju poslovni proces jer pristup ekspertnim znanjima organizaciju čini manje ranjivom;

c) školovanje i vrijeme obuke postojećih i novih zaposlenika je kraće s obzirom na to da viša razina organizacijskog znanja i kulture znači ujedno i kraći te djelotvorniji ciklus edukacije kadrova;

d) viša je razina senzibiliteta zaposlenika na povratne informacije kupaca i drugih tržišnih signala zbog toga što educirani i sposobni zaposlenici bolje mogu prepoznati tržišne signale, kao i brže reagirati na njih;

e) rješavanje zahtjeva kupaca je brže i kvalitetnije, nastali problemi se bolje rješavaju, a rezultat je veće zadovoljstvo i viši stupanj lojalnosti kupaca;

f) zaposlenici koji kvalitetno i uspješno obavljaju svoj posao su motivirani, a pobjednik daju u organizaciji znatno poboljšavaju performance organizacije.

Predstavljanje alata za upravljanje znanjem tek je osnova za uspostavljanje sustava upravljanja znanjem, no svojšestnost tehnologije postiže se tek njezinim osnovama za uspostavljanje sustava upravljanja znanjem, no

D. Znanje kao kapital pojedinca

Promjene na tržištu rada danas su opće poznata stvar u cijelom svijetu, a nezaposlenost mladih problem je kojem se globalno rješenje ne nazire jer svaki dan donosi nove izazove. Iako je, u još ne tako davnoj prošlosti, više obrazovanje i diploma bila „garancija“ zaposlenja, danas se sve češće potvrđuje kao istina: „Ne mogu naći posao jer nemam iskustva, a nemam iskustva jer ne mogu naći posao“. U okolnostima koje se našezgled čine kao začarani krug, poslodavci mladim ljudima sve češće poručuju: „da je lijepo i dobro što znaju baratati vještinama na društvenim mrežama i tehnologijom, ali da je vrijeme da se vrate na 'stare vještine', a to je da znaju komunicirati bez patentnog telefona u ruci i napisati tekst bez pomoći Interneta“[16]. Portal Dnevnik.hr isto tako navodi izvor News.com.au koji prenoseći stavove poslodavaca kaže da 'Igeneracija', osim što je vješta s novim tehnologijama i tehnikama, treba znati uvjeriti poslodavce da su motivirani za rad, komunikaciju, da su pouzdanii i završavaju započeta, da su kao osobe pozitivni i entuzijastični, a odabirom odjeće trebali biti poručivati da su patenti i profesionalni[16].

Kao sve češći razlog koji mlade ljude usporava prilikom traženja posla jest činjenica da im nedostaju 'meke vještine' odnosno 'soft skills', navodi isti izvor tvrdnje analitičar austrijskog Odjela za zaščito i zaščito Ivana Nevila, kao što su primjerice razvijene komunikacijske vještine, rada u timu, viša poziranost u situacijama, prezentacijske vještine, pouzdanost i prilagodljivost na promjene, te da su poslodavci skloniji 'prostititi' nedostatak tehnoloških znanja nego što će primjerice progledati kroz prste kandidatu koji ne bi znao različitim ljudima"[18].

MIPRO 2017/CE
Neke od najčešće traženih "mekih vještina" su – visoka motiviranost, uspostavljanje i odražavanje kvalitetnih odnosa, učinkovitost i rad u timu, komunikacijske vještine, sposobnost rješavanja konflikata, prilagodljivost, poštivanje radne etike, analitičke vještine, vještina kritičkoga razmišljanja, sposobnost brzog učenja, organizacija, planiranje i drugo. Prema nekim autorima navedene se vještine mogu objediniti pod pojmom "emocionalna inteligencija"[19] pa tako Goleman, kao jedan od vodećih na tom području, navodi kako naša emocionalna inteligencija određuje potencijal za učenje djelatnog vještina koje se temelje na pet elemenata: samosvijest, motivacija, samokontrola, empatija i prilagodljivost u odnosima. Naša emocionalna kompetencija, pak, govori o tome koliko smo svoga potencijala preveli u djelatne"[20]. Bitno je napomenuti i kako se emocionalne kompetencije, prema Golemanu, mogu podijeliti na osobnu kompetenciju i društvenu kompetenciju.

Osobna kompetencija odražava sposobnost nošenja s vlastitim poteškoćama te uključuje:
- samosvijest – emocionalna svjesnost, točna samoprocjena i samopouzdanje;
- samosvladavanje – samokontrola, vjerojatnost, savjesnost, prilagodljivost, inovativnost;
- motiviranost – težnja za postignućem, predanost, inicijativa, optimizam;

Društvena kompetencija odražava sposobnost ophođenja u odnosima s okolinom te uključuje:
- empatiju – razumijevanje drugih, potpomaganje drugih, usmjerenost prema klijentu, oslonac na razmolkostima, politička svijest;
- društvena umijeća – utjecajnost, komunikativnost, razješavanje sukoba, vodstvo, poticanje promjena, stvaranje veza, suradnja, sposobnosti timskoga rada.

Navedene kompetencije odnosno vještine, one su koje čine razliku među kandidatima koji se pripjavljuju za isti posao te su često presudne za dobivanje posla naročito u tržištu kada tehnologija i znanja zastarijeva, a osobito u IT sektoru koji se neprestano razvija i širi, pa tehnologija zastarijeva, a sustav 'kako-je-nekad-bilo' ne funkcionira[27].

Udruga Osijek Software City u lipnju 2016. godine provedla je istraživanja o mišljenju poslodavaca iz IT sektora o znanjima i vještinama osječkih studenata, a kriteriji nisu uključivali samo bazna tehnička znanja i vještine (algoritmi i strukture podataka, objektno-orientirano programiranje, upravljanje softverskim projektima, internet tehnologije i razvoj web aplikacija, razvoj mobilnih aplikacija, rad s bazama podataka, testiranje i osiguravanje kvalitete), već i 'soft skills' (usvajanje novih znanja i vještina, samostalnost u radu i motiviranost) te opći dojam. Rezultati su pokazali da su osječki studenti uglavnom svjesni važnosti soft skills vještina, čime su poslodavci zadovoljni, te da najmanje znanja stječu u tehničkom aspektu, dok im je motivacija i želja za učenjem uglavnom na zadovoljavajućoj razini[28].

Ponukani navedenim spoznajama o sustavu upravljanja znanjem u organizaciji, utjecajem vlastitog angažmana pojedinca na 'samopromociju' i 'samoprodaju', te rezultatima istraživanja Udruga Osijek Software City, autori su proveli istraživanje na studentskoj populaciji Visokog učilišta Algebra kako bi iz rezultata bilo razvidno koliko su studenti upoznati s kretanjima na tržištu rada te koliko su svjesni presudne uloge vlastitog angažmana i društvenih vještina u pronašću posla i daljnjem napretku karijere.

E. Istraživanja

Istraživanje je provedeno kroz anketni upitnik na studentskoj populaciji Visokog učilišta Algebra. Anketni upitnik ispunilo je 70 studenata. (tablica I). Sami upitnik sastojao se od općih podataka i pitanja sa višestrukim izborom vezanih uz temu ovoga rada. Na svako pitanje moglo se odgovoriti odabirom jednog ili više odgovora. Sama obrada podataka rezultata ankete napravljena je kroz program Excel i program za analitičku obradu podataka Orange.
Osnovna hipoteza ovog istraživanja je da studenti ne preduj dovoljno veliku važnost motiviranju za rad, te mekim vještinama, već najviše vjeruju u tehničku znanja stećena na fakultetu.

Jedno od temeljnih pitanja ovog istraživanja bilo je pitanje što studenti smatraju bitnije ili što im je po prioritetu važno za budući pronalazak posla? Istraživanje je pokazalo da najveći prioritet imaju tehnička znanja i vještine, te „soft skills“. Zanimljivo je što je diploma fakulteta dosta nisko rangirana na listi prioriteta. Detaljan prikaz dobivenih rezultata prikazan je u tablici 2. Ako izdvojimo samo tehničku znanja i društvene vještine, odnosno proanaliziramo odgovore na pitanje „Smatrate li društvene/tehničke vještine bitnim u pronalasku posla?“ (slika 1) vidljivo je da je podjednaki broj studenata odgovorilo potvrdno za jednu i drugu vještinu. Tehnička vještine odgovor da 55%, a za društvene vještine 50% studenata je odgovorilo potvrdno.

Rezultati pokazuju da je ipak veliki broj studenata osvješten s činjenicom da osim bitnih tehničkih vještina (kao što su npr. algoritmi i strukture podataka, objektno orijentirano programiranje, upravljanje softverskim projektima, internet tehnologije i razvoj web aplikacija, razvoj mobilnih aplikacija, rad s bazama podataka, testiranje i osiguravanje kvalitete) su ipak bitne i društvene vještine (kao što su npr. vještine komuniciranja, e-komunikacije). Po pitanju kvalitete usvajanja znanja 49% studenta smatra da ima kvalitetno i sustavno usvajanje znanja, njih 18% djelomično, a samo njih 2% smatra da ne sustavno i ne kvalitetno usvaja nova znanja.

Ono što se ističe kao jako bitno u upravljanju znanjem, a samim time i pojedinca pokazuje se samopromocija. Rezultati anketiranja (Slika 2.) pokazuju da su studenti vrlo skloni samopromociji. Čak njih 20% nikada, 48% vrlo rijetko radi bilo kakav oblik samopromocije, a tek samo 3% se samopromovira.

Završni dio ispitivanja i analize posvećen je prioritetima za uspjeh na poslu. Rezultati prioritora prikazani su u tablici 3. Iz tablice je vidljivo da kao i kod prioriteta kod pronalaska posla, tako i za sam uspjeh na poslu studenti najbitnijim smatraju tehnička znanja i vještina (njih 13%). Drugi po listi prioritora je sposobnost komuniciranja (njih 10%) što u biti spada u „soft skills“.

Najmanji prioritet kod uspjeha na poslu studenti su dali utjecajnosti (njih 4%), te diplom i osobnosti (njih 5%).
III. Zaključak

Upravljanje znanjem postaje jedan od temeljnih resursa na kojima se temelji efikasnost i efektivnost modernog poduzeća. Osim tehničkih znanja i vještina, društvene vještine postaju ključne za upravljanje znanjem pojedinca, pa tako i poduzeća. Ključnim se pokazuje investicija u vještine koje podržavaju interakcije u poslovnim svrhom lancima. Osim tehničkih znanja i vještina, korisni su i srodni znanja, kao i samopromocija ili slično.

Provedeno istraživanje na studentskoj populaciji Visokog učilišta Algebra je pokazalo da studenti najvišeg prioriteta smatraju svoja tehnička znanja i vještine što se neposredno odnose na njihov uspjeh u poslovnom svijetu. Studenti su se većinom istaknuli vještine koje se odnose na profesionalnu učinkovitost.

Interakcija i komunikacija studenata prilikom učenja – primjer studenata Visokog učilišta Algebra

Tihana Babić, Iva Vunarić i Ana Lokas Čošković
Visoko učilište Algebra, Zagreb, Hrvatska
tihana.babic@algebra.hr, iva.vunarić@algebra.hr, ana.lokascoskovic@racunarstvo.hr

Sažetak - Razvoj informacijskih i komunikacijskih tehnologija snažno je utjecao na razvoj obrazovanja na svim razinama pa se uz tradicionalne oblike učenja pojavilo online učenje. Osnovne prednosti tradicionalne nastave kao konvencionalnog načina poučavanja i učenja liećem u liće sadržane su u socijalnom i interaktivnom elementu (face-to-face interakcije), dok je online učenje na daljinu, nazivano još i e-ucenje ili učenje temeljeno na webu, koncipirano kao nastava u kojoj su skupine studenata razdvojene, a poučavanje i učenje odvija se uz pomoć računala kao medija za komuniciranje. Online učenje često je asinkrono odnosno ne odvija se u stvarnom vremenu, ali može biti i sinkrono, pri čemu nastavnik i studenti imaju međusobnu interakciju uživo, u stvarnom vremenu, kao što je slučaj na Visokom učilištu Algebra na kojem studenti mogu predavanja pratiti putem videokonferencijskog sustava. Cilj rada bio je na primjeru studentske populacije Visokog učilišta Algebra istražiti koji oblik nastave, učenja i poučavanja studenti preferiraju: tradicionalnu (licem u lice) ili online nastavu, kao i koju vrstu interakcije studenti preferiraju prilikom svladavanja novih znanja i vještina: uživo ili na daljinu te postoji li povezanost između preferiranog oblika nastave, poučavanja i učenja u odnosu na to preferiraju li komunikaciju liećem u liće ili računalno posredovanu komunikaciju.

I. UVOD

Razvojem informacijskih i komunikacijskih tehnologija te njenim prodiranjem u sve segmente društva, stvorila se potreba za promjenom samog načina učenja i obrazovanja kao doniranog pokretača razvoja društva.

U nastavnom procesu najvažnija je komunikacija između predača i studenata. Shodno promjenama koje u obrazovanju unose konstireњe suvremenih tehnologija, posljednjih nekoliko desetljeća fokus s učitelja, kao i učenika čime učitelj postaje samo jedan od resursa u nastavnom procesu. Sukladno tome, online učenje može se jednostavno definirati kao „sustav u kojem su resursi za učenje, uključujući i samog nastavnika, učenicima dostupni putem interneta“ [1]. U stručnoj literaturi se kao prednosti online učenja, nasuprot klasičnom učenju liećem u liće u učionici, najčešće ističu vremenska i novčana fleksibilnost, smanjeni vremenski i novčani troškovi koji bi nastali u slučaju da se profesor i studenti moraju sastati u učionici. Također, u usporedbi s tradicionalnom nastavom u učionici, jedan od nedostataka online učenja jest sloboda koju studenti imaju u smislu da ih predača ne vidi pa pravo i ne moraju pratiti predavanja već mogu raditi što žele, ali i činjenica da prilikom e-učenja može doći do različitih tehničkih problema kao što su kvar mikroforma ili kamere u dvoranii ili učionici, problemi s internetskim vezom ili problemi koje studenti mogu imati na svojim računalima pomoću kojih sudjeluju nastaviti. Takvih problema u tradicionalnoj nastavi liećem u liće nema.

S obzirom na to da se profesor i studenti ne nalaze na istim lokacijama, stjecanje znanja online učenjem, kao i njihova međusobna interakcija, vrše se uz pomoć računala [3]. U stručnoj literaturi se primjeri online učenja nasuprot klasičnom učenju u učionici, najčešće ističu vremenska i novčana raznina pa se uz tradicionalne oblike učenja pojavilo online učenje. S obzirom na to da se profesor i studenti ne nalaze na istim lokacijama, stjecanje znanja online učenjem, kao i njihova međusobna interakcija, vrše se uz pomoć računala [3]. U stručnoj literaturi se učenja online učenje, kao i prilikom e-učenja može se jednostavno definirati kao „sustav u kojem su resursi za učenje, uključujući i samog nastavnika, učenicima dostupni putem interneta“ [1]. U stručnoj literaturi se kao prednosti online učenja, nasuprot klasičnom učenju liećem u liće u učionici, najčešće ističu vremenska i novčana fleksibilnost, smanjeni vremenski i novčani troškovi koji bi nastali u slučaju da se profesor i studenti moraju sastati u učionici. Također, u usporedbi s tradicionalnom nastavom u učionici, jedan od nedostataka online učenja jest sloboda koju studenti imaju u smislu da ih predača ne vidi pa pravo i ne moraju pratiti predavanja već mogu raditi što žele, ali i činjenica da prilikom e-učenja može doći do različitih tehničkih problema kao što su kvar mikroforma ili kamere u dvoranii ili učionici, problemi s internetskim vezom ili problemi koje studenti mogu imati na svojim računalima pomoću kojih sudjeluju nastaviti. Takvih problema u tradicionalnoj nastavi liećem u liće nema.
Sve više obrazovnih institucija u nastavi uvodi različite informacijske i komunikacijske tehnologije, a nasuprot klasičnoj nastavi licem u lice u učionici, različite informacijske i komunikacijske tehnologije, a nastava se izvodi bez kontakt-a nastavnika licem u lice [6].

Interakcija, kao aktivn o odnos očituje se u međusobnom djelovanju osoba koje obostrano određuju svoja ponašanja na temelju stavova koja jedna prema drugoj zauzimaju. Stoga komunikaciju možemo definirati kao proces stvaranja značenja između dvije ili više osoba [11]. Najveći dio interakcije ostvaruje se putem komunikacije. Interakcija prilikom nastave u kojoj predavač ne vidi svoje studente otežana je iz nekoliko razloga. Ukoliko tijekom predavanja ima pitanja, ta se pitanja postavljaju s odmakom od nekoliko sekundi i predavač se mora zaustaviti kako bi pročitao i odgovorio na pitanje. Situacija u kojoj predavač vidi pitanje i na njega odgovora, ali ne vidi istovremenu reakciju na svoj odgovor u smislu mimike lica, geste ili položaja tijela otežava samo shvaćanje predavača je li odgovor koji nudi dovoljno jasan [9].

Stoga, kao što je navodi CARNet, “komunikacija licem-u-lice mnogo je fleksibilnija i neposrednija te omogućava brzo i lako iznošenje uputa, dobivanje povratnih informacija, dogovaranje, podjelu zadataka i učenja”. Nakon što je začeo znanstveni prirodno-vještinski i socijalno-vještinski vještinski u toku velikom dana studenti uskoro se na istom mjestu susreću, a to je izuzetno važno za shvaćanje svog učenja i razvoj novih vještina. Ukoliko se studenti odluče za tradicionalan oblik nastave obvezni su dolaziti na predavanja u postotku koji je propisan pravilnikom Visokog učilišta. Ako se odluče za predavanja online, nastavu prate putem videokonferencijskog sustava. Upotrebom video-konferencijskih sustava moguće je stvoriti obrazovno okruženje koje se malo razlikuje od tradicionalne učionice, ali posjeduje sve vrijednosti obrazovanja na daljinu. „Video-konferencija još uvijek nisu najpopularniji alati za učenje na daljinu, ali nove tehnologije i novi programi potrebni za taj oblik komunikacije putem računara omogućavaju sve veću primjenu tih sustava” [10].

### A. Opis uzorka

Istraživanje je realizirano na Visokom učilištu Algebra tijekom siječnja 2017. godine odnosno u zimskom semestru akademske godine 2016./2017. na uzorku od 91 studenata 1. i 2. godine prediplomskih studija Primijenjenog računarstva, Multimedijalnih tehnologija i Digitalnog marketinga u školskoj godini 2016./2017. od ukupno aktivno upisanih 712 studenata na prediplomske i diplomske studije Visokog učilišta Algebra. Također, zbog malog udjela ispitanika ženskog spola, kao i izvanrednog statusa studenata, rezultati ovog istraživanja nisu prema tim varijablama predočeni u prikazu.

Tablica I. prikazana je struktura sudionika s obzirom na upisani studij, spol, status studija i upisanu studijsku godinu.

### B. Ciljevi istraživanja

Svrha provedenog istraživanja bila je:

- Ispitati koji oblik izvođenja nastave studenti preferiraju: licem u lice ili online te identificirati značajke koje izdvajaju kao prednosti preferiranog oblika nastave.
- Utvrditi koju vrstu interakcije i komunikacije studenti preferiraju.
Uočiti postoji li korelacija preferiranog oblika izvođenja nastave u odnosu na preferirane vrste interakcije i komunikacije.

**C. Korišteni instrumenti u istraživanju**

Anketni upitnik sastojao se od ukupno 10 pitanja, koji je dijelom sadržavao unaprijed ponuđene odgovore zatvorenog tipa, te je 8 od 10 pitanja imalo ponuđenu opciju slobodnog unosa odgovora kao i mogućnost višestrukog izbora. 1 pitanje imalo je unaprijed ponuđene odgovore na skali od 5 stupnjeva Likertovog tipa (uvijek, često, povremeno, rijetko, nikad) te su imali mogućnost jednostrukog odabira odgovora na navedena 2 pitanja. Studentima je objašnjena svrha ispitivanja, te su zamoljeni da iskreno odgovore na pitanja.

**D. Rezultati istraživanja**

Većina podataka dobivenih u ovom istraživanju su kvalitativni, stoga, iako su odgovori ispitanika osim kvalitativnom obrađeni i kvantitativnom analizom, statističke mjere centralne tendencije i varijabilnosti nije bilo moguće prikazati.

**a) Preferirani oblik/oblici izvođenja nastave te njihove prednosti**

Studentima je postavljenje pitanje 1. Koji oblik izvođenja nastave preferirate? U upitniku su unaprijed ponuđene odgovore opcije: a) Online nastavu (putem videokonferencijskog sustava), b) Nastavu licem u lice i c) Drugo (što)? I sudionik nije odgovorio na pitanje, N=90. Kao što je prikazano na Slici 1., sudionici su mogli birati više odgovora, a ukupna frekvencija odgovora je 93. Čak 79% sudionika preferiraju rad sa licem u lice, a online nastavu (putem videokonferencijskog sustava) preferira 13%. Za treći ponuđeni odgovor sa slobodnim unosom odlučilo se 8% sudionika, od kojih je 4% navelo kombinaciju dvije vrste nastave, dok je 4% sudionika navelo sljedeće: individualne konzultacije, projekte s profesorima i video snimke kakve ima profesor (matematička na Visokom učilištu Algebra) Toni Milun.

**Slika 1. Preferirani oblik/oblici izvođenja nastave**

Drugo pitanje anketnog upitnika glasilo je: Koje biste značajke online nastave (putem videokonferencijskog sustava) izdvojili kao prednosti: a) Nastavu možete pratiti s bilo koje lokacije, b) Fleksibilnost u usklađivanju poslovnog i obiteljskog života, c) Umrežavanje nastavnika i studenata, d) Smanjenje troškova poput transporta, materijala za učenje i obroka, e) Učestalost vremena (za transport, pauze ili „rupe“ između predavanja), f) Mogućnost samostalnog rada, g) Komunikacija sa predavačima, brojem kolega/studenata (kad to želimo), h) Fleksibilnost u usklađivanju sustava za poslovno i obiteljsko živote. Dodatno, 40% njih smatra prednošću online nastave to što omogućava veću fleksibilnost u usklađivanju poslovnog i obiteljskog života, a 39% ispitanika kao prednost percipira smanjenje troškova poput transporta, materijala za učenje i obroka, 22% umrežavanje nastavnika i studenata, a 19% mogućnost samostalnoga rada. Komunikacija sa manjim brojem kolega/studenata, a 50% ispitanika smatra izravnu interakciju s drugim studentima glavnom prednošću nastave licem u lice (face to face) izdvojili kao prednosti: a) Izravna interakcija (kad to želimo), b) Fleksibilitet u usklađivanju nastave i pauziranja bez „rupe“, c) Mogućnost samostalnog rada, d) Smanjenje troškova poput transporta, materijala za učenje i obroka, e) Ušteda vremena (za transport, pauze ili „rupe“ između predavanja), f) Mogućnost samostalnog rada, g) Komunikacija sa predavačima, brojem kolega/studenata (kad to želimo), h) Fleksibilnost u usklađivanju sustava za poslovno i obiteljsko živote.

Treće pitanje bilo je: Tempus forum online lekcija u lice (face to face) izdvojili kao prednosti: a) Izravna interakcija sa nastavnicima, b) Izravna interakcija sa drugim studentima, c) Smanjenje troškova poput transporta, materijala za učenje i obroka, d) Smanjenje troškova poput transporta, materijala za učenje i obroka. dodatne prednosti: a) Izravna interakcija sa nastavnicima, b) Izravna interakcija sa drugim studentima, c) Komunikacija sa predavačima, brojem kolega/studenata (kad to želimo), d) Fleksibilnost u usklađivanju sustava za poslovno i obiteljsko živote, e) Učestalost vremena (za transport, pauze ili „rupe“ između predavanja), f) Mogućnost samostalnog rada, g) Komunikacija sa predavačima, brojem kolega/studenata (kad to želimo), h) Fleksibilnost u usklađivanju sustava za poslovno i obiteljsko živote. Dodatno, 74% sudionika smatra izravnu interakciju s drugim studentima, a 70% kao prednost online nastave, a 53% smatra izravnu interakciju s drugim studentima.
Četvrto pitanje glasilo je: Koliko često biste koristili mogućnost online nastave kada bi vam se ona brojila u dolaznost na nastavu? Studentima su ponuđene opcije odgovore na skali od 5 stupnjeva Likertovog tipa učestalosti (uvijek, često, povremeno, rijetko, nikad). Svi sudionici su odgovorili na pitanje, N=91. Studenti na Visokom učilištu Algebra nastavu mogu pratiti online putem videokonferencijskog sustava, ali samo predavanja, dok za vježbe tu opciju ne mogu koristiti.

Također, bitno je istaknuti kako im se praćenje nastave putem videokonferencijskog sustava ne broji u obveznu dolaznost, koju redoviti studenti, prema Pravilniku o studijima i studiranju trebaju ostvariti 50% iz predavanja i 70% iz vježbi, a izvanredni 40% iz predavanja i 60% iz vježbi. Navedeno pitanje imalo je za svrhu istražiti koliki postotak studenata bi tu opciju koristio češće kad bi im ta opcija povećala obveznu dolaznost koju trebaju ostvariti kako bi dobili potpis predmetnog nastavnika iz nekog kolegija odnosno kako bi mogli polagati kolegij.

Na šesto pitanje: Koju vrstu interakcije prilikom učenja (svladavanja novih znanja i vještina) preferirate? 52% sudionika je odgovorilo da najviše preferiraju kad im nove nastavne sadržaje izravno licem-u-lice prenosi nastavnik/mentor (učenje: mentor/nastavnik-student), a čak 47% kad sami svladavaju sadržaj predavanja (učenje: student-sadržaj), dok 25% ispitanika preferira kad nove nastavne sadržaje svladava s kolegama studentima (učenje: student-student), a 20% kad nove nastavne sadržaje svladava putem tehnoloških medija (učenje: student-online interaktivni informacijski i komunikacijski sustav). 3% ispitanika kao vlastite odgovore navelo je da preferiraju učenje s društvom, rad na projektima, rad na vežbama. 2 ispitanika nije odgovorilo na šesto pitanje, N=89, a odgovori su prikazani postotno u Tablici II.

Iz odgovora ispitanika vidljivo je da bi samo njih 40% tražili online nastavu u načinu izvođenja nastave. Četvrto pitanje glasilo je: Koliko često biste koristili mogućnost online nastave kada bi vam se ona brojila u dolaznost na nastavu? Studentima su ponuđene opcije odgovore na skali od 5 stupnjeva Likertovog tipa učestalosti (uvijek, često, povremeno, rijetko, nikad). Svi sudionici su odgovorili na pitanje, N=91. Studenti na Visokom učilištu Algebra nastavu mogu pratiti online putem videokonferencijskog sustava, ali samo predavanja, dok za vježbe tu opciju ne mogu koristiti.

Također, bitno je istaknuti kako im se praćenje nastave putem videokonferencijskog sustava ne broji u obveznu dolaznost, koju redoviti studenti, prema Pravilniku o studijima i studiranju trebaju ostvariti 50% iz predavanja i 70% iz vježbi, a izvanredni 40% iz predavanja i 60% iz vježbi. Navedeno pitanje imalo je za svrhu istražiti koliki postotak studenata bi tu opciju koristio češće kad bi im ta opcija povećala obveznu dolaznost koju trebaju ostvariti kako bi dobili potpis predmetnog nastavnika iz nekog kolegija odnosno kako bi mogli polagati kolegij.

Iz odgovora ispitanika vidljivo je da bi samo njih 10% tradičnu nastavu zamijenilo online nastavom. Četvrtina ispitanika (25%) bi mogućnost online nastave koristila vrlo često uz tradicionalni oblik održavanja nastave, a 37% povremeno. 8% sudionika izražavaju online nastavu ne bi preferirala ni u kom slučaju, a 20% tu opciju bi koristila u rijetkim slučajevima.

Odgovori na peto pitanje prikazani su postotno na Slici 2., a pitanje je glasilo: Biste li klasičnu nastavu zamijenili online nastavom kad bi postojala ta mogućnost na Visokom učilištu Algebra? Na pitanje su ponuđene sljedeće opcije odgovora: a) Da, zamijenio bih ju u potpunosti, b) Da, djelomično bih ju zamijenio, c) Ne bih ju uopće zamijenio, d) Nemam mišljenje. Na postavljeno pitanje nije odgovorio 1 ispitanik, N=90. Od ukupnog broja odgovora ispitanika, 50% studenta, 25% ispitanika, 15% ispitanika i 10% studenata odgovorila je "Da, zamijenio bih ju u potpunosti", a 40% ispitanika, 25% studenta, 15% ispitanika i 10% studenata odgovorila je "Da, djelomično bih ju zamijenio", a 20% studenta, 15% ispitanika i 10% ispitanika odgovorila je "Ne bih ju uopće zamijenio", a 5% ispitanika, 5% studenta i 5% studenta odgovorila je "Nemam mišljenje". 12% ispitanika, 12% studenta i 12% studenta odgovorili su "Drugo".

Iz odgovora na peto pitanje, N=90: Koju vrstu interakcije prilikom učenja (svladavanja novih znanja i vještina) preferirate? 52% sudionika je odgovorilo da najviše preferiraju kad im nove nastavne sadržaje izravno licem-u-lice prenosi nastavnik/mentor (učenje: mentor/nastavnik-student), a čak 47% kad sami svladavaju sadržaj predavanja (učenje: student-sadržaj), dok 25% ispitanika preferira kad nove nastavne sadržaje svladava s kolegama studentima (učenje: student-student), a 20% kad nove nastavne sadržaje svladava putem tehnoloških medija (učenje: student-online interaktivni informacijski i komunikacijski sustav). 3% ispitanika kao vlastite odgovore navelo je da preferiraju učenje s društvom, rad na projektima, rad na vežbama. 2 ispitanika nije odgovorilo na šesto pitanje, N=89, a odgovori su prikazani postotno u Tablici II.

Kao odgovor na sedmo pitanje: Koju vrstu interakcije prilikom neobaveznog druženja s kolegama studentima preferirate? 84% studenata navelo je da prilikom neobaveznog druženja preferiraju interakciju lice u lice, a samo 6% preferira izključivo online komunikaciju, dok 10% ispitanika oba oblika smatra jednako prihvatljivima. 2 ispitanika nije odgovorilo na navedeno pitanje, N=89.

Iz odgovora na osmoh pitanje, N=89: Koju vrstu komuniciranja s kolegama studentima preferirate?, prikazanim na slici 3., skristaliziralo se da se 71% ispitanika i s kolegama studentima preferira komunikaciju licem u licem, a online (e-mail, sm, chat...) samo 13%. 16% studenta podjednako preferira obje mogućnosti.
Odgovori na deveto pitanje, vidljivi na Slici 4., Koju vrstu komuniciranja s nastavnicima/mentorom preferirate? Pokazali su da čak 80% ispitanika i nastavnicima/mentorom preferira komunikaciju licem u licem, dok online komunikaciju (e-mail, sms, chat...) preferira 10%, kao i da 10% podjednako koristi obje mogućnosti, te to ovisi o temi ili im je svejedno. 2 studenata nije odgovorilo na pitanje, N=89.

Slika 4. Preferirana vrsta komunikacije studenata s nastavnicima/mentorom

Odgovori na posljednje, deseto pitanje, N=89: Koju vrstu komunikacije prilikom neobaveznog druženja preferirate? Pokazali su da najviše ispitanika, njih 81%, prilikom neobaveznog druženja preferira komunikiranje u malim grupama (licem u lice) ili komunikaciju jedan na jedan (licem u lice), njih 47%. Online komunikaciju (e-mail, sms, chat...) u malim grupama preferira 25% sudionika istraživanja, a komunikaciju s 1 osobom putem online komunikacije (e-mail, sms, chat...) preferira 21% studenata. U velikim grupama preferira komunicirati (licem u lice) samo 13% studenata, dok ih samo 7% u velikim grupama preferira komunicirati online (e-pošta, sms, chat...).

IV. ZAKLJUČAK

Iako online nastava kao i e-učenje zbog mnogih mogućnosti što pružaju moderne informacijske i komunikacijske tehnologije, postaju sve češći oblik izvođenja nastave, istraživanje na primjeru studenta Visokog učilišta Algebra pokazalo je da studenti u većem broju slučajeva preferiraju tradicionalne oblike nastave. S obzirom na nedostatak recentnih istraživanja preferencija studenata u načinu izvođenja nastave, istraživanje na primjeru studenta Visokog učilišta Algebra pokazalo je da studenti u većem broju slučajeva preferiraju tradicionalne oblike nastave. S obzirom na nedostatak recentnih istraživanja preferencija studenata u načinu izvođenja nastave, online nastavu prate online te mnogim prednostima od kojih se osobito ističu vremenska i financijska ušteda, studenti Visokog učilišta Algebra i dalje najiniju klasičnoj nastavi licem u lice.

Naime, pokazalo se da studenti, kako u neformalnoj interakciji i komunikaciji s kolegama, tako i u komunikaciji s nastavnicima, ipak preferiraju komunikaciju licem u lice te da ne bi u potpunosti klasičnu nastavu zamijenili online nastavom. S obzirom na postotak odgovora na korist komunikacije licem u lice u svim segmentima interakcije, na temelju dobivenih rezultata, unatoč ubrzanom razvoju informacijskih i komunikacijskih tehnologija i prednosti koje pruža, vidljivo je da studenti, kako u osobnom, tako i u studentijskoj interakciji preferiraju komunikaciju licem u lice.

Sažetak - Pojava i korištenje interneta promijenili su cjelokupan život suvremenog čovjeka, a bez interneta komunikacija i u privatnom i u poslovnom svijetu postaje gotovo nezamisliva. Shodno tome, nije zanemariv niti utjecaj interneta na promjenu jezika odnosno na stvaranje tzv. mrežnog jezika ili netspeaka. Netspeak je usko povezan s engleskim kao globalnim jezikom, ali ima vlastita razlikovna obilježja u svojim pojavnostima. U ovom radu prikazana su osnovna obilježja netspeaka, kao posebnog jezika, kratica i izraza koje ljudi koriste u komunikacijskim putem interneta, te su prikazani rezultati istraživanja provedenog na studentskoj populaciji Visokog učilišta Algebra o utjecaju interneta na vokabular mladih i u kojoj mjeri studenti koriste „kodirani domaći jezik“ odnosno netspeak razini situacija u kojima će se i netspeak odatka dobivenih iz eng. speak odatka eng. speak znači odgovora studenata u provedenoj anketi pokazalo se da koristi netspeak dominira u neformalnoj online komunikaciji, ali da se u formalnoj online komunikaciji i dalje radije koriste riječi iz hrvatskog standardnog jezika.

I. UVOĐ

Pojava i korištenje interneta promijenili su cjelokupan život suvremenog čovjeka, a bez interneta komunikacija i u privatnom i u poslovnom svijetu postaje gotovo nezamisliva. Sve više pojedinaca upotrebljava internet u svrhu komuniciranja što donosi promjene na razini konkretno jezike rječki prakse koja se formira u e-komunikaciji. Računalno posredovana komunikacija (engl. CMC – computer-mediated communication) koncem prošloga stoljeća postala je važna komunikacijsko sredstvo pojedinaca te se njegova uporaba proširila na poslovno područje i edukaciju, a počela se također upotrebljavati i u „rekreacijskim“ svrhem [1].

II. UTJECAJ RAČUNALNO POSREDOVANE KOMUNIKACIJE NA JEZIK

Poznajemo više tipova računalno posredovane komunikacije odnosno mrežnih situacija u kojima će se i jezik znatno razlikovati, a što je elektronička pošta (e-mail) odnosno korištenje računalnih sustava za prijenos poruka između korisnika: pričaonice (chatgroups) koje podrazumijevaju rasprave o određenoj temi organizirane po „sobama“ (chatovima) na specijaliziranim internet stranicama; zatim virtualni svjetovi (Virtual worlds) tj. zamišljeni okruženja; te svjetska mreža (World Wide Web) koja označava skup povezanih internetom [2].

Računalno posredovana komunikacija svojstva korisnike s novom mogućnošću pisanja koja uključuje neke ključne značajke govora, pogotovo ako je riječ o sinkronnim tipovima računalne komunikacije (primjerice pričalice) gdje se komunikacija odvija „uživo“. Takvo komuniciranje, odnosno razgovor, postoji jedino kroz pisanje što je posebna novina [1]. U klasičnoj govornoj komunikaciji oslanjamo se na neverbalne elemente komunikacije te na kontekst u kojemu je poruka smještena. U računalno posredovanoj komunikaciji širi vidik kontekstova u velikom je broju slučajeva odsutan je i tako poštijetnik poruke uočen s manjkom nekih kontekstualnih elemenata zbog čega ne može kontrolirovati kako će primatelj poruke tu poruku interpretirati. Dakle, govoreći o značajkama računalno posredovane komunikacije nasuprot klasične govorne, susrećemo se s pojmovima sinkrono i asinkrono pri čemu je bitno naglasiti da je „govorni jezik sinkron upravo zbog toga što je vrijeme njegove produkcije jedini pravilno jednako vremenu njegove „potrošnje“ dok se pisani jezik smatra asinkronim jer postoji vremenska razlika između pisanja teksta i njegova čitanja“ [1]. Iako se načini uporabe mreže često preklapaju i međusobno ne isključuju, uspostavljen je pojam mrežnoga jezika koji se naziva netspeak [3].

A. Netspeak

Mrežni jezik (engl. netspeak) se kao oblik kombinacije oslanja na karakteristike koje obilježavaju, kako govornu, i pisano komunikaciju: „kratkocu, kovanje novih riječi, često pokazuju i međusobne ne isključuju, uspostavljen je pojam mrežnoga jezika koji se naziva netspeak [3].

Iako, dakle, njegovo ime sugerira da se netspeak koristi samo u govornu (eng. speak znači govoriti), on se jednako tako koristi i u pisanju. Danas se komunikacija između dvoje ili više sudionika najčešće odvija putem tekstualnih poruka i elektroničke pošte jer je postalo lakše...

1128
poslati jednu tekstualnu poruku većem broju ljudi odnosno lakše je napisati jednu elektroničku poštu i poslati je na više adresa nego svakom sudioniku pojedinačno.

Zanimljivo je također promotriti razlike između službene, poslovne pisane komunikacije i neslužbene, svakodnevne pisane komunikacije. U poslovne komunikacije na papiru ubrajamo poslovna pisma i memorandume, a u elektroničke pisane poslovne komunikacije ubrajamo elektroničku poštu, Web i čavrljanje (chat komunikacije). Što se tiče stila i jezika u poslovojnoj pisanoj komunikaciji sadržaj poruke treba biti precizan, jasan i stroži nego svakom sudioniku.

III. ENGLISH KAO GLOBALNI JEZIK

A. Studenti i upotreba engleskog jezika

Jedan od razloga tako široke rasprostranjenosti uporabe engleskog jezika je to što mu je većina stanovništva najviše izložena. U Hrvatskoj smo okruženi glazbom na engleskom jeziku, gledamo filmove koji nisu sinkronizirani, imamo pristup knjigama i časopisima na engleskom jeziku i koristimo ga za pretraživanje interneta. Mnogi u glavnom koriste internet za sve navedene radnje, a budući da je pristup internetu u našoj zemlji omogućen u gotovo svim privatnim i javnim prostorima, neprestano su izloženi engleskom jeziku.

MIPRO 2017/CE

1129
Internet World Stats na svojoj službenoj stranici navodi da je 30. lipnja, 2016. procijenjeno kako na svijetu ima 3,611,758,813 internet korisnika, a engleski jezik koristi 58% građana starijih od 15 godina, a svakodnevno korištenje njime najviše je zastupljeno kod najmlađih (15 do 17 godina – 94% te kod 18 do 24 godine – 90%) [13]. U istraživanju iz 2007. godine, Engleske jezice potrebe hrabrih studenata, Narančić Kovač i Cindrić dolaze do podataka u kojima "skoro svi ispitani studenti (99,2%) izjavljuju da je engleski jezik za njih nužan i nezaobilazan ne samo u profesionalnom (i obrazovnom) području nego, čak i znatno više, u njihovu privatnom životu. Najčešća situacija u kojoj studenti trebaju engleski jezik jest služenje internetom" [14].

B. Komunikacija mladih danas

Komunikacija je proces razmjene informacija preko dogovorenog sistema znakova, odnosno proces slanja informacija sebi ili bilo kojem drugom entitetu, najčešće putem jezika. Riječ komunikacija doslovno znači: podijeliti, učiniti nešto općim ili zajedničkim [15]. Prof.dr.sc. Anja Nikolić Hoyt u svom predavanju Simbolički aspekti uporabe suvremenoga engleskog jezika: konstruiranje prestižnih i poželjnih identiteta, kaže: "Kao dio društvene strukturiranosti mladi obrazuju se i stvaraju svoj svijet, koji je način na koji se može postiži sile vlastitih stvari, s ciljem onog nešto većeg koja se ne može postići samotom. Mladih ljudi obično koriste engleski jezik za njihovu komunikaciju i izražavanje svojih identiteta pripadnika mlade generacije [16]. Mladi u Hrvatskoj se koriste engleskim jezikom, ali isto tako mnoge engleske riječi riječ koriste i u svakodnevnoj komunikaciji na hrvatskom jeziku (npr. thanks, please, sorry, email, site, web itd.). Novi jezik koji ujedinjuje mlade svijeta mijenja se zbog utjecaja medija i moderne tehnologije. Korišćenjem zajedničkog jezika postajemo dio jednog, jednakog svijeta.

Netizens je kovanica engleskih riječi „Internet“ i „citizens“, a opisuje „grđane mreže“ tj. osobe koji aktivno sudjeluju u online komunikaciji [17]. Da bi postali „punoopravni“ netizens potrebno je poznavati netspeak uz poznavanje netiquettea. Netiquette je pojam koji se odnosi na smjernice ili pravila poželjnog ponašanja u Internet zajednici i komunikaciji [18], odnosno riječ je o internetskom bontonu koji služi kao putokaz na tim komunikacijskim putevima [19].

IV. ISTRAŽIVANJE – PRIMER STUDENATA VISOKOG UČILIŠTA ALGEBRA

A. Opis uzroka

S obzirom na mali udio ispitanika ženskog spola, kao i izvanrednog statusa studija, rezultati ovog istraživanja nisu predočeni prema tim varijablama u prikazu, a prosječna dob sudionika ovog istraživanja je između 18 i 20 godina. U Tablici I. prikazana je struktura sudionika s obzirom na upisani studij, spol, status studija i upisanu studijsku godinu.

C. Instrumenti korišteni u istraživanju

Anketni upitnik koji se sastoji od ukupno 11 pitanja sudionici su popunjavali anonimno pismenim putem. Podaci su prikupljeni ispitivanjem pomoću upitnika koji je na 10 pitanja sadržavao unaprijed ponuđene odgovore zatvorenog tipa, a na 1. pitanju postojala je mogućnost i slobodnog unosa odgovora. Unaprijed ponuđeni odgovori bili su izraženi frekvencijama (uvijek, često, praktično, rijetko, nikad). Sudionicima istraživanja objašnjena je svrha istraživanja te su zamoljeni da iskreno odgovore na pitanja iz anketnih upitnika.

V. REZULTATI ISTRAŽIVANJA

Odgovori ispitanika obrađeni su kvalitativnom i kvantitativnom metodom.

a) Korištenje angilzama ili izvornih engleskih riječi naspram hrvatskih riječi za izraze koji se tiču interneta

Na pitanje: Koristite li jezično sučelje za sustav Windows: a) Na engleskom jeziku, b) Na hrvatskom

B. Svrha istraživanja

Ciljevi provedenog istraživanja bili su saznati:

- Koriste li sudionici i koliko često angizlame ili izvorne engleske riječi naspram hrvatskih riječi za izraze koji se tiču interneta?
- Koriste li sudionici i koliko često angizlame ili izvorne engleske riječi i emotikone za izražavanje emocionalnih staca?
- Poštiju li sudionici ili barem nastoje poštovati pravopisna pravila hrvatskog standardnog jezika?

jeziku ili c) Drugo (što)?, N=92, čak 79% sudionika odgovorilo je da koristi jezično sučelje za sustav Windows na engleskom jeziku, 18% na hrvatskom jeziku, a tek 3% sudionika unijelo je vlastiti odgovor: "kombinacija sučelja na engleskom i hrvatskom jeziku", "ruski jezik", "Mac na engleskom jeziku".

Sudionicima je bilo postavljenj pitanje: Koliko često koristite anglizme ili izvorne engleske riječi za izraze koji se tiču interneta (npr. mail, site, web) u neobaveznoj privatnoj online komunikaciji? Svi sudionici su odgovorili na pitanje, N=92, a čak 79% ispitanika uvijek ili često koristi anglizme ili izvorne engleske riječi za izraze koji se tiču interneta, kao što su npr. mail, site i web, njih 20% to čini povremeno, a samo 2% rijetko. Niti jedan sudionik ispitivanja nije naveo da te izraze ne koristi baš nikad.

Treće pitanje bilo je: Koliko često koristite anglizme ili izvorne engleske riječi za izraze koji se tiču interneta (npr. mail, site, web) u službenoj komunikaciji online (za potrebe studija) s nastavnim i nenastavnim osobljem Visokog učilišta Algebra? Iz odgovora sudionika, N=92, iskristaliziralo se da gotovo polovica ispitanika, njih ukupno 49% često ili uvijek koriste anglizme ili izvorne engleske riječi za izraze koji se tiču interneta, kao što su mail, site, web, i u službenoj online komunikaciji (za potrebe studija) s nastavnim i nenastavnim osobljem Visokog učilišta Algebra, iako je taj postotak manji nego u neobaveznoj privatnoj online komunikaciji u kojoj to čini više od ¼ ispitanika. Povremeno i rijetko to čini njih čak 49%, a samo 2% ispitanika to ne čini nikad.

Na pitanje: Koliko često radjete koristite hrvatske riječi za izraze koji se tiču interneta (npr. e-pošta, stranica, mreža) u neobaveznoj privatnoj online komunikaciji? odgovor ispitanika, N=92, pokazali su da 25% ispitanika nikada u neobaveznoj privatnoj online komunikaciji ne koriste hrvatske riječi za izraze koji se tiču interneta, kao što su npr. e-pošta, stranica i mreža, rijetko ih koristi gotovo polovica, njih 49%, povremeno 18%. Samo 7% studenata ispitanika to čini često, a uvijek samo 1%. Temperljem odgovora na pitanje: Koliko često radjete koristite hrvatske riječi za izraze koji se tiču interneta (npr. e-pošta, stranica, mreža) u službenoj komunikaciji online (za potrebe studija) s nastavnim i nenastavnim osobljem Visokog učilišta Algebra?, N=92, vidljivo je da je u službenoj online komunikaciji (za potrebe studija) s nastavnim i nenastavnim osobljem Visokog učilišta Algebra, nešto veći postotak studenata nastoji koristiti hrvatske riječi za izraze koji se tiču interneta, kao što su te e-pošta, stranica, mreža, pa tako njih 13% to čini često ili uvijek, 76% povremeno ili rijetko, a nikad 11%, što je više nego upola manje nego u privatnoj neobaveznoj komunikaciji.

a) Korištenje anglizama ili izvornih engleskih riječi i emotikona za izražavanje emocionalnih stanja

Šesto pitanje bilo je: Koliko često koristite anglizme ili izvorne engleske riječi za izražavanje emocionalnih stanja (kao što su npr. thanks ili thx) u neobaveznoj privatnoj online komunikaciji?, N=91. 17% sudionika uvijek koristi anglizme ili izvorne engleske riječi u neobaveznoj privatnoj online komunikaciji kako bi izrazili emocionalno stanje, a 35% ispitanika to čini često. 39% studenata to čini povremeno ili rijetko, a 8% ispitanika za izražavanje svojih emocionalnih stanja u neobaveznoj privatnoj online komunikaciji ne koristi anglizme ili izvorne engleske riječi.

Sedmo pitanje: Koliko često koristite emotikone ili izvorne engleske riječi za izražavanje emocionalnih stanja (kao što su npr. thanks ili thx) u službenoj komunikaciji online (za potrebe studija) s nastavnim i nenastavnim osobljem Visokog učilišta Algebra?, N=91, pokazalo je da je u službenoj komunikaciji online (za potrebe studija) s nastavnim i nenastavnim osobljem Visokog učilišta Algebra, studenti puno manje koriste anglizme ili izvorne engleske riječi za izražavanje emocionalnih stanja, pa tako uvijek to čini samo 2%, a često 8%. Povremeno ili rijetko to čini 40%, ali čak 49% nikad, odnosno gotovo polovica ispitanika.

Osmo pitanje anketnog upitnika bilo je: Koliko često koristite emotikone u službenoj komunikaciji online (za potrebe studija) s nastavnim i nenastavnim osobljem Visokog učilišta Algebra? Prema odgovorima sudionika, N=91, vidljivo je da je u službenoj online komunikaciji rjeđe koriste emotikone nego u privatnoj neobaveznoj komunikaciji, pa tako čak 64% studenata emotikone u službenoj komunikaciji uopće ne koristi, a 30% to čini rijetko ili povremeno. Samo 3% ispitanika emotikone koristi često u službenoj online komunikaciji s nastavnim i nenastavnim osobljem Visokog učilišta Algebra, dok se za odgovor uvijek nije odlučio niti jedan sudionik.

b) Poštivanje pravopisnih pravila hrvatskog standardnog jezika

Deseto pitanje postavljeno studentima bilo je: Koliko često nastojite poštovati pravopisna pravila hrvatskog standardnog jezika u neobaveznoj privatnoj online komunikaciji?, N=91. U neobaveznoj privatnoj online komunikaciji pravopisna pravila hrvatskog standardnog jezika 14% ispitanika nikad ne nastoji poštovati, a 38% ispitanika to čini povremeno ili rijetko. 29% studenata to nastoji činiti često, a 17% uvijek.

Jedanaestoj postavljanje pitanja glasio je: Koliko često nastojite poštovati pravopisna pravila hrvatskog standardnog jezika u službenoj komunikaciji online (za potrebe studija) s nastavnim i nenastavnim osobljem Visokog učilišta Algebra?, N=91. U službenoj online komunikaciji (za potrebe studija) s nastavnim i nenastavnim osobljem Visokog učilišta Algebra čak 63% studenata nastoji poštovati pravopisna pravila hrvatskog standardnog jezika, a 27% to nastoji činiti često. Povremeno ih to nastoji činiti tek 7%, a rijetko ili nikad ukupno samo 2% studenata sudionika ovog istraživanja.

MIPRO 2017/CE 1131
V. ZAKLJUČAK

Mrežni jezik (eng. netspeak) je termin skovan prije desetak godina kako bi opisao novi oblik komunikacije koji se oslanja na kratkocu, kovanje novih riječi, često uporabu žargonja, izostavljanje interpuncijalnih znakova i velikih slova, a koji je vrlo blisko povezan s engleskim kao globalnim jezikom.

Proučavanjem dostupne literature, uočen je nedostatak recentnih istraživanja širenja i utjecaja mrežnog jezika. Naime, većina značajnijih studija fokusira se na leksičke promjene u jeziku pod utjecajem interneta, odnosno leksičko-semantičku obrazu mrežnog jezika, nasuprot čemu je cilj ovoga rada bio, na studentskoj populaciji Visokog učilišta Algebra, istražiti učestalost korištenja netspeaka u formalnoj i neformalnoj komunikaciji.

Studenti Visokog učilišta Algebra spadaju u dobru skupinu koja internet koristi svakodnevno, što za slanje i primanje tekstualnih poruka i elektroničke pošte, što za proučavanje događaja na društvenim forumima, uočena je, a zatim i za razgovore uživo. Upravo zbog specifičnosti IT područja u kojem se studenti Visokog učilišta obrazuju, a u kojem je posebno neizostavno svakodnevno korištenje računala i interneta, dodatno je zanimljivo bilo istražiti u kojoj mjeri studenti transformiraju jezični praksu u službenoj i neslužbenoj online komunikaciji koristeći „kodirani domaći jezik” odnosno mješavinu engleskog i hrvatskog jezika.

Istraživanje je bilo fokusirano na elektroničku poštu (email) kao dominantan tip računalno posredovane komunikacije između studenata i nastavnog/nenastavnog osoblja na Visokom učilištu Algebra. Jezik elektroničkih poruka veoma je heterogen te varira od poruka koje su formalne do poslovnih poruka u kojima se uglavnom poštju norme hrvatskog standardnog jezika.

Svjesni činjenice da se mrežni jezik uvek u svoje segmente komunikacije, prvotna pretpostavka bila da studenti danas netspeak pojačano koriste, kako u formalnoj, tako i u neformalnoj komunikaciji. Samo istraživanje provedeno među studentima Visokog učilišta Algebra pokazalo je da je širenje netspeka i dalje ograničenog obujma, odnosno, na što ukazuju i sami rezultati ankete, da netspeak ipak dominira u neformalnoj online komunikaciji između studenata dok se u formalnoj online komunikaciji sa nastavnim i nenastavnim osobljem studenti i dalje radije koriste riječima iz hrvatskog standardnog jezika.

LITERATURA

Suvremene metode poučavanja u vojnom obrazovanju

I. UVOD

U RH se za potrebe obrambenih i vojnih sustava u području vojnog obrazovanja na Hrvatskom vojnom učilištu „Dr. Franjo Tuđman“ organizira, priprema i provodi e-učenje. E-učenje i učenje na daljinu primijenjuju se u obrambenim i vojnim sustavima zemalja članica NATO saveza i EU. U obrambenim i vojnim sustavima zemalja članica NATO saveza e-učenje se koristi i primjenjuje pod nazivima: JADL (engl. Joint Advanced Distributed Learning) i ADL (engl. Advanced Distributed Learning).

Open source sustavi za upravljanje učenjem tj. LMS-ovi (engl. Learning Management Systems) MOODLE (engl. Modular Object-Oriented Dynamic Learning Environment) i MERLIN najviše koriste akademske zajednice, a u obrambenim i vojnim sustavima zemalja članica NATO saveza i EU koristi se, uz navedene sustave, i ILIAS (njem. Integriertes Lern Informations und Arbeitsko-operations System). U MORH-u i OS RH u sustavu vojnog obrazovanja za e-učenje se koriste LMS sustavi MOODLE, MERLIN i ILIAS kao platforme i skupovi alata.

Također, na HVU „Dr. Franjo Tuđman“ provodi se projekt “Uvođenje novih načina usvajanja i održavanja znanja” odnosno e-obrazovanje u OS RH i MORH-u.

Određeni pripadnici OS RH i djelatnici MORH-a, a poglavito nastavnici Hrvatskog vojnog učilišta „Dr. Franjo Tuđman“ osposobiljeni su vlastitim resursima, učinkovitim korištenjem LMS-ova MOODLE, MERLIN i ILIAS, razvijaju i primjenjuju online ADL tečajeve i module za obrambene i vojne potrebe.

Jedan od oblika usavršavanja nastavnika, na početku akademske godine, je provedba tečaja Suvremene metode poučavanja u vojnom obrazovanju.

Svrha je poboljšati kvalitetu provedbe nastave za polaznike vojnih škola usvajanjem suvremenih nastavnih tehnika i metoda od strane nastavnika

Provedbom tečaja unaprijedit će se nastavna umijeća vojnih nastavnika kroz siječnjačku područja: poticanje timskog rada između polaznika škola, osposobljavanje nastavnika za provedbu suvremenih metoda nastave korištenjem kreativnih modela nastave (kreativno čitanje, kritičko čitanje i drugo), uvođenje inovacija, problemsko-istraživački modeli, recepcijsko-estetički modeli, egzemplarno-paradigmatski modeli, multimedijsko-više izvorni modeli, vođenje razreda i fleksibilno rješavanje nastalih izazova u provedbi nastave.

II. VOJNO OBRAZOVANJE

HVU, kao buduća sveučilišna sastavnica ili samostalna sveučilište, kroz vojni vojnovi sustav treba osigurati proces stvaranja vojne profesije kao uvjet primjene znanosti i umijeća. Profesionalne vojne kompetencije uvjet za stjecanje odgojnih vrijednosti. U nastavi imamo odnos modela, od modela učenja do modela stvaralaštva. Za proces poučavanja najvažniji je odnos...
između nastavnika i učenja. Učenje poučavanjem se razlikuje od učenja stvaralaštvom. Za stvaralaštvo je važnije pitanje *kako*, nego što. Kod poučavanja je bitnije što (sadržaj) a ne kako (način, metoda). Ipak ne bi se moglo reći da su poučavanje i učenje stvaralaštvom radnje suprotne jedna drugoj. Podučavanje je umijeće i znanost.

**Poučavanje** (što) je za danas, a **učenje** (kako) je za sutra.Tradicionalna nastava transformira se u učenje putem stvaralaštva. Stvaralaštvo je najveća čovjekova ambicija. Trebamo naučiti učiti.

**Modeli kreativne nastave**

Na ovome svijetu nema toga što bi pročišćavalo bolje od mudrosti. „Mudrost koju temeljito naučimo nikada nećemo zaboraviti.“ (Pitagora)

**Nastavne strategije**

Pod *nastavim strategijama* podrazumijevamo ukupnost odnosa zasnovanih na pojedinačnoj i simultanoj primjeni oblika, metoda i sredstava nastavnog rada. Postoje tradicionalne i suvremene nastavne strategije. Također, postoje alternativni i kreativni modeli u nastavi.

**Suvremeni nastavni modeli** ili kreativni modeli nastave su:

1. kreativno-stvaralački modeli - na sistematičan način upućuje recipijente u sadržaje, metode i tehnike stvaralačkog rada. Krajnji cilj je razvijanje sposobnosti stvaralačkog mišljenja.
2. problemsko-otkrivajući/istraživački modeli - Sadržaj ovog modela čine istraživačka-misaoani postupci: formuliranje problema, dekomponiranje, formuliranje hipoteza, sastavljanje plana istraživanja, zaključivanje problema i sastavljanje liste problema.
3. recepcijsko-estetički modeli - zasnivaju se na postupku recepcije podataka. Učenik se javlja kao aktivna ličnost koja prima poruke, obavlja njihovu preradu i transformaciju.
4. ejejističko-sintetički modeli - pružaju mogućnost za spoznavanje u nastavi, ali i za biološko-psihološke, pedagoško-didaktičke i estetsko-etičke sadržaje kojima se djeluje, osim na kognitivno i na afektivno i konativno (voljno) podrucje učeničke ličnosti.
5. algoritamsko-matematički modeli. Ovaj model najveći doprinos u osposobljavanju za stvaralaštvo daje procesima samostalnog otkrivanja algoritama i razvršavanju procesa stvaralačkog mišljenja.
6. egzemplarno-analogni/paradigmatski modeli predstavljaju veliku mogućnost u osposobljavanju učenika za samoučenje, ali istodobno pruža mogućnost učenicima za istraživački rad. Nastavnik ne izlaze cjelokupno gradivo nego uzima ograničeno dio gradiva, egzemplar, uzorni sadržaj, i to izlaže učenicima.
7. multimedijsko-vidjezovni modeli oslobađaju ličnost učenika uniformnosti i monoističkih nastavnih postupaka.
8. compjutorsko-simulacijski modeli imaju veliki edukativni i konativni značaj za razvoj svakog pojedinca. Dvije kratke riječi koje imaju presudnu ulogu - počnite odmah.
9. književno-umjetnički modeli ili kreativno-umjetnički modeli na vrlo jednostavan i svakom pristupačan način uvode u procese stvaralaštva. To su konkretni mentalni procesi koji vode rješenjima, idejama, konceptualizaciji, umjetničkim formama, teorijama i proizvodima koji su jedinstveni i koji su novost i
10. strukturalno grafički omogućavaju na poseban način razvijanje stvaralačkih sposobnosti učenika. [1]

Svaki model sadrži se u sebi više podmodela koji nude alternativne i pluralističke mogućnosti stvaralaštva u nastavi.

Vrijednost primjene svakog modela ovisi od njegovog odnosa prema ostalim modelima.

Kreativni nastavnici su glavni pokretači i inspiratori stvaralačkih aktivnosti svojih učenika i studenata. Ovim modelima se tradicionalna nastava u školi/fakultetu može transformirati u učenje putem stvaralaštva. Modeli su otvoreni, što znači da se mogu mijenjati, dopunjavati, transformirati i kombinirati. Smisao modelskog pristupa je upravo u činjenici što su neovezujući i što ih svaki nastavnik može primijeniti prema svojim potrebama i mogućnostima.

Bitno je za kreativne metode nastave: znati - znanje, htjeti - volja i smjeti - hrabrost.

**Tehnike i metode učenja**

Tehnike učenja su umjetnost ili spretnost da se koriste tehnike stvaralačkog rada. Krajnji cilj je razvijanje stvaralačkih sposobnosti učenika.

**A. E-učenje**

E-učenje je vrsta komunikacijskog kanala, kanala kroz koji se odvija učenje.

Postoje dvije skupine definicija e-učenja i to: 1. skupina "tehničkih" definicija stavlja naglasak na tehnologiju (na "e" dio u imenu). Primjer jedne od "tehničkih" definicija glasi: "E-obrazovanje je bilo koji oblik učenja, poučavanja ili obrazovanja koji je potpomognut uporabom računalnih tehnologija, a posebno računalnih mreža temeljenih na..."
Internet tehnologijama.“ i 2. skupina "pedagoških" definicija ima naglasak na obrazovanju, tj. na učenju i poučavanju ("learning" dio u imenu). Jedna od takvih definicija je: "E-learning je interaktivna ili dvomjeran proces između nastavnika i učenika uz pomoć elektroničkih medija, pri čemu je naglasak na procesu učenja, dok su mediji samo pomoćno sredstvo koje upotpunjuje taj proces [3]." U skladu s navedenim e-ucenje je presjek dvaju svjetova, i to: svijeta „informacijskih i komunikacijskih tehnologija“ i svijeta „obrazovanja“. E-ucenje kao oblik obrazovanja postoji na više razina: kao po potpuno samostalan oblik, ali i kao sastavni dio ili nadopuna klasičnog obrazovanja. Proširena klasifikacija ili "vremenska crta" e-obrazovanja prikazuje obrazovanje kao kontinuum e-ucenja.

B. Učenje na daljinu

Učenje na daljinu (engl. distance learning, distance education) je obrazovanje ili obuka koja se nudi učeniciima na različitim mjestima odnosno fizički udaljenima od učitelja ili izvora informacija. U praksi je učenje na daljinu puno složenije od ove definicije jer uključuje korišćenje novih tehnologija i novih interaktivnih nastavnih metoda. Termin učenje na daljinu u novije vrijeme se zamijenio terminom online učenje, čime se naglašava da je riječ o posebnom obliku e-learninga ili e-obrazovanja.

Department of Defense (DoD) je uvidio da sa konstanim brzim i neplaniranim promjenama lokacija vojnih snaga ne može omogućiti konstantnu potrebu za edukacijom u novim tehnologijama. Pošto je vremenski interval razmještaja postrojbiji kao i vrijeme implementiranja novih tehnologija kraće sve više pojavljuje se potreba za edukacijom "right time, right place", gdje je vrijeme često sada, a mjesto bilo gdje na planeti. Dolazi se do zaključka da u informacijskom dobu vojska mora biti sprema odgovoriti na nove prijetnje odmah i sada sa najnovijim tehnologijama. Kao odgovor na takve izazove razvijalo se i dalje se razvija e-ucenje odnosno JADL i ADL čija je svrha postavljanje okvira koji će omogućiti DoD službenicima (od ratnika - do tajnika) pristup: a) kvalitetnoj edukaciji i treningu prema individualnoj potrebi, b) relativno mali troškovi i c) kada god i gdje god to bude potrebno. Kao jedna od najvećih prednosti učenja na daljinu smatra se to što omogućuje stalno učenje (engl. lifelong learning) i profesionalno usavršavanje.

E-ucenje omogućuje izbor mjesta, vremena i trajanja učenja. Također, omogućuje pristup udaljenim korisnicima kojima je preskupu putovati. Kvalitetno oblikovan sustav e-ucenja omogućuje prilagodbu korisniku uz praćenje dinamike i kvalitete prijeđenog sadržaja, a sam sadržaj, kako bi ostavio odgovarajući dojam i bio što jasniji, nije riječ o istim oblicima obrazovanja. E-ucenja omogućava: učenje prilagođeno individualnim potrebama studenta (bilo kada, bilo gdje), aktivno sudjelovanje studenata, aktualnije i ažurnije obrazovanje i aktivna uloga polaznika, a kvalitetna povratna informacija, izravno praćenje napretka u procesu učenja. Učenje na daljinu omogućuje: učenje na daljinu u novim tehnologijama, koje se učenje na daljinu omogućuje prilagodbu korisniku uz praćenje dinamike i kvalitete prijeđenog sadržaja, a sam sadržaj, kako bi ostavio odgovarajući dojam i bio što jasniji, nije riječ o istim oblicima obrazovanja.

V. KONCEPT, UPRAVLJANJE I TEHNIKE E-UCENJA

a) KONCEPT E-UCENJA

Danas je sveprisutna potreba ali i želja da se unaprijedi kvaliteta i dostupnost različitih obrazovnih programa. Pri tome je obrazovanje postalo cjeloživotnim procesom i potrebom, pa se briga o dostupnosti i kvaliteti odnosi na sveukupni ciklus cjeloživotnog obrazovanja. E-ucenje je proces obrazovanja (proces učenja i poučavanja) uz uporabu informacijske i komunikacijske tehnologije, koja pri tome doprinosi unaprijedjenju kvalitete toga procesa i kvalitete ishoda obrazovanja.

E-ucenje omogućava: učenje prilagođeno individualnim potrebama studenta (bilo kada, bilo gdje), aktivno sudjelovanje i aktivnu ulogu studenata, aktualnije i ažurnije obrazovne materijale, globalni pristup različitim obrazovnim sadržajima, smanjenje „pritiska“ na fizičke resurse (omo- gućavajući virtualne učionice, virtualne laboratorije), više...
komunikacije nastavnik-student i student-student, timski rad, projektni rad nastavnika i studenta, bolju iskoristenost vremena (za kvalitetnije sadržaje) pri kontaktima nastavnik-student, samostalnu provjeru znanja i kontinuirano mjerenje i praćenje napretka studenta [7].

To je učenje i poučavanje koje je usmjereno na studente.

b) UPRAVLJANJE PROCESIMA E-UČENJA

PLANIRANJE procesa e-učenja je iznimno bitan za cjelokupni uspjeh e-učenja, a najčešće obuhvaća aktivnosti od analize suvremenih trendova u obrazovanju i identificiranje karakteristika polaznika tečajeva za e-učenje; zatim osmišljavanje okoline za učenje koja odgovara vremenu sadržaja, ciljanoj publici i tehničkoj platformi te odabira odgovarajuće platforme za e-učenje; pa sve do formuliranja očekivanih ishoda e-učenja i izrade operativnog plana odnosno scenarija e-učenja. Cilj faze planiranja procesa e-učenja je osmišljavanje ishoda i scenarija e-učenja prema određenom kontekstu. Ishodi učenja predstavljaju instrumenat razvoja plana i programa, te provjere njegove konzistentnosti. Na razini programa preporučeno je definirati 15 do 30 ishoda učenja, na razini predmeta 5 do 10, a na razini nastavne cjeline 5 do 15 ishoda učenja [9].

PLANIRANJE procesa e-učenja je iznimno bitan za cjelokupni uspjeh e-učenja, a najčešće obuhvaća aktivnosti od analize suvremenih trendova u obrazovanju i identificiranje karakteristika polaznika tečajeva za e-učenje; zatim osmišljavanje okoline za učenje koja odgovara vremenu sadržaja, ciljanoj publici i tehničkoj platformi te odabira odgovarajuće platforme za e-učenje; pa sve do formuliranja očekivanih ishoda e-učenja i izrade operativnog plana odnosno scenarija e-učenja. Cilj faze planiranja procesa e-učenja je osmišljavanje ishoda i scenarija e-učenja prema određenom kontekstu. Ishodi učenja predstavljaju instrumenat razvoja plana i programa, te provjere njegove konzistentnosti. Na razini programa preporučeno je definirati 15 do 30 ishoda učenja, na razini predmeta 5 do 10, a na razini nastavne cjeline 5 do 15 ishoda učenja [9].

2. CBT (engl. Computer Based Training)

CBT je obrazovni ili obučni tečaj dostavljen direktno na studentsko računalo putem CD-ROM-a ili nekog drugog uređaja za pohranu. On se razlikuje od ADL-a po tome što se ne isporučuje preko weba ili putem sustava za upravljanje učenjem.

Slika 7. Oznaka ili logo za CBT

3. „URONJENO“ UČENJE (engl. Immersive learning)

„Uronjeno“ (engl. Immersive) učenje koristi računalno simulirano okruženje koje se događa u stvarnom životu ili hipotetsku situaciju u grafički bogatom i dinamičnom okruženju. Studenti su stavljeni u situaciju i uključeni su u proces učenja kroz interaktivne simulacije i igre temeljene na game-based aplikacijama. Immersive učenje podupire jednog učenika ili više malih timova da rade zajedno kako bi riješili problem, uvježbali tehnike ili poboljšali svoje vještine.

4. MOBILNO UČENJE (engl. M-learning)

Mobilno učenje (engl. M-learning) je uporaba prijenosnih računalnih uređaja, kao što su različiti iPad-i i drugi tableti, prijenosna računala, osobni digitalni pomoć-nici (PDA) i pametni telefoni povezani s bežičnim mrežama. To omogućuje da se podučavanje i učenje proširu na prostore izvan tradicionalne učionice te daje nastavnicima i polaznicima povećanu fleksibilnost i nove mogućnosti za interakcije koje su prikladne i dostupne virtualno s bilo kojeg mjesta.

5. SURADNIČKO ILI KOLABORATIVNO UČENJE

Suradničko ili kolaborativno učenje (engl. Collaborative learning) podupire nastavu kroz interaktivne metode ili online komunikacije koristeći društvene medijanske alate kao što su chat sobe, tribine i video alate kao što su webi-nari i web-emitiranja. Ovi alati se mogu implementirati u učionici i online okruženju kako bi podržali tijek nastave. Oni daju mogućnost velikom broju polaznika da rade zajedno s nastavnikom-instruktorem.

6. KOMBINIRANO ILI HIBRIDNO UČENJE

VI. LMS SUSTAVI

U zemljama članicama NATO saveza i EU koriste se LMS-ovi: ILIAS, MOODLE i MERLIN. LMS sustavi koji se koriste na HVU su: ILIAS i MOODLE (MERLIN).

HVU „Dr. Franjo Tuđman“ je u procesu transformacije u visoko obrazovnu i znanstveno-istraživačku vojnu ustanovu odnosno instituciju tij. sastavnicu sveučilišne zajednice. Od 2014. godine provodi dva nova predдiplomska sveučilišna studijska programa za potrebe OS RH. Vizija je da se uvođenjem e-učenja želi u procesu obrazovanja ostvariti aktivan partnerski odnos nastavnika i polaznika, prilagođen osobinama i potrebama svakog polaznika, s jasno postavljenim obrazovnim ciljevima i jasno dodijeljenim odgovornostima za postizanje tih ciljeva. Uvođenjem i aktivnom primjenom e-učenja HVU „Dr. Franjo Tuđman“ namjerava ostvariti četiri strateška cilja: unaprijediti kvalitetu obrazovanja, omogućiti nastavnicima i studentima ostvarivanje novih uloga u obrazovnom procesu, povećati konkurentnost i dostupnost učilišta i učilišnih programa i osposobiti studente za uporabu tehniologija cjeloživotnog učenja.

I u europskom, kao i u hrvatskom, vojnom obrazovanju ponuđen je određeni broj tečajeva i zajedničkih modula u području e-učenja. Svaki od njih obuhvaća IDL i f2f fazu. Sadašnje sposobnosti su na zavidnoj razini, a njihovim daljnjim razvojem, koje su precizirane Smjernicama za daljnje unapređenje sustava e-učenja, osnažit će se novim sposobnostima, a polaznici će sistematički postojeca i usvojiti nova znanja, vještine i sposobnosti kojima će biti osposobljeni za još učinkovitije njihovo primjenu u svakodnevnim zadaćama.

VIII. ZAKLJUČAK

U informacijskom društvu i vremenu e-učenje dobiva sve više na značenju poglavito u europskom i hrvatskom vojnom obrazovanju. Prikazane su suvremene metode poučavanja i sustavi koji se koriste za njihovu primjenu na HVU „Dr. Franjo Tuđman“. I na taj način dostiže se postavljeni ciljevi poboljšanja i unapređenja kvalitete i nastavna umijeća tijekom provedbe nastave na HVU „Dr. Franjo Tuđman“. Prikazan je proces umrežavanja sa NATO i EU organizacijama koje provode vojno obrazovanje. Nastavnici (vojni i sa sastavnica Sveučilišta u Zagrebu) koji provode nastavu - obrazovanje pripadnika OS RH primjenjuju suvremene metode poučavanja koje su stekli na istoimenom tečaju „Suvremene metode poučavanja“ na kome su definirani ishodi učenja i detaljno je razrađen sadržaj tečaja. Načini praćenja kvalitete provedbe suvremenih metoda poučavanja osiguravaju stjecanje izlaznih kompetencija. „Znanjem u budućnost“ moto je sadašnjih naraštaja i ostat će moto i naraštajima koji će doći na vojno obrazovanje u škole Hrvatskog vojnog učilišta „Dr. Franjo Tuđman“ u Zagrebu.

LITERATURA

Stavovi strukovnih udruga i visokoškolskih institucija o preobrazbi predmeta Informatika u hrvatskom školstvu

*** XV. Gimnazija, Zagreb, Hrvatska

leo.budin@fer.hr, smladen@pmfst.hr, zmark@mioc.hr, marko.rosic@pmfst.hr, dejan.skvorc@fer.hr

Sažetak - Nastavni predmet Informatika uveden je u hrvatski školski sustav prije nekoliko desetljeća kada je središnja tema bila izučavanje svojstava računalnih sustava. Međutim, danas se naglasak stavlja na računalne postupke i algoritme koje su primjenljive u svim granama ljudske djelatnosti uključujući sva područja znanosti i obrazovanja. Međutim, danas se naglasak stavlja na računalne postupke i središnja tema bila izučavanje svojstava računalnih sustava.

Strukovne udruge i visokoškolske ustanove koje djeluju u području informacijskih i komunikacijskih tehnologija i računarstva zadnjih nekoliko godina upozoravaju na važnost uvažavanja tih činjenica i s tim u vezi pripreme su niz preporuka za preobrazbu hrvatskog obrazovnog sustava. U ovom se radu podrobnije opisuju te aktivnosti kako bi se ukazalo da preporuke za preobrazbu nastave informatike nisu samo trenutna inspiracija pojedinaca ili manjih interesnih skupina već da one imaju široku potporu u svim gospodarskim i obrazovnim sredinama. Okrugli stolovi održani u zadnje tri godine okupili su učitelje i nastavnike osnovnih i srednjih škola, predstavnike akademske zajednice, gospodarstvenike i predstavnike prosvjetnih vlasti. Svi ti skupovi istaknuli su potrebu korijenite promjene nastave informatike u hrvatskom obrazovnom sustavu.

U ovom se prikazu predstavljaju osnovne postavke i preporuke četiriju većih okupljanja koji su održani tijekom 2014. i 2015. i to:

- okrugli stol pod naslovom Digitalna pismenost i računarstvo u predvisokoškolskom obrazovnom održan u okviru 37. međunarodnog skupa MIPRO 2014 u svibnju 2104. godine u Opatiji. Okrugli stol organizirale su četiri strukovne udruge: Hrvatska udruga za informacijsku i komunikacijsku tehnologiju, elektroniku i mikroelektroniku (MIPRO), Hrvatska sekcija IEEE, Hrvatska ACM sekcija i Hrvatsko društvo za promicanje informatičkog obrazovanja (HDPIO) [1].
- okrugli stol pod nazivom Informatika u novom Okviru nacionalnog kurikuluma i kompetitivnost Hrvatske održan u okviru godišnjeg skupa Računalo u školi u organizaciji Hrvatskog društva za promicanje informatičkog obrazovanja (HDPIO) u rujnu 2014. godine u Šibeniku [2].
- okrugli stol Nastava informatike u hrvatskom obrazovnom sustavu održan u travnju 2015. godine na Fakultetu elektrotehniike i računarstva Sveučilišta u Zagrebu. U pripremu okruglog stola uključile su se sljedeće visokoškolske institucije četiri hrvatskih sveučilišta: Elektrotehnički
fakultet i Odjel za matematiku Sveučilišta J. J. Strossmayera u Osijeku; Učiteljski fakultet Sveučilišta u Rijeci; Prirodoslovno-matematički fakultet i Fakultet elektrotehnike, strojarstva i brodogradnje Sveučilišta u Splitu; Fakultet elektrotehnike i računarstva, Fakultet organizacije i informatike, Filozofski fakultet, Prirodoslovno-matematički fakultet i Učiteljski fakultet Sveučilišta u Zagrebu [3].

okrugli stol Nastava informatike u hrvatskom obrazovnom sustavu održan u studenom 2015. godine na Prirodoslovno-matematičkom fakultetu Sveučilišta u Splitu [4].

Nakon održanih skupova pripremljeni su izvještaji u kojima su opisani motivi za održavanje skupova, osnovne postavke koje su pripremili njihovi uvedbenci i pojedini sudionici u raspravama te preporuke koje su pripremili redakcijske skupine pojedinih skupova. Dokumente su potpisi čelnici institucija odnosno udruga organizatora okruglih stolova te se iznesene preporuke mogu smatrati svojevrsnim službenim stavovima sveukupne stručne javnosti.

Iz tih se dokumenata u ovom radu prenose osnovne postavke s naglaskom na preobrazbu hrvatskog obrazovnog sustava, posebice nastave informatike.

II. OBRAZOVANJE I KONKURENTNOST DRUŠTVA

U dokumentu [2] ukazuje se na to da obrazovanje određuje kompetitivnost zemlje u globalnom okruženju. Utvrđuje se da se tržište rada globaliziralo na način da poslodavci sele svoje poslove u zemlji u kojima nalaze ljude s odgovarajućim kompetencijama. U zemlji s nižim razinama kompetencije sele se poslovi koji se obavljaju rutinski i koji se manje plaćaju. Pritom su konkurentnije one zemlje koje nude istu razinu kompetencija uz manji trošak rada.

Međutim, rutinski poslovi koje mogu obavljati slabije obrazovani ljudi se napretkom tehnologije sve više automatiziraju pa je takvih poslova sve manje jer je cijena automatizacije manja od cijene ljudskog rada. Bolje plaćeni visokostručni poslovi (engl. knowledge work) zahtijevaju višu razinu znanja i vještina. Prema tome, u svjetskoj konkurenciji zemlja može biti uspješna samo ako obrazuje ljude koji kreativnošću i inovativnošću stvaraju nove proizvode, sustave i usluge.

Takva gospodarska dinamika prisiljava države na uspostavu sustava obrazovanja koji će u uvjetima svjetske konkurencije omogućiti ljudima dostojan život. Svim svojim građanima država mora stoga osigurati obrazovanje koje će im omogućiti stjecanje kompetencija za složene poslove, za kreativno i inovativno djelovanje, za rješavanje složenih problema (edukacijska tehnologija, e-učenje). U prijedlogu kurikuluma za predmet Informatika za osnovne i srednje škole je pripremljen program, ispitivanje programa i uporaba rješavanja problema i programiranje.

Digitalnu pismenost (posebice primijenjenu na e-učenje) učenici bi trebali stjecati usputilo i u kontekstu njezine stvarne primjene u realnim okolnostima. To znači da elemente digitalne pismenosti treba stjecati i produbljivati u pojedinim predmetima u kojima se digitalne tehnologije rabe. Za uporabu tih tehnologija moraju se pripremiti i odgovarajuće međupredmetne teme. Osim savladavanja tehničkih vještina za uporabu različitih programskih pomagala, učenici moraju usvojiti i odgovarajuće društvene, komunikološke i etičke načela u uporabe tehnologije te načine njene sigurne i neškodljive primjene.

Sve mogućnosti uporabe educacijske tehnologije (e-učenja) prvenstveno moraju usvojiti, istraživati i poticati učitelji i nastavnici u svojim obrazovnim područjima. Nužno je i da sudjeluju u pripremi digitalnih sadržaja te stvaranju digitalnih repozitorija. Području rješavanja problema i programiranju treba posvetiti posebnu pažnju. Njime se potiče razvitak rješavanja problema i programiranje.

III. PREOBRAZBA NASTAVE INFORMATIKE

Pod nazivom Informatika uobičajeno se u hrvatskom obrazovnom sustavu podrazumijeva:

1) upoznavanje informacijske i komunikacijske tehnologije koja služi za uobičajavanje multidijalognih komunikacija, pretraživanje i prijenos na udaljena mjesta (informacijska tehnologija);

2) uporaba računala u obrazovnom procesu (eduakcijska tehnologija, e-učenje);

3) rješavanje problema računalom uporabom programskog jezika pri čemu su prepoznavljivi sljedeći koraci: specifikacija i računala problema, analiza problema i odabir postupaka za njegovo rješavanje, priprema i izrada programa, ispitivanje programa i uporaba programa (rješavanje problema, programiranje).

Djelomično pismenost (posebice primijenjenu na e-učenje) učenici bi trebali stjecati usputilo i u kontekstu njezine stvarne primjene u realnim okolnostima. To znači da elemente digitalne pismenosti treba stjecati i produbljivati u pojedinim predmetima u kojima se digitalne tehnologije rabe. Za uporabu tih tehnologija moraju se pripremiti i odgovarajuće međupredmetne teme. Osim savladavanja tehničkih vještina za uporabu različitih programskih pomagala, učenici moraju usvojiti i odgovarajuće društvene, komunikološke i etičke načela u uporabe tehnologije te načine njene sigurne i neškodljive primjene.

Sve mogućnosti uporabe educacijske tehnologije (e-učenja) prvenstveno moraju usvojiti, istraživati i poticati učitelji i nastavnici u svojim obrazovnim područjima. Nužno je i da sudjeluju u pripremi digitalnih sadržaja te stvaranju digitalnih repozitorija. Području rješavanja problema i programiranju treba posvetiti posebnu pažnju. Njime se potiče razvitak rješavanja problema i programiranje.
kurikularne reforme u Republici Hrvatskoj u dobroj su
mjeri uvaženi stavovi okruglih stolova te se u obrazovnim
ishodima pojavljuje cjelina računalnog razmišljanja i
rješavanja problema [5]. U daljnjem procesu razrade i
konačnog prihvaćanja tih kurikularnih dokumenata bit će
potrebno pažljivo razmotriti sve primjedbe i prijedloge za
konačno oblikovanje tih dokumenata. U daljnjoj razradi
kurikuluma trebat će uvažiti i sve dostupne izvore kao što
Informatics education: Europe cannot afford to miss the
boat [7], National curriculum in England: computing
programmes of study [8], Interim CSTA K-12 Computer
science standards (revised 2016) [9].
Području rješavanja problema i programiranju pridaje
se posebna pažnja i u europskom obrazovnom prostoru. U
dokumentu Developing Computational Thinking in
Compulsary Education, Implication for policy and
practice [10] ukazuje se na potrebne promjene u
obrazovnoj praksi i opisuje trenutno stanje u pojedinim
europskim zemljama. U tom pregledu sasvim su jasno
izraženi trendovi koje zagovaraju i naše spomenute
strukovne udruge i visokoškolske institucije u prethodno
spomenutim izvještajima s okruglih stolova.
IV. INOVIRANJE NASTAVE INFORMATIKE U
POSTOJEĆEM NASTAVNOM PLANU I PROGRAMU
ZA OSNOVNE ŠKOLE
U izvještajima sa sva četiri okrugla stola [1, 2, 3, 4 ]
provlači se zamisao o početnoj preobrazbi nastave
informatike u okviru postojećeg Nastavnog plana i
u tom je nastavnom planu izborni predmet. Nastavnim
planom predviđeno je sljedeće tjedno opterećenje
obveznim predmetima: u 5. razredu 22 sata, u 6. razredu
23 sata te u 7. i 8. razredu po 26 sati. Osim toga, od 5. do
8. razreda predviđeno je i ukupno 6 sati opterećenja
izbornom nastavom. To je opterećenje raspoređeno na
sljedeći način: 2 sata je predviđeno za predmet Vjeronauk,
2 sata za Strani jezik i 2 sata za ostale izborne predmete.
Međutim, u cijelom tom dokumentu nije opisan
sadržaj niti jednog drugog izbornog predmeta osim
predmeta Informatika. U nastavnom programu, sadržaj
izbornog predmeta Informatika od 5. do 8. razreda opisan
je na stranicama 526-538, a izvannastavne aktivnosti koje
se može provoditi od 1. do 4. razreda opisane su na
stranicama 538-544. Prema tome, u skladu s važećim
nastavnim planom potpuno je moguće nastojati da izborni
predmet Informatika upisuju svi učenici i to bez ikakve
smetnje za bilo koji drugi predmet. Na taj bi se način
omogućila nastava iz predmeta Informatika za sve učenike
bez obzira na to što je on izborni predmet. Time bi se
osigurao i kontinuitet u informatičkom obrazovanju
učenika koji će svoje školovanje nastaviti u srednjim
školama.
Sadržaj predmeta Informatika predviđen nastavnim
programom trebalo bi, međutim, osuvremeniti u skladu s
istim postavkama koje su prethodno opisane kao podloga
za pripremu novog Okvira nacionalnog kurikuluma. Na
taj bi se način stvorili uvjeti da predmet Informatika
kasnije bez većih poteškoća preraste u redoviti predmet u

MIPRO 2017/CE

budućoj reformiranoj (osmogodišnjoj ili devetogodišnjoj)
osnovnoj školi.
V. OTKLANJANJE PREPREKA ZA UVOĐENJE
OSUVREMENJENE NASTAVE INFORMATIKE U
POSTOJEĆOJ OSNOVNOJ ŠKOLI
Kao što je u Strategiji obrazovanja, znanosti i
tehnologije [12] istaknuto, preobrazba obrazovnog sustava
pretpostavlja autonomiju odgojno-obrazovnih ustanova uz
naglasak na postizanje odgovarajuće razine ovlasti i
slobode odgojno-obrazovnih djelatnika i ustanova u
odlučivanju, ponajprije o kurikulumu, ali i o organizaciji
poučavanja i učenja i rada škole u cjelini. Ustanovljuje se
da je to moguće ostvariti sustavnim unapređivanjem
inicijalnog i kontinuiranog obrazovanja i usavršavanja te
osiguravanjem boljih uvjeta rada kako bi se u profesiji
zadržali najbolji pojedinci spremni na cjeloživotno učenje
i profesionalni razvoj. Dakle, ostvarenje preobrazbe
predtercijarnog obrazovanja bitno ovisi o ostvarenoj
autonomiji škola u kojima djeluju kompetentni učitelji.
U promišljanju promjena i u našem obrazovnom
sustavu mogu poslužiti ocjene američke znanstvenice
Linde Darling-Hammond sa Sveučilišta Stanford koja je
provela podrobnu analizu uspješnih obrazovnih sustava u
Finskoj, Koreji i Singapuru i predložila nužne zahvate u
američkom obrazovnim sustavu [13]. Sve tri spomenute
zemlje ostvarile su velika poboljšanja svojih obrazovnih
sustava u proteklih 30 godina. Njihovi su ih napori
smjestili u sam vrh međunarodnih usporedbenih ljestvica
učeničkih postignuća.
Iako se te tri zemlje međusobno kulturno i povijesno
znatno razlikuju, njihove strategije imaju mnogo toga
zajedničkog:


Sve su tri države izgradile svoj obrazovni sustav
na egalitarnom načelu, suzbijajući sve
potencijalne izvore neravnopravnosti. Dok je
finski sustav skoro u potpunosti javan, Koreja i
Singapur su postupno privele njihove privatne
škole (nastale tijekom kolonijalnih vremena) pod
javni kišobran, pokrivajući dio njihovih troškova
i podmirujući školarine za učenike.



Velika se pažnja posvećuje obrazovanju učitelja i
nastavnika. Programi obrazovanja su vrlo
razvijeni i studentima se plaćaju stipendije
tijekom obrazovanja. Plaće učitelja i nastavnika
su usporedive s plaćama inženjera i ostalih
ključnih profesija. Učitelji su poštovani,
omogućeni su im dobri uvjeti rada. Oni aktivno
sudjeluju u odlukama o kurikulumu, poučavanju,
ocjenjivanju i profesionalnom razvitku.



Nastavnici početnici dobivaju svoje mentore. Za
mentore je predviđeno 15 do 25 sati tjedno za
zajedničke aktivnosti analize procesa učenja,
pripremu nastave, istraživanje, uzajamno
praćenje nastave u razredima, što sve pridonosi
unapređivanju rada. U sve se tri zemlje očekuje
njihov angažman u tim aktivnostima i
sudjelovanje u suradnji sa sveučilištima i ostalim
školama.

1141


Aktivnosti na unapređivanju i ujednačavanju obrazovnog sustava su konzistentne i trajne. Provodi se promišljeno ulaganje u poboljšanje kompetencija djelatnika u školama kao osnovnog preduvjeta za uspješnost sustava. To je dobrim dijelom omogućeno čvrstom profesionalizacijom ministarstava obrazovanja koja su suštinski zaštićena od političkih utjecaja.

Linda Darling-Hammond, nadalje, ustanovljuje da se u sve tri države gore opisane mjere provode sustavno bez trošenja snaga na potporu improviziranim novacijama koje se mijenjaju svake godine.

Cjelokupni hrvatski obrazovni sustav trebao bi se zasnivati na sličnim postavkama. No, za ovakve je promjene potrebna korjenita promjena obrazovne politike koje se mijenjaju svaki pet godine.

Postavlja se pitanje kako ubrzati procese promjena u našem sustavu i kako u tom kontekstu u našim školama omogućiti provođenje bitno promijenjenog informatičkog kurikuluma. Danas je stanje vrlo šaroliko. Bolji i spretniji omogućiti provođenje bitno promijenjenog informatičkog kurikuluma koji su nezalaganje sustava koji nije u stanju osigurati znanja i provedbi kurikuluma. Učenici dobivaju zbrkanu nastavu nekorisnih rješenja.

Ovakve kontraproduktivne uvjete moglo bi se ublažiti. Provodi se promišljeno ulaganje u poboljšanje kompetencija djelatnika u školama kao osnovnog preduvjeta za uspješnost sustava. To je dobrim dijelom omogućeno čvrstom profesionalizacijom ministarstava obrazovanja koja su suštinski zaštićena od političkih utjecaja.

VII. ZAKLJUČAK

Okrugli stolovi održani na temu osuvremenjivanja nastave informatike u hrvatskom školstvu s naglaskom na računalno razmišljanje i programiranje u zadnje tri godine okupili su učitelje i nastavnike osnovnih i srednjih škola, predstavnike akademskih zajednica, gospodarstvenike i predstavnike prosvjetnih vlasti. Upozoreno je da u svjetskoj konkurenciji zemlja može biti uspešna samo ako obrazuje ljude koji kreativnošću i inovativnošću stvaraju nove proizvode, sustave i usluge. Posebnu važnost u tom obrazovnom procesu ima obrazovanje iz područja matematike, prirodoznanja i tehnike i, posebice, informatike.

Obrazovno područje informatike se pogrešno poistovjećuje s uporabom informacijske i komunikacijske tehnologije u obrazovnim i administrativnim processima te se zanemaruje složenost područja rješavanja problema i programiranja. Težište osuvremenjene nastave informatike stoga treba biti na razvijanju računalnog i algoritmskog načina razmišljanja te na rješavanju problema programiranjem.

Iako su u tijeku intenzivne aktivnosti u okviru cijelovite kurikularne reforme kojom su predviđene promjene i u načinu izvođenja predmeta Informatika, u ovom se radu izlagaju čelne područje preodvojila prijedlog provedbe osuvremenjene nastave informatike u okviru postojećeg nastavnog plana i programa koji će povećava opterećenje učenika niti remeti odnose s ostalim predmetima.. Međutim, kako je za izvođenje takva osuvremenjene nastave informatike potrebno pripremiti nastavne materijale i doškolovati učitelje i nastavnike, predlaže se usmjereno na rješavanje problema i programiranje.

Planirana dugoročna reforma

Važno je naglasiti da današnje stanje razvoja radnih okruženja omogućuje da se za sve razine obrazovanja (od predškolskog odgoja i obrazovanja pa do završnih razreda srednjih škola) praktična nastava može obaviti na razumnom skromnom opremi pri čemu čak i svaki učenik može takva okružena kriminale osnovne škole preoblikići u skladu s planiranim dugoročnom reformom.

Presume, vođenje nastave preodvojila

Prema tome, provođenje nastave preodvojila usmjereno na rješavanje problema i programiranje može se odmah provesti u svakoj školi koja ima samo skromnu opremu, izbor predmet Informatika i izvannastavne aktivnosti u srednjim školama) praktična nastava može obaviti na razumnom skromnom opremi pri čemu čak i svaki učenik može takva okružena kriminale imati i na svojoj vlastitoj opremi.

Važno je naglasiti da današnje stanje razvoja radnih okruženja omogućuje da se za sve razine obrazovanja (od predškolskog odgoja i obrazovanja pa do završnih razreda srednjih škola) praktična nastava može obaviti na razumnom skromnom opremi pri čemu čak i svaki učenik može takva okružena kriminale imati i na svojoj vlastitoj opremi.

I. UVOD

Danas, u eri brzog razvoja informacijske i komunikacijske tehnologije, javila se potreba za ubrzanim razvojem kompetencija svakog pojedinca za primjenu iste u različitim poslovnim okruženjima, koja uključuje razumijevanje načina rada računala i na višoj razini. Stoga se u obrazovanju veća pažnja posvećuje računalnom razmišljanju (eng. computational thinking, CT) i srodnim pojmovima (npr. programiranje, kodiranje, algoritamski razmišljanje) koja temelji se na razvoju računalnog razmišljanja koja se može razvijati i povezane koncepate s STEM kolektivom. razvoj kompetencija u drugim okruženjima neovisno od područja. Rezultati provedenog istraživanja mogu doprinijeti praktičarima i znanstvenicima u daljnjem radu u razmatranom području.

Pod pojmom računalno razmišljanje podrazumijeva se „sposobnost korištenja informatičkih koncepata za točno i jasno izlaganje i rješavanje problema“ [4].

García-Peñalvo [5] ističe da je računalno razmišljanje temeljiti kognitivni proces rješavanja problema i kako tako pretpostavlja osnovu za razvoj programerskih vještina, no isto tako riješenja kod pojedinca sposobnost rješavanja bilo kojeg problema u drugim okruženjima neovisno od područja informaticke.

Danas na tržištu postoji veliki broj programskih jezika koji se mogu upotrebljiti za učenje programiranja kod male djece (npr. Logo, Kodu, Scratch, Alice i Greenfoot i drugi) te veliki broj primjera edukativnih računalnih igara sa istom svrhom (npr. Code Combat, Lightbot i drugi).

Međutim, prema Shelton [6], razvoj računalnog razmišljanja kod djece u osnovnoj školi ne zahtjeva nužno korištenje računala te u svom radu razmatra primjenu “unplugged” metode poučavanja računalnog razmišljanja bez računala, pri čemu ističe da “unplugged” aktivnost nije alternativa za korištenje računala već se može primijeniti kao pomoćna aktivnost u razumijevanju i rješavanju zadanih problema.

Na osnovu dosadašnjeg teorijskog istraživanja, kao i iz rezultata nastavnih praksi, može se zaključiti da postoji potreba za razvojem inovativnih metoda iz područja tzv. „CT
pedagogije“ za djecu predškolskog i ranog školskog uzrasta. U nastavku rada, u drugom poglavlju, dan je kratak opis metode ranog učenja programiranja pomoću igračke Mema, pri čemu je zasebno opisana njena primjena za djecu ranog školskog i predškolskog uzrasta. Treće poglavlje donosi opis metodologije istraživanja stavova studenata – budućih odgajatelja i učitelja prema korištenju Meme u odgojne i obrazovne svrhe. U četvrtom poglavlju prikazani su i opisani rezultati provedenog istraživanja u ovome radu te je na kraju rada dan kratak zaključak rada.

I. METODA KOJA KORISTI IGRAČKU MEMA ZA RANO UČENJE PROGRAMIRANJA

Prije 40-tak godina Marina Ćićin-Šain je razvila metodu za rano učenje programiranja pomoću igračke Mema, koju je sama izmislila i izradila, kako bi zorno predočila glavnu memoriju elektroničkog računala [7].

Igračka Mema je izvorno građena od devet praznih kutija za slike slijepljenih u tri reda i tri stupca tako da tvore jedan redoslijed naredbi, ulaz, izlaz, …) - Da

Važan je redoslijed naredbi. - Da

Pretinaci, a u svaki pretinac stane ograničena vrijednost varijable. - Da

Adresa. Adresa postoji i u realnom životu. Da Da

Kapacitet memorije. Memorija računara je devet boja (slika 1.) [7]. Zadaci koji se mogu izvoditi pomoću igračke Meme za školsku djecu svode se na sljedeće [8]: simulaciju ulaznih operacija (npr. „unos podataka preko tipkovnice koji se čuva u memoriji računala i kojemu se pristupa preko simbolične adrese.“), kompatibilnost (npr. sva djeca moraju imati iste boje na pretinima ako rješavaju isti zadatak), adresiranje (postiže se bojom na pretincu Meme), binarni brojevi pomoću kojih se može kodirati slova, brojke, slike i drugo (sadržaj pretinca igračke Meme je uvijek broj).

A. Metoda Mema za djecu ranog školskog uzrasta

Budući da djeca u ranom školskom uzrastu već razlikuju boje, svaki pretinac igračke Meme može biti obojan u neku od boja (slika 1.) [7]. Zadaci koji se mogu izvoditi pomoću igračke Meme za školsku djecu svode se na sljedeće [8]: simulaciju ulaznih operacija (npr. „unos podataka preko tipkovnice koji se čuva u memoriji računala i kojemu se pristupa preko simbolične adrese.“), kompatibilnost (npr. sva djeca moraju imati iste boje na pretinima ako rješavaju isti zadatak), adresiranje (postiže se bojom na pretincu Meme), binarni brojevi pomoću kojih se može kodirati slova, brojke, slike i drugo (sadržaj pretinca igračke Meme je uvijek broj).

Slika 1. Igračka Mema za djecu ranog školskog uzrasta - svaki pretinac je obojan drugom bojom (po ideji izvorne autorice M.Ćićin-Šain)

U metodi koja koristi igračku Mema predviđeno je da nastavu izvodi učitelj ili učiteljica razredne nastave (vidjeti detaljne upute [9-11], [12]). Tijek rješavanja zadataka pomoću igračke Meme odnosno programi zapisuju se grafičkim pseudokodom (npr. program za zbrajanje dva broja je prikazan na slika 2.).

Slika 2. Program za zbrajanje dva grafičkih brojeva (po ideji M.Ćićin-Šain)

B. Metoda Mema za djecu predškolskog uzrasta

Danas vrlo mala djeca imaju mogućnost rada sa računalima te se smatra da se u tako ranoj dobi može započeti sa razvojem računalnog razmišljanja i programiranja na način prilagođen tako malom uzrastu djece [13]. Još prije 40-tak godina izvorna autorica Marina Ćićin-Šain je prilagođila spomenutu metodu za rad s predškolskom djecom na način da je za djecu koja ne poznaju boje dodala na pretince sličice raznih predmeta (sunce, kišobran, snjegovič druge) [8] (slika 3.).

Slika 3. Igračka Mema upotrijebljena sličicama predmeta (po ideji M.Ćićin-Šain)

Tijek rješavanja zadataka pomoću igračke Meme može se prikazati stripom [8]. Kao primjer na slici 4. prikazan je postupak kojim pomoću Meme djeca „mogu izračunati koliko u označeni pretinac treba staviti kuglica“ [8].

Slika 4. Program prikazan stripom (po ideji M.Ćićin-Šain)
II. METODOLOGIJA ISTRAŽIVANJA

U ovome radu cilj je bio ispitati stavove studenata – budućih odgajatelja i učiteljica prema uvođenju programiranja pomoću metode koja koristi igračku Mema za djecu u predškolskom i ranom školskom uzrastu.

A. Sudionici u istraživanju

Istraživanje je sudjelovalo 51 ispitanika studenata Učiteljskog fakulteta u Rijeci koji su svi bili ženskog spola te su imali između 18 i 24 godina. Sve sudionice u istraživanju su bile studentice preddiplomskog sveučilišnog obrazovanja (slika 5.) vrlo mali postotak njih, 23,3%. Usredotočavanje na studenatice iz obje skupine ispitanika nije procijenila svoje znanje vrlo dobrim i izvrsnim. Navedeni rezultati pokazuju da neki broj sudionica u ispitivanju programiranja te uvođenju programiranja pomoću igre Mema za djecu predškolskog i ranog školskog uzrasta. Nakon održanog predavanja uvođenja programiranja, sudionici su zamoljeni da popuni upitnik za dobrom razini, između 30 i 58,82% između njih je programiranih pomoću igre Mema za djecu predškolskog i ranog školskog uzrasta. Najveći broj sudionica je iz prvog dijela samoprocjenjene znanja iz programiranja i automatskog odgajatelja, a drugi po postotku sudionica je iz drugog dijela samoprocjenjene znanja iz programiranja, između njih je samo 8% između sudionica, a drugi je samo 2% između sudionica ne raspolaže sa znanjem iz područja programiranja pomoću igre Mema za djecu predškolskog i ranog školskog uzrasta. U istraživanju je sudjelovalo 51 ispitanika studenata Učiteljskog fakulteta u Rijeci koji su svi bili ženskog spola te su imali između 18 i 24 godina. Sve sudionice u istraživanju su bile studentice preddiplomskog sveučilišnog obrazovanja (slika 5.) vrlo mali postotak njih, 23,3%.

B. Procedura i korišteni instrumenti u istraživanju

Istraživanje je provedeno u siječnju 2017. godine na Učiteljskom fakultetu u Rijeci nakon održanog predavanja autorica ovog rada. Tijekom predavanja ispitanci su upoznati s opcijom pojma računala i programiranja, te postupkom uvođenja programiranja pomoću metode koja koristi igračku Mema za djecu predškolskog i ranog školskog uzrasta. Nakon održanog predavanja ispitanci su zamoljeni da popune anketni upitnik u papirnom obliku koji je bio anoniman i zasnovan na dobrom razini. Na posebno danom praznom papiru su ga prema osobnoj želji mogli i potpisati. U istraživanju su se koristila dva anketna upitnika od kojih se jedan koristio za prikupljanje podataka od studenata – budućih odgajatelja, a drugi za prikupljanje podataka od studenata – budućih učitelja koje su se razlikovale samo u dijelu 8. pitanja vezanih uz obrazovno okruženje u kojem se metoda može primjenjivati (vrtić ili osnovna škola). Oba upitnika su sastavljena od dva dijela. Prvi dio upitnika je sadržavao 5 pitanja vezanih uz opća demografska pitanja, zatim uz odnos broja pohijanja školskih sati nastave informatike i od toga sati učenja programiranja u osnovnoj i srednjoj školi te mišljenja sudionika – budućih odgajatelja i učitelja o uzrastu djeteta za koji je Mema najviše primjerena. Drugi dio upitnika je sadržavao 8 pitanja vezanih uz znanje iz programiranja, uvođenje programiranja pomoću igre Mema za djecu predškolskog i ranog školskog uzrasta. Odgovore su studenti mogli dati na Likertovoj ljestvici od 1=potpuno netočno do 5=potpuno točno.

III. REZULTATI ISTRAŽIVANJA

A. Samoprocjena znanja studenata iz programiranja

Sudionici su svoje znanje iz programiranja ocijenili u prosjeku slabom ocjenom (sudionici – budući učitelji: M=4,00; σ=0,69; sudionici – budući odgajatelji: M=4,19; σ=0,81) na skali od 1=izvrsno do 5=vrlo slabo. Među sudionicama (slika 5.) vrlo malo postotak njih, 23,3% sudionica – budućih učiteljica; 23,8% sudionica– budućih odgajateljica, iskazao da ima dobro znanje iz programiranja dok ni jedna ispitanica iz obje skupine ispitanika nije procijenila svoje znanje vrlo dobrim i izvrsnim. Navedeni rezultati pokazuju da najveći broj sudionica u ispitivanju programiranja te uvođenju programiranja pomoću igre Mema za djecu predškolskog i ranog školskog uzrasta, to potvrđuju rezultati u nastavu ovoga rada.

B. Pohiđanje nastave informatike te od toga slučajno sati programiranja u nižim razredima osnovnoškolskog obrazovanja

Najveći broj sudionica iskazao je da u nižim razredima OŠ nisu slušali niti jedan sat informatike te da je najveći postotak, njih 29,4%, pohiđao nastavu informatike u 4. razredu OŠ (slika 6.).
Slika 7. Postotak sudionika (N=51) raspoređen prema tome koliko su od broja šk. sati nastave informatike slušali sati programiranja u nižim razredima OŠ

C. Pohađanje nastave informatike te od toga slušanje sati programiranja u višim razredima osnovnoškolskog obrazovanja

Velika većina sudionika pohadala je 2 školska sata tjedno nastavu informatike u svim višim razredima osnovne škole (slika 8.). S druge strane, 23,5% sudionika je izjavilo da nisu slušali niti jedan sat informatike u višim razredima OŠ, što ukazuje na činjenicu da je informatika na različite načine zastupljena u različitim obrazovnim okruženjima, kao izborni i/ili redovni predmet.

Vrijedi istaknuti da je najveći postotak sudionika, njih 27,5%, slušalo 1 sat programiranja od ukupno 2. šk. sata tjedno informatike u 7. i 8. razredu.

D. Pohađanje nastave informatike te od toga slušanje sati programiranja u razredima srednješkolskog obrazovanja

Uzorak ispitanika (slika 10.) čini više od polovice budućih odgajatelja i učitelja koji u 3. razredu SŠ (njih 58,8%) i 4. razredu SŠ (njih 64,7%) nisu pohađali nastavni predmet Informatiku. Najveći postotak (83,6%) ispitanika je slušao informatičke nastavne predmete u 1. razredu SŠ, a najveći postotak (87,5%) na programiranju u razredima SŠ je slušao 1 sat programiranja od ukupno 2. šk. sata tjedno informatike.
E. Stavovi studenata - budućih odgajatelja prema ranom učenju programiranja pomoću metode Mema za djecu predškolskog uzrasta

Odgovore na tvrdnje odabrane za ovo istraživanje sudionici-budući učitelji (N=30) su mogli dati na Likertovoj skali od 1 do 5 na sljedeći način: 1=potpuno netočno, 2=uglavnom netočno, 3=niti netočno, ni točno; 4=uglavnom točno; 5=potpuno točno. Prema dobivenim aritmetičkim sredinama (tablica II.) vidljivo je kako studenti-budući učitelji uglavnom smatraju da je programirati teško (M=4,0). Zatim sudionici-budući učitelji u prosjeku uglavnom smatraju da je igračka Mema korisna kao pomoć u svladavanju brojeva (M=4,0) i motorike (M=4,0) te uglavnom smatraju da je igračka Mema korisna kao pomoć u savladavanju boja (M=4,0). Prema dobivenim aritmetičkim sredinama (tablica III.) vidljivo je kako sudionici u prosjeku (M=3,9) smatraju dugotrajnim svladavanje znanja o osnovnim algoritmima i naučila/naučio više. 0,0 0,0 19,0 47,6 33,3

F. Stavovi studenata - budućih odgajatelja prema ranom učenju programiranja pomoću metode Mema za djecu predškolskog uzrasta

U tablici III. dan je usporedni prikaz postotaka odgovora sudionica – budućih odgajatelja (N=21) na Likertovoj skali od 1 do 5 (kao i kod sudionica-budućih učitelja). Prema dobivenim aritmetičkim sredinama vidljivo je kako sudionici-budući odgajatelji uglavnom smatraju da je programirati teško (M=4,1). Zatim sudionici-budući odgajatelji u prosjeku uglavnom smatraju točnom svladavanju da je igračka Mema korisna kao pomoć u savladavanju brojeva (M=4,3) i motorike (M=4,3) te za učenje algoritama (M=4,1). Zatim sa tvrdnjom da je Mema korisna u svladavanju motorike slaže se 66,7% sudionika-budućih odgajatelja. Zanimljivo je da 38% sudionika-budućih odgajatelja smatra da nije lako naučiti koristiti igračku Memu te je njih 33,3% bilo neodlučno pri iskazu na ovu tvrdnju. Želju za budućom edukacijom o korištenju Meme iskazalo je 37% sudionika-budućih odgajatelja, dok se njih 33,3% bilo neodlučno.

G. Stavovi sudionika prema primjerenosti uzrasta djece za uvođenje računalnog razmišljanja i programiranja pomoću metode koja koristi igračku Mema

Studenti – buđući odgajatelji (RPOO; N=30) i učitelji (US; N=21)) (slika 12.) mogli su na danoj skali procijeniti dob djece za koju je primjereno koristiti igračku Memu pri uvođenju računalnog razmišljanja i programiranja. Najveći udio ispitanika, njih 40%, smatra da je Mema najprimjerenija za djecu 5 godina starosti. Nadalje, kod skupine sudionika-budućih odgajatelja najviše ispitanika, njih 38,10%, smatra da je metoda najprimjerenija za djecu 6 godina starosti.

Slika 12. Postotak sudionika s obzirom na uvjerenje o primjerenom uzrastu djece za uvođenje programiranja pomoću Mema

IV. ZAKLJUČAK

Jedna od osnovnih kompetencija svakog pojedinca na tržištu rada postaje sposobnost računalnog razmišljanja, stoga navedeno postaje sastavni dio kurikuluma Informatike u okviru kojeg je predviđeno da se računalno promišljanje i programiranje započne razvijati već kod djece predškolskog i ranog školskog uzrasta. Računalno razmišljanje se može razvijati kroz informatičke i neinformatičke predmete za što su potrebne odgovarajuće metode poučavanja sa i/ili bez računala. Danas na tržištu postoji mnogo različitih metoda pomoću kojih mala djeca mogu naučiti osnovne koncepte programiranja (npr. programskih jezika, edukativnih računalnih igrica i sl.). U ovome radu dan je opis metode poučavanja programiranja pomoću igračke Meme čija je posebnost u tome što se njenom primjenom na jednostavan i zabavan način malo djeca može poučiti kaj ona je potrebna za uvođenje računalo razmišljanja i programiranja kod malih djece. Rezultati istraživanja ovom radu su pokazali da su sudionici-budući učitelji i odgajatelji iskazali slabo znanje iz programiranja te je velika većina njih izjavila da je programirati teško. Vrlo mali broj sudionika je slušao informatičke predmete u nižim razredima OŠ, zatim samo nešto više njih je pohadalo informatičke predmete u višim razredima OŠ, dok je u SŠ najviše njih pohadalo informatičke nastavne predmete jednu do dvije šk.god. Navedeni rezultati upućuju na nedovoljnu informatičku edukaciju prije upisa na studij. Nadalje, rezultati istraživanja stavova studenta prema upotrebi metode koja koristi igračku Memu pri uvođenju programiranja kod djece predškolskog i ranog školskog uzrasta pokazali su da velika većina sudionika smatra da spomenuta metoda omogućuje kod male djece usvajanje i razvoj informatičkih i općih sadržaja, zatim smatraju da je metoda zanimljiva, no ne i laka za naučiti koristiti. Najveći broj sudionika smatra da je metoda najprimjerenija uzrastu djece u rasponu od 5 do 8 godina (što je u skladu s ciljanom skupinom djece u izvornoj metodi Mema), a većina njih je izrazila želju za nastavkom edukacije o korištenju Mene. Ovo istraživanje ima i neka ograničenja koja se ogledaju u malom broju ispitanika. Rezultati ovoga rada mogu poslužiti svima koji žele uvoditi računalno razmišljanje i programiranje kod djece malog uzrasta.

Abstract – The challenge of the new globalized market and the current steel market outlook characterized by plant underutilization, are the elements leading metal producers to seek for low Capex investments, aiming at improving the efficiency of the production facilities, the quality of the products, the health and safety of the workers as well as the environmental sustainability. In this scenario, DANIELI has created a new cross-functional business unit named DIGI&MET whose mission consists of developing and implementing new plant design concepts, based on digital innovation, and also new business models, based on servitization and outcome economy principles. DANIELI summarizes in this article its approach for both brown and green field plants.

I. INTRODUCTION

The global economy is adjusting to a slower level of Chinese growth – what is called the “new normal”. Between 2000 and 2014, global steel production doubled from approximately 800 million ton to 1.6 billion ton mainly driven by rising production capacity in China. During the same period, demand in China rose of approximately the same rate. Once the “construction” growth of China slowed down, the exceeding capacity was put on the foreign market causing a dumping of steel prices. As a result, the overall production faces a -3% in 2015 followed by a very limited growth in the following years. The steel market is then expected to enter in an inflection point with limited growth in the next years [1] [2].

There are other important trends, which are influencing the steel market: the research for newer materials with improved mechanical characteristics (high-strength steels), the greenhouse gas emissions reduction, the circular economy and the requirement for a safer working environment.

Metal producers have then to seek for low Capex investments, aiming at improving the efficiency of the production facilities, the quality of the products, the health and safety of the workers as well as the environmental sustainability.

During last decade, we have seen an incredible development and diffusion of ICT technologies: the availability and speed of mobile internet connections is increased. The possibilities of billions of people connected by mobile devices, with unprecedented calculation power is then boost by emerging technology such as artificial intelligence, robotics, autonomous vehicles and quantum computing. These changes are not only affecting our way of living but will affect the way we work and are the milestones of a new industrial revolution the fourth one where the new technologies are blurring the line between the physical and digital spheres.

In this scenario, DANIELI has created a new cross-functional business unit named DIGI&MET to provide customer digital innovation under new business models.

II. VISION, MISSION, OBJECTIVES & STRATEGY

The DIGI&MET vision can be summarized by the statement “From a Plant to a Smart Plant”. The Smart Plant is a safe, flexible, efficient and environmentally friendly concept of manufacturing founded on the extensive digitalization of processes, the deep integration of cyber and physical worlds and the strong interconnection of intelligent systems and humans. In a Smart Plant, systems and equipment autonomously execute complex tasks and support humans in complex decision-making or even provide decision-automation. The below figure 1 shows the DIGI&MET vision but also its mission, which represents the path to follow in order to achieve the objectives.

![Figure 1. DIGI&MET Vision & Mission](image)

The mission consists of:

- Increase data collection getting data also directly from the field (e.g. installing by default required sensors and instrumentation on the equipment), creating and using for this purpose a common and certified analytics platform.
- Aggregate and integrate data, transforming it into information.
- Analyze information in order to transform it into knowledge.

Part of DIGI&MET mission is also to get closer to customers, establishing a relationship based on trust,
loyalty and confidence, in order to be selected as partners in their business evolution path from the “running the business” to the “improving the business” approach. This process, which requires building a culture around filling customer needs and then engaging them every step of the way, will also transform DANIELI from a product supplier to a service/solution partner.

In light of the above, the DIGI&MET short-term objectives consist of implementing a customer-centric model that allows its customers to:

- Increase the overall plant efficiency in terms of higher productivity, higher yield, reduced lead times, increased plant availability and optimized usage of resources.
- Deliver quality products to its customers in order to establish stable and effective relationships, creating the so-called customer intimacy.
- Improve the workers’ health and safety by adopting solutions aiming at avoiding accidents or reducing their effects.
- Monitor and control the plant energy and utility consumption as well as to implement efficient recovery strategies, which is currently one of the most important objectives of the metals industry and represents a first step ahead towards the so-called “Green Metals” challenging target.

Which is the DIGI&MET strategy to accomplish its objectives? The strategy consists of applying the most innovative technologies in the field of Information & Communications Technology, Process Automation and Sensors in order to implement the following levels of integration [3]:

- Vertical Integration: The hierarchical automation pyramid and its organizational and technical barriers are going to be replaced by a flat structure of intelligent, flexible and autonomous units; these units are the so-called cyber-physical systems that, through their control, computational and communication capabilities, implement the decentralized intelligence concept.
- Horizontal Integration: Product traceability and real-time quality assessment require a strong supply-chain integration, including all the internal processes that are part of the production chain as well as the external ones involving raw material suppliers and customers.
- Transversal Integration: Taking into consideration economical, technical and environmental aspects at the same time is mandatory in order to get the best decision-making support.

### III. APPROACH

The process of pursuing the Smart Plant target, starting from plant digitalization, is justified by the large benefits expected in terms of overall plant efficiency, product quality, workers’ health and safety and environmental sustainability. In order to drive its customers in this business evolution path DIGI&MET has designed and developed a specific and effective approach. It consists of a first phase aiming at the delivery of a digital-enabled plant and then a second phase focusing on its transformation process towards the Smart Plant target.

The DIGI&MET approach is summarized in the following figure:

![Figure 2. DIGI&MET Approach](image)

A key step of this approach is represented by the Digital Maturity Assessment, which consists of understanding if a given plant is enabled for digitalization, eventually performing the gap analysis, assessing its current digitalization degree and addressing digitalization efforts and investments considering their impact on the above-mentioned major objectives. In fact, today every function can be supported by digital systems, however a huge amount of economic resources should be invested to explore the overall spectrum of possibilities or, looking from another perspective, the risk to invest in directions with lower return could be even very high; this analysis definitely aims to support the business in selecting the best opportunities.

The assessment is performed through the following tasks:

- Estimation of a Basic Digital Index, which indicates whether a plant is enabled for digitalization and it is based on the sum of contributions of a given set of enabling technologies grouped into the following categories:
  - Connectivity & Data Sharing: It represents the capability of collecting, storing and sharing data for its further transformation into information; this capability is measured considering the presence of sensors, instrumentation, data repositories and network infrastructure.
  - Data Processing: It represents the capability of manipulating data in order to produce valuable information through validation, aggregation and analysis steps.
  - Human in the Loop: Human-in-the-Loop (HTIL) is the concept based on systems and models that require human interaction inside the computation chain for accomplishing tasks. This concept includes applications where humans and machines cooperate for accomplishing tasks having the following characteristics: complexity, high cost to implement a fully automatic...
execution, need of human wisdom to speed up decision-making process.

- Modelling: It considers the availability of process control and optimization models, either of deterministic or statistic nature, and technological packages.
- Autonomous & Robotic Systems: Autonomous and robotic systems are foreseen to replace humans in highly repetitive and dangerous jobs, especially the ones performed in very harsh environments like steelmaking plants, in order to increase both efficiency and safety.

- Estimation of a Global Digital Index considering the implementation of a given set of smart plant enabling solutions (later on described in this article) as well as the contribution of an extended Manufacturing Execution System (or a subset of its modules).

The approach applies to both brown and green field plants with some obvious differences that are described here below.

A. Brown-Field Plant Approach

In this scenario, it is very important during the assessment phase to understand if the customer is already able to measure the performances of its business process or not. In the latter case, such monitoring solution can be designed and implemented, with the minimum impact for the plant operations, starting from the customer requirements and the DANIELI know-how and expertise in the metals industry, which has led to the creation of a large KPI library that covers supply-chain, technological and maintenance business processes.

B. Green-Field Plant Approach

The design of a green-field smart plant starts from the layout, which should at least take into consideration possible automated logistic, robotic and material identification solutions, and then from plant engineering, which means smart sensors, instrumentation, equipment-embedded condition monitoring and control modules as well as all the required infrastructures for data collecting and sharing.

IV. KEY-ENABLING FACTORS

The key-enabling factors that DIGI&MET applies to its innovative solutions are represented in figure 4 and include the following elements that are briefly described in the next paragraphs:

- Data-driven Approach, which represents the core of the digitalization process and the most disruptive innovation among the ones introduced by the Fourth Industrial Revolution.
- Digitalization Enabling Technologies, which represent the foundations of a digital-enabled plant.
- Smart-Plant Enabling Solutions.

A. Data-Driven Approach

It represents the most innovative and disruptive element among the ones introduced by the Fourth Industrial Revolution and aims at applying innovative digital technologies such as machine learning and artificial intelligence to extract knowledge from data for supply chain and technological process optimization.

In the metals industry this approach is not supposed to supersede the deterministic one but to integrate it, thanks to its capabilities of estimating process variables that are not observable, identifying process variables correlations and providing accurate results where process is too complex or chaotic.

An excerpt of DIGI&MET business cases based on data-driven approach is the following:

- Quality Compliance Prediction: It consists of predicting the mechanical properties of the final product starting from the process conditions. This can be done both online, for the certification of the product, but also offline, to study the effects of the changes of the process conditions. The goal is to reduce the costly laboratory tests (whenever the standards allow it) and reduce the occurrence of non-prime quality thanks to fast prediction time.

- EAF Process Fingerprint: A robust strategy for EAF automatic process control based on the fingerprint concept. It allows an adaptive control of the chemical package for a smart management of the oxygen injection, considering both the slow process modifications over time and the feedback from the field in real time.

B. Digitalization Enabling Technologies

This category includes the following disciplines:
Robotics & Cobotics

Robotic solutions can be employed to replace humans in several shopfloor tasks, which are executed in a hot, noisy and polluted environment, are regularly heavy and demanding on the body and often subjected to process-related hazards. At the same time robot-based automated solutions can also replace workers in executing regular and repetitive tasks, which, especially on long-term and when the work environment is not friendly, may become soul-destroying and even produce psychophysiological effects. The design of these solutions, aiming at improving both plant efficiency and safety, takes of course into consideration the safety constraint represented by the fact that, in some cases, operators and robots share the same spaces.

Some examples from the DIGI&MET robotic solutions portfolio [5] are the following:

- Q-Robot Sample: Robotic solution designed for automatic sampling of temperature and chemical composition of a steel bath in both Electric Arc Furnace and Ladle Furnace applications.
- Q-Robot Zinc: Robotic solution designed to skim, using a special tool, the surface of the zinc bath to remove dross, and place it in a dross container.
- Q-Robot Antimix: Robotic solution designed for automatic anti-mixing, color-marking and labelling of special steel bars.

The long-term challenging target of this approach, together with the automated logistic solutions that are described later on in this article, can be summarized by the sentence “No man on the shopfloor” which aims to a fully automatic plant with all the personnel sitting in control rooms and performing only supervision and control.

Advanced Human-Machine Interface

Pursuing efficiency and product quality often implies increasing complexity and increasing use of complex machines, processes or systems, which leads to an increase in operators’ mental workload. In this scenario, the human-machine interaction is of particular relevance in order to create a comfortable and safe work environment combined with ergonomic and friendly user interfaces.

In these regards, the DIGI&MET 3Q Digital Pulpit represents a revolutionary solution. One of the key points of the digital pulpit concept is the provision of a full “soft-desk”, totally based on computer screens, through which the operator can both monitor the plant and operate it; in most cases, there is no hard-wired indication facility, with the exception sometimes of an emergency shutdown system. Simply by substituting the software of its automation system, this revolutionary pulpit is then able to drive processes like Electric Arc Furnace, Continuous Caster or Rolling Mill.

The most important components of this desk are:

- The Operator Assistant (OA), a tool that offers a new approach to the control of the process, by reducing the number of commands that the operator previously had to operate with and by minimizing his intervention to a limited number of situations. There are three control modes to drive the plant: Auto Pilot, Assisted Manual and Maintenance Mode. Ergonomic and Cognitive Engineering are the key elements in the development of this system.
- The Area Performance Indicator (API), which provides a detailed view of a specific process, highlighting the main set points, the relevant KPIs (e.g. Production Rate[%], Production Yield [%] or Time Utilization [%]), the most significant trends and, where possible, the estimated time to end.
- The Plant Performance Indicator (PPI), an advanced monitoring system that allows the production manager to obtain an overall vision of the given process area and of the upstream/downstream ones. The goal of this function is to provide a graphic overview across most areas of the plant areas in order to simplify the synchronization of the production flow.

In this field, an important role is also played by the mobile technologies, which provide several advantages such as real-time access to all information independently from location and simplicity in collecting and sharing information. These technologies have been extensively applied by DANIELI over the last years for different purposes such as:

- Q3-Mobile Intelligence: Mobile access to reporting and analytics platform.
- Q3-Mobile Shopfloor: Equipment local control (smart local control boxes).
- Q3-Mobile Recognizer: Equipment information retrieval in combination with maintenance management system.
- Q3-Mobile Safety: Passive safety support through operators’ localization.

Today the new challenge consists of applying to the metals industry the latest innovative technologies.
like augmented reality, taking into consideration the most critical safety-related constraints which are the following:

- The selected devices must be either certified as personal protective equipment or compatible with the personal protective equipment in use in the plant.
- The operating procedures in terms of safety must be defined considering the usage of such devices in a dangerous environment (e.g. moving equipment, extreme environmental conditions).

- Simulation
  
  DANIELI entered this field of technology already some years ago with the development and the successful implementation of innovative solutions such as:
  
  - Kinematic Simulator (iStand), for personnel training as well as for virtual commissioning purposes.
  - Plant Logistic Simulator, having the purpose of simulating plant operations in order to verify overall productivity, machine workload, transportation equipment utilization and sizing, storage yard sizing, potential bottlenecks and to perform relevant “what-if” analysis by changing machine/equipment characteristics and/or plant layout. Moreover, this solution is also applied for the simulation and validation of the production schedules generated by MES Production Scheduling module.
  
  The new challenge in this field is to fully connect such virtual systems to the physical ones allowing the real plant and its digital twin to run and be maintained in parallel for off line multi-objective optimization strategy design, deployment and fast tuning. In these regards, DIGI&MET has already made a step ahead developing a process simulator called Q-Live, a tool that adopts real-time prediction technologies for simulating material, mechanics and their interactions.

- Smart Sensors & Instrumentation
  
  The plant digitalization process starts from a wide deployment of intelligent sensors giving access to data that was not accessible or monitored before; such sensors should not be considered only as suppliers of information but as intelligent units capable of direct evaluation and processing of measured values. This approach allows to significantly improve the efficiency, availability and utilization of the plants as well as to leverage high rationalization opportunities through the integration of new systems.
  
  In light of the above, the new DIGI&MET plant design concept includes the following:
  
  - Install instrumentation on the equipment by default.
  - Install smart sensors on the equipment.

- Embed in the equipment a smart and flexible automation module in order to perform critical real-time control tasks as well as condition monitoring.

  Continuous research, in electromagnetic fields, infrared detection, lasers and x-rays, are the key factors in the development of new sensors and new instrumentation for the metals industry.

- Identification & Localization
  
  The adoption of these technologies can provide a great contribution supporting automatic identification and localization of materials, assets and workers; therefore improving plant efficiency, product quality but also enhancing workers safety. Even if the work environment and the extreme operating conditions of the involved items often represent a restraint to their application in the metals industry, DANIELI has developed several solutions based on optical, radio frequency and barcode/QR code technologies.

C. Smart-Plant Enabling Solutions

The implemented solutions are the following:

- Manufacturing Execution & Optimization
  
  An extended Manufacturing Execution System is a solution in charge of supporting, at plant-level, manufacturing coordination, execution and optimization; it includes the functionalities of a MES system plus some features which are which are normally provided by ERP or APS systems, with the purpose of supporting the entire customer order lifecycle from its acquisition up to material dispatch, through planning and execution steps. For this reason, its contribution to plant digitalization is unique for an integrated plant.

- Predictive Maintenance
  
  The digitalization of plant maintenance processes is important in order to cut the relevant operating costs, which are normally very high. It is well known that large benefits in these regards can be gained with the implementation of predictive maintenance solutions that could be quite costly, despite its benefits.

  Taking as a reference a given number of steel plants, it has been estimated that almost the 70% of maintenance activities (and therefore costs) is normally carried out on the 20% of the plant equipment. Moreover, the experience suggests also to take into consideration the following basic assumptions:

  - Not all the equipment in a plant is of equal importance to either operations or safety.
  - Equipment design and operation differs and different equipment will have a higher probability to undergo failures from different degradation mechanisms than others.
  - A plant does not have unlimited financial and personnel resources.
In light of the above, the maintenance strategy pursued by DIGI&MET is the so-called “Reliability-Centered Maintenance” which represents a systematic approach to evaluate a facility’s equipment and resources to best mate the two and result in a high degree of facility reliability and cost-effectiveness. In a few words, this strategy suggests to perform a deep analysis of plant equipment in order to:

- Identify the most critical ones (for either operations or safety) and implement preventive maintenance only for such subset of plant equipment.
- Implement preventive maintenance for most of the remaining equipment by developing relevant job guidelines with life counter-based frequency (when possible) or time-based frequency.
- Perform reactive maintenance for all the equipment that is not mission-critical.

This maintenance strategy includes also the implementation of combined Condition and Process Monitoring using a common analysis platform; it allows, when it is not possible to monitor equipment health directly, to infer a possible equipment malfunctioning from the relevant process data (e.g. a roll wear early deterioration can be inferred from a material surface quality defect).

- Energy Monitoring & Control

The capability to monitor and control the plant energy and utility consumption as well as to implement efficient recovery strategies is currently one of the most important objectives of the metals industry and represents a first step ahead towards the so-called “Green Metals” challenging target. Energy and utility consumption and recovery are not only important for what concerns the environmental aspect but also represent an important factor for the overall steel manufacturing costs, considering that actual energy market is highly variable due to local and geopolitical factors.

In these regards, DIGI&MET has addressed its efforts to the implementation of an integrated Energy Management System, which allows energy control and optimization, intelligent access to power market on the basis of reliable forecast of energy demand associated with manufacturing planning and scheduling. In Europe, where the current trend is to focus on the increment of renewable sources, the most power-demanding operations are planned preferably during lower global power demand time windows such as during night shifts or weekends. This can be a regional opportunity to offer balancing services to the network in moments characterized by high level of power offered to the short-term free market, in particular for the electrical steelmaking but also for oxygen one. These opportunities ask for reliable power demand forecast and intelligent and flexible scheduling systems.

- Smart Logistics

The DIGI&MET strategy is also focused on automated logistic solutions, especially automatic yards with relevant automation and control systems that improve the plant overall efficiency through the following functionalities:

- Material Tracking & Inventory
- Yard Optimization
- Crane Movement Optimization
- Automatic Material Classification (for raw materials)
- Vehicle Identification & Tracking

Logistic operations in the metals industry are also critical in terms of safety due to the presence of heavy material items, vehicles and overhead cranes, which expose workers to several risks such as falls, being hit by falling objects and crushing injuries. Moreover, logistics often involve third-party personnel, which is not fully aware of plant specific risks and safety procedures. In these regards, automatic yard solutions can significantly improve safety conditions thanks to:

- Remote control rooms where the crane operator can comfortably and safely supervise the operations through cameras (eyes-on technology).
- Automatic execution of vehicle loading and unloading operations.
- Yard fencing and relevant automated entrance procedures designed to avoid personnel to enter the yard when cranes are in operation.

This approach applies for raw material, semi-finished and finished product handling.

- Product & Asset Traceability

Significant improvements have been achieved over recent years in terms of both product and asset tracking, thanks to a strong integration between automation and process control systems. The point of weakness of such solutions is represented by the manual identifications that are foreseen in the relevant processes and represent a source of possible mistakes.

Today the adoption of the above-mentioned innovative identification and localization technologies allows, even in harsh environments, to overcome these problems and provide product and asset visibility along the entire production chain.

This approach applies for raw materials, semi-finished and finished products as well as operational equipment with a common goal, which consists of having the right item in the right place at the right time.
V. CONCLUSION

The metals industry has historically been very conservative and generally skeptical and reluctant to embrace possible technology innovations. In this case, the large benefits of digitalization have been quickly understood but, at the same time, also some restraints have been already identified.

In these regards, a survey [4] involving more than 150 metals companies has been conducted and has produced some interesting key findings:

- Metals companies plan to invest 4% of annual revenue in digital operations solutions over the next five years. Nearly two-thirds (62%) expect to reach an advanced level of digitalization and integration within the next five years.

- The expected benefits of digitalization over the next five years are increased revenues (2.7% per annum) and cost savings (3.2% per annum).

- The two top challenges identified by metals companies are the unclear economic benefits of digital investments (49%) and the lack of a digital culture (49%). The third biggest challenge is the absence of a clear digital operations vision and leadership from top management (39%).

- Today only 11% of metals companies have advanced data analytics capabilities.

- The pace at which metals companies expect to accrue benefits from digitalization investments leads a majority (58%) to estimate a return on investment timescale of two years or less. Just over a third (37%) of companies anticipate a longer timescale of two to five years but relatively few (5%) think that it will take any longer than five years.

The above results are valuable and clearly have to be taken into consideration while approaching customers on digitalization topics.

ACKNOWLEDGMENT

Thanks to all DIGI&MET team members for the professionalism, commitment and enthusiasm that they constantly put into this challenging path.

PAPERS
IoT Gateway for Smart Metering in Electrical Power Systems - Software Architecture

M. P. Shopov
Technical University of Sofia / Department of Computer systems and Technologies, Plovdiv, Bulgaria
mshopov@tu-plovdiv.bg

Abstract - The paper presents an implementation of IoT gateway for smart metering in electrical power systems. The gateway is based on Ubuntu Core operating system and connects power meters with external cloud services. Several software architecture design patterns are evaluated. Adaptation of them for the design of the software architecture of the gateway application is described in the paper. Based on the proposed software architecture an example IoT gateway implementation is suggested.

I. INTRODUCTION

With the development of sensor networks, wireless mobile communication, embedded system and cloud computing, the technologies of Internet of Things (IoT) have been widely used in areas such as smart meters, public security, smart homes and so on [1]. There are three essential components of IoT [2]: embedded devices consisting of both low cost/low power devices and high-end gateways; scalable connectivity – each embedded device should be connected; cloud-based mass device management – centralized management of distributed devices.

The support of legacy devices and devices without proper communication capabilities, will require the use of IoT gateways. These gateways could also be used for some local intelligence and value-added services [2]. Smart metering is an example of IoT application. It integrates communication capabilities with electrical power systems and delivery infrastructure to automate monitoring and control. Dynamically linking utility supply with demand could result in optimization of resource consumption [2].

The paper presents a software architecture and its implementation on an IoT gateway for smart metering in electrical power systems based on the scenario presented in [3].

II. BACKGROUND AND RELATED WORK

The Internet of Things brings new challenges for software developers. One major aspect in connecting things is that there is little value by providing just the connection. The benefit from being connected always goes hand in hand with the provision of a specific service, which is generating the benefit from the connection [4].

IoT gateway for smart metering applications has many responsibilities: communication with smart meters; communication with cloud-based services; locally processing data; caching data and synchronization; configuring devices and sensors; providing user interface. All these requirements and their dependencies bring additional complexity to the implementation of IoT gateway system and appropriate software architecture is very important.

There have been various proposals for IoT gateway architecture in the research literature. In [5] the authors propose an architecture of IoT gateway consisting of a south interface for connecting to sensors and a north interface for connection to client applications. The integration of sensors is done through M2M proxies. Architecture of a semantic gateway as service (SGS) is presented in [6]. The authors suggest the use of multi-protocol proxy as a central part of the architecture, mediating between other functional blocks. The integration with higher-level services is achieved through gateway interface.

In a closely related research, the authors of [7] suggest an architecture for open smart metering. The proposed architecture deals with the heterogeneity of smart metering equipment by the use of advanced metering infrastructure (AMI) and a central meter data management (MDM) system. The authors also suggest an UML data model that defines the objects and their attributes, exchanged between the components of the system. Although all these architectures define the functional blocks of IoT gateway and their interfaces with external systems, they do not present insights into the architecture of the application software that will run on the gateway device and implements these functional blocks.

The software architecture of a program or computing system is a depiction of the system that aids in the understanding of how the system will behave. It serves as a blueprint for both the system and the project developing it. The architecture is the primary carrier of system qualities such as performance, modifiability, and security. It is an artifact for analysis to make sure that a design approach will yield an acceptable system. By building effective architecture, one can identify design risks and mitigate them early in the development process [8].

Supported by the National Science Fund of Bulgaria – contract E02/12.
Design patterns provide approved generic solution for recurring architecture design problems, created to achieve quality-attribute goals and requirements [8-12]. Following, an overview and discussion on some of the design patterns evaluated as candidates for IoT gateway is given.

A. Model-View-Controller

Model-view-controller (MVC) design pattern [13] divides the software application into three interconnected components to separate internal representations of information from the presentation to and interaction with the user (Fig. 1). The model component is responsible for the application data, the view component is responsible for presentation of model data to the user, and the controller component is responsible for updating view, handle user interactions and updating the model.

![Figure 1: Model-View-Controller](image1)

In MVC design pattern the three components are tightly coupled, which reduces their reusability and testability. Another shortcoming of MVC in the context of IoT gateway is that the controller component has to deal with too many responsibilities. This breaks the single responsibility principle and result in complex implementations [14, 15].

B. Model-View-Presenter

Model-View-Presenter (MVP) is a derivate of MVC first proposed in [16]. In MVP the view and model components are decoupled which increase their testability. The presenter retrieves data from the model and formats it for the view (Fig. 2).

![Figure 2: Model-View-Presenter](image2)

The presenter component is responsible for keeping the application synchronized [9, 11]. It improves testability of the model component in the price of doubling the amount of code compared to MVC [14].

C. Model-View-ViewModel

Model-View-ViewModel (MVVM) [17] is another derivate of MVC and MVP, where the controller/presenter component is replaced by view model. The view model is an abstraction of the view – independent representation of the View and its state – exposing public properties and commands [14]. The view and view model comprise the presentation logic of the application. The synchronization between them is mediated through software bindings (Fig. 3).

![Figure 3: Model-View-ViewModel](image3)

D. Clean Architecture

The clean architecture [18], as its author suggests is an attempt to integrate different architecture principles and practices into a single independent of technologies and frameworks idea (Fig. 4). Each circle represents a different areas of software. The outer circles are mechanisms and the inner circles are policies. The overriding rule beside this architecture model is the dependency rule - source code dependencies can only point inwards. Entities represent the business objects of the application. The use cases layer encapsulates and implements all of the use cases of the system. It orchestrates the flow of data to and from the entities. Next layer represents a set of adapters that convert data from the format most convenient for the use cases and entities - MVC, MVP, and MVVM belongs to that layer. The outermost layer is generally composed of frameworks and tools [18].

![Figure 4: Clean architecture [18]](image4)

E. Micro-services

A micro-service is a small application that can be independently deployed, scaled, and tested and with a single responsibility. The micro-service architecture is defined as developing an application as a set of small
independent services, where each of the services is running in its own independent process [19].

Three micro-services communication patterns are presented and discussed in [19]. By considering the asynchronous nature of IoT applications the authors suggest the use of service/message bus (Fig. 5). It is based on Publish/Subscribe model and allows addition of new components without changing the existing components of the system [19].

![Figure 5. Message bus [11]](image)

III. IoT GATEWAY SOFTWARE ARCHITECTURE

In a previous work [3] the author presents an example solution for smart metering in electrical power systems. The solution is based on a power meter, an IoT gateway, cloud services and client applications. This paper continues the work in the part constituting the applications running on IoT gateway.

By following the common functional requirements for smart metering systems (2012/148/EU Recommendation) the main features of the smart metering application can be identified – these are the use cases in the context of clean architecture:

- provide frequent readings of the consumption data from sensors;
- store consumption data locally for a reasonable time;
- provide local and remote standardized interface which provides visualized individual consumption data to the consumer, any third party designated by the consumer, and operators;
- provide a local reasoning capabilities based on on-line and past consumption data and other sensors readings and notify user to stimulate energy-savings;
- provides two-way communication for remote maintenance and control;
- provides secure data communications and data privacy.

Some of the functionality, like remote access to sensor readings and remote management and control, can be extracted to the cloud service. This reduces IoT gateway application use cases to: providing local user interface; integration of power sensor(s); two-way connection to cloud service(s); local storage of power consumption data (Fig. 6).

![Figure 6: IoT gateway software architecture](image)
The local storage use case uses an entity gateway interface and its implementation to interact with a database for persistent storage. This is used to abstract the concrete database mechanism used. Entity gateway implementation converts entities data to/from a form convenient to the persistence framework being used. In case of a SQL database it will encapsulate all the SQL statements, in case of NoSQL – all query mechanisms.

The proposed IoT gateway software architecture is shown on Fig. 6. It follows the clean architecture dependency rule – inner layer knows nothing about the outer layers, and the interface segregation principle. The two-way interaction between layers is achieved through dependency inversion principle. Each component of the architecture also follows single responsibility principle.

Security is not a single component of the system, rather it is distributed in layers. There are application specific security policies that are addressed in the use case layer. There are also communication security that should be part of the adapters layer and external interfaces layer. Security policies should also be applied on the message bus securing the message bus for micro-service.

IV. IMPLEMENTATION AND TESTING

This section provides information about a concrete implementation of the proposed software architecture. The IoT gateway is based on an A20-Debian embedded hardware platform. On the hardware platform an Ubuntu Snappy Core [20] operating system is installed and running. Ubuntu snappy is a stripped down version of Ubuntu, designed to run securely on autonomous machines, embedded devices and other Internet-connected devices. IoT gateway application is implemented as a snap package that runs confined under a restrictive security sandbox.

The micro-services message bus is implemented on top of the standard Linux system bus – D-Bus. It is an inter-process communication mechanism that supports two modes of interchanging messages between parties – one-to-one request-response and publish/subscribe.

The electrical power meter used is PST04. It measures the values of the main parameters of the three phase electric power system – voltage, current, frequency, active power, reactive power, and power factor [21]. The power meter sensor is integrated through a Linux device driver that implements its serial protocol.

The integration with cloud services is based on a cloud adapter that implements the DeviceHive [22] RESTful API. DeviceHive is an open-source M2M framework that contains a set of services and components for establishing a two-way communication with the remote devices using cloud technologies as a middleware. The devices can be anything connected: sensor networks, smart meters, telemetry, smart home devices and etc [22].

The document-oriented NoSQL database MongoDB [23] is selected for realization of the local persistence storage. Map-reduce algorithm can be used for batch processing of data and aggregation operations. PyMongo database driver is used as an implementation of database API component.

The implementation of the rest of the system components uses Python programming language. For implementation of MVP a wxPython is used. wxPython is a wrapper for the cross-platform GUI API. The dependency inversion principle is implemented by passing dependency code as a parameters in constructors. Another possibility is to use broadcasters-broker implementation.

Currently, the following operations are implemented:

- configuration and management of sensors and remote service – currently only one sensor and one remote service are supported. Since the sensor does not accept any configurations those are implemented in device driver component and include naming the sensor, selecting communication interface and configuring readings period. The remote service configuration include service endpoint and credentials;
- fetching sensor readings periodically – these are stored in local persistent storage and synced with the remote storage if/when a remote connection is available;
- providing local user interface for user management and visualization of consumption data (charts, diagrams and reports).

Data collection can be initiated both locally and remotely – by default it is initiated locally. The IoT gateway implementation does not require a persistent network connection, although in current implementation it uses one. In case of no remote connection local persistent storage is used and the remote service also support queue for commands sent to the gateway.

Since the software architecture comply with the dependency rule it is intrinsically testable. Each of its components can be tested separately. The Python unit testing framework is used and a number of unittests – for each component of the system and mocks – for the user interface are written. Python unittests are also written for testing the D-Bus micro-services. These kind of testing allows the testing of each component independently. All prepared unittests pass successfully, however testing with unittests is as accurate as the percentage of coverage of all possible input/output data. Finally, the system operations are tested and verified as a whole through real life tests where each operation worked as expected.

V. CONCLUSION

The paper presents the design and implementation of IoT gateway for smart metering in electrical power systems. Several software architecture design patterns and principles are envisioned and discussed in the paper. These are later mapped to the functional requirements for smart metering systems and are used for the design of the IoT gateway application software architecture. The proposed software architecture follows the clean
architecture dependency rule, single responsibility and interface segregation principles for easy extendability and testability of the system.

Based on the proposed software architecture an example IoT gateway implementation is suggested. It uses an A20-Olinuxino embedded hardware platform running Ubuntu Snappy Core operating system. The system integrates a power meter, a smart energy application, local persistent storage and cloud connection. The use of cloud integration increase reliability and protection of collected data (it is stored and replicated in multiple secure, commercial-grade storage systems) and eases the software developers in management of remote devices – the actual devices are managed through web services and provided REST-based interfaces.

The future work includes continuing the process of implementing the IoT gateway application with more power meters and cloud services, developing of a local reasoning algorithms based on power consumption data and possibly other sensors readings for power-saving suggestion, and introduction of a complete security audit test suits.

Application Models for Ubiquitous Systems with Sporadic Communication Availability

I. Čavrak, I. Žagar and A. Dražić*
* University of Zagreb, Faculty of Electrical Engineering and Computing, Zagreb, Croatia
{igor.cavrak, ivan.zagar, alen.drazic}@fer.hr

Ubiquitous computing systems are predominantly characterized by limited computing power, communication capabilities and energy sources. Yet novel usage scenarios shift their roles from basic data acquisition and forwarding to performing more sophisticated tasks such as data processing, local service provisioning and actuation. To meet their goals, horizontal or vertical collaboration and task distribution are often required; utilizing resources identified in the nearby communication environment or offered by remote, cloud- or edge-based services. However, different infrastructural and energy-related constraints can severely influence device’s communication capabilities thus dictating the level of provided functionality. In this paper, we focus on the class of ubiquitous systems without permanent communication links, utilizing only sporadic communication with global computing infrastructure. Such systems exploit the short-term presence of third-party communication and computational resources in their environment, adapting their service level to available resource properties. Several identified communication and computation scenarios are described for such a resource constrained and time-variable environment, along with the incentive model for using and provisioning of short-term resources. A general model of adaptive distributed applications exploiting such sporadic communication and computation environment is presented, relying on the cloud- and edge-computing paradigms and microservices as its building blocks.

I. INTRODUCTION

Ubiquitous computing [1] and succeeding Internet of Things [2,3] have brought a new perspective on computing and collaboration, where computing is dispersed in space over numerous computational nodes pervading the human environment. Such pervasive computational nodes, by their sheer number and diversity, require the change in interaction paradigm, emphasizing machine-to-machine communication and collaboration over direct human-to-machine interaction.

The advent of the cloud computing [4,5], on the other hand, addressed the need for efficient computing resource usage by centralizing the computing infrastructure into large data centers and allowing for their on-demand provisioning. In addition to centralized cloud resources in data centers, fog or edge computing introduced an additional layer of computational resources, bringing the computation to smaller centers closer to service users [6].

Collaboration between application components running on mobile devices and cloud computing has been studied extensively [7,8] where complex and resource demanding application sub-functionality is off-loaded from mobile devices to resource-rich and elastic cloud computing infrastructure. With the proliferation of edge computing, additional application layering is introduced, assigning application tasks between edge and cloud layers with the aim of enhancing user experience and optimizing overall resource usage [9].

The introduction of microservice architectural style [10,11], based on independently deployable services further added to the resource elasticity of edge- and cloud-computing, enabled the application components to be deployed and orchestrated in an efficient manner using different underlying infrastructural layers with additional support of containerization technology [12,13]. Proposals of microservice usage in the context of cloud and IoT are also starting to emerge [14,15].

Our proposed ubiquitous application model strives to provide a uniform, component-based model, spanning all computational layers of the ubiquitous system; embedded, mobile, edge and cloud. In this model, application components are hosted in different layers, on platforms with diverse computational, communication and power resources. The component and application design reflects the microservice architectural style, allowing for fast deployment of components on computational nodes and using specific layer properties to achieve application flexibility such as spatial and temporal component redundancy in embedded and mobile layers, and elasticity and containerization in edge and cloud layers.

The application adaptation mechanism is based on the chain of components’ Quality of Service (QoS) profiles and profile usage prices, where each component exposes a single service interface with QoS profiles and current usage price of each profile. QoS profile prices reflect the current resource state of the component’s hosting platform, communication channels and QoS profile prices of components the service providing component relies on in providing its service. The proposed adaptation mechanism allows for upstream (application-dictated) and downstream (resource level-dictated) dynamic adaptation of ubiquitous application, both in parametric space (QoS levels of used components) and in structural space (application graph; the set of used components and their deployment hosts in computational layers).

In the paper, we specifically describe the ability of the proposed model to provide the application adaptation in situations of sporadic communication availability among computational layers, in particular between the embedded
and the mobile layers. This application adaptation mechanism should enable preservation of application functionality, albeit with reduced QoS, efficiently utilizing computational resources within the communication range by agile adaptation of the application structure.

The rest of the paper is organized as follows. Section II presents our ubiquitous application model for component-based applications with application composition adaptable to changing component QoS parameters. Section III focuses on the usage of the model in ubiquitous applications with sporadic communication availability between computational layers. Section IV presents two example applications based on the model, forming a model testbed, and Section V concludes the paper.

II. UBQUITOUS APPLICATION MODEL

We divide our ubiquitous computational model into two basic sub-models: (i) computational model representing the diversity of computational resources found in ubiquitous computing and forming the highly heterogeneous execution environment for the (ii) application model, comprised of heterogeneous service components, dynamically composed in space and time to perform desired application-defined functions.

A. Computational Layer

In our model of ubiquitous computing, resources and their hosting devices forming the computational substrate for ubiquitous applications are conceptually divided into four layers, each having distinct properties (Table I.):

- Embedded layer – computational devices statically embedded into the environment.
- Mobile layer – computational devices can traverse spaces at different speeds, autonomously or as part of a larger system.
- Edge layer – computational resources are available at network edges - fixed communication infrastructure.
- Cloud layer – computational resources are elastic, available within a computational cloud.

We use a simplified model of computational devices, focusing on the ones present in the first and second computational layers, assuming almost unlimited resources availability for edge- and cloud-layer devices. Each device state is defined using the following tuple:

\[ D_x = \langle E, P, C \rangle \]  

where \( E \) denotes device’s energy-related, \( P \) denotes processing and \( C \) denotes communication properties, each property being a compound one.

Device energy-related property \( E \) consists of the (i) currently available energy in the power subsystem, (ii) maximal power the subsystem can deliver at any time and (iii) predicted inflow of energy from external sources or by energy harvesting. Derived parameters, constraints and predictions can be used in higher level decision making such as energy level flow, estimated battery life, estimated energy inflow, maximal power consumption in relation to current energy levels, etc. Device processing properties \( P \) are modeled with regards to the inbuilt (i) computing capabilities and related parameters (number of cores, core processing power, adjustable clock frequencies, power consumption) and (ii) available memory and memory types. Communication properties \( C \) portray all the available wireless and/or wired communication subsystems and their major properties (available modes of operation, throughput, latency, communication range and power consumption).

B. Component-based Application Layer

We model a distributed ubiquitous application as a directed acyclic graph (DAG)

\[ App = \langle C, L \rangle \]

where \( C \) is a set of vertices representing the required application’s software components and \( L \) is a set of directed edges representing data and control flows among application components.

A software component forms a basic building block of a ubiquitous distributed application, where each component implements a single and narrowly-scoped functionality, following the microservice architectural style approach. Each component defines one or more quality of service (QoS) profiles, consisting of an internal and external sub-profile. External sub-profile declares the QoS capabilities of the component to other components - potential consumers of component’s service. Internal sub-profile defines (i) the set of execution properties for the component (required power, computation and communication resources and their usage) as well as (ii) additional application components and their (external) QoS profiles required to implement the component’s service. Application initiator components originate application activities, partially implementing application logic and using services implemented by other application components down the application graph. Initiator components do not need to expose their service to other components.

Data and control flows, represented as edges, connect application components forming an application graph and allowing the execution of an application on a distributed, heterogeneous computational substrate. The type of directed edge in the application model represents either one-way flow (signal) between application components or a request-reply form of communication. Active QoS profile of a component can dictate different data and control flows, thus making the application topology a function of the set of active QoS profiles of all application’s components.

Components are hosted on computational devices in the computational substrate, as depicted in Fig. 1. In the lower two layers, embedded and mobile, it is expected that

<table>
<thead>
<tr>
<th>Layer</th>

<td>high</td>
</tr>
<tr>
<td>cloud</td>
<td>High</td>
<td>high</td>
<td>high</td>
</tr>
</tbody>
</table>
hosted components are of lower computational, communication and power requirements, and are deployed statically. In the upper two layers, deployment is dynamical and, considering available resources, scaled according to service demand. Multiple QoS profiles of the component can reflect different levels of the service provided by the component itself: (i) by mirroring the usage of resources of the hosting device depending on the service level, (ii) reflecting the current state of resources of the hosting device by offering all or reduced service levels, or (iii) by acting as a proxy towards the component implementations residing on hosts in resource-rich layers.

The model’s topology, defined by the underlying DAG, allows easier and power-efficient calculation of a component’s QoS profile price, dependent on the prices further down the application graph. However, it permits only partial ordering of component interactions in the application model and only a single appearance of a component instance in an application graph. The current model restricts the application state to be held only at the initiator components, and a tiny amount of data representing application state to be transferred to service-providing components down the application graph during (i) the component binding process and (ii) as part of the individual service invocations. Allowing robust mechanisms for the state to be preserved at each application component, even replicated in case of dynamic component re-binding, would allow for the model to be applicable to a wider class of applications, but would introduce a significant burden to component hosts’ resources, especially in the embedded and mobile layers.

To form a functional distributed application, according to the proposed model, it is necessary that the application graph is connected, i.e. that all the required application components are present (i) in the application neighborhood (spatial dimension), i.e. within the communication neighborhood of the devices hosting the components, (ii) in the same timeframe (temporal dimension) during which the application is declared operational and that (iii) all interacting components are bound, forming links among application’s graph nodes.

The application graph is formed and maintained using a dynamic process of local negotiations between application components. A component informs other components of its services either by broadcasting service announcements or by replying to a request for service queries. Service offer is based on the set of currently available QoS profiles for a service and associated prices. Components enter the process of negotiation resulting in a component binding (creating a link of an application graph) or abandoning the negotiation process. A derivative of ContractNet interaction protocol [16] has been adopted allowing the selection of one, or even more, components out of collected offers. A component can, due to changes in resource availability of the host or in changes of QoS of the used components, inform the client component of the QoS changes, where re-negotiation process can be triggered between them, possibly resulting in unbinding components and loss of application functionality.

The role of prices in local inter-component negotiations is two-fold: they reflect the required resource consumption of the service-offering component for an offered service QoS, and they act as a resource-preserving mechanism at the application level, directing the application to use the application’s QoS profile, and all the application components’ QoS profiles, with the best QoS/price ratio at a given time moment. Service prices for the components in the lower two layers are expected to be considerable and fluctuating, highly dependent on the host’s current resource availability. In contrast, components hosted on the edge and cloud layers are expected to have significantly lower service prices, dominated by costs of data transfer from two lower layers, encouraging their usage in the application graph.

III. SPORADICALLY CONNECTED APPLICATIONS

In the previously described distributed application model, for the application to be functional it is necessary for the application graph to be connected. However, in many ubiquitous application scenarios, such requirement is almost impossible to satisfy for prolonged periods of time.

Extending our previously described application model, we extend it with two probabilistic functions (Q – set of available QoS profiles for a specific application component, C – set of application components):

\[ App = \{C, L, \Pi_{QoS}, \Pi_{PRICE}\} \]

the function

\[ \Pi_{QoS}(q,c,t) \in [0,1], \]

where \( q \in Q, c \in C, t \in \mathbb{R}_{\geq0} \) models the probability of the component \( c \) supporting the QoS profile \( q \) at the time moment \( t \), and the function

\[ \Pi_{PRICE}(v, q, c, t) \in [0,1] \]

where \( v \in [0,1], q \in Q, c \in C, t \in \mathbb{R}_{\geq0} \) models the probability of normalized price \( v \) for a given QoS profile \( q \) at time \( t \) for the component \( c \), where the price value 0 indicates unavailability of the component under the given QoS profile.

The extended model allows for simulation and assessment of different application properties, for example (i) the availability of QoS profiles for different application...
components in time periods of interest, (ii) resource consumption of the application on different computational substrate nodes and in different application components and (iii) the availability of redundant application components residing in different computational layers.

We classify distributed applications with sporadic communication availability into two main usage scenarios:

- **Soft scenario** - applications whose functionality is preserved, but with a lowered QoS and/or increased price because of irregular communication availability; include applications employing one or more nodes from the embedded layer, with sporadic assistance of components from upper layers during (short periods of) communication availability.

- **Hard scenario** – applications whose functionality is available only during (short periods of) communication availability towards the upper layer devices.

Each application component can be realized as an implementation component – implementing component’s service and exposing supported QoS levels, optionally using other components – and proxy component – implementing the same interface as the implementation component, but only forwarding service requests to another component instance on a host possibly in another computational layer. Proxy components are predominantly used in the mobile layer, where a mobile node can host the implementation component and provide real services to the client nodes, as on Fig. 2, or act as a dynamic link between lower-layer clients and services residing on the upper layer hosts, as shown in Fig. 3.

In the hard scenario, the problem of application connectivity is augmented with the problem of connection duration, highly dependent on communication technology used, with minimal duration \( T_{\text{min}} \) defined as

\[
T_{\text{min}} = T_{\text{discovery}} + T_{\text{negotiation}} + T_{\text{service}} \tag{6}
\]

where \( T_{\text{discovery}} \) denotes the time required for the discovery of services offered by mobile node by embedded node, \( T_{\text{negotiation}} \) as the time required to finish the QoS level negotiation and \( T_{\text{service}} \) as the time to forward data to the component’s service, process the data and return the result to the client component. In the case of fast mobile nodes with relatively short time span within communication range with other application components, time available might not be long enough to complete the service usage transaction. Application components, with the assistance of their hosts and depending on the communication technology used, can assess the speed and available timespan using different techniques usually based on monitoring received signal strength indicators (RSSI). If supported by the proxy component and the implementation component, asynchronous proxy service transaction can be employed, with Fig. 4 providing an example of the service request and reply being two separate, decoupled transactions using different mobile nodes present in communication neighborhood at different times.

Other scenarios addressing the short available communication timespan might include:

- Assessing time span according to RSSI and selecting the component with the longest predicted availability and acceptable QoS/price ratio.

- Selecting multiple negotiation winners according to the best QoS/price ratio regardless of the predicted availability, thus increasing the cost of resources used, but increasing the success rate.

- Assessing time span according to RSSI and selecting between proxy (less resource spent) or asynchronous proxy (more resources spent) scenarios.

To perform an early evaluation of our application model in the context of soft and hard sporadic communication availability scenarios, we have conducted simulations of application behavior for a simple ubiquitous application.
The application is comprised of initiating application component C_I, residing on a single host in the embedded layer, and component C_S offering two QoS profiles for an exposed service, with instances hosted in multiple layers, on a single or multiple hosts at a time, and with a variable availability of those instances. All simulations have been conducted within an extended custom Java-based simulation framework, initially developed for simulating self-organizing distributed applications within the context of wireless sensor networks [17], including modeling of node mobility and stochastic communication links.

Fig. 5 presents the simulation results of the soft scenario by depicting the QoS profile price variability of C_S as perceived by the initiating component instance C_I (1), with C_S instances residing in embedded, mobile and cloud layers. In the timespan framed by points A and B, the C_S instance C_S (1,QoS-A) residing on the embedded layer host is used by the C_I (1), with price persistently rising due to host resource consumption. At the moment B, the C_S (1,QoS-B) QoS profile is selected by the C_I (1), lowering the usage price due to lower resource consumption of the selected profile. At the time moment C, the C_S (1,QoS-A) host resources are exhausted, and the price reaches 0 (service unavailability), re-linking shortly the application graph to redundant host and component instance C_S (2,QoS-A). At the time moment D, C_S (2,QoS-B) host resources are depleted and the application graph is incomplete due to C_S instance unavailability in the C_I (1) communication neighborhood until the time moment E when the component instance C_S (3,QoS-A) residing in the mobile layer becomes available. Implementation of C_S for the mobile layer hosts allows for service forwarding, and after negotiation with cloud-layer host and C_S instantiation, at the time moment F cloud-hosted C_S (4,QoS-A), with the lowest QoS/price ratio takes over the service provisioning.

Fig. 6 presents the simulation of price variability for the hard scenario and a single component C_S QoS profile A, where at time point A, the component instance C_S (1,QoS-A) becomes available for only a short period on a mobile node with low available resources and high QoS price. Point B marks the availability of instance C_S (2,QoS-A) on a mobile node with adequate local resources but only during a short period. At time point C there is a longer availability of instance C_S (3,QoS-A) in the cloud layer, with mobile layer instance C_S (3,QoS-A) acting as proxy. At time points D, there are two short periods of reachability of instance C_S (4,QoS-A) in the cloud layer, employing asynchronous proxy communication between it and C_I (1). Also depicted are different QoS prices reflecting resource levels of mobile nodes hosting component proxies C_S (5,QoS-A) and C_S (6,QoS-A).

IV. TESTBED APPLICATIONS

As a proof-of-concept, besides simulations, we are implementing two ubiquitous applications based on the proposed model, thus providing a testbed for developing more time- and power-efficient negotiation protocols over multiple communication channels and technologies.

The first example application uses a LoPy [18] multimodal wireless communication node with Bluetooth LE and LoRa [20] as communication channels. The application component A on the LoPy module performs periodic ambient measurements and tries to forward them to the central monitoring and storage component B using LoRa communication channel and one of the modes, depending on the channel availability. If LoRa-based channel persists to be unavailable for a prolonged period or the change rate of acquired data is high, the component seeks the assistance of nearby mobile phones equipped with Bluetooth LE and hosting the proxy component B to relay the data to the implementation monitoring and storage component B, as shown in Fig. 7. Each hardware device in this scenario hosts only one application component, where component A is the application’s initiator component.
The second example scenario, depicted in Fig. 8, includes clusters of low-resource wireless sensor nodes using ZigBee [21] communication protocol and TinyOS platform [22] for a power-efficient collection of ambient data over large areas. In this scenario, devices or execution environments, denoted by dashed rectangles, can host multiple application components. The statically deployed data collection system is augmented with mobile nodes in the form of wearables (Intel Edison [23]) wearable platform and Android-based smartphones, providing the environment with variable sensing, forwarding and processing demands reflected in variable component QoS. Data are forwarded to components in upper layers using both direct or proxy communication, subject to variable data link availability. While basic data processing is available at the cluster and mobile nodes, complex data processing and storage is reserved for application components in the edge and cloud layers utilizing OpenStack [24] as the IaaS platform and Docker [25] as the microservice container.

![Figure 8. Test application deployment – multimodal communication, forward- and backward-adjustable component QoS](image)

V. CONCLUSION

The ever-increasing complexity and adaptability of novel ubiquitous distributed systems present a challenge to the architects of ubiquitous applications, requiring composition and interplay of many adaptable application components spread among different computational layers; from tiny resource-constrained pervasive devices to large-volume data systems in clouds.

In this paper, we proposed a general model of adaptive ubiquitous applications based on components and application graphs defining current application configurations based on the available or required quality of service profiles. Particular attention was given to applications lacking permanent communication links towards application components in higher computational layers: edge and cloud. We proposed different interaction and computation scenarios exploiting sporadic resource availability in the mobile layer.

Our future work will, besides enhancements to the model itself and the accompanying modeling and simulation tools, include devising more time- and power-efficient negotiation protocols and communication strategies for scenarios with short periods of component availability due to high node dynamism in the mobile layer.

Towards the Utilization of Crowdsourcing in Traffic Condition Reporting

P. Rantanen*, P. Sillberg* and J. Soini*
* Tampere University of Technology, Pori, Finland
petri.rantanen@tut.fi

Abstract - The use of traffic information in map applications designed for stand-alone navigation devices as well as in mobile devices has become a common trend. This information is often governed by the various service providers with little or non-existent feedback from the users. Using a wide user base it is possible to collect information on traffic conditions faster and more efficiently. Additionally, many of the events faced on the road can be challenging to detect by automatic means, but are easily noticed by the road users – animals on the road and broken or missing road signs are only a few examples.

To better facilitate the utilization of information gathered from road users, simple and easy-to-use software solutions are required. This paper presents a prototype mobile application, which the road users can take advantage of for both following the on-going traffic conditions while driving and for collectively reporting traffic events other users might be interested in. The high-level architecture, application and data utilized in the reports are presented in addition to the preliminary findings of the on-going research. This paper will also discuss the challenges identified while developing the application.

I. INTRODUCTION

There have been several studies on how to take advantage of automated means in the traffic environment. Topics such as the detection of pavement conditions [1], winter conditions [2], vehicles [3][4] and road signs [5] have been of constant interest for the past decade. There is little doubt that the use of automated means will increase in the future. Nevertheless, events such as animals on the road, broken road signs and poor visibility are easily recognized by humans, but can be challenging use cases for automatic methods. Thus, the potential wide user base offered by the people travelling on the roads should be more tightly integrated into the road condition reporting.

Most map applications provide “layers” that show basic details (for example, road works, traffic jams) concerning the current road conditions, but generally, no option is given to the user to give feedback on the accuracy of the information. In Finland, there is an official telephone number provided by the local road agency the road users can call to report bad road conditions, and several radio stations accept calls concerning events met on the road. Unfortunately, these services are very seldom connected to the devices and the services the people use in their everyday lives. In essence, the application (or service) presented in this paper could be seen as a more modern replacement for these telephone-based services currently available.

The initiative to develop the application presented in this paper came from one of the corporate partners (a logistics and transportation company) of our project. They had a need for a very simple and easy-to-use application that the professional drivers of the company could use to notify each other about various road incidents, events and road conditions that could affect the deliveries.

This paper presents the preliminary results of the APILTA (Avoin Plvipalvelukonsepti joukkoiostetu Liikennedatan TArpeisin, or “Open Cloud Platform for Crowdsourcing Based Services”, in English) project currently on-going in Tampere University of Technology, Pori Department. The primary purpose of the research within the context of this paper is to design an easy to use application (user interface) that would not distract the driver and the users would be willing to take advantage of while travelling. Keeping this goal in mind, the following section (Section II) discusses the related studies, Section III provides a high-level look on the architecture and the use case in general, Section IV will describe the application itself, Section V offers a discussion on the challenges and opportunities, and finally, Section VI summarizes this paper.

II. RELATED STUDIES

The use of traffic data in crowdsourcing applications is not a completely new idea. For example, in [6] the focus was on evaluation of anonymized data created by an electronic travel journal to be used as study material for mobility research. If the collected data was accurate enough, it could be used in design of the traffic network. There are efforts to estimate the traffic conditions with data that are gathered from different sources and by different methods (e.g. traffic monitoring by inductive loop detectors, satellite positioning, and mobile phone positioning) [7][8]. To reliably evaluate the traffic conditions a lot of traffic monitoring is required. This is where the crowdsourcing can become a feasible source of data.

Efforts for the concept of Smart City (SC) can be useful as transportation and traffic are typically studied together with this topic. Sensor networks, data collection and data management are key components in development of Smart City applications. Literature review [9] classifies a wide range of architectures and technologies used in the
field of SC. The newest trend seen was the introduction of IoT (Internet of Things) and in the future IoE (Internet of Everything) is expected to be the next important milestone. IoT enabled SC applications often employ Smart Objects (SOs) in the monitoring of traffic and environment. A large number of devices, software and services (e.g. mobile phones or even vehicles) can be categorized as a SO [10][11].

In the use case of Smart Transportation [10], the sensor data is seen to have a crucial role in managing the transport system. The trustworthiness, robustness, timeliness, and security of the communicated data together with maintaining the privacy of users is of major importance in a SC system [10]. The security and reliability of a cloud-based city management platform have also been studied [12].

There have been studies on using mobile phones as location location sensors in a Smart City service for car sharing to improve the traffic conditions in the City of Barcelona [11]. Furthermore, there has been research on utilizing event-based architecture to conduct Machine to Machine (M2M) communication in vehicular context [13], the Internet of Vehicles (IoV) and the Social Internet of Vehicle (SiIoV) [14], detecting road conditions using smartphone sensors [15], and analyzing video with a computer vision system to recognize overall road conditions and the status of traffic infrastructure [16].

There are several applications that are similar to our approach. Beat the Traffic [17] used to offer real-time traffic information partially provided by users in the United States and Canada. Waze [18] similarly offers its users to participate in gathering new traffic information. Inrix [19] provides a more complex service for traffic management including several mobile applications for tracking traffic conditions, but lesser options for user to manually create reports. In Finland, a new pilot (NordicWay Coop) was launched last year in co-operation with industry partners and the Finnish Transport Safety Agency with a goal of allowing people to report traffic conditions [20].

When it comes to reporting new alerts, each application has a slightly different approach: Beat the Traffic offered more complicated forms and a simpler “shake to report” feature; Waze uses speech recognition; and NordicWay Coop utilizes a more traditional menu-based approach. Based on the literature each controlling method (voice recognition [21][22][23], touch, tactile and gesture [24]) have their own advantages and disadvantages with perhaps no clear winner to be found amongst the options.

Similarly to Beat the Traffic, Inrix and NordicWay Coop, our application utilizes touch-based controls with the main difference being in the user interface design – the look’n feel of the application and the user interface “flow” when creating a new alert. In our case, the goal is on enabling an easy reporting of alerts where as many of the commercial applications are primarily focused on map-based features (e.g. navigation).

As mentioned before, the initiative for our application development came from a logistics and transportation company. An individual company might have the need to report alerts that are not by default included in the system, and the company might not be willing to share the reports outside the company, or the company might only trust the alerts received from a particular user group. User groups and customization would also allow regular users to team up with friends or colleagues for sharing alerts in a more social way. With the exception limited features offered by the Waze service there seems to be apparent lack of customization and user grouping options in the existing applications.

III. Architecture

The system architecture (seen in Fig. 1) is based on receiving alerts from different clients, and transmitting the alerts to clients who are or would be affected by them. The service is implemented by utilizing commonly used open source components such as Apache Tomcat, Apache Solr and Oracle MySQL.

In the first prototype of the client, the available alert types are predefined to contain just a few examples, but the architecture and alert syntax itself are extendable. Also, the system can accept photos attached to the alerts, but this feature is not used in the application presented in this paper. City road maintenance is one use case where the additional info could be useful.

The alerts on the client are updated by regularly polling the representational state transfer (REST) Application Programming Interface (API) to retrieve the newest alerts that affect the user. Thus, the clients do not need to subscribe to listen for new alerts. The client would need to continuously report its location to the service to receive up-to-date alerts in any case, but in our approach the service will immediately respond with alerts that are in range. This would also allow anonymous or unregistered users to use the API. In our case, because of the limited computing resources available, the service is open only for users accepted to participate in our piloting phase. In practice, there could also be real business cases (e.g. pay-to-use, providing user preferences across devices based on the user account) that require the users to be authenticated before using the service.

Each alert reported by the clients includes the geographical coordinate of the event and the search method provided by the API accepts a polygon based area filter and a heading based filter. This way the client device can construct more accurate search terms that cover more area in front of the device than behind. The client can also adapt to the increasing speed by retrieving the alerts more often, or by growing the search area bigger.

![Figure 1. High level architecture.](image-url)
In the first phase of the pilot tests, there are only a few alert types to be included (animals, broken street signs, slow traffic). The architecture is built to accept new, user created alert types for extending the usability of the system. Any authenticated user can create a new alert type, but by default the application presented in this paper will only utilize the built-in types. New types must be configured (chosen from a list of types known by the service) in the application settings – this is to prevent users from spamming the service with unnecessary global alerts, but the approach will still allow the utilization of custom tags with relative ease of use.

The API provides the data in Extensible Markup Language (XML) documents by default, and supports JavaScript Object Notation (JSON) format as well. The data format of the alert includes a timestamp, location (coordinate), alert type, alert description and information about how long the alert is valid. The validity period of the alert varies case by case, and at the moment there is no good approximation when or how a certain alert should become inactive. In accidents and similar events an official user such as the police or ambulance staff could be given the permission to remove the corresponding alert, but in the case of animal alerts the validity period can be challenging to predict. The default validity period for each alert can be defined when the alert type is created in the service. In our use cases, alerts will be automatically invalidated within a couple of hours. In principle, the validity period could also be set by the client though choosing the correct time value when posting a new alert would probably be just as difficult as choosing a correct pre-defined validity time.

IV. PROTOTYPE APPLICATION

As the main use case is driving a car, this poses certain requirements for the application. Most importantly, the application should not distract the driver. For this goal, the application has been designed to require as little interaction as possible with emphasis on automation both in the information gathering and in the flow of the user interface.

There are no technical limitations why the application could not be used, for example, when walking, and alternative means of transport could provide possibilities for features purposefully not implemented in the current version. Features such as alert rating (feedback) or reporting of incorrect alerts, or zooming and panning of the map view could be easily managed by the user when walking, but could be too distracting when driving a car.

The application has two basic functions (or features): reporting new alerts to the service; and showing alerts that are near to the user. The features are shown in Fig. 2 and in Fig. 3. Additionally, the application contains a settings view (not visible in the figures), which allows the user to change the common configuration parameters such as the credentials used to authenticate the user with the service. The settings view can also be used to select the alert types the user wishes to listen for new alerts and the option to select the types available for reporting new alerts.

The screenshots are taken from a Google Nexus 7 device running the Android 7 operating system. The application should work on any relatively recent (even low-end) Android phone or tablet with a touch screen and an Internet connection. As the transferred data consists of simple Hypertext Transfer Protocol (HTTP) GET and POST requests with small XML or JSON payloads (depending on the amount of alerts, generally from ten to 50 kilobytes) even a relatively low bandwidth network connection can be utilized.

A. Feature 1: Report a New Alert
Fig. 2 illustrates the user interface flow applied when the user reports a new alert. The first picture (left side, Fig. 2) shows the default (idle) view visible when no alerts are in range. In this example case the user has configured the application so that there are two alert types available for reporting new alerts: reports for animals on road (center, Fig. 2); and reports for slow moving traffic (right, Fig. 2).

To browse the available alert types the user only needs to touch anywhere on the screen. This will automatically show the next view: from the default view to the “animal on road” view; from the “animal on road” view to the “slow traffic” view; and from the “slow traffic” back to the default view – as seen in the Fig. 2. A move from one view to another is accompanied by a sound (the spoken name of the alert type). This allows the use of custom alert type names by utilizing text-to-speech features provided by the Android platform.

![Figure 2. User interface flow when user reports a new alert.](image-url)
If the user does not touch the screen within a predefined time and the active screen is one of the alert views, a new alert (with applicable details such as timestamp and user’s location) will be automatically sent to the service. The time left until the alert will be sent is indicated to the user by a countdown timer visible on-screen (as can be seen in Fig. 2 middle and right, below the icons).

The time until the alert is posted can be configured from the application and a longer time will naturally give the user more time to react. Touching anywhere on the screen while the counter is running will abort the operation and screen will change to show the next view. If the next view is an alert view a new counter will start, if the next view is the default view the application will return to the idle state.

The audio cues and the fact that the user can touch anywhere on the screen are designed to allow navigation without looking at the screen. On devices that do not have a touch screen the navigation could also be implemented by providing a single button to use for changing the views. The user interface is also meant to be simple enough to be usable on various screen sizes. Alternative approaches such as multiple buttons provided for navigation or a scrollable list of alerts could cause difficulties for the driver for using the application especially on devices with smaller screen sizes.

In principle, there could be any number of alert types to choose from, and if more alert types were used, new views would appear in the user interface cycle (for example, in Fig. 2, a view with a new traffic sign could be between the elk sign and the slow traffic sign). In practice the operator should use the application settings to configure only the alert types he/she is planning to use to be visible in the user interface to reduce the total amount of browsing needed.

Another option could be to allow the user to speak the name of the alert type when choosing the alert to be reported, but in a location with a potential ambient noise (e.g. in a car) it can be challenging to implement reliable speech recognition. Additionally, this would require the user to remember the actual names of the alerts or implementation should be smart enough to decipher the user’s meaning from alert names pronounced only partially correct. Furthermore, as the application is entirely separate from the in-car systems, the voice control could also interfere with the built-in speech recognition features of the car itself or the use of two separate systems could confuse or annoy the user.

B. Feature 2: Show Nearby Alerts to the User

The user interface flow for showing the nearby locations is can be seen in Fig. 3. As long as the visible view is the default (idle) view (Fig. 3, left) the application will automatically show the map when alerts are detected within a pre-configured range or the travel time to the alert is within a pre-defined threshold (for example, the location indicated by the alert is within 100 meters, or the location would be reached in 30 seconds). The change to the map view is also indicated by an audio cue. If the user is currently browsing for alert types and is not in the default view, only a sound cue is played and the application will wait for the user to return to the default view before showing the map view. After the alerts go out of range, the application will automatically switch back to the default view. The user can also change to the map view by tapping the “Map” option on the top right, and the user can return from the map view to the default view (and to reporting new alerts) by simply touching anywhere on the map screen or by touching the “Home” option on top right. The “Home” option can also be used to return to the main view from any other view, and can be used at any time to cancel a reporting of a new alert.

![User interface flow when an alert becomes range.](image)

In the current version of the application, the map will automatically zoom to and follow the user’s current location. Manual panning and zooming of the map often implemented by touch gestures are disabled. The primary purpose of this is to allow quick and easy navigation back from the map view.

The upcoming alerts are illustrated using the same icons as seen in Fig. 2. In our use case, the alerts are represented by road signs, which are easily recognized and associated by the driver to the events in question. Naturally, in many cases new icon designs are required as not all alert types can be illustrated by road signs alone. If the range of the event is known, it is illustrated by a transparent area around the icon. In Fig. 2, the “Animal on road” event contains range information, but the “Slow traffic” event does not. In the current service implementation, the area is visible only on alert types that have the range predefined (e.g. animal warning have a default range of 200 meters). The prototype application (user interface) does not support the creation of new alerts with range defined.

In the background the application will continuously poll the service for every couple of minutes requesting new alerts (i.e. alerts reported after the previous request) within a larger area (for example, within two kilometer radius) around the user’s location. The retrieved alerts are cached by the application. The cache is checked whenever the user’s actual location changes (within certain accuracy) and alerts that have moved too far from the user...
are automatically removed from the cache and alerts that are close enough are shown in the map view.

The new alerts could be requested from the service each time the user’s location changes as opposed to more relaxed background polling, but this would both increase the amount of requests on the server-side as well as use more power and network bandwidth on the device itself. The downside is that the alerts do not appear on the client devices in real time, but in practice, real-time updates are seldom needed.

V. DISCUSSION

In essence, there have been two main challenges in developing the application: to make the user interface as easy to use as possible; and to validate the achieved results in the larger context of crowdsourcing.

To further aid the use of the application, automation would provide assistance for the user, and there are several promising, emerging and already implemented technologies such as speech recognition, image analysis (for example, the detection of objects or events from frames captured from a video camera), and the utilization of various sensors embedded in road modern road vehicles. Unfortunately, the most in-car systems cannot be directly accessed or extended with new features either because of security reasons or closed nature of the systems. This also means that buttons located, for example, in the steering wheel cannot be easily used to control a smartphone application.

Similarly, extending commonly used navigator devices and map applications can be a challenging task. Several companies (e.g. Google, Microsoft) provide online APIs for navigation applications, but the utilization of these APIs often require redundant work for the implementation of basic navigation features already present in the mobile device itself. Due to the fact that the user would need to use multiple applications for two closely related tasks (for example, the application presented in this paper and a proper navigation application) may decrease the user’s willingness to use the provided, otherwise advantageous features. In an optimal situation, the functionalities presented in this paper would be integrated with an existing system or device, preferably in a navigation application.

As explained earlier, this paper presents only the preliminary results of an on-going study. The piloting phase utilizes people participating in the project either directly in the university or in the co-operating companies. The initial feedback on the idea has been positive, but because of the smaller user base, it is difficult to validate whether a larger audience would be willing to participate in reporting the alerts. A wider user base would be required for conclusive results, but unfortunately organizing a larger crowdsourcing effort can be challenging both for finding the applicable audience and because of the increased (computing) resources required for hosting the service online. In principle, it could also be possible to realize a working service even with a help of a smaller, but more motivated group enthusiasts.

Another issue, closely related to the widening of the target audience is the validation of the alert reports the users have submitted. Within a smaller and more controlled user base it is easier to protect the service against malicious use. By nature the reports are only “alerts” and, for example, spamming the service with incorrect alerts should not pose danger to the users (drivers), but it might render the service unusable, or at the very least, lower the users’ interest in the service. Possible solutions could be to allow “rating” of the alerts or to require a certain amount of alerts of the same type to be reported within an area before the alert is shown publicly.

In the first solution, the primary problem would be how to implement the feature in the application so that it does not distract the driver. On one hand, it is entirely possible that the feature would take the user’s attention away from driving causing more accidents than the application would prevent. On the other hand, if the feature would be implemented on a separate web portal, it is unknown how many of the users would bother to report the alerts after arriving at their destination.

The problem with the second approach is that if there are only a few users that report alerts using a road, the reported alert may never be published, or it might take a longer time before the reported alert becomes public causing potentially a larger number of road users to miss the alert. As the service does not allow anonymous access, rating alerts and users could (at least in theory) in time filter out users that post unnecessary or incorrect alerts. In the case of animals on the road, one way to verify a low number of reports could be done by making a cross-check with another database with details of animal density in that area to determine the chance for a such event to occur.

Information and guidelines for minimizing driver distraction have been released by [25][26]. Furthermore, there have been studies on user interface and system response design in the context of minimizing driver distraction [27]. However, the guidelines are only applicable to original equipment electronic devices, and do not cover aftermarket or portable devices. This means that because there is less control over mobile applications in official requirements, the applications can be organized in a more liberal way, possibly even in a distracting manner to the driver. Thus, it can be easy to overlook traffic safety aspects, especially if the recommendations would interfere with the designer’s vision for the look’n feel of the application.

In conclusion, it can be said that there remain several currently unresolved and challenging tasks. Regardless, the authors of this paper believe that more could be achieved for the goals of averting accidents and reporting road conditions through better integration of road users’ feedback potential into the overall road ecosystem.

VI. SUMMARY

Despite the progress in the development of automatic means to detecting road conditions, there are still cases where humans are more capable of detecting the events faced while travelling. Yet, the commonly used navigation devices and applications seldom offer any means for the
user to provide feedback on the accuracy of the road information.

To better realize the potential of the road users in reporting road conditions, easy to use applications that the users can take advantage are required. This paper presented an example of an application the road users can utilize to report events faced while travelling by car. The high-level architecture utilized in the overall service was briefly introduced in combination of the data used to describe the alerts. Additionally, this paper provided a discussion on the challenges and unresolved issues identified while designing the application.

Abstract Sensor networks are a highly researched application area in the field of Internet of Things (IoT). A key cost and resource question in the development of IoT network sensor solutions is prototype implementation. In this study, the Raspberry Pi—a widely used single board computer—is investigated as it is one of the most commonly used prototyping devices available and is also widely used in scientific research. In this paper, we address which technologies, the usefulness and what kinds of issues arise when the prototyping of a sensor network solution is done with Raspberry Pi. The extant literature is studied by selecting papers with the systematic literature review method. Based on an extensive survey of the selected studies, we found several sensor-based implementations where Raspberry Pi has been used. In addition, this survey revealed subjects, such as e-health and education, which expanded the research topic in new ways. Further research opportunities have been identified in specifying the usefulness of various technologies with single board computers.

I. INTRODUCTION

The Internet of Things (IoT) is the expansion of Internet services, which connects everyday physical objects to a network. This connection between a network and physical objects makes it possible to access remote sensor data and to control the physical world from a distance. The first mention of the term ‘IoT’ is said to have come from Kevin Ashton in 1999. A survey of the areas of “Internet of Things” was made by Atzori, Iera and Morabito [1]. In this research, the focus has been redirected toward the Wireless Sensor Network (WSN) type of solution. The basic features of sensor networks were compiled in a survey conducted in 2002 [2].

‘Sensor networks’ refer to distributed autonomous sensors that are used to monitor the physical environment, e.g., temperature or pressure. Sensor networks are a widely-studied area. For example, the use of embedded Linux for sensor networks has been proposed [3] and a simple model of a sensor network has been introduced earlier [4]. There has also been research on long-range wireless sensor networks with geolocation tracking [5] and on a low energy algorithm for a sensor network [6]. Sensor networks have several development possibilities, such as the one introduced in Fog the gateway unpublished [7] study.

Single-board computers, such as Intel Galileo, BeagleBone and Raspberry Pi, are low-cost development devices for testing or educational purposes. These are fully customizable and programmable, and have the features required to implement small and low-cost IoT devices [8]. The Raspberry Pi is the most popular of these three in the field of research according to the keyword search. Single-board computers are an rising technology area in the development of prototypes. Often, developing a prototype is experienced as difficult and expensive due to the costs of hardware design, software design and developing as well as hardware manufacturing and building. However, by using single-board computers, these costs can be easily reduced. Ready-to-use hardware solutions already exist, such as Raspberry Pi, which have ready-to-use software with embedded Linux. Furthermore, there are many communities and user groups available online where a developer could ask for help and support.

Despite the potential value that single-board computers could provide, we are currently lacking a good overall picture of the studied and tested information on the real benefits and drawbacks brought about by the use of single-board computers. The objective of this study is to fill this research gap by mapping the current state of the art in the use of single-board computers in prototyping sensor networks. Thus, we seek answers to the following research questions:

RQ1: What do we know about the benefits and limitations of using the single-board computer Raspberry Pi in supporting prototyping work?

RQ2: How is the functionality in these single-board systems tested?

RQ3: Are there any specific test methods?

To answer these questions, we performed a literature study. We used the Systematic Literature Review approach (SLR) [9] to collect primary studies regarding this topic. The selected primary studies were then analyzed and categorized with the content analysis method.

The rest of this paper is structured as follows. In Section II, we introduce the research approach used in this literature study. In Section III, we present the analysis of the findings. Section IV includes a discussion and suggestions for future research on the topic and finally, the study is summarized in Section V.
II. RESEARCH APPROACH

As previously mentioned, to answer the presented research questions, we decided to perform a literature study in order to map the extant knowledge on this domain. We decided to use the SLR method for collecting relevant primary studies and followed the guidelines given by Kitchenham and Charters [9].

For the SLR, we decide to do an electronic search. The database used was IEEE Xplore Digital Library, the search engine of which was used in this study. The survey was started by selecting the following search terms: “Raspberry Pi” AND “Internet of Things” AND “Sensor Networks.” We decided to use these simple keywords in order to receive good coverage of potential primary studies.

The keywords were commonly used alone: “Raspberry Pi” returned over 500 hits, “Internet of Things” returned over 12,000 hits, and the most popular was the third keyword “Sensor Network,” returning over 110,000 hits. Together the keywords returned 11 (IEEE), and 1 (ACM) results. These were only the keyword search. The full text search gave too many hits, over 400, for this research. Nevertheless, this result combined with the search keyword “smart home” gave us 24 hits. The final searches were targeted to keywords and limited only to research papers.

In the first phase of the research, we selected studies based on abstracts. We used the following inclusion and exclusion criteria: Peer-reviewed studies conference and journal articles as well as book sections written in English focusing on all three aspects were included. We excluded studies written in languages other than English, posters, abstracts, and short papers, as well as studies only mentioning the keywords but not focusing on the issue.

In the second phase of the research, the selected studies were read through carefully. In this phase, we still excluded studies unless they focused on the development of sensor networks with Raspberry Pi. In the end, we selected 15 primary studies for inclusion in this study. The selected studies were read through and analyzed. We studied which technologies were used, what kinds of issues were faced, how the testing was reported, and whether there were any problems in testing or not. Finally, the notes were reviewed and the results were analyzed.

In the remaining sections of this paper, we will first present the selected key studies in the section III. This is followed by a discussion section where we answer the presented research questions.

III. RESULTS

In total, we selected 15 relevant primary studies for this paper. The primary studies found and selected were [10-24]. In the following, we will briefly summarize the key primary studies and their findings.

Baranwal, Nikita and Pateiya [10] presents a monitoring system for detecting and preventing rodents in grain stores. The system consists of a webcam, a repeller for undesirable rodents, and Raspberry Pi with a set of sensors, which were an Ultrasonic Range Detector (URD) and a Passive Infrared sensor (PIR). The algorithm for the software was introduced. The test cases consisted of functionality tests where the hardware and software were tested. The test results showed that the observation distance was small, seven centimeters. In addition, the reliability of the system was tested. This test shows that 85 percent of system notifications were real. The 15 percent of tests that were unsuccessful were due to the connectivity of the device, data transmission, notification, and other factors such as PIR sensors being configured to generate discrete values.

Two studies [11] and [12] introduced the developed IoT-based E-learning testbed developed on the basis of a combination of five Raspberry Pis and a microwave sensor. The testbed controlled several factors: Chair Vibrator Control, Light Control, Smell Control, Sound Control, and Remote Control Socket. The purpose was to improve and stimulate the e-learner’s motivation by using this testbed. The study introduced the usage of Optimized Link State Route protocol (OLSR) technology in the testbed software. The first study introduced the idea and the second study from the same authors handled the same issue more profoundly. In the second study, the testbed network communication was tested and the results were shown. The testbed usage for improving and stimulating e-learner’s motivation was not tested. Also, the functionality of the testbed was not tested apart from the communication protocol.

Mahmoud and Qendri [13] introduced a sensor shield, the Sensorian platform, for Raspberry Pi. The aim was to transform Raspberry Pi into an IoT platform. This study could be categorized as hardware development. The shield consists of sensors: light, accelerometer, temperature, pressure, touchpad. It also includes a TFT display, LEDs, a real clock, and memory for software development. This shield was developed by means of crowdfunding. However, the functionality tests were not presented. It was mentioned regarding software testing that the firmware had been tested with the Raspbian operating system, but no test cases or results were mentioned.

References [14] and [15] focused on education on their research. The first study introduced the challenges and experiences of introducing IoT as an open elective course. The second focused on teaching Python programming. In these courses, Raspberry Pis and a set of sensors were used for teaching purposes. Students on this course built prototypes using the hardware mentioned. These studies did not handle testing the built prototypes and the focus was more on education than the other pieces of research in our study. However, these studies were included because of the good requirement specifications of the systems.

Maksimovic, Vujovic and Perisic introduced IoT-based e-health systems. The research also highlighted the economic impacts of IoT applications and especially the economic growth of healthcare applications. This research compares different applications: one is the e-health sensor shield V2.0 for Raspberry Pi and the other is a custom-made body sensor measuring system. Both enable data gathering and sending to the server application. This research does not have any special
testing part but the research extensively points out the security issues of the gathered data.

The research by Hsiao, Liang and Sung [17] introduced a smart home system. This system uses infrared communication inside a room, Zigbee communication inside the house, and Wifi communication for data transfer to the cloud. The research focus was the combination of communication types in one system. The actual sensor or controller was not introduced. The features of these communication methods were also compared. A comparison of different means of communication was made at a general level, but no specific test cases were presented.

Hentschel, Jacob, Singer and Chalmers [18] introduced a smart campus system based on Raspberry Pis. This system uses hardware-software-service architecture, where the hardware consists of Raspberry Pis and sensors. This combination has software for collecting and sending data. The cloud has a service where the data are stored and served. This research presents sensor-to-sensor technology and delay-tolerant data transfer. This is for not-so-urgent data in the case of disrupted network connectivity. This research described several use cases of the system: Room temperature, free meeting room, room occupancy, custom event triggering, and robotic support infrastructure. These use cases are interesting but the physical test cases for them were not described. There were a few cases where the improvement of hardware design was introduced by changing the type of sensors.

As above, sensor network based systems were introduced in several studies [19-24]. These systems present the different ways to use master node - sensor node type solutions. Common to all these studies was the model of one master node and several sensor nodes. The sensor nodes collect the data and send it to the master node. The master node processes the data or sends it to the cloud service. These studies present systems from different angles or focus only one part of the system. In these studies, the test cases focused on functionality tests, communication test, or processing power tests. These tests usually support the main ideas of the studies and test cases which did not support them were dealt with.

IV. DISCUSSION

This study aims to resolve three research questions: What do we know about the benefits and limitations of using the single-board computer Raspberry Pi in supporting prototyping work (RQ1); how are the functionalities in these single-board systems tested (RQ2); and, finally, are there any specific test cases (RQ3)?

To answer the first research question, it can be said that there are a reasonable number of studies focusing on prototyping sensor networks with Raspberry Pi devices. However, most of the papers reported a single case study on the development of an interesting system. There is a clear lack of formalized approaches, methods, and tools.

The second research question dealt with the practices used in the testing of a prototyped Raspberry Pi sensor network solution. Again, only little has been reported on the testing practices utilized, problems faced, and approaches used in the development of a sensor network or a module for it. As the testing of interconnections between the nodes in IoT networks is of utmost importance for the reliability of the system, the lack of studies is a worrying finding.

The third research question focused on whether specific test methods were used. This research shows that formal software testing was used only in the minority of research. For example, often it was only mentioned that the test cases were passed. Of course, the software parts are small, especially in sensor nodes, but if the developed system has some algorithms to process the gathered data, the software may have several functionalities. These should be tested in some way. One good test is: Will the software perform its functions within acceptable time? Data validation tests were used in a minority of studies. Validation might be important when a system uses the gathered data or the results of processed data in some way.

The results of the RQs raised several new research topic ideas. One possible future research topic that this paper does not analyze in depth is embedded operation systems. There are several types of single board computers on the market and usually each device has its own operating system. These operation systems are mostly Linux-based. An interesting topic would be the variety or modifications of these Embedded Linux components when the target is the increase of processing power.

The second research topic focuses on reliability. The Raspberry Pi based prototypes are usually connected using an experiment board and soldering of connections is not common. This came up from the studies explored. During our previous studies [3], [4] and [5], connection faults were common and it was attempted to prevent them by soldering all possible connections. However, the articles explored in this study did not commonly handle these reliability issues. Only a few of them even mentioned these problems.

Another interesting topic is recovery from faults. When we have noticed that the reliability might be an issue, so we should think about how to recover from the fault and which kinds of faults we could recover. Power failure is one common fault. However, only a few of the studies have handled this situation and the recovery process from power failure. In particular, the Raspberry Pi and its generally used Linux-based operating system are vulnerable to this kind of fault.

These selected studies tested the developed systems in various ways. This research shows the lack of systematic testing procedures of the systems of this kind. If there are systematic ways of testing Raspberry Pi based systems, those were not used. This might be also an interesting future research topic.

V. CONCLUSIONS

This survey showed that the Raspberry Pi is a widely-used device in research implementations of different kinds. The Raspberry Pi is an inexpensive, fully customizable, and programmable credit card-sized single board computer, which supports a large number of
peripherals and network communication. Therefor the Raspberry Pi is suitable for small scale prototype testing. In this paper research on sensor network solutions were focused on using a literature review. This paper identified three research questions, which were answered using the systematic literature review approach. The answer of RQ1 showed a lack of formalized approaches, methods, and tools. RQ2 highlighted the minimal use of testing practices and methods, and the third RQ tried to find specific ways of using test methods. Some methods were found: software testing, software performance testing, and validation of data tests. Some further research topics were also identified. These include modifications to the embedded operating system for better performance, reliability, or fault recovery.

VI. ACKNOWLEDGMENT

This study was performed in intensive collaboration between the Tampere University of Technology (TUT) in Finland and Keio University in Japan. The survey was carried out at the TUT Pori department in December 2016.

Abstract - In this paper we evaluate the robustness of perceptual image hashing algorithms. The image hashing algorithms are often used for various objectives, such as images search and retrieval, finding similar images, finding duplicates and near-duplicates in a large collection of images, etc. In our research, we examine the image hashing algorithms for images identification on the Internet. Hence, our goal is to evaluate the most popular perceptual image hashing algorithms with the respect to ability to track and identify images on the Internet and popular social network sites. Our basic criteria for evaluation of hashing algorithms is robustness. We find a hashing algorithm robust if it can identify the original image upon visible modifications are performed, such as resizing, color and contrast change, text insertion, swirl etc. Also, we want a robust hashing algorithm to identify and track images once they get uploaded on popular social network sites such as Instagram, Facebook or Google+. To evaluate robustness of perceptual hashing algorithms, we prepared an image database and we performed various physical image modifications. To compare robustness of hashing algorithms, we computed Precision, Recall and F1 score for each competing algorithm. The obtained evaluation results strongly confirm that P-hash is the most robust perceptual hashing algorithm.

I. INTRODUCTION

The image tracking has recently become an interesting problem since a significant number of images get uploaded on various social network sites instantly. For instance, the recent statistics show that Facebook handles over 350 million image uploads each day. Once the image gets uploaded on the social network, other users and influencers share the image, modify it and upload it as their own content. In case the image becomes very popular, it is very hard to distinguish who is the original author (source) without having an insight in social network private data.

In general, it is very hard to obtain such insider statistics since social networks have very strict policy about their data. A possible approach to track images online would be to utilize steganography [1]. However, this approach is very limited due to a fact that social network usually performs image compression prior to image upload which results in all hidden data being lost. The only promising solution to track images on various social networks from outside is to utilize image hashing algorithms.

The classic hashing algorithms used in cryptography such as MD5 and SHA1 are not suitable for this purpose since their aim is to hash entities with high dispersity. This means that similar entities are very likely to hash to quite different hashes. Even small changes in input will result in completely different hash value which is a good property of cryptographic hashing algorithm. On the other hand, we need a different family of hashing algorithms that will hash similar entities to similar hashes. Generally, the hashing algorithms having such property are called locality-sensitive hashing algorithms [2] [3]. More specifically, for image entities, perceptual image hashing algorithms are used, which possess the property of invariance for “perceptually similar” media objects x and x’ [4].

In this paper, we analyze robustness property of perceptual image hashing algorithms. We consider the following algorithms: A-hash, D-hash, W-hash and P-hash. We conducted experiments in which we evaluated robustness property of mentioned image hashing algorithms. In our experiments, we measured robustness of image hashing algorithms regarding visible image modifications (1), and with the respect to images upload to popular social network sites: Facebook, Instagram and Google+ (2). To compare robustness of competing algorithms, we used well established measures: Precision, Recall and F1 score. The evaluation results obtained from conducted experiments strongly suggest that P-hash algorithm is the most successful algorithm for image identification upon visible modification is applied or image is uploaded on social network.

The rest of the paper is organized as follows. Section II presents the related work. The competing hashing algorithms are described in section III, while the evaluation is presented in section IV. Section V concludes the paper.

II. RELATED WORK

The researchers have proposed a variety of image hashing algorithms that extract popular image features (i.e. HOG, DOG, SIFT, GIST etc.) as large high-dimensional vectors which are later reduced using some dimensionality reduction technique with the aim to detect near-duplicate images. For instance, in [5], the authors extract local features based on DOG for image representation, and then use locality sensitive hashing as the core indexing structure. In [6], spectral hashing is used by performing PCA to find the principal components of the data, and then the data is fit to a multidimensional rectangle. Similar as previous, the approach proposed in [7] finds the maximum variance direction using PCA, except that the original covariance matrix gets “adjusted” by another matrix
arising from the labeled data. Instead of representing an image using a single feature vector, the approach proposed in [8] independently indexes large number of local descriptors derived from PCA-SIFT which results in approach highly resistant to occlusions and cropping. In [9], the authors use bag-of-words techniques for text analysis for creation of bag-of-visual-words using vector quantized local feature descriptors (SIFT), and they propose Min-Hash algorithm for retrieval of similar images. In addition, geometric image hashing [10] is proposed to improve standard Min-Hash by considering the spatial dependency among visual words. Further improvement over geometric Min-Hash is a hashing scheme for partial duplicate image discovery [11] i.e. finding groups of images in a large dataset that contain the same object. An interesting novel graph-based approach which automatically discovers the neighborhood structure inherent in the data is introduced in [12]. Kernelized locality sensitive hashing for scalable image search is proposed in [13]. More recent works propose deep learning frameworks to generate binary hash codes for fast image retrieval [14] [15].

All mentioned approaches are quite complex and computationally challenging since they usually create high dimensional image representation which is later reduced. However, our goal is to focus on perceptual image hashing algorithms that can produce fast image fingerprint and still preserve image identity.

III. PERCEPTUAL IMAGE HASHING ALGORITHMS

In this section, we briefly describe the following perceptual image hashing algorithms: A-hash, D-hash, P-Hash and W-hash.

A. A-Hash

Average hash (A-hash) is a perceptual image hashing algorithm that creates compact 64-bit image hashes by focusing on properties of image structure. As image is decomposed into its underlying harmonics, the higher frequencies represent image details, while the lower frequencies represent image structure. To make the image fingerprint as small as possible, the higher frequencies are eliminated by reducing the image in its size. Specifically, prior to computing the hash, the image is scaled down to an 8x8 block and it thus contains a total of 64 pixels. Each pixel is then converted to greyscale. Note that all perceptual image hashing algorithms employ this step since the essential semantic information is preserved in the luminance component of an image. Next, an average color for all 64 pixels is computed. Subsequently, the hash is constructed so that each bit representing a single pixel is set based on whether the color value of that pixel is below or above the computed image average.

B. D-Hash

Difference hash (D-hash) is a perceptual hashing algorithm that leverages image structure, much like in the A-hash approach. The hashing principle focuses on the image structure and it achieves so by reducing the image size, i.e. by removing higher frequencies from the image spectrum. Unlike in the A-hash approach where the fingerprint was computed by averaging out the pixels, the D-hash approach tracks image gradient. Prior to hashing, each image is reduced to a 9x8 block and converted to gray scale, i.e. a total of 72 pixels. Then for each row, the difference between each two adjacent pixels is computed, a total of 8 differences per row. Thus, 64 differences are computed for each image and then subsequently used to construct the fingerprint. This is done by setting each bit based on the computed difference $d$. For instance, if $d < 0$, the hash bit is set to 0, and if $d \geq 0$, the bit is set to 1.

C. P-Hash

The P-hash algorithm [4] is based on discrete cosine transformation (DCT). The algorithm produces a 64-bit length binary sequence as an image hash. First, the image is converted to a greyscale representation using its luminance. Next, a mean filter (i.e. smoothing, averaging or box filter) is applied to the image. To apply the filter, a kernel with dimension $7 \times 7$ is used. The kernel is applied using a special convolution function [4].

Once the convolution is applied, the image is resized to 32x32 pixels. To extract the hash, 64 low frequency coefficients are used except the lowest frequency coefficients are omitted. The low frequency coefficients are used because they are mostly stable under various image modifications. Moreover, most of the signal information is preserved in low frequency components of the DCT. The reason the lowest frequency coefficients are omitted is they tend to be quite different from others and can significantly throw off the average.

To produce the hash, DCT coefficients from $(1, 1)$, which is the upper left corner of 64-size matrix, to DCT coefficient $(8, 8)$, representing the lower right corner of the same matrix, are concatenated to an array of length 64. Next, the median $m$ of coefficients array is computed. Finally, the hash is transformed into a binary form using the following procedure:

$$h_{i} = \begin{cases} 0 , & \text{if } C_{i} < m \\ 1 , & \text{if } C_{i} \geq m \end{cases}$$

where $C_{i}$ is the $i^{th}$ coefficient in the constructed array, and $h$ is the $i^{th}$ bit in a 64-bit length perceptual hash.

D. W-Hash

Wavelet hash (W-hash) algorithm is a perceptual image hashing algorithm that transforms the original problem into frequency domain. Similar as P-hash, W-hash utilizes frequency domain, but instead of discrete cosine transform, W-hash uses discrete wavelet transform (DWT). Wavelet transform represents a signal using wavelet functions with different locations and scales. Wavelets are particularly well suited for the representation of signals with the aggressive change in input signal, thus resulting in smaller amount of information in the frequency domain. DWT is often used to remove redundancy in a data with highly correlated neighboring values, such as pixels in images. DWT is successfully used for noise reduction [16], image compression [17], dimensionality reduction [18], EEG analysis [19] and audio signal analysis [20]. Basic W-hash algorithm used
during the experiments works by first scaling the image followed by transformation of an image to frequency domain using the Haar wavelet (optionally removing the lowest low level frequency). Provided implementation of the W-hash algorithm is using the wavelet transform software for the Python programming language.

Due to the nature of the wavelet transformation, it is expected that W-hash will perform better on images with smaller amount of intense changes i.e. high contrast spatial data. Also, it is reasonable to assume that P-hash will perform better for images with more restrained spatial changes.

IV. EVALUATION

In this section, we evaluate the robustness of perceptual image hashing algorithms. The implementation we use is https://pypi.python.org/pypi/ImageHash. To evaluate the robustness property, we define two different experiments. In the first experiment, we evaluate the algorithms robustness with respect to various visible modifications applied to images. In the second experiment, we evaluate algorithms robustness regarding the ability to track images on the Internet. To be more specific, we uploaded, and subsequently downloaded, images on various social network sites such as: Facebook, Instagram and Google+

A. Evaluating robustness on visible image modifications

In this experiment, our goal is to check which is the most robust algorithm when considering various visible image modifications. First, we collected an image dataset containing 1480 original images. We computed a local database containing hashes for each considered image hashing algorithm: A-hash, D-hash, W-hash and P-hash. Then, we performed various image modifications for all images in the dataset. More specifically, the following image modifications were applied: resizing, rotating, noise injecting, swirling, sharpening, adding border color, contrast-stretching, colorizing, thresholding and drawing. To introduce all mentioned modifications, we used a very popular open source tool ImageMagick [21] which exposes its functionalities using Python API. The modification parameters were chosen randomly under the appropriate constraints. All together, we created an amount of 8868 modified images. We introduced the appropriate naming convention for modified images so we can easily track which is the original image used to obtain each modified image. For instance, if the original name was “100201.jpg”, for modified image obtained by resizing the original image was named “100201_resized N.jpg”, where N is the index of modification created from the respected original image.

To evaluate the sole robustness of each image hashing algorithm, we used well established measures for this purpose: precision, recall and F1 score. Precision measurement is defined as:

\[
\text{Precision} = \frac{TP}{TP + FP}
\]

where \(TP\) is the number of true positives and \(FP\) is the number of false positives. Recall measurement is defined as:

\[
\text{Recall} = \frac{TP}{TP + FN}
\]

where \(FN\) is the number of false negatives. Finally, the \(F_1\) score is defined as follows:

\[
F_1 = \frac{2 \times \text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}}
\]

Once we have the number of true positives, false positives and false negatives, we can easily compute measures for each competing hashing algorithm. To compute number of true positives, false positives and false negatives in our experiment, we try to reconstruct which is the original image, for each modified image. Specifically, for each modified image, we compute its hash. Then, we search the original images hashes database to see if the computed hash matches any of hashes in the database. To determine if the two hashes \(A\) and \(B\) are considered equal, we examine hashes’ in binary representation and we compute their Hamming distance as follows:

\[
d(A, B) = \sum |A_i - B_i|.
\]

To consider two hashes \(A\) and \(B\) equal, we require:

\[
d(A, B) \leq N,
\]

where \(N\) is a system parameter which can be tuned for each environment and each algorithm. During the evaluation, we perform the procedure depicted in Figure 1.

Knowing the ground truth based on a modified image name, and having a Hamming distance for each modified image and each original images hashes pair, we can easily figure out if some hash pair (i.e. original image hash, and modified image hash) is a true positive, false positive, true negative or false negative. We repeat the depicted procedure for each algorithm, varying the parameter \(N\) in range from 0 to 30. It should be noted that the hash size for each algorithm is 64 bits.

The precision, recall and F1 score results for algorithms A-hash, D-hash, W-hash and P-hash are depicted in Figure 1, Figure 2, Figure 5, and Figure 66, respectively. As can be seen in the figures, the most successful algorithm is P-hash, which achieves F1 score value of 0.738 at Precision value of 0.856 and Recall value of 0.649 for a distance threshold \(N = 14\). The second most successful algorithm is D-hash, which reaches F1 score value of 0.641 at Precision value of 0.641.
0.745 and Recall value of 0.563 for a distance threshold $N = 10$. The third place is reserved for A-hash algorithm, which gains $F_1$ score value of 0.406 at Precision value of 0.431 and Recall value of 0.385 for a distance threshold $N = 1$. Finally, the worst performance is obtained by W-hash algorithm, which obtains $F_1$ score value of 0.271 at Precision value of 0.249 and Recall value of 0.297 for a distance threshold $N = 0$.

As already described in the beginning of this section, the modifications introduced in this experiment setup were quite aggressive. This means that it is relatively hard to associate the original and the modified image for some examples by sole human visual inspection. Figure presents an assembled collage of some randomly chosen examples of original images (marked with yellow border), and their modifications. The modifications whose original was successfully identified using P-hash algorithm at distance threshold $N = 14$ are marked with green border, while modified images whose original could not have been discovered are marked with red border.

One could also argue the effectiveness of various algorithms depends of what the goal function is. In case the aim is finding very similar images, P-hash algorithm may be considered too tolerant to aggressive image modifications, i.e. the results will contain some images which are not similar to the original image. In this case, more appropriate choice would be A-hash algorithm which is less tolerant to visible image modifications.

B. Evaluating robustness on images uploaded on social networks

In this experiment, our goal is to analyze robustness on less aggressively modified images — images uploaded on social network sites. More specifically, in our experiment we included the following social network sites: Facebook, Instagram and Google+. It is well known that all considered sites provide users the ability to upload and share images as part of their profiles and feeds. However, while being uploaded the images are resized to dimensions dominantly used on uploading site (1), and the images are processed by jpeg compression engine which removes any irrelevant information (2). The resizing operation is quite likely to change the aspect ratio and the quality of the original image. Hence, it is likely that the image will change after being uploaded. Our goal is to determine the robustness of hashing algorithms with the respect to upload on social network sites.

We selected an amount of 150 original images from the dataset used in the previous experiment (see IV.A). Then, each image was uploaded to all considered social networks. After the upload, the images were downloaded from social networks and included to modified images dataset containing overall 450 images. In the same manner, as in the first experiment we created a database of hashes for each original image and each competing hashing algorithm. To measure the robustness for each competing algorithm, we used the same evaluation measures as in the first experiment: Precision, Recall and F1 score. Furthermore, we used the same evaluation procedure described in pseudocode in shown Fig. 1.

The results for algorithms A-hash, D-hash, W-hash and P-hash are depicted in Figure 2, Figure 3, Figure 4, and Figure 5, respectively. Same as in the first experiment, the most successful algorithm is P-hash, which achieves F1 score value of 0.864 at Precision value of 0.926 and Recall value of 0.81 for a distance threshold N = 16. The second most successful algorithm is D-hash, which reaches F1 score value of 0.846 at Precision value of 0.952 and Recall value of 0.761 for a distance threshold N = 14. D-hash is followed by A-hash algorithm, which gains F1 score value of 0.804 at Precision value of 0.974 and Recall value of 0.685 for a distance threshold N = 1. Finally, the worst performance is obtained by W-hash algorithm, which obtains F1 score value of 0.781 at Precision value of 0.886 and Recall value of 0.698 for a distance threshold N = 1.

It is obvious that all algorithms perform significantly better on social network dataset when compared to the original image modification dataset. However, this behavior is expected since some of the introduced image modifications are quite intense, and it is hard for a human observer to associate modified image with its origin.
V. CONCLUSION

In this paper, we studied robustness property of the following perceptual image hashing algorithms: A-hash, D-hash, W-hash and P-hash. To be precise, we analyze how robust image identification and tracking is with the respect to: visible physical image modifications (1), and image upload on social networks (2).

To assess robustness with the respect to visible image modifications, we created a dataset containing original images and their modifications. To evaluate robustness regarding upload on social network, we selected original images and uploaded them on the following social networks: Facebook, Instagram and Google+. To compare the performance of different algorithms, we used common measures: Precision, Recall and $F_1$ score.

The evaluation results, obtained on visible image modifications and both social networks uploaded dataset, strongly confirm that the most robust algorithm is P-hash which achieves $F_1$ score value of 0.738 on image modifications dataset, and $F_1$ score value of 0.864 on social networks uploaded dataset.

A detailed analysis of how a particular image hashing algorithm is robust with respect to a particular image modification is left for future work.

{kakanak, mshopov}@tu-plovdiv.bg

Abstract – The paper presents an example Sensor-cloud architecture that integrates security as its native ingredient. It is based on the multi-layer client-server model with separation of physical and virtual instances of sensors, gateways, application servers and data storage. It proposes the application of virtualised sensor nodes as a prerequisite for increasing security, privacy, reliability and data protection. All main concerns in Sensor-Cloud security are addressed: from secure association, authentication and authorization to privacy and data integrity and protection. The main concept is that securing the virtual instances is easier to implement, manage and audit and the only bottleneck is the physical interaction between real sensor and its virtual reflection.

I. INTRODUCTION

The wide use of intelligent devices at home, industry, transportation, medicine and education lead to new challenges in technologies of data protection, security and privacy. Many researchers and businesses search for effective and reliable way for collection of data and statistics from internet-based objects, services, people, information without crossing the border of privacy and security of the people and society. Some of the new challenges in front of the intelligent connected object consists of: secure and reliable association of autonomous devices; secure and protected communication in uncontrolled environment; trust on services, people or devices; authentication of users and connecting them to their devices, data and services without compromising their privacy. There are some solutions on the market that can be applied as RFID (Radio Frequency Identification), NFC (Near Field Communication), SSO (Single Sing-On), OAuth (Open Authentication) but none of them is widely adopted or applicable in all areas of Sensor-Cloud application. The new model of Internet which encompasses of Internet of Thing (IoT), Internet of Data, Internet of Services and Internet of People (social networks) requires a security model that address all types of instances in the architecture, the producers of intelligent devices and providers of services for them are applying different technologies to protect and secure the information but often without success or with many trade-offs. The challenge is bigger when you need to protect personal data but making it available for research and statistics. This is crucial for electronic public services as e-Health, e-Government, Intelligent Transportation Systems (ITS), Smart Home and Smart Cities.

Development and research of adaptive models for applying security and data protection could provide a base for systematic analyses and application of best practices and security techniques in variety of use cases. This could provide environment to look for general and standardized security decisions that suit the high demand of dynamic internet-based applications and smart objects.

II. RELATED WORK

A. IoT models and virtual devices

The models for development of IoT are a subject of research of many authors. Most of proposed models are based on a layered approach with varying number and varying functionality of layers. The most commonly used layers are [1, 2, 3, 4, 5]: Hardware, Middleware and Application layers.

Hardware layer (object/perception layer) – main tasks of this layer are identification of devices, interaction with environment (sensing and actuating) and data preparation. Some authors define this layer as wireless sensor network with heterogeneous devices – various interfaces and communication media and unstructured or semi-structured data [6]. Their main characteristics are limited processing and storage resources, energy constrains and autonomous living. Due to the restriction of the objects data processing on this layer is limited.

Middleware layer – the main task on this layer is reliable and secure transportation of the data from hardware layer to the data processing service or unit. It includes managing the data formats, filtering and adding context (data meaning, location, local conditions, precision, units of measurement, etc.). In common case this layer includes sub-layers – e.g. object-abstraction, service management [2] and service composition [5]. Object-abstraction sub-layer [7] could be used to announce and present the functions available on hardware layer to the upper services. In [8] and [9] such layer is called Virtualized Object (VO) and store data for current and previous states of a physical devices from the hardware layer. The main advantage of using VO as a virtual copy of a physical devices are: device and services lookup; development of mash-up measurements, integration of data sources for complex analyses, energy consumption optimization, abstracting the heterogeneity of interfaces and communication protocols, scalability [10].

National Science Fund of Bulgaria, project number E02/12

1192  MIPRO 2017/CTS
Application layer – the main task on this layer is to present and provide services and functionality to the end users. It may include some data processing, data mining, filtering, and in most cases primitives and services of data presentation and statistical analyses of the data. It should use the functions of the middle-ware to present structured and processed information to the end user based on the data from multiple sources to support decision making.

Other authors [11] discuss the benefits of using virtual sensor in sensor-cloud architecture to cope with communication heterogeneity, geographical distribution and simultaneous multi-user access. Virtual sensors provide data series as the physical ones but can easily change context and omit some physical properties (e.g. manufacturer, battery status, network address).

B. Main security issues

Most of the research on IoT security propose an application of common protection methods on common security problems focusing on communication security. This addresses important threats like: network access control, device authentication, data confidentiality and integrity, but is limited on RFID, Wireless Sensor Networks (WSN) and 6LoWPAN [12], [13].

But addressing IoT and Cloud some specific threats should be taken in mind [14]:

- Secure hardware initialization, Secure boot and OS initialization;
- Secure update and reconfiguration;
- Authorized association to networks;
- Trust between peers;
- Access control;
- Secure communication;
- Internal Data protection;
- Denial of service and energy waste.
- Depersonalization of data but keeping the context.

In [11] it is suggested that the IoT to Cloud architectures should have three main pillars of protection: trust, security and privacy. The trust should be based on: lightweight Public Key Infrastructure (PKI) or decentralized self-configuring key management; metadata to control the quality of information; novel methods for assessing trust in users, devices and data; policies to control the usage of data; and methods to assure the trust in hardware and software platforms used. Security should be integrated in the data model used but need to be expanded to provide defense to IoT specific Denial-of-Service (DoS) attacks and provide reliable security monitoring and audit. The device producers should provide security reconfiguration through all device lifecycle and even provide intelligent self-configuration. Privacy could rely on encryption but it is more appropriate to keep data minimized according to the specific use (e.g. removing user/device location if not used, removing, processing and filtering information as local as possible to reduce its leakage) and take advantage of the use of soft identities (user can use different soft identities for different applications and services) [11].

Some authors [15] suggest that IoT security should be network-based not host-based as the devices have limited resources. The proposition is to use Software defined networking (SDN) for dynamic adaptation of network security to match the application and context requirements. The reconfiguration could be managed by using hierarchical control structure with logical partitioning based on device interactions.

III. PROPOSED ARCHITECTURE

Taking in mind the benefits of using virtual devices for scalability and flexibility and considering different security issues at a different step of transferring data from devices to the Cloud and vice-versa, we propose the following architecture for integration of IoT and Cloud - “Fig. 1”.

![Device-Cloud architecture with virtual devices](image)

The device-cloud architecture is complex and comprises of many interactions which leads to many points that should be secured – devices should be securely paired to local gateway (or cloud adapter); each physical device should be securely mapped to its virtualized entity; communication from device to gateway should be protected; communication from gateway to the cloud should be protected; data in the cloud should be kept in privacy; users should be authenticated in the cloud and their access rights should be defined. None of these elements can be underestimated as the whole system is as secure as its weakest element.

The first level of protection in such architecture is based on the separation between user-to-cloud and device-to-cloud data exchange. This will significantly reduce the low level DoS attacks on the devices which is considered as one of the main issues in battery base IoT objects. The second simple additions is the use of firewall at cloud adapter gateway and every entrance point of the cloud. The third thing is keeping the device network private and secure – authentication and encrypted messages should be
used. And the last pillar of secure architecture is the simplification of communication channels – physical devices will pair only with its virtual instances. Thus, it will be easier to monitor communication and provide trust.

Nevertheless, keeping the device protected can be achieved by minimizing the communication from Cloud to it. Device can periodically request configuration and/or command from its virtual entity. In such case physical devices will not need access control as they always will be clients in communication. With one way communication the use of asymmetric encryption is possible which will increase reliability.

One specific situation must be considered – the cloud security rely on the isolation between instances but in the case of virtual devices some grouping should be considered as virtual devices often work in groups (sensor networks). If virtual devices exchange data and messages between each other, it could be done using internal sharing in the cloud. This will increase the performance but reduce isolation.

Additionally, in complex applications in the Cloud and IoT domain many services and devices from different vendors and providers could be used. In such cases chain of trust and policies for data protection should provided that spread over the whole ecosystem and allow audit and certification of security.

A. Security technologies and protocols

Such complex implementation as IoT and Cloud cannot be secured with one general protocol. On every layer of the architecture different requirements should be fulfilled – secure pairing, authorization, confidentiality, integrity, reliability, low power consumption, low processing complexity, low delay and latency, transparency and ease of use. In Table 1 some of off-the-shelf protocols and technologies in IT security are shown and mapped to appropriate layer in proposed architecture.

Devices should encompass some method for secure pairing with the gateway which can be chosen from available methods on the market: Resurrecting Duckling, WPS (WiFi Protected Setup), WCN (Windows Connect Now), exchange of patterns as in Bluetooth or existing wireless security protocols can be used. But more important is to secure the mapping between the physical and virtual device. It could be done with pre-shared keys or certificates but should be reliable and error prone as it must be done once for the whole life-cycle of the device. Even emerging services at hardware layer could be applied for establishing trust – like Near Field Communication (NFC). The security can be increased with keeping the state of the device both on its physical and virtual instance – the huge difference in states could be used as an alarm for an attack. Moreover, the mirroring of configuration and data at both instances will allow faster recovery after attack. The main drawback of existing methods for secure pairing is that they are based on some user interaction and most of them work interactively (exchange of keys, entering pins, pressing buttons, preliminary setup in vicinity, etc.) The expansion and independence of IoT devices will call for finding more pervasive methods for pairing based on some internal seamless and secure identification – something that RFID lacks.

In industrial and automotive applications the communication channel are kept private and therefore secured more easily. In IoT there is always possibility to connect through public insecure network, so data integrity, confidentiality and identification of endpoints should be provided. The public communication channels could be secured by network-based protocols as IPSec, SSL/TLS or SSH transport protocol and if it is needed the messages could be secured separately on application layer. On hardware layer this could be expanded using wireless security (WPA, 802.1X) or point to point authorization (PAP/CHAP).

For proving the identity of endpoints and defining their access rights ticket based systems could be used (Kerberos, Radius). This will allow even providing temporally access to objects and will limit the possible brute force attacks. If the chosen middle-ware is based on web services, WS-Security could be used for proving the data origin and separation of public and private parts in the messages. If the data is encoded in JSON format the endpoints could be secured using JSON Web Token (JWT). Depending on the application level protocol PGP (Pretty Goog Privacy) or S/MIME (Secure/Multipurpose Internet Mail Extensions) could be used for keeping integrity and confidentiality of messages.

<sup>a</sup> Hardware layer  
<sup>b</sup> Middleware layer  
<sup>c</sup> Application layer
The general communication between a user and a device should be limited to the connection to the virtual instance using the appropriate protection for the purpose. If a strong encryption is needed it will be easier to implement on the virtual device in the cloud than on the low-resource physical device. Removing the shortcuts from user to physical devices will reduce significantly the security requirements for the architecture and will reduce the complexity. The use of VO could be in benefit of privacy protection as different VO could be assigned to one physical device that provide only the data that is appropriate for the application which will limit the chance of data leak and privilege stealing. Each user cloud have its personal view of the device services and parameters implementing Senor-as-a-service or Sensing-as-a-service paradigm.

No matter what security protocols and technologies are applied the best practices in complex security systems as IoT and Cloud are relying on regular monitoring and vulnerability checks [16]. The issue is that in such complex systems the monitoring of the security is a BigData task which is complex by itself.

IV. CONCLUSION

The integration of smart devices and data services to internet has lead to new security requirements that need new adaptive decisions. In such systems many aspects of security should be taken in mind from secure association via data protection and depersonalization to reliable authentication and authorization. The proposed architecture should provide application of security at each level will provide flexibility and scalability and will allow provision of security needs at design level.

The application of security at design level will fasten the integration of important new systems as intelligent transportation, public e-services, smart home, smart grid, e-health and so on.

The development of proposed model and architecture could lead to direct integration of security best practices in areas like:

- e-Health and m-Health and especially in Personal Health-care Systems and Clinical Information Systems and Ambient Assistance Living for elder people;
- Energy consumption monitoring and control in Smart Home and Smart Grid systems;
- Intelligent Transportation systems for smart railway, smart city and autonomous automobiles.

Some performance benchmarks could be made to evaluate the prefab security protocol for each practical implementation and test bed experiments could be carried out to compare performance

Making a Smart City Even More Intelligent
Using Emergent Property Methodology

andrej.saric@croatia.rit.edu, branko.mihaljevic@croatia.rit.edu, kristina.marasovic@croatia.rit.edu

Abstract - With the emergence of IoT (Internet of Things) smart cities have assumed a crucial role in providing intelligent services in real time to residents and visitors, by integrating services such as smart transportation, smart parking and smart people management. By introducing emergent properties as the system's new behaviors or new structures, the system gains another higher level of intelligence that cannot be derived from its underlying substructures individually. In this paper we propose a new model for introducing emergent properties by integrating existing smart city subsystems which are already in use in the city of Dubrovnik, Croatia. The article starts with an overview of the smart city technologies and emerging property methodology. The existing smart city subsystems are explained along with their integration within emergent properties model. The paper concludes with our findings and recommendations, open issues and future research possibilities.

I. INTRODUCTION

With rapid evolution of computing and technology, and increased communication using modern devices like smartphones, people started a new way of life through constant connectivity and ubiquitous computing. Aside from enabling people to use their smart devices anywhere and anytime, most important change happened in the universal, continuous and omnipresent connectivity. Evolution of pervasive technologies enabled ubiquitous computing-based connectivity such as connecting people to various systems and accompanying information gathered from numerous heterogeneous Internet of Things (IoT) devices as data sources.

This shift to constant connectivity provides even more data for an even better analysis. Ability to use such data in real-time analysis and prediction allowed to discover correlation within the data to control the system in real-time, and avoid undesirable conditions. As with all emerging technologies, these too have found their way to the place where people mostly live – cities.

Cities are becoming overpopulated, having a negative impact on the citizens' quality of life. To provide citizens with better services, a smart city, as a new way of managing city's assets and services, could prove to be quite useful for this type of urban environment. By integrating modern technologies such as IoT into an existing municipal infrastructure and services, improvements can be made towards expansion, sustainability and budget saving. Connecting various IoT devices to smart city background services and subsystems we can achieve a network-shaped smart city system that can later lead towards a fully integrated smart city.

In this paper we introduce emergent property methodology as the system's new behavior along with additional structures that help the system achieve a higher level of intelligence. This new approach enables the smart city an ease of integration with other services such as smart transportation, smart parking system and smart people management. Through predefined protocols, procedures and standards, data exchange across all integrated subsystems is being made possible. This architecture is flexible and allows for any future extension which may include integrating additional subsystems with new services and features.

The remainder of this paper is organized as follows. Section 2 introduces smart cities, and explains the driving force behind this concept. Section 3 describes what emergent property is and how it is applied to different software solutions, in particular to smart city subsystems. Section 4 presents an overview of existing smart city services and subsystems found in the city of Dubrovnik, Croatia, along with the technical specifications, concerns and possibilities for improvement. Section 5 discusses possible changes and adaptions of the existing smart city subsystems to introduce and apply the emergent property methodology. Section 6 concludes the paper with our findings, recommendations, open issues and future research possibilities.

II. SMART CITIES

With more than half of the world’s population living in cities and constant growth there is a need to find new ways of improving cities to become more efficient while providing citizens with better services in the areas of mobility, energy, building and home infrastructure, transparency, public services and others. The popular term "smart city" appeared almost two decades ago [1], however, its definition, meaning and understanding varies according to context, problem domains and used technologies. A more recent survey of smart city research and literature could be found in [2][3].

To make necessary changes to implement smart city concept older cities need to be redesigned starting with their infrastructure to allow easy integration of IoT and various sensors, as well as new information and communications technology (ICT) based services. Newer
cities need to be designed with smart city concept in mind from the start, which consequently allows easier integration of overall ICT infrastructure and IoT devices.

By making people conscious of this smart city implementation options and by introducing them to overall smart city concept there will be valuable feedback that will help in building and designing new services that will improve governance, transparency and efficiency. To achieve all of this investments need to be made in public city infrastructure, ICT services and their integration, as well as increasing public awareness about advantages and benefits of living in a smart city.

With the emergence of the new IoT market which has enabled smart cities to easily integrate new services using these production-ready platforms and associated IoT devices [4]. Smart cities can also aim towards building completely new smart city systems which will be based on selected IoT platforms, subsystems and technologies. To build smart city IoT system a city needs to invest into infrastructure and hardware, which is usually consisting of various sensors and other control smart devices integrated together with supported with backend servers or cloud, which will both collect data from the environment and consequently trigger appropriate actions. Since any such system will highly rely on connectivity, which is usually smart devices and sensors sending and receiving data over the cloud, second step should be implementation of standardized protocols and format for data transfer and storage. Final step is achieved through implementation of various software, which will analyze the data collected from the sensors and use internal decision making subsystem to instruct other smart devices to initiate actions based on decisions made. Software should be also responsible for providing monitoring dashboards and control interfaces with integrated statistics and analytics, where administrators will have access to real-time graphically presented data and easy to use management controls, while public might have access to client apps mostly used for information dissemination.

III. EMERGENT PROPERTIES

Concept of emergent properties occurs in many different areas; most prominent ones would be philosophy and biology but it can also be applied on software system designs. There are many definitions about what emergent properties are and more about it can be found in [5]. In a nutshell, emergent properties are properties that some complex system has but its individual components such as underlying modules and subsystems do not have. Emergent properties concept can be easily extended to software development [6] and implemented in software design and architecture. In this paper we are introducing emergent properties as new behaviors that add value to the existing smart city systems and overall whole smart city platform.

IV. SMART CITY SUBSYSTEMS

Smart city is composed of multiple services which are in fact specific subsystems. These subsystems provide services which can be directly consumed by citizens or used by city officials. These systems focus on domains such as public services, mobility, energy, buildings, etc. In this section we will present some of the smart city subsystems already implemented in the city of Dubrovnik.

A. Smart Parking System

Smart Parking System [7] (Fig. 1) is a complete smart city solution developed a year ago with the goal to be easily replicable and installable to any location that has GSM network coverage. Solution is cloud based which makes it fully scalable and it makes no difference if the system implementation happens on one parking lot in a small city or many parking lots in a metropolis. Hardware part of this solution is composed of battery-powered infrared wireless sensors that are designed to be easily placed on each parking spot. Their installation is simple and fast, which is an advantage compared to some other implemented solutions which require extensive construction work as well as power and communication lines. These sensors communicate and send data to the router using standard HTTP [8] and MQTT protocol [9]. They come with multiple useful features such as:

- Network reconfiguration in case of router failure
- Automatic registration and network configuration of newly added sensors
- Error states and malfunction reports are sent using same channel to simplify maintenance and diagnostics

Figure 1. Smart Parking System overview

Technological stack used in the system is PHP for server and Angular (Version 2) in TypeScript with Bootstrap 4 for web interface.
1) Sensor Node for Smart Parking System

Sensor node (Fig. 2) is a device which main task is car detection so that it can provide information whether the parking spot is vacant or not. Every single sensor contains the information about current status of the parking spot. The main goal of every sensor node is to send information to the router as fast as possible over HTTP using MQTT. HTTP usage is based on common REST API and MQTT is using standard publish/subscribe pattern which enables other clients to subscribe to publishers. All sensor nodes are wireless, which allows to easily install them onto parking spots, and battery-powered with battery life expectancy estimated to three or more years.

Figure 2. Sensor node for Smart Parking System

2) Routers and Server for Smart Parking System

Router (Fig. 3) uses two communication methods; one to get information about parking spot vacancy, which is retrieved from sensor nodes, and second method using wireless network to forward information to the server in the cloud.

Server gathers information from routers over wireless network for every single sensor node using its id, GPS location and other available information, and it is responsible for saving their current state in the database. All states are stored in the relational database so that we could use that data for statistics, analytics and overviews.

3) Software and User Interface

Solution comes with a publicly available web site that has an integrated interactive map which presents current state of a parking lots in terms of vacant and non-vacant spots. Mobile applications are implemented for both iOS and Android devices (Fig. 4) that show to end users the information about current state of the parking lot. Mobile applications are also used to gather usage data for analytics.

An administrator's web-based dashboard is used for monitoring the system and its components, and it provides important control functionalities such as remotely resetting or enabling and disabling sensor nodes.

Figure 3. Router for Smart Parking System

Figure 4. Smart Parking Mobile Application user interface

4) Possibilities for improvement

This system relies on network reliability to send and receive data so going towards edge and fog computing might be one of the largest improvements. More about fog and edge computing can be found in [10]. Other improvements can be made in the area of features towards end users and data collection. Suggested improvements include but are not limited to:

- Integrating fog and edge computing into the system.
- Providing a hotspot with internet connection to end users which would allow more information gathering about end users and application usage.
- Parking spot reservation which would allow users to block entrance to a parking spot using mobile application.
- Payment system that will be fully integrated with mobile applications.
B. People Counter System

People Counter System (Fig. 5) is a smart city solution that was motivated by the need of solving the problem of too many people visiting the Old City of Dubrovnik and the main street – Stradun. To fully resolve the problem this solution must be dependent on full integration with smart city platform and other smart city subsystems. Solution is composed of both hardware and software parts; hardware part of this solution are Hikvision cameras that are installed on five locations around the Old City of Dubrovnik area. All designated camera locations are on entrances to the Old City and the primary goal of this solution is being able to count the number of people (visitors) in that area in real-time. Technology stack used by the system is as follows; server is developed using ASP.NET Core in C# and web interface using Angular (Version 2) in TypeScript with Bootstrap 4. Solution is deployed on Windows Azure Web service using three slots: development, staging and production.

1) Cameras for People Counter System

Since all cameras used are network-based cameras, once they are installed they need constant and reliable network access used to transfer the data. Providing cameras with the network and power cables needs construction work upon the installation and can extend the development process. These cameras have already implemented people counting capabilities which are currently used to count how many people enter and exit the area of Old City. All cameras are located at all possible entrances to this area at the position and angle that allows them to give precise data about entrances and exits of visitors.

2) Server for People Counter System

Server gathers information from the cameras and stores it into a relational database. Information that is gathered provides an overview of real time situation in that area, as well as statistics and analytics for different time ranges.

3) Software and User Interface

Solution is initially integrated with public website that provides information about current status and number of visitors in the Old City of Dubrovnik. Public website also provides more detailed view for every single camera and statistics dating back to one week. Aside from public website, solution provides administrator dashboard which contains more information about current status in the Old City area, including single camera information and management with exact count of entrances and exits for that area (Fig. 6), "heat maps" showing current situation and which of the entrances is most commonly used to enter or to exit the Old City area (Fig. 7), and general statistics for overall readings.

4) Possibilities for improvement

Improvements that can be done in this subsystem focus on hardware and data gathering which would enable achieving better and more precise data, which can later be used in other subsystems of smart city. Some of the improvements include but are not limited to:
• Using wireless cameras so that maintenance is easier and with less construction work on the Old City walls when installing.
• More cameras on "hot spot" locations in the city which would help in tracking movements and finding movement patterns.
• Integration with other smart city subsystems to provide better pattern recognition and possible traffic and movements predictions.

V. ADOPTION OF EMERGENT PROPERTY METHODOLOGY

In the previous sections already implemented services and smart city subsystems were discussed and we propose how to adopt emergent property methodology through already existing subsystems and integrate it into new overall smart city system.

Emergent property methodology is derived from the concept of emergent properties and its integration in software design and architecture [6], [11]. This methodology enables better testability of subsystems as individual components of a larger system, exploration of new possibilities and features that can be achieved through the emergence.

To achieve this, we propose a smart city framework and platform that allows multi-subsystem integration. The smart city platform is a top-level system into which all other subsystems integrate and where we have emergent properties developed as new services, which weren’t possible to implement before. This smart city platform system implementation is in test in the city of Dubrovnik, using its already implemented smart city subsystems, as discussed in previous section. Those are used to explain integration in smart city framework and introduction of emergent properties.

Our smart city platform proposal is using as a cloud-based servers that have two ways of providing integration for subsystems via Deep linking or Superficial linking. Deep linking assumes that platform hosts the database, server and backend of a whole subsystem, while Superficial linking presumes that subsystems will be deployed externally.

Every smart city subsystem needs to be able to collect and store data, share that data with the platform and have control commands. Smart city framework defines generic standardized inputs and outputs needed for every subsystem integration, together with protocols and procedures that subsystems need to adhere to.

Smart city framework’s core components are:
• Schema that allows edge computing on devices and parsing libraries, and
• Support for various data interchange formats and transfer protocols.

Schema brings the logic down to the smart IoT devices and defines device’s sensors, readings and controls, which enables easy device-client configuration. Client apps are able to read schema and request data from the device, thus knowing which sensors and mapping for data is used. This enables flexibility and allows clients to connect and parse readings from any device that adheres to this standard without previously knowing device’s sensor and data mapping.

Data interchange formats that are supported by the framework are JSON and XML based; JSON is supported because it is widely used today and XML because of legacy systems that still use it and want to integrate with the platform. Transfer protocols supported are HTTP [8] and MQTT [9]; we use REST-enabled services for platform-subsystem communication and lightweight MQTT [12] to leverage almost instantaneous message publish and topic subscribe, which is crucial for IoT systems that have critical performance and need to be deployed on any kind of network.

First step in adopting smart city framework is having all devices use schema to map their controls, sensors and readings. The next step is using framework parsers on server or in client apps to read schema and data from devices. Once the subsystem is able to communicate with devices it needs to adopt REST service that will enable smart city platform connection and data transfer. Upon successful integration of subsystems smart city platform achieves emergent property methodology environment. Because of multiple integrations and different data sources smart city platform provides three data categories:
• Paid Data – data that can be used if paid
• Private Data – internal data, only accessible to administrator and city officials
• Open Data – data that is free to use for public

These data categories are crucial for achieving emerging properties, and depending on integrations within the platform we can develop different systems and services emerging from it.

A. Smart City use case example

Smart City use case example is based on previously implemented subsystems in city of Dubrovnik and we are presenting how each of this subsystems is able to adopt the smart city framework by adhering to its standards.

Smart parking subsystem implements schema to map different sensors and controls needed for smart devices to operate. This enables server to parse the schema and receive the data from devices. In the long run this will prove crucial if changes to the smart devices are made or additional IoT sensors are added, because by updating the schema server is able to parse new data from devices without any additional mediation needed. Smart devices implement MQTT to send data to the router, and router implements HTTP to forward the data to the server in the cloud. Server implements REST API needed for integration to the smart city platform and gives access to subsystem’s data.

People counter subsystem’s communication protocol for cameras is HTTP because performance is not critical. Subsystem integrates with the smart city platform through REST API and shares its data with it. However, this subsystem varies from some standards needed to fully adopt the smart city framework. Since this subsystem uses
commercial cameras unable to adopt dynamic schema mapping, subsystem implements static schema saved on the server. For example, if changes are made to just a couple of devices, server will still use local schema that will not be retrieved and updated for every individual device.

Both of these systems collect different kinds of data from accompanying applications. Smart parking subsystem data includes the location and time of the day, collected from users when they using the mobile application to find available parking spot. Additionally, parking spot related data includes timeframes when with most frequent changes in vacancy, which can be used to find patterns and predict traffic increase. Data collected by people counter subsystem includes current number of people in the Old City area, as well as which entrances are mostly used to enter and exit. Based on this information system can limit the number of people entering the Old City area and predict which locations will have big influx of people.

B. New emergent services

Before abovementioned integration to smart city system all of this data was confined within its own subsystem, therefore having limited use. Once the subsystems integration will be totally completed and data will be collected and analyzed, system will be able to create data categories from which we can easily create new emerging services. For example, emerging services that we can develop are People management subsystem and Traffic management subsystem.

People management system comes from data collected by cameras in People Counter System and mobile applications from Smart Parking System, which can be used to direct people to different streets, exits and entrances to avoid overcrowding and traffic jams.

Traffic management system includes public transportation such as buses and taxies and allows control over possible paths, i.e. when to enable passage for taxies and buses towards the Old City. This system will use parking spot data about vacancy of public transportation parking spots. It will be used to inform when there are vacant spots for taxies and buses to stop. It will be used in conjunction with data from People Counter System to know when there is a lot of people leaving the Old City so that number of buses and taxies can be increased without creating traffic jams.

VI. CONCLUSION

It is important to stress that this research and smart city platform and framework proposal would not be able without previous implementation of smart city subsystems in the city of Dubrovnik, Croatia. This research has proved to be successful based on results achieved through smart subsystems integration into the smart city platform. Authors believe that they have proved the achievability of Emergent Property Methodology in a smart city system using smart city platform and framework to easily integrate its subsystems. Future research will focus on how new technologies influence on already implemented architecture and possible improvements in areas of security and reliability in smart city subsystems.

ACKNOWLEDGMENT

This research was supported by City of Dubrovnik and DURA City of Dubrovnik Development Agency.

Abstract—This paper addresses a novel concept of digital chess board realized with an array of Hall-Effect sensors. Main task of digital chess board is autonomous detection of player’s moves. Therefore, players do not have to write down their own moves on a sheet of paper. Non-invasive piece moves detection is considered, with minimum required installations in a game room. The digital chess board presented in this paper has a Hall-Effect sensor placed under the middle of each field on the chess board, while each chess piece has a permanent magnet placed on its bottom. Sensors, total of 64, are organized as 8x8 array. Microcontroller reads sensor data and sends them to a remote PC for storage in a database and board visualization. Rows are multiplexed in time, i.e. one row is active in a certain time instance. States in the column of the currently active row are stored in a corresponding matrix column. Con to this approach is in its ability to detect piece presence on the field, without the information about the piece type. The proposed approach is low cost, non-invasive and requires only power and communication cable.

I. INTRODUCTION

Development of computer science and technology advances are followed by integration of new technologies into social games, and chess is one of them. First aspirations were focused on creating a computer system that can beat the chess Grandmaster. One of the most famous chess games, which marked a milestone in the pursuit of creating a superior chess computer system is a chess game between, at that time the world’s best chess player, Garry Kasparov and IBM supercomputer Deep Blue in 1997. Deep Blue defeated Kasparov and became the first computer which defeated world chess champion [1]. With further development of computer technology, there is a remaining tendency of creating new algorithms for chess playing and chess learning. On the other hand, there is a need for automation of chess game itself and developing possibilities of remote access and control. A novel approach is an implementation of Hall-effect sensors for detecting the presence of chess pieces and getting access to a current position on a chess board, cf. Fig. 1.

Figure 1. Digital chess board with: 64 Hall-effect sensors placed under each field, PC communication and power cables.

II. RELATED WORK

In recent years, many papers and projects are published about computers and chess. Chess playing combine elements of artificial intelligence for player’s move decision, computer vision and robotics for position detection and performing a movement of pieces. Considering developments in computer vision, numerous papers are published in the field of recognition and detection of chess pieces. Despite that, some of the papers are published with the aim to improve automation of the game. This allows playing against computer in real world, playing from remote location and improving playing possibilities for people with disabilities.

Usually, camera-based systems for visual inspection require adequate and constant level of light source without shadows from surrounding objects. Therefore, overhead camera is used in [2] with ambient lightning to detect player’s moves. Human and chess piece shadows caused difficulties in moves detection. Lighting source was adjusted so that each white piece does not have a black shadow. Specular reflection from pieces is removed with image filtering. Like a chess game, Janggi chess board detection under severe conditions in camera point of view is described in [3]. Using Hough transform, Harris corner detection and Canny edge detection, Janggi chess board and pieces are detected. Piece detection problem is relaxed in Janggi chess due to smaller piece heights and less lines hidden with pieces. Another camera-based approach is presented in [4] where authors created multimodal interface for making chess moves. Using a stereo camera and difference in image entropy, hand gestures are detected and translated to chess moves.
One approach in detection of chess position is detection based on player's hand movement (not piece's). Authors in [5] realized their project named "Hand-Motion Chess" using gloves with sensors and a microcontroller. Hand gestures are detected with sensors and are translated into chess move. This approach can be implemented in creating universal equipment (glove) which could detect chess moves regardless of variations in size and color of pieces and chess board.

Due to rapid development of commercial robotic arms, accessibility to this technology is increasing. Numerous projects were made with educational purposes on moving chess pieces around the chess board using robotic arm. Authors in [6] presents autonomous chess playing system based on robotic manipulator arm. Fully autonomous chess playing robot "MarineBlue" is presented in [7]. It combines elements of computer vision, chess engine and robot control. Authors in [8] implemented detection of chess pieces using Reed sensors that are triggered by the magnetic field from permanent magnet placed on the bottom of each piece. Computer Numerical Control (CNC) machine with 2D Cartesian coordinate system is used for moving chess pieces around the board. Interactive chess board is presented in [9]. It detects player's move based on 8x8 membrane keypad, and makes its own move using 2D CNC machine. The idea behind proposed approach is to enable players to play chess over the internet on a real chess board. Thus, when player makes a move on his board, chess piece moves on another board, keeping synchronized positions between boards.

A commercial product commonly used in FIDE chess tournaments is digital chess board named "DGT e-Board" [10]. The board is using passive LC-circuits with ferit core in pieces with active LC-circuit in each chess field [11]. Passive LC-circuits are induced with active LC-circuit and resonant frequency is measured. However, development of digital chess board using Hall-effect sensors is an approach for educational purposes because of relatively low price and simplicity of assembling.

III. DEVELOPMENT OF CHESS BOARD

This section describes the main components of the digital chess board proposed in this work. The board consists of embedded microcontroller system for detection of chess pieces, chess pieces with integrated permanent magnets and acrylic board with printed wooden chess board image. System for detection of chess pieces is connected to a PC with a USB cable.

A. Chess Board and Chess Pieces

Chess is a game that is usually played on wooden chess board with corresponding pieces. That is not an explicit rule, but more a part of tradition of a chess game. Chess is a two-player game, where each player has 16 chess pieces: 8 pawns, 2 rooks, 2 bishops, 2 knights, 1 queen and 1 king. The game is played on board with 8x8 (64) chess fields (32 black and 32 white) [12]. According to the World Chess Federation (FIDE) official width of each chess field is ranging from 5 to 6 cm [13]. To make a digital chess board applicable for real tournaments, a width of 5 cm is used in this work. The total dimensions of the digital chessboard are 52x52 cm, of which 40x40 cm goes for chess fields and 6 cm for borders. In the bottom part of each chess piece two permanent are placed. Magnets diameter is 10 mm, with height 2 mm. Experimental testing of 3 and 5 mm acrylic board thickness showed that both are good for detection of magnetic field. Due to better mechanical properties, 5 mm acrylic board is used.

B. Microcontroller System for Chess Position Detection

The system for detection of chess pieces is consisted with platform Arduino Nano platform, a set of 64 A3144 Hall-effect sensors and 5V power supply. Additional power supply is involved since the overall current consumption is 100 mA per pin, while the maximum is 40 mA. Connecting a single Hall-effect sensor A3144 requires one 10kΩ pull up resistor per pin, cf. Fig 3.

Figure 2. Dimensions of the board

Figure 3. Connecting Hall-effect sensor to row and column of an array.

Printed Circuit Board (PCB) is made for detection of chess position method proposed in this work. Electronic scheme of designed PCB is presented, cf. Fig 4, as well as the final look of the board, cf. Fig. 5.

Internal pull-up resistors, which ATmega328p microcontroller has, can't be used since 8 sensors in a row require more power per pin than available. P-channel MOSFET transistors are used to activate each row with
5V power supply. Total of 4 dual-transistor ICs APM4953 are used with 10kΩ pull up resistors, cf. Fig 4.

![Electronic scheme of proposed system for chess position detection.](image)

**Figure 4.** Electronic scheme of proposed system for chess position detection.

**C. Programming Microcontroller**

Serial communication (UART) is used as a communication protocol between a microcontroller and a PC. Communication is done in two directions, in a master (PC) and slave (microcontroller) fashion. Firstly, master is requesting data from slave by sending request character "R". Subsequently, slave collects data from sensors and responds with 8 bytes of data, where each bit corresponds to an occupied (1) or free (0) field, cf. Fig 6.

![Designed Printed Circuit Board (PCB): bottom layer (left); top layer (right).](image)

**Figure 5.** Designed Printed Circuit Board (PCB): bottom layer (left); top layer (right).

Microcontroller (slave) is programmed to receive states from 64 sensors and send data to a PC. Due to a limited number of input and output pins, an array of 64 sensors is multiplexed [14]. Multiplexing is done row-wise, meaning that at one time instance only one row is active. Columns are active all the time and states from entire row can be read. In this way, 8x8 binary matrix is reconstructed, where 1 (0) corresponds to an occupied (free) field.

![Flowchart of Arduino code](image)

**Figure 6.** Flowchart of Arduino code

**D. Player's Move Detection**

Algorithm for player's move detection is done on a PC. It is based on a difference between two subsequently received binary matrices. Proposed method compares the currently received and previously received matrix. Difference between the two is calculated with

\[
\Delta M(x, y) = M(x, y, n) - M(x, y, n - 1),
\]

where \(x\) and \(y\) are denoting chess field index, ranging from 1 to 8, respectively, \(n\) is the current time instance and \(n - 1\) is the previous time instance.

In the case when there are no changes on the chess board (no moves), 8x8 matrix \(\Delta M\) is a zero matrix, cf. eq. (1). On the other side, when a player starts a move, one must take a chess piece and lift it up and away from the chess board field. Moving the piece from the field will be detected at a corresponding \(x, y\) location, and a value -1 is assigned to \(\Delta M(x, y)\). The first occurrence of value -1 in \(\Delta M(x, y)\) denotes either a moving chess piece or taking chess piece. Distinction between the two is done by knowing the player's color. If a piece's color corresponds to player's color, it is a moving chess piece, otherwise it is a taken chess piece. Taken chess piece is removed from the board. Finally, when a value +1 appears in \(\Delta M(x, y)\) it denotes a destination location of a moving chess piece. Commonly used algebraic chess notation is used for tracking chess moves [12].

**E. Visualizing the Game of Chess**

Instead of using an open-source chess Graphical User Interface (GUI) (Winboard, Stoßkötch, GNU Chess, etc.), our own GUI is made for educational purpose and further
developed. Chess programs. GUI is done on a PC and is integrated with the logic described in Section III. D. When the chess board position is set, GUI requires an information about it. Therefore, a user can set-up an initial position by a button click, cf. Fig. 7. Chess positions, beside initial position, must be manually synchronized in a GUI to start from a desired position.

![Chess game Graphical User Interface (GUI).](image)

Figure 7. Chess game Graphical User Interface (GUI).

F. Performance analysis

Proposed approach is incrementally reconstructing a chess game by recognizing each move independently. In this paper, a chess move is recognized by detecting presence or absence of a chess piece. Limitations of proposed approach are in terms of inability to reconstruct starting chess position without a user interaction. Except starting position, the user interacts in pawn promotions. One can choose to automatically promote to queen, or to manually set each promotion. However, even if the chess board position could detect piece's type and color, it would still require the following inputs from the user: possibilities of the chess position: side to move, allowed castling moves, allowed en-passant move, piece move counter without taking (required for a 50-move rule) [12].

If the program fails to recognize one move, following moves will also be incorrect. Therefore, a user interaction is required to correct a false move detection. An experiment is done to objectively express. Total of 50 trials for every type of chess move is tested and illustrated in Table 1. Moves are made on an empty and occupied, respectively.

IV. CONCLUSION AND FUTURE WORK

Chess remains a popular domain for experimenting in the field of robotics, computer vision and artificial intelligence. This paper gives an overview of the design and implementation of an autonomous digital chess board. Proposed approach combines low-cost elements with an array of Hall-effect sensors controlled by a microcontroller. Con to proposed approach is in possibility to detect only piece presence and not its type and color. Also, false move detection requires a user interaction to correct misdetections.

In the future, we intend to improve robustness of proposed system by considering better wiring and improved noise resistance in hardware and software, respectively.

Abstract—Mobile robots are becoming ubiquitous, with applications which usually include a degree of autonomy. However, due to uncertain and dynamic nature of operational environment, algorithms for autonomous operation might fail. In order to assist the robot, the human operator might need to take control over the robot from remote location. In order to efficiently and safely teleoperate the robot, the operator has to have high degree of situational awareness. This can be achieved with appropriate human-computer interface (HCI), so that the remote environment model constructed with sensor data is presented at appropriate time, and that robot commands can be issued intuitively and easily. In the research, influence of HCI elements on performance of teleoperated mobile robot was studied for several tasks and with several HCI setups. The user study was performed, in which accuracy and speed of completion of given tasks were measured on a real robot. Statistical analysis was performed in order to identify possible setup dependencies. It showed that, in majority of analysed cases and based on introduced metrics, there is no significant difference between the setups, and between the visual control and teleoperation. Finally, conclusions were drawn with emphasis on benefits of information technology in particular case.

I. INTRODUCTION

Mobile robots are becoming more popular for various applications in everyday life \cite{1, 2, 3}. The robots usually have a certain degree of autonomy while performing their tasks. However, occasionally it is necessary that the operator takes control over the robot, usually from remote location, either because robot’s algorithms for autonomous operation failed or in order to complete a task that robot cannot complete during autonomous operation.

For efficient teleoperation of the robot, the operator must be well aware of robot’s state and state of its environment. This is often referred to as situational awareness \cite{4}. Situational awareness is understanding of the conditions of dynamic environment and is defined as “\textit{The perception of the elements in the environment within a volume of time and space, the comprehension of their meaning, and the projection of their status in the near future.}” \cite{5}. When interacting with a robot, it is also required that the operator is aware of the consequences of the robot’s actions both for the robot and for the operational environment. Hence, high degree of situational awareness is of great importance because it is a prerequisite for the efficient and safe teleoperation. This in turn can be achieved with appropriate and efficient design of HCI which should present all necessary information about the robot, it’s state and the state of the environment. The interface should be designed in a way that it offloads some of the workload from the operator and makes robot control easy and intuitive.

For the purpose of this research, safe navigation is defined as one with minimal (preferably zero) collisions with objects from the robot’s operational environment. This is not always a trivial task due to dynamic and uncertain nature of the robot’s environment, which is made more difficult by implementation of teleoperation control. Given only live video information from a camera mounted on the robot, operator is usually not sufficiently aware of the state of the robot’s environment, especially robot’s distance to obstacles (lack of depth perception), and possible nearby obstacles (camera’s limited field-of-view). Therefore, some additional data must be provided to improve the operator’s awareness. This can be achieved by using different sensing modalities like infrared, ultrasound or laser-based proximity sensors, RGB-D cameras, panospheric cameras, or usage of multiple cameras mounted on the robot. Additional information that is often included in navigation tasks, which provides limited amount of data, is the environment map. It can be a helpful aid, since the operator may determine robot’s pose within environment at any time during navigation, as well as provide approximate information about proximity of (static) obstacles, and can be used as a reference.

The manner in which information from sensing devices is presented to the operator also affects performance of teleoperation \cite{6}. Graphical interfaces containing multiple information fused in one frame (a form of augmented reality) were shown to be more efficient than arrangement when they were presented in multiple frames, side-by-side. Additional element that can influence operator’s performance in teleoperation tasks is choice of HCI, which is considered as means for communication and interaction between the human and computer \cite{7}. Choosing efficient HCI is a challenging task and may not be unique for different operators, because it may depend on operators’ level of training \cite{8}. Studies showed that virtual reality (VR) approach to teleoperation of robots is possible as a way to enhance both display and situation awareness \cite{9}. Additional benefit of virtual reality is that safe training of operator in teleoperation can be achieved.

Another important variable that needs to be addressed is time (network) delay. It is well known that teleoperation is affected by latency, that may have a significant impact on
Teleoperation performance [10]. High time delay can make teleoperation impossible regardless of quality of HCI, while variable time delay (which is frequent in practical applications) can contribute further to degradation of performance in teleoperation. The sources of delay are various, and include both network delays and processing and sensing delays. The impact of time delay on teleoperation performance is not studied in this paper, but is only recorded and reported. This means that it changed freely, but due to dedicated network equipment used in the experiment is kept as low as possible.

Teleoperation of a mobile robots has been extensively studied topic and various and innovative approaches have been proposed recently. In [11], various aspects of newly proposed ecological 3D interfaces are compared to traditional 2D interfaces, while in [12] different control interfaces (including virtual reality based ones) are compared in order to assess impact on operator’s performance. In [13], a haptic interface is proposed for teleoperation of mobile robots. However, to our best knowledge, majority of research on teleoperation was done in simulations [6], [11], [10]. In the paper we present a study of teleoperation that was performed on a real mobile robot, and draw conclusions based on it.

The rest of the paper is structured as follows. In Section 2 experimental design and setup are explained and used analysis tools are briefly presented. Section 3 presents obtained results as well as associated discussion, while in Section 4 conclusions are drawn and possible future research directions discussed.

II. MATERIALS AND METHODS

A. Experimental Design

The experiment was designed as a between-subject user study where each participant had to complete set of four tasks using one of four setup designs. One variable was input method which had two levels: gamepad (joystick) and steering wheel. Second variable was graphical interface elements, again with two levels: with and without depth information. This resulted in 2x2 design setup. Besides depth information, both graphical interfaces included live video from robot-mounted camera and map of the location with robot model localized within it.

The user study was performed with 32 test subjects, 8 in each of four setups: gamepad + GUI (Graphical User Interface) without depth, gamepad + GUI with depth, steering wheel + GUI without depth and steering wheel + GUI with depth. Participants were all volunteers recruited from Faculty staff and students which gave informed consent for participation in the study. Summary of participants’ demographics are presented in Table I.

The experiments were performed using Turtlebot 2, differential drive mobile robot, depicted in Fig. 1. Developed software support was based on Robot Operating System (ROS) [14]. The robot was equipped with a laptop, running Ubuntu 14.04 with ROS Indigo (which was used as a ROS master), live camera and 3D Kinect sensor with 640 px × 480 px resolution and 30 fps for both camera and depth streams.

The communication between the robot and the PC on which experiment was conducted was based on dedicated IEEE 802.11n wireless network. On robot’s side, Asus RT-N12+ wireless router was used, while on PC side, running Ubuntu 16.04 and ROS Kinetic, TP-Link TP-WN722N USB wireless antenna was used. This setup ensured robot range of about 25 m radius (in non-ideal, out-of-line-of-sight conditions). The setup is depicted in Fig. 1. Robot’s base ROS node (used for robot control) and Kinect driver for capturing both live camera and depth data were running on robot’s laptop, while control interface driver, map (localization) and depth information interpreter (if used) were running on a PC.

The map of the environment (Fig. 2) in which the experiments were conducted was also provided to the test subjects, with robot’s location visible on it in the real time. The map itself was built prior to the experiments using LIDAR sensor mounted on another (in-house built) robot and ROS package gmapping, which is based on [15]. More advanced robot was used for mapping due to better odometry and depth sensors, which resulted in more precise environment map.

All test subjects were given 10 minutes before the experiments to get familiar with the system and to try controlling the robot (both visually and in teleoperation mode).

Fig. 3. Control interfaces used in the experiment

(a) Gamepad
(b) Steering wheel

1) Control Interfaces: All control interfaces used in the experiment were programmed so that the operator could use holonomic or differential control mode and could easily switch between them (if needed). Also, all interfaces have keys for both smooth and emergency stop. Control interfaces that were used in the experiment were MS Industrial Console 6in1 wireless gamepad which communicates on 2.4 GHz frequency with 6 m range, and Trust GXT 570 gaming steering wheel (which was used without floor pedals).

Both control interfaces (gamepad and steering wheel) used the same command interpreter that generated robot’s velocity commands based on input commands given by the test subject. The maximum velocity of the robot was set to 0.45 m/s for linear motion and 1 rad/s for angular motion, with constraint that the velocity of each robot wheel cannot exceed 0.5 m/s in case of combined linear and angular motion. This configuration enabled cornering while driving at maximum allowed linear velocity.

2) Graphical User Interface: The intuitive and efficient GUI is one of the key factors for efficient and safe navigation of the robot from remote location. Our aim was to assess if performance of the operator improved when (s)he was presented with depth information as opposed to only being presented with camera (2D) information. Depth information from Kinect sensor was overlaid on top of the live image from camera, reducing number of windows which test subject had to observe. Depth information was provided in a form of three transparent green arrows: one pointing directly forward and two at 25 degree angles to the left and to the right from central arrow (see Fig. 4). The length of the arrows was proportional to the distance to the nearest obstacle in direction of the particular arrow. Additionally, over each arrow a number representing distance in meters was added so to provide full information with minimal effort of the operator. In cases when obstacle distance was out of the range of sensing device, the arrow turned red and in that case last good measurement distance was displayed. Please note that this type of interface can easily be upgraded with additional arrows covering wider field of view since Kinect 1.0 has 57° horizontal field of view and angular resolution of 0.09°.

3) Operator tasks: The operators, regardless of used design setup, had to complete four tasks. In the first two tasks, the operators had to guide the robot to a desired position and orientation as accurately and as fast as possible (without emphasising either), both visually, without any feedback from the robot (T1), and in teleoperation mode (T2). The starting point, as well as desired position and orientation were the same in both tasks, and were marked on the floor. Both locations were known to test subjects. While teleoperating the robot, the test subjects could not see or hear the robot due to physical barriers (cardboard screen) and the fact they wore earmuffs. Time of completion, distance between desired and actual position (in direction of x and y axes) and orientation (angle) were measured, and number of collisions was counted (if any). It should be noted that there were no obstacles in the direct path of the robot (from start to goal position) but there were obstacles outside it, and some of the subjects collided
Fig. 5. Example of comparison of motion trajectories obtained using visual and teleoperated conditions for two test subjects.

Fig. 6. Example of labels used for search and rescue task and their location on the map (marked in red and blue along with their locations on the map).

with them while trying to position the robot more accurately. Example of resulting robot motion trajectories can be seen in Fig. 5 for two test subjects for tasks T1 and T2.

Another, more challenging, steering task in teleoperation mode (T3) was also performed. The goal of this task was the same as previous one, i.e. to steer the robot to given position and orientation as accurately and as fast as possible, but this time the route the operator had to take was significantly longer than in previous tasks (please see Fig. 2). Time of completion, distance between desired and actual position (in direction of x and y axes), and orientation (angle) were measured, as well as number of collisions.

The final task was a simulation of a simple search and rescue mission (T4) where the goal was to find as many objects as possible in a dislocated environment in a limited time frame of five minutes. In the experiment ten white labels (examples shown in Fig. 6) with unique random three-digit codes were printed in different font sizes (from 20 pt to 200 pt) and were attached to objects of interest that the test subjects had to find. Test subjects had to identify the codes. The labels were positioned so that they were concealed and that they were visible only from some (relatively) small part of the environment. This in turn resulted in the requirement that the operator had to steer the robot around the environment to a specific position and orientation to be able to identify it (just like trying to find victims in urban search and rescue operation). The time of completion of the task was measured (in case test subject successfully found all the objects before time limit), number of collisions, as well as number of identified labels (and which ones).

Tasks T1, T2, T3, and T4 were given to each test subject in predefined random order, so to compensate for possible learning effects.

B. Statistics

1) Two-Sample Student’s t-test: This test was used to test the null hypothesis that means and variances of two population samples are equal.

2) Kruskal-Wallis test: This test is a non-parametric test which aims to determine if medians of multiple groups are different (similar to ANOVA but without underlying assumptions). In case of our experiments, these groups are experiment setups. The null hypothesis for Kruskal-Wallis test is that population medians are equal. Rejecting the null hypothesis provides the information that there is significant difference between the populations, but will not indicate which ones are different and thus post-hoc testing needs to be performed (Tukey Honestly Significant Difference test in our case).

All statistics calculations were done at $\alpha = 0.05$ significance level. For more details about statistical tests, please refer to [16].

III. RESULTS AND DISCUSSION

A. Comparison of visual and teleoperated steering

The analysis was performed on the results of steering tasks where test subjects had to steer the robot from initial to final position and orientation using both visual feedback and teleoperation. Summary of obtained results are presented in Fig. 7. They show that steering tasks were completed, on average, 20% slower in teleoperation, as well as that positioning error was almost doubled in teleoperation (per individual setup). However, both for T1 and T2, considering time of completion there is no statistically significant difference between the setups, according to Kruskal-Wallis test. This is a bit surprising, but might be due to relatively simple tasks which required short amount of time. Similar results were obtained for positioning error (Euclidean distance from the desired position to the measured position). The two-sample t-test was used to test if means of visual and teleoperation controls (for all three dependent variables) were different with
statistical significance. Tests for all the setups, after applying Bonferroni correction for multiple comparisons, showed that samples do not differ, which might suggest that either tasks were relatively simple so differences did not emerge or that operators’ situational awareness was good in both cases. However, when considering positioning errors along x and y axes separately, the two-sample t-test significant difference was observed only for steering wheel with depth test setup and only along y axis ($p = 0.0343$ after applying Bonferroni correction), but not along x axis. We believe this might be due to test setup configuration (i.e. distances between start and goal point in x and y direction), but further testing is required.

Considering number of collisions, a very low number of such events occurred, a total of 6 in T1 and 9 in T2. In T1 number of collisions was almost equal for each of the setups, while in T2 8 out of 9 collisions occurred in setups with depth, which might suggest that users were distracted with additional information which was presented to them.

B. Assessment of teleoperation steering setup

In third task (teleoperation in more demanding conditions), there was also no statistically significant differences between the setups, in time of completion, deviation from desired final position and absolute deviation from desired final orientation. Results obtained in this task are presented in Table II, which demonstrates that, on average, subjects that used steering wheel completed their task faster than subjects using gamepad.

C. Search and rescue analysis

For search and rescue task, summarized results for all test setups are presented in Fig. 8. They demonstrate that for setup with steering wheel without depth information operators achieved less collisions (in total) than in other setups. However, no statistical significance was detected both for number of identified labels and for number of collisions (using Kruskal-Wallis test).

The maximum number of identified labels in this task was seven, while only one of the labels was not been found by any of the test subjects. The average number of identified labels per setup was 5.875 for gamepad, 5.25 for gamepad with depth, 4.875 for steering wheel and 4.5 for steering wheel with depth. The average number of identified labels across all setups was 5.125.

D. Time delay

The time delay was measured for live camera feed and for depth feed. The summary of delay data, which was recorded with a resolution of up to 1 ns, is shown in Table III. From the table it can be seen than latency was on average similar across all test conditions.

IV. CONCLUSIONS

In the paper, the impact of user interface elements on teleoperation of mobile robot was studied with two control interfaces and two GUIs for a total of four setups. The experiment was designed as a between-subject user study in which a subject had to complete three steering tasks and a search and rescue task. Obtained results showed, as was expected, that all performance parameters were better for visual feedback control than for teleoperation mode (regardless of used setup). It was also observed that although various parameters degraded for teleoperation setups in most cases they did not have statistically significant difference, which was

The Challenge of Measuring Distance to Obstacles for The Purpose of Generating a 2-D Indoor Map Using an Autonomous Robot Equipped with an Ultrasonic Sensor

R. Rodin and I. Štajduhar
University of Rijeka, Faculty of Engineering, Department of Computer Engineering, Rijeka, Croatia
rino.rodin@hotmail.com

Abstract – In this paper, we deal with some preliminaries concerning the problem of creating a reasonably accurate 2-D indoor map, using an autonomous mobile robot equipped with an ultrasonic sensor. For this purpose, we utilize the robotic frame DiddyBorg, coupled with the latest Raspberry Pi model. The accuracy of the used ultrasonic sensor is tested in a simulated and a real-world environment. Ultrasonic sensor flaws cause errors in the area mapping process, in the form of precision decline and unwanted ghost points, usually around the corners of an indoor environment. We present a method for filtering these unwanted occurrences. The method has been tested in a controlled test box environment and in the real-world indoor environment. We have used a square, a triangle, and a hexagon as shapes for the testing environment. As a basis for the mapping process, ordinary trigonometry was used, whereas cluster analysis was used for the removal of errors. Experimental results suggest that the proposed method is reasonably accurate in determining correct position and distance of measured points from single-point scans.

I. INTRODUCTION

One of highly important features of autonomous robots is their ability to move independently (i.e. without human intervention) in different environments. This feature can find its application in many different areas. For example, a robot capable of moving autonomously can be used in human rescue missions [1], as a means for daily transportation [2], for firefighting [3], or for security and military-related applications [4]. In order to move autonomously, i.e. to calculate a path from its source to its destination, a robot must be able to position itself with regard to its environment. The best way for a robot to obtain information about its current position is to have a genuine map of its current surroundings stored inside its memory. This problem is generally known as SLAM or Simultaneous localization and mapping [5]. To acquire a spatial model of its surroundings, a robot should have a sensor that helps it perceive its environment. Seeing that there exists a need for reducing the cost of building an autonomous robot [1], we opted for using a low-cost ultrasonic sensor instead of a significantly more expensive laser rangefinder. A short comparison of sensor prices is shown in Table I. Furthermore, the measuring accuracy of ultrasonic sensors is not affected by any changes in type, color or shade of the reflecting surface. However, ultrasonic sensors also have some drawbacks. In order to obtain the highest possible accuracy of an indoor map using limited hardware resources, we have primarily focused on improving the accuracy of the data obtained from the ultrasonic sensor. Seeing that our ultimate goal is to create an autonomous robot capable of mapping and navigating in an indoor environment entirely by itself, we have also described the robotic platform used to achieve that goal. However, the focus remains on the challenges concerning the ultrasonic sensor and their plausible solutions.

II. HARDWARE USED

In this section we describe the hardware necessary for assembling a robot which can be utilized for the purpose of indoor mapping.

A. Raspberry Pi 3 Model B

We decided to use the latest Raspberry Pi 3 model B as a control unit for our robot. Raspberry Pi is a COTS (Commercial-off-the-shelf) small-size computer that runs Linux Raspbian operating system. It is powered by Broadcom 1.2GHz 64-bit quad-core ARMv8 CPU, having 1GB RAM. Seeing that the Raspberry Pi 3 offers a relatively high computing power for a low price, and has rather small dimensions (85x56mm), we concluded that it should meet our needs. Furthermore, the chosen model has a built-in 802.11n Wireless LAN module, which

allowed us to access the robot remotely and, therefore, made parameter changing during our experimenting a lot easier.

B. Ultrasonic sensor HC-SR04

The ultrasonic sensor uses sonar to determine distance to an object. There are two main pins on HC-SR04, trig pin and echo pin. By connecting the high level signal for at least 10μs to the trig pin, the module transmits a 40kHz sound wave and we store the start time into a variable. As the sound wave reflects and returns to the module, Echo pin comes to a state of a logical 1. At this point, we store an end time. We get the measured distance dist using the following expression:

\[
\text{dist} = \frac{(\text{EndTime}-\text{StartTime})}{2} \times 340 \text{ m/s} \quad (1)
\]

As stated in the datasheet [6], the ultrasonic ranging module HC-SR04 provides 2cm-400cm non-contact measurement functionality with ranging accuracy up to 3mm. However, our tests show different results. Measuring short distances matches the data in the datasheet [6], whereas measuring long distances produces repeatable errors. While driving or rotating the robot, the CPU usage is usually around 25%. Seeing that the measuring is performed before any computationally intensive tasks, the percentage of the CPU usage does not affect measuring accuracy. Regardless of that fact, the repeatable errors are still present. This is an important factor because it means that we have to define the optimal distance range at which our sensor works well enough for creating an accurate map. Therefore, the plane surface had been placed at a distance of 2 cm in front of the robot and 10 measurements have been made. We compared each distance measurement acquired using the ultrasonic sensor against the real distance measured by a meter, and noted the number of accurate measurements and the number of inaccurate measurements. A measurement was considered inaccurate if it differed by more than 2cm from the one measured by a meter. After every 10th measuring, the distance was incremented by 2cm. At the end, the number of correct measurements was divided by the total number of measurements for each group of distances, expressing the accuracy as a percentage. The results of the measuring experiment are shown in Table II. The results suggest that the distance obtained using a sensor at a distance from anywhere between 2cm and 80cm has a high probability of matching the real distance. This means that our sensor has to be at most 80cm away from an obstacle to be certain how far the obstacle really is. If a sensor is more than 80cm away from the obstacle, the obstacle will not be represented on a map. The obstacle will be represented on a map as soon as the robot moves close enough to the obstacle. Also, the minimum distance is 2cm, meaning that the robot should never approach the obstacle in a way that puts an obstacle closer than 2cm to the sensor. Otherwise, the sensor could be damaged.

C. DiddyBorg frame

As a backbone for our robot, we decided to use DiddyBorg. Produced by Freeburn Robotics Limited, DiddyBorg is a COTS bundle of chassis, motors with motor controller, wheels, power converter and a battery holder. Chassis is laser-cut 3mm cast acrylic perspex of robust build quality, having 5kg maximum carrying load. Robot characteristics are shown in Figure 1 and Figure 2. The bundle includes six 1:71 (60rpm) 6V 220mA motors. Each motor has the output power of 1.3W and produces 0.35 kg cm of torque. For a power converter, we have used the BattBorg. The BattBorg is also produced by Freeburn Robotics Limited and is based on OKI78SR DCDC converter with maximum 1.5A output. It allowed us to power the Raspberry Pi using 1.2V 2500mAh Panasonic Eneloop batteries.

III. GENERATING THE MAP

First attempts of creating a space (obstacle) map were executed in a controlled environment. We constructed three small wooden boxes and placed the robot in the center. For the shape of the box we chose a square, a triangle and a hexagon. Those shapes were chosen because we believe them to be representative for closed indoor environments. The polygons with the measurements are shown in Figures 4-6. By rotating the robot for 360° in the direction shown by the blue arrow on Figures 4-6, we scanned the entire environment. Clockwise direction of rotation is, otherwise, not important. To calculate the x, y coordinates of the points measured inside the boxes, the following expressions were used:

\[ x = \text{len} \times \cos(\alpha \times \pi/180) \]
\[ y = \text{len} \times \sin(\alpha \times \pi/180) \]

Len variable represents the measured length received from the sensor, whereas \( \alpha \) is the angle of rotation relative to the origin converted to radians. Every 5° or \( \pi/36 \) radians a new point was obtained. This angle was optimal for the type of surface under the robot because the robot changes the speed of the wheels to match the given angle of rotation. A wider angle requires a higher speed of rotation. A higher speed causes the robot to lose traction and finish the rotation after the point from which it started. An angle of rotation of 6° on the same surface would result in the robot not stopping at 360° but rather at 384°. The results of the mapping are shown in Figures 7-9.

Figure 4. Square test box. Dimensions: 400x400mm. Direction of rotation: right. Angle of rotation: 5°.

Figure 5. Triangle test box. Dimensions: 700x700mm. Direction of rotation: right. Angle of rotation: 5°.

Figure 6. Hexagon test box. Each edge is 310mm long. Direction of rotation: right. Angle of rotation: 5°.

IV. SONAR LIMITATIONS

Because of the limitations of the used ultrasonic sensor, raw maps are not accurate, primarily due to the phenomenon known as “ghost points” [7]. When the robot rotates 35° from the initial orientation, the emitted sound wave does not reflect directly back to the sensor. On its way back to the sensor, the wave reflects from other surfaces of the box as well, causing an unwanted time delay. This creates an illusion that the corners of the box are further away from the edges of the box, as shown in Figures 7-9. The ghost points are visible in the square and in the triangle, but not in the hexagon. This only seems so because of the angle between the edges of the hexagon, but the phenomenon is still present. Blue line in Figures 7-9 represents the real outline of the testing boxes used, whereas the red points represent the locations obtained using the ultrasonic sensor. The ghost points are in the corners far away from the outline of the boxes. When performing a real indoor environment mapping, this problem is also expected to appear. Therefore, in order to obtain an accurate map, it has to be solved. We discuss a possible solution next.

Figure 7. Raw map of the square test box. The blue line represents the real edges of the test box.

Figure 8. Raw map of the triangle test box. The blue line represents the real edges of the test box.
V. ELIMINATING MEASUREMENT ERRORS

For solving the problem of ghost points, we decided to use cluster analysis. Cluster analysis or clustering is a technique that groups individual measurements in a population together, based on their similarity. The idea is to group the nearest values obtained from the ultrasonic sensor into clusters. Once the clusters are formed, the robot has to decide which ones consist of ghost points and which ones are populated with accurate measurements. The overview of the proposed method is given in Figure 10.

A. Cluster analysis

In order to cluster points, K-means algorithm was used [8]. K-means is an iterative algorithm which operates in three steps. First, it randomly selects a predetermined number of points called centroids among the data points. Second, it assigns each data point to the closest centroid, thus forming a cluster. Finally, it calculates the average of all data points in a cluster, and moves the centroid to that average location. Cluster analysis was performed using the Python library scikit-learn.

K-means algorithm requires setting the number of clusters to work properly. Each of our controlled test-box environments required a different number of clusters. For example, the triangle required 3 clusters for the accurate measurements, and 3 for the ghost points. The square required 4 clusters for the accurate measurements, and 4 for the ghost points. Finally, the hexagon required 6 clusters for the accurate measurements, and 6 for the ghost points. To determine the optimal number of clusters for each individual setup, a function for estimating the efficiency-of-clustering [9] was used. This score, called silhouette score, is determined using the mean intra-cluster distance $x$ and the mean nearest-cluster distance $y$ for every cluster. The expression is given in (4).

silhouette score = $(y-x) / \max(x, y)$ \hspace{1cm} (4)

Silhouette score is calculated independently for different numbers of clusters, ranging from 2 to 10. The upper bound was chosen as such because the optimal number of clusters in our experimental environments has never surpassed 10. This, however, can be adapted to the complexity of an indoor environment under inspection. The number of clusters having the highest score will be set as the optimal number of clusters for that specific set of data points.

B. Discarding the ghost points

After the robot has successfully estimated the correct amount of clusters, it will start discarding the clusters populated with the ghost points. Since the ghost points clusters are always smaller than the clusters populated with the accurate measurements, our method will find the biggest cluster and discard all the clusters that are smaller than the size of the biggest cluster, minus the tolerance. The tolerance represents the permissible limit of variation in the size of the biggest clusters, i.e. the clusters populated with the accurate measurements. In our experimental environment, the tolerance of -3 points was sufficient. However, the tolerance should be adjusted depending on the angle of rotation because any change in the angle of rotation affects the overall number of data points on the graph. The clusters generated by the method for every test-box environment are shown in the Figures 11-13. The final elimination of ghost points is shown in the Figures 14-16. Figure 17 shows the polygon and the result of applying the method to the real-world environment.

Algorithm 1. Pseudocode for the proposed method of eliminating measurement errors.

VI. RESULTS

Experimental results are presented in this section. Figures 11-13 are depicting clusters found by the K-means algorithm. The accurate measurements that remain after filtering the ghost points are shown in Figures 14-16.

By observing the results, we can state that the method is highly efficient in the removal of ghost points. However there are also some imperfections of the method to be aware of. For example, it can be noticed that in Figure 12 and in Figure 13, the number of clusters does not match the number of clusters that we would intuitively assign to that set of data points. The 3 sets of ghost points in Figure 12 are divided into 4 clusters, but only 3 are necessary to distinguish the ghost points from the accurate data points. Furthermore, in Figure 13 it is possible to see that the number of clusters is 5, but we...
Figure 11. Cluster analysis of the square. Every color represents a different cluster. Centroids are in the middle of each cluster.

Figure 12. Cluster analysis of the triangle. Every color represents a different cluster. Centroids are in the middle of each cluster.

Figure 13. Cluster analysis of the hexagon. Every color represents a different cluster. Centroids are in the middle of each cluster.

Figure 14. Accurate measurements of the square after the removal of ghost points.

Figure 15. Accurate measurements of the triangle after the removal of ghost points.

Figure 16. Accurate measurements of the hexagon after the removal of ghost points.

Figure 17. The real-world environment with the office chair and the bottle next to the robot (left), cluster analysis with each cluster in different color (middle) and accurate measurements with the ghost points removed (right).
would expect the number of clusters to be 6 in a hexagon. This is an imperfection inherited from the K-means algorithm. The K-means algorithm assigns the clusters randomly, therefore causing minor deviations in the total number of clusters. This does not pose a great problem, since the method will usually assign more clusters than necessary, therefore reducing the size of each cluster. If cluster size is reduced, then there exists a higher probability that the cluster will be discarded, since we tend to keep only the biggest clusters. If a cluster is discarded, it only means that the area where that cluster would be is now empty. An empty area suggests that there is a part of an indoor environment that is yet to be discovered, and the robot should approach it and examine it more thoroughly.

Considering that the robot will ultimately operate in a real-world indoor environment we decided to test our method in one. We placed the robot between the walls in different sizes with the sensor facing the closed doors. An office chair and a bottle were added since we believe them to be the objects that the robot will often meet during the process of mapping. The raw map was then acquired by rotating the robot for 360° and measuring the distance every 5°.

Figure 17 shows the real-world indoor environment, the cluster analysis for the acquired set of data points and the final removal of ghost points. This experiment suggests that rejecting small clusters and keeping only the biggest ones also comes with a price. A small obstacle, bottle, visible in a real-world environment in Figure 17, represented with a gray cluster in cluster analysis, is not visible on the graph showing the accurate measurements. This happens because a bottle is represented by a small cluster and is therefore mistaken for a set of ghost points. This is an imperfection of the proposed method that has to be approached in a different way. One of the possible ways to detect such small objects would be to equip the robot with a tactile sensor that would additionally complement the accuracy of the map. However, this is a topic for our future work.

VII. CONCLUSION

The main focus of this paper was on solving the problem of ghost points caused by the imperfections of the ultrasonic sensor. We presented a method for elimination of ghost points, based on cluster analysis. An important task concerning the described method, was automatically determining an optimal number of clusters for any given environment. This was successfully solved using the silhouette scoring function. Another important task was the correct detection and removal of the ghost-point clusters. This is done with respect to the cluster sizes, i.e. smaller ones were discarded, whereas the larger ones were kept. It is important to note that the tolerance in the size of the clusters, not to be rejected, should be set with respect to the angle of rotation. The proposed method has shown some imperfections dependent on the K-means algorithm, but it has also successfully eliminated the ghost points from the test box environments as well as from the larger part of the used real-world indoor environment.

Our research can be viewed as an extension to the research performed by Ilias et al. [10]. In their paper, the authors have presented a method for eliminating ghost points from data collected using an ultrasonic sensor bank attached to a mobile robot. However, there are some considerable differences. The method presented in [10] uses a trigonometric approach to eliminating the ghost points, whereas our method uses cluster analysis based on the K-means algorithm. As it can be observed in Figure 6 in [10], the method proposed by the authors leaves some fragments in the corners of the scanned environment, whereas our method completely removes all the ghost points. Furthermore, the authors have used 16 ultrasonic sensors while we managed to reduce the number of sensors to only one. The contribution of our paper is expressed in the use of the K-means algorithm for the purpose of eliminating the ghost points.

Automated Posture Assessment for Construction Workers

R.J. Dzeng*, H.H. Hsueh*, and C. W. Ho*

* National Chiao-Tung University/Department of Civil Engineering, Hsinchu, Taiwan

Abstract - Construction workers often suffer various kinds of musculoskeletal disorders (MSDs), which are injuries in the human musculoskeletal system. MSDs are often aroused due to sudden exertion such as lifting heavy equipment, or repeated and cumulative stressed motions. OWAS (Ovako Working posture Assessment System) may be used to evaluate the exposure of MSDs risk by sampling the snapshots of a worker’s postures and categorize the postures. However, tracking and categorizing postures of different body parts by human eyes are tedious work with limited accuracy and easy to make mistakes even with facilitation of video recording. This research develops an automatic tracking and categorizing system, named Posture Assessment System for MSD (PAS-MSD) for OWAS using Microsoft Kinect. The PAS-MSD captures human postures during his/her movement, recognizes human skeleton, and assesses the risk of MSD. An experiment with typical construction activities such as handling and moving of materials, hammering, and tiling was conducted. Except for the hammering activity where the subjects’ body parts were easily blocked by the target hammered box and could not be detected by Kinect, the posture identification accuracies for all other activities exceed 90% (i.e., 91.6%-93.9%). The OWAS categorization accuracies are also satisfactory, ranging from 85.4%-88.5%.

I. INTRODUCTION

Construction industry has been a major contributor to work injuries. Majority of the research and workplace guidelines has been focusing on mitigation of specific event-based or accidental injuries. Cumulative injuries caused due to prolonged adoption of stressful positions, occur in considerable measure and warrant an equal attention on development of solutions for helping in reduction of their occurrences. For this purpose, a tool has been developed that employs the body tracking abilities of Kinect to identify the adopted postures and evaluates them based on a predefined method specified in OWAS [1] to obtain an improved understanding of the long-term hazards of the common work postures of construction workers. OWAS was developed in the 1970s for identification of work postures that cause discomfort and are detrimental to workers’ health. The developed system can be used as an assisting tool for health professionals and occupational health experts for identifying poor working postures and diagnosing possible musculoskeletal injuries. It can also lead to improved work health regulations and reduced instances of occupational injuries in the future.

Musculoskeletal disorders (MSDs) refer to injuries and disorders that affect the human body movement or musculoskeletal system such as muscles and tendons. Since repetitive motion or stress is one major risk factor contributing the MSDs, many other similar terms such as repetitive motion injury, cumulative trauma disorder, and repetitive stress disorder were also used in the literature. According to NIOSH report [2] based on annual surveys from 1982 to 1996 conducted by Labor of Statistics of U.S Department of Labor, while the number of cases and the rates increased slightly for most of the illnesses over the time period, disorders associated with repeated trauma increased nearly 10-fold. In 1996, repeated-trauma disorders accounted for close to two-thirds of reported occupational illnesses. The proportion of occupational illnesses due to repeated trauma was nearly twice as high as in 1986. Later on the rate declined and was speculated to have occurred as a result of a better recognition of MSDs and the implementation of industrial health and safety programs [3].

The prevention of the development of MSD for workers requires the efforts on both company and each worker. Some researchers have worked on improving the work environment. For example, Hisao and Stanevich [4] investigated various tasks pertaining to scaffolding to identify the risks of overexertion injury and also develop an assistive device to help lifting scaffold end frames.

In a review of epidemiological studies on low-back, neck, shoulder, and upper extremity disorders, several physical load factors were identified as risk factors for the disorders. Many of these factors have been repeatedly identified, and for different types of outcomes of an anatomical area (e.g. pain, disc herniation, disc degeneration of the low-back or neck) [5].

Many postural observational methods, e.g., Joseph et al. [5] and Pehkonen et al. [6], have been developed to evaluate the posture exposed to the MSD risk. The OWAS (Ovako working posture analysis system) is also a postural observational method commonly used to identify poor postures at a worksite. OWAS has been widely used in several industries for postural analysis (e.g., [8], [9], [10], and [11]), and also in the construction industry (e.g., [12], [13], [14], [15], [16]). The OWAS evaluation is based on sampling from typical working postures of major body parts including back, forearms, and legs, and the information about the force exerted or load carried during work upon the observed subject. This research adopts OWAS as the postural evaluation method. Other related measurement methods that were not used in this research...
include the subjective Nordic Musculoskeletal Questionnaire developed by Nordic Council of Ministries [17], RULA (Rapid Upper Limb Assessment) [18], REBA (Rapid Entire Body Assessment, 2000) [19], and LUBA (Loading on the Upper Body Assessment) [20]. Both RULA and LUBA focused only on upper limbs, and RULA requires the measurement of muscular forces and frequency of muscular force exertions. REBA’s approach is also based on RULA.

OWAS uses a four-digit code to describe various postures and weight combinations. As shown in Fig. 1, the codes include four back postures, three forearm postures, seven leg postures, and three levels of exerted force. For example, three forearm postures are (1) both below elbow joint, (2) one above elbow joints, and (3) both above elbow joint. The OWAS then categorizes the total number of 252 possible combinations of the four digits into four levels of actions according to their risk of injuries.

Figure 1. OWAS postures [1]

AC1: postures are normal and natural with no particular harmful effect on the musculoskeletal system, no action is required;

AC 2: postures have some harmful effect on the musculoskeletal system, corrective actions are required in the near future;

AC3: postures have a distinctly harmful effect on the musculoskeletal system, corrective actions should be done as soon as possible;

AC4: postures have an extremely harmful effect on the musculoskeletal system, immediate corrective actions for improvement are required.

Although OWAS has broken down common human postures contributing to MSDs into precise categorization of postures of body parts, the utilization of OWAS still remains somehow subjectively and imprecise due to the inconvenience of statically measuring angles of body parts in a dynamic continuous motion. Motion capture has been widely used in a variety of industries such as cinema, entertainment, and computer games. Sharma et al. [21] reviewed several motion capture methodologies including marker-based motion capture (e.g., acoustical system, mechanical system, magnetic system, optical system) and marker-less motion capture such as Microsoft’s Kinect solution, which is low-cost and does not require any special equipment attached to the observed subject. This research used KINECT as a tool for tracking the movement of human skeleton to implement the proposed system for its low cost and availability of SDK (software development kit) [22].

II. SYSTEM DESIGN

This study develops an automated system, named Posture Assessment System for Construction Workers (PAS-CW) for MSDs for assessing postures of construction workers and identifying high-risk postures pertaining to MSDs. The following describes first the OWAS categorization, and how the system is used with the user interface, and then the design of the system so that the text is easier to follow.

Figure 1 shows the main control user interface of the system. Once the Kinect is setup and the observed subject is ready to perform his/her regular work activity, the ergonomics expert or physiotherapist starts the posture capture and evaluation according to the following steps (from top to bottom on the right hand side of Fig.2).

1. Click the appropriate weight carried by the subject. This is necessary because the OWAS evaluation requires the carried weight information which cannot be detected by the Kinect camera.
2. Adjust the angle of camera so that it covers the activity area.
3. Press the red recording button to start capturing and recording the subject’s skeleton motion.
4. The result window (shown in the bottom of Fig. 1) instantaneously displays the categorization of the postures and the subject’s body parts including back, forearm, leg, and the previously input carried weight, and also the injury risk level assessed based on the OWAS.

Figure 2. Main control user interface for PAS-CW
The system was developed using Microsoft Visual Studio 2010 in C# language, and Kinect for Windows SDK [22]. The system also uses SQLite Database, a popular public-domain database engine for local data storage, and EmguCV, a cross platform that allows Intel’s OpenCV’s image processing functions to be called from .NET compatible languages such as C# and Visual Basic.

The system includes several modules as shown in Figure 3. The Kinect video cameras record the observed subject. For each video image frame, the skeletal tracking module tracks the posture of the subject at a frame rate of 2 Hz, and transforms into skeleton with information of twenty joint positions. The posture categorization module categorizes the posture type for each body part (e.g., back, arm). Given the categorization of each body part, the general posture of the subject in the frame can be determined, and the corresponding OWAS's AC levels can be determined.

The user interface module controls the main display windows of the system, and includes the video display of the subject’s skeleton (window left), the input area (window top right), and the analysis result area (window bottom right). With the estimated exerted force input by the user, for each video frame, the analysis module receives the data of the skeleton and the joint positions and determines the postural categorization of back, forearms, and legs. The output of the analysis includes the categorization of each body part and the resulting AC levels according to OWAS. The database module stores the video images, and the data of the skeleton and joint positions with the determined AC levels. The display module displays the statistics of the data visually to provide the expert a holistic view of the subject posture in a continuous fashion instead of a single frame. Examples are bar chart graphics showing the AC level at intervals of 0.5 seconds, or the average or peak AC levels for the choice of intervals of 5, 10, 15, and 30 seconds.

![Figure 3. PAS-CW’s implementation modules](Image)

The Kinect cameras can provide the positions for 20 joint of a human skeleton (e.g., head, hand right, wrist right, elbow left, hip center, knee left, ankle left, and foot right) in a three-dimension coordinate system. With this information, the relative distances, positions of joints, angles of the associated limbs or other body parts can be derived. The individual posture of back, arms, and legs need to be categorized first in order to categorize the entire body posture of each sampled video frame based on the OWAS.

For example, the OWAS categorizes the back posture into 4 types, e.g., Straight-back, Bent-back, Twisted-back, and Bent&twisted-back. The back posture will be identified as Straight-back if the smaller angle between Vector1 passing through the spine and the shoulder center and Vector2 passing through left hip and right hip is greater than or equal to 75°. The back posture will be identified as Bent-back if the smaller angle between Vector1 passing through the spine and the shoulder center and Vector2 passing through left hip and right hip is smaller than 75°. The back posture will be identified as Twisted-back if the angle measured in the X-Z plane, between the vectors normal to Vector1 passing through left shoulder and right shoulder and Vector2 passing through left hip and right hip is smaller than 15°. The back posture will be identified as Bent&twisted-back if both Bent-back and Twisted-back conditions are met.

III. SYSTEM EVALUATION

The evaluation of the PAS-MSD focuses on two aspects: skeleton identification accuracy and OWAS categorization accuracy. The skeleton identification accuracy represents the rate of frames in which all necessary skeletons and joint positions required for the OWAS assessment are successfully identified. Skeleton identification may be incorrect or even fail in some frames due to obstructed view, extreme twisting or bending, or sudden movement. The OWAS categorization accuracy determines the rate of the correct assignment of AC level for each frame by the PAS-MSD system compared to the participating experts.

Fifteen graduate students with or without construction working experience were recruited to participate the experiment. The participants were asked to perform four tasks: (1) materials moving, (2) materials handling, (3) nail hammering, and (4) tiling.

Taking task-1 as an example, it required the participant to lift a bucket of materials (19 kg for male, and 9 kg for female), move the bucket, and place at the designated area. The task requires 4 repetitions. The MSD risk factors [23] included in the task are unnatural work posture, repetitive work, and exerted force. The task was designed to include common risk factors to MSDs but not actually result in MSDs to the participants.

All the tasks were performed on the same position except for Task-1, for which the subjects were required to walk 2 to 3 steps. During the tasks, the subjects were asked to perform the tasks naturally without any special constraints on body rotation or blocking camera view from body parts. Because the participants may turn around their bodies in all directions while performing the tasks,
we set up three Kinect cameras in the face angle and side angle horizontally, and another from a 45° birds eye angle.

Three experts participated in the evaluation of the experimental result, and include a rehabilitation medical physician, a professor in physiotherapy, and a professor in medical engineering.

Table 1 shows the identification accuracy and categorization accuracy results for each work task. Except for Task 3, all other tasks show similar results. First, the identification accuracies all exceed 90% (i.e., 91.6%-93.9%), and all categorization accuracies exceed 85% (i.e., 85.4%-88.5%). Such performances make the proposed PAS-CW feasible to be used to help analyze the posture of construction workers for MSDs. Note that the calculation of the identification and categorization accuracies was first prepared by the authors, and then examined by the participating professionals because the process was too time consuming due to the large amount of data involved.

Task 1 required subjects to lift heavy bucket, moved it, and placed it at the designated place. The motions involved large and slow movement, which result in the highest accuracy in terms of identification and categorization.

Task 2 required subjects to take materials from the bucket and put them in place piece by piece. The data showed that the PAS-CW successfully identified the skeleton of the upper body most of the time, but often failed in identifying the skeleton of the legs due to the squat posture and view blocked by the bucket. Nevertheless, since legs were successfully identified when subjects were standing and the legs seldom make large movement, the lack of updating on the leg part did not affect the accuracy significantly. Task 4 requires subjects to take tiles at squad position and place the magnetic tiles, which was customized designed for this experiment, on the wall. Even the PAS-CW’s camera was facing the subjects from behind, the detection accuracies were still satisfactory.

Task 3 is the one that resulted in poorer identification accuracies compared to all the other tasks. The subjects were required to hammer nails on the designated wood box (Fig. 4), which was specifically designed to protect the subjects from accidental injuries. As shown in Fig. 5, the wood box blocked the Kinect camera’s view of the subject’s legs most of the time during the task and resulted in the poor identification accuracies.

| Table 1. Identification and Categorization Accuracy Result |
|-----------------|-----------------|-----------------|-----------------|-----------------|
| Task 1 Identification accuracy | 93.9% | Task 2 Categorization accuracy | 88.5% | Task 3 Identification accuracy | 69.4% | Task 4 Categorization accuracy | 85.4% |
| Task 1 Categorization accuracy | 91.6% | Task 2 Identification accuracy | 92.2% | Task 3 Categorization accuracy | 48.4% | Task 4 Identification accuracy | 91.6% |

The experts took much longer time in evaluating the captured images without precise constant sampling frequency. After long hour of evaluation, the experts may also give inconsistent categorizations within themselves or among them. The inconsistency usually occurred when the subjects posed bending legs or waists, and turning backs. In conclusion, all participating experts agreed the accuracy rates of the machine identification and categorization are good enough to be helpful to their diagnosis.

IV. CONCLUSION

Construction workers often suffer various kinds of MSDs due to sudden exertion such as lifting heavy equipment, or repeated and cumulative stressed motions. This research uses Microsoft Kinect tool kit to develop an automatic tracking, named Posture Assessment System for MSD. The PAS-MSD captures a worker’s postures during his/her movement, recognizes human skeleton, and produce and assesses the risk of MSD based on OWAS.

An experiment of four types construction tasks was designed to evaluate the PAS-MSD. Except for the nailing task, in which the target box easily block Kinect’s view of subjects’ legs and which had poor identification performance, both the identification and OWAS categorization accuracies were satisfactory (i.e., from 85% to 93.9%). The experiment also provided the following lessons learned.

- The PAS-MSD has satisfactory identification and OWAS categorization as long as the cameras’ view of any worker’s body part is not blocked by surrounding environment, work object, self’s body, or other people.
- The PAS-MSD is able to provide an evaluation of much higher sampling rate of captured images and consistent categorization compared to human experts. This is particularly beneficial when longer observation time is required for determining the postural causes of MSDs.

- In addition to the one facing the observed worker, we set up additional two Kinect cameras in the side angle horizontally and from a 45° bird’s eye angle to capture the participants’ gestures in all directions especially when they turned their bodies around during the task. However, while the gestures were captured in video, the successful rates for identifying the skeletons were too low to be useful. This is because the current skeleton capturing algorithm provided by Microsoft work poorly for side view and top view. New sets of capturing algorithms need to be developed if additional cameras are really needed to avoid blocking the camera’s view. The categorization rules are also needed to develop to transform the side view or top view body postures into the normal view of the conventional OWAS.

Due to the limitation of the Kinect-based PAS-CW, we also learned that the system is not suitable to be directly used on a normal-daily-setting construction site to monitor the postures of construction workers. Other workers, temporary work, and equipment may easily affect the image capturing ability of Kinect and the setup and the clearance of the area between the cameras and the observed worker may also affect the normal construction operation. A temporary cleared and safe area such as a room inside the jobsite office needs to be setup to use the PAS-CW directly on a construction site. This research only tested four types of construction operations, but the experiment already indicates that some workers may not be applicable if the postures of the observed body part or potentially high-risk posture may be blocked by the working elements, temporary works, or self body parts.

Software Toolbox for Analysis and Design of Nonlinear Control Systems and Its Application to Multi-AUV Path-Following Control

Sergey Ul’yanov and Nikolay Maksimkin
Institute for System Dynamics and Control Theory, Irkutsk, Russia
Email: sau@icc.ru

Abstract—In the paper, we present a software toolbox for rigorous analysis and design of nonlinear continuous and discrete-continuous (digital) control systems based on the reduction method and sublinear vector Lyapunov functions. For these systems, the toolbox provides solution of the following problems: verification of dynamic properties of dissipativity, asymptotic and practical stability; computation of estimates of basic direct indicators of dynamic quality (accuracy, domains of attraction and dissipativity, settling time and others); synthesis of parameters that ensure desirable or optimal quality of the system. In addition, we show how the toolbox could be applied to solve the path-following control problem for a single autonomous underwater vehicle (AUV) as well as for multi-AUV formations. In our statements of the path-following control problem, we take into account together uncertainties of AUVs model, inaccuracy of measurements, and constraints on control actions.

I. INTRODUCTION

Nowadays the classical and modern control theories provide a wide range of methods for analysis and design of control systems, most of which are efficiently implemented in software and used in practice. However, these techniques are mainly applicable to linear systems and do not give satisfactory results when dealing with complex and highly nonlinear models. Existing tools for analysis and design of nonlinear systems lack of constructiveness and therefor the development of new techniques that have the potential to be developed up to explicit computing algorithms as well as their efficient software implementation is a high-priority problem in control theory.

In this paper, we present a software toolbox VLF-REDUCTOR for rigorous analysis and design of nonlinear continuous and continuous-discrete (hybrid) control systems designed in MATLAB environment. The toolbox implements a numerical technology for analysis of nonlinear systems based on the reduction method [1], [2] and sublinear vector Lyapunov functions (VLF) [3], [4]. The main features of the technology are the possibility to formulate analysis and design problems in terms of system requirements, which are convenient for engineers, and its constructiveness, which implies that after reduction of an investigated model to some standard form, subsequent computations are performed, for the most part, automatically. The main aim of the paper is to demonstrate how the developed software can be applied to solve challenging control problems arising in practice. As an example, the path-following control problem is addressed.

Steering a vehicle to converge to and follow a desired spatial path is a traditional problem in robotics. With regard to autonomous underwater vehicles (AUV), the problem is studied in [5] where a nonlinear path-following control algorithm, which takes into account the AUV dynamics and exploits the idea of tracking the motion of a virtual target along the path by controlling explicitly its progression rate, is proposed. This approach is extended then to deal with uncertainties [6]. The path-following problem for AUV with actuator saturations is also considered in literature [7]. This paper concerns the path-following problem under parameter uncertainties, measurement errors, and saturations of control signals. We consider the case when the discrete (sampled-data) control of AUV is used. It proves to be reasonable for formation control of multi-AUV systems, as will be shown below.

The formation control problem for multi-AUV systems is being actively studied by researchers from all over the world due to a wide range of its applications: exploring and monitoring underwater environment, seafloor mapping, and search-and-rescue operations. To get an insight about advances in this area, we refer the reader to survey papers [8], [9].

Most of the known multi-AUV formation control algorithms are based on the leader-follower approach [10]–[12], according to which all the vehicles in the formation are connected in pairs by the leader-follower relation so that there is a vehicle, being not a follower for others and called the formation leader, that determines the motion of the group, whereas other vehicles as followers try to maintain a desired position with respect to their leaders.

Since only slow and unreliable acoustic communications are available under the water, the issue of delays and packet dropouts is also addressed [12], [13]. The path-following control scheme for multi-AUV systems is proposed in [14]. It assumes that all vehicles in formation have to follow their own predefined paths and communications are used to synchronize their speeds. In our study, we admit that only the formation leader is aware of the path to be followed. This condition arises when the path is constructed or reconstructed during the motion in order, for example, to avoid obstacles.

The rest of the paper is organized as follows. Section II
gives a brief description of the designed software toolbox for analysis and design of nonlinear systems. Particularly, it introduces classes of control system models and formulations of analysis and design problems captured by the toolbox. Path-following digital controllers for a single AUV and multi-AUV systems are built with the use of the toolbox in Section III. Section IV provides simulation results for the designed controllers. Section V contains the conclusions and expiations of future work.

II. SOFTWARE TOOLBOX FOR ANALYSIS AND SYNTHESIS OF NONLINEAR SYSTEMS

A. Control System Models

The software toolbox is designed to deal with a wide range of continuous and continuous-discrete (digital) control systems. It assumes that a system under consideration is represented in some typical form. Such a representation for continuous systems has the form

\[
\begin{align*}
(J + \Delta J(t, x)) \dot{x} & = (A + \Delta A(t, x)) x + (B + \Delta B(t, x, u)) u + G F(t, x, u) + H \Phi(t, x, u), \\
\dot{u} & = \varphi(\cdot, \sigma), \\
\sigma & = C \psi(\cdot, \eta), \\
\eta & = D x, \\
x & = x(t),
\end{align*}
\]  

where \( x \in \mathbb{R}^n \) is the state vector of the system formed by stacking state variables of the plant as well as other elements of the system (state observers, dynamic filters and so on), \( u \in \mathbb{R}^m \) is the control input, \( \eta \in \mathbb{R}^l \) is the output vector; \( \Delta J(\cdot) \), \( \Delta A(\cdot), \Delta B(\cdot), F(\cdot), \Phi(\cdot) \) are functions that specify uncertainties and nonlinearities of the system, external disturbances and satisfy inequalities: \( |J^{-1} \Delta J(\cdot)| \leq \delta_0, |J(\cdot)| \leq A^0, |\Delta A(\cdot)| \leq B^0, |\Delta B(\cdot)| \leq B^0, |F(\cdot)| \leq U/\theta, \theta = \Theta x \in \mathbb{R}^q, |\Phi(\cdot)| \leq \Phi^0 \in \mathbb{R}^r \) (henceforward, inequalities between two matrices (vectors) and modulus of a vector are understood as the component-wise ones); \( A, B, C, D, G, H, J_0, A_0, B_0, U, \Theta \) are constant matrices and vectors of appropriate dimensions. Functions \( \varphi(\cdot, \cdot), \psi(\cdot, \cdot) \) describe various characteristics of actuators and sensors with their nonlinearities, noise and quantization errors, saturation of signals and belong to a special class of functions called \( SN \) [3, 4]. For a function \( \theta(\xi) \) of variable \( \xi \in \mathbb{R}^k \), we will write \( \theta(\xi) \in SN^{K_{\xi}}(K_{\xi, 0}, 0, \xi, 0, \xi) \) if

\[
\min \left[ K_{\xi} \left( \xi - \xi^0 \right) - K_{\xi} \left| \xi \right| ; K_{\xi} \right] \leq \theta(\cdot, \xi) \leq \max \left[ K_{\xi} \left( \xi + \xi^0 \right) + K_{\xi} \left| \xi \right| ; -K_{\xi} \right],
\]

where \( 0 \leq \xi^0 < \xi \leq \infty, \xi^0 \in \mathbb{R}^k_+, \xi \in \mathbb{R}^k_+, K_{\xi}, K_{\xi}^0 \) are diagonal matrices. Parameters \( K_{\xi}, K_{\xi}^0 \) specify the nominal values and admissible uncertainties of the gain coefficients, respectively; \( \xi^0 \) characterize noise and quantization errors, \( \xi^0 \) defines saturation levels of actuators or the operating ranges of sensors. Using the notation above, assume that \( \varphi(\cdot) \in SN^{K_{\xi}}(K_{\xi}, K_{\xi}^0, \xi^0, \sigma), \psi(\cdot) \in SN^{K_{\xi}}(K_{\xi}, 0, \eta^0, \eta) \).

In the case of continuous-discrete systems, the model also includes continuous part (1), but now control signal \( u(t) \) is generated by a zero-order hold function with a sequence of hold times \( t_k = t_0 + kh \); \( k = 0, 1, 2, \ldots \) as \( u(t) = u(t_k) \equiv u_k \), \( t \in T_k \equiv [t_k, t_{k+1}) \) and feedback control law, instead of (2), is defined as follows:

\[
u_k = \varphi(\cdot, \sigma_k), \quad \sigma_k = C \psi(\cdot, \eta_k) + C_2 z_k,
\]

where \( \eta_k = D x(t_k) \in \mathbb{R}^l \) is the output vector, \( z_k \in \mathbb{R}^m \) is the state of a discrete controller, \( C_2, C_2 \) are some constant matrices.

The discrete controller is described by difference equations

\[
\begin{align*}
z_{k+1} & = A_d z_k + B_d u_k + \sum_{i=1}^{\mu} C_{\psi}^i \psi_d(\cdot, \eta_k) + H_d \Phi_d(\cdot), \\
u_k & = \varphi_d(\cdot, \sigma_{dk}), \quad \sigma_{dk} = C_d \psi_d(\cdot, \eta_k) + C_d z_k, \\
\eta_{dk} & = D_d x(t_k), \quad \eta_k = D_d x(t_k), \quad k = 0, 1, 2, \ldots
\end{align*}
\]

where \( u \in \mathbb{R}^m \) is the control input of the controller, \( \eta_{dk} \in \mathbb{R}^l, \eta_k \in \mathbb{R}^l \) are output vectors sampled at time moments \( t_k \) and \( t_{k+1} = t_k + \tau, i = 1, \mu, \tau_i \leq \tau, \mu \geq 1 \) is the number of samples available on each control step (memory depth); \( \Phi(\cdot) \) is a vector function satisfying \( |\Phi(\cdot)| \leq \Phi^0 \in \mathbb{R}^l, \varphi(\cdot) \in SN^{K_{\xi}}(K_{\xi}, 0, \xi^0, \xi), \psi(\cdot) \in SN^{K_{\xi}}(K_{\xi}, 0, \eta^0, \eta) \), \( A_d, B_d, C_d, D_d, C_d, \) \( D_d, \Phi_d, \) are constant matrices and vectors of appropriate dimensions.

To specify a control system for further investigation using the software toolbox, one needs to assign values to all or a part of elements of the matrices included in the definition of the model. In case of partial specification, undefined parameters are assigned default values: \( J^0 = 0, \Theta = 0, G = 0, U = 0, H = 0, \Phi^0 = 0, H_d = 0, \) \( K_{\xi}^0 = 0, d \) is the number of matrices \( k \times l, E_k \) denotes the identity matrix of size \( k, k_0 \) is the all-zeroes column vector of size \( k, \) \( e_0 \) is a column vector of size \( k \) filled with infinite values.

Using the toolbox, the problems arising in practice can be solved for both continuous model (1), (2) and continuous-discrete model (3), (4)-(6): verification of dynamic properties of dissipativeness, asymptotic and practical stability; estimation of basic indicators of dynamic quality.

1. stabilization accuracy \( \gamma^0 \) (steady state error) with respect to the output vector \( \gamma = \Gamma^T [x \ z] \in \mathbb{R}^r \), that is, a vector \( \gamma^0 \) that satisfies the following inequality:

\[
\lim_{t \to \infty} |y(x(t), z(t))| \leq \gamma^0, \quad (7)
\]

2. domain of attraction (dissipativity)

\[
\Omega_0 = \{ (x_0, z_0) : |y_0(x_0, z_0)| \leq c \gamma_0 \}
\]

with respect to the vector \( \gamma_0 = \Gamma_0 [x_0 \ z_0] \in \mathbb{R}^m \) for the given direction \( \gamma_0 \in \mathbb{R}^m_+ \), \( c > 0 \);

3. maximum deviations \( \max |y(x(t), z(t))| \) with respect to the vector \( \gamma \) from a given set of initial states of the form \( |y_0(x_0, z_0)| \leq \gamma_0 \);

4. control time up to a desirable accuracy \( \gamma^0 \) from the given initial state \( |y_0(x_0, z_0)| \leq \gamma_0 \);

1For brevity, we list here only indicators for the continuous-discrete model.
the Lyapunov exponent (exponential decay rate).

Solution of the problems above is based on the construction of an auxiliary (comparison) monotonous system related to the initial one by sublinear VLF and subsequent analysis of the auxiliary system using a special theory of monotonous comparison systems. For details, we refer the reader to [3], [4], [15], [16].

One of the key features of the toolbox is the possibility to design control systems with desired or optimal dynamic quality. Typically, the design problem is formulated as follows: find unknown parameters of the system (e.g., controller feedback coefficients) that provide its dissipativeness for all admissible uncertainties and disturbances and minimize the steady-state error of the system.

More formally for the continuous-discrete system, it can be stated as follows. Let \( \beta \in \mathcal{B} \) be the vector of parameters to be determined and \( \mathcal{B} \) be the admissible domain for \( \beta \). Define the domain of dissipativity \( \Omega_0 \) as a set of initial states containing the neighborhood of the origin, for which the relation (7) holds.

The control design problem consists in finding \( \beta \in \mathcal{B} \) that minimize criteria \( J_f = \alpha^T \gamma^0 \) (\( \alpha \in \mathbb{R}^n \) is a given vector of weighting coefficients) provided that closed system (1), (3)-(6) is dissipative, i.e., \( \Omega_0 \neq \emptyset \) (domain of dissipativity is not empty).

The posed problem cannot be rigorously solved, since, in the general case, it is impossible neither to get the exact value of the criteria, nor to test the feasibility of the restrictions. To deal with it, we adopt an approach, in which, instead of exact values of performance indicators included in criteria and constraints, their estimates computed on the basis of sublinear VLF, are exploited. In the toolbox, the given optimization problem with computable criteria and constraints is efficiently solved by use of the penalty function method and non-gradient methods of optimization.

The advantages of the technology implemented in the toolbox are, on the one hand, the strictness of results obtained and guaranteed nature of the judgments and estimates, and, on the other hand, its constructiveness. It is for the accuracy of numerical results VLF method is advantageous over other known methods. It is important that analysis problems are formulated directly in terms of system requirements, which are convenient for engineers; the results are also obtained in this form. After reduction of an investigated model to some standard form, subsequent computations are performed, for the most part, automatically.

In the following section, we will demonstrate the application of the designed software to path-following problem for multi-AUV systems.

III. PATH-FOLLOWING CONTROL OF MULTI-AUV FORMATION

A. Dynamic Model of AUV

In this paper, we use the full dynamic model of the INFANTE AUV borrowed from [5]. The kinematic and dynamics equations of the vehicle can be defined using a global coordinate frame \( \{U\} \) and a body-fixed coordinate frame \( \{B\} \) (see Fig. (1)).

\[
\begin{aligned}
\dot{x} &= u \cos(\psi_B) - v \sin(\psi_B), \\
\dot{y} &= u \sin(\psi_B) + v \cos(\psi_B), \\
\psi_B &= r,
\end{aligned}
\]

where \( x, y \) are the coordinates of the center of mass of the vehicle, \( \psi_B \) denotes the yaw angle, \( u \) and \( v \) are respectively the surge and sway velocities expressed in \( \{B\} \) and \( r \) is the angular yaw rate.

Neglecting the equations in heave, roll and pitch, the equations for surge, sway and yaw can be presented as

\[
\begin{aligned}
\mathcal{F} &= m_u \dot{u} + d_u, \\
0 &= m_v \dot{v} + m_{ur} \dot{u}r + d_v, \\
\mathcal{G} &= m_r \dot{r},
\end{aligned}
\]

where

\[
\begin{aligned}
m_u &= m - X_u, & d_u &= -X_{uu} \dot{u}^2 - X_{uv} \dot{v}^2, \\
m_v &= m - Y_v, & d_v &= -Y_{uv} \dot{u} \dot{v} - Y_{vv} |\dot{v}|v, \\
m_r &= I_z - N_r, & d_r &= -N_i u \dot{v} - N_i |\dot{v}|, \\
m_{ur} &= m - Y_r.
\end{aligned}
\]

\( m \) is the mass of the AUV, \( I_z \) is the moment of inertia around AUV’s vertical axis, \( X_{i|j} \), \( Y_{i|j} \), \( N_{i|j} \) are classical hydrodynamic derivatives, and \( [\mathcal{F} \mathcal{G}]^T \) is the vector of force and torque applied to AUV.

B. Path-following Controller Design for Single AUV

The conception of the virtual target is used here to design path-following controller for a single AUV. Define a virtual target as a point \( P \) moving along the path to be followed by the AUV. Associated with \( P \), consider the corresponding Serret-
Frenet frame \( \{F\} \) (see Fig. 1). As shown in [5], the dynamics of the virtual target in \( \{F\} \) can be described by

\[
\begin{align*}
\dot{s}_1 &= v_1 \cos \psi - \dot{s} + \dot{\psi}_F y_1, \\
\dot{y}_1 &= v_1 \sin \psi - \dot{\psi}_F s_1, \\
\dot{\psi} &= r + \beta - \dot{\psi}_F, \\
\end{align*}
\]  

(10)

where \( s_1, y_1 \) are the coordinates of the target in \( \{F\} \), \( s \) is the signed curvilinear abscissa of \( P \) along the path, \( \beta = \arctan(v_y/v_x) \) is the side-slip angle, \( v_1 = (v_x^2 + v_y^2)^{1/2} \) is the absolute value of the total vehicle velocity vector; \( \dot{s} \) is the path curvature, \( \dot{\psi} \equiv \dot{s}_B + \beta - \dot{\psi}_F \). In this study, we suppose that the virtual target move along the path with constant velocity \( \dot{s} = u_d \) and the path curvature is constrained \( |c_\psi| \leq \bar{c}_\psi \).

Now, the path-following control problem can be formulated as follows. Given the AUV model (8) and a path to be followed, derive feedback control laws for the force \( \mathcal{F} \) and torque \( \mathcal{G} \) that minimize the steady-state values of \( y_1, s_1, \) and \( \psi \).

To solve the problem, the following discrete control law is proposed:

\[
\mathcal{T}(t) = \mathcal{T}_c + \mathcal{T}_s, \quad \mathcal{G}(t) = \mathcal{G}_c + \mathcal{G}_s, \quad t \in T_k,
\]

\[
\mathcal{T}_c = \mathcal{d}_u(t_k), \quad \mathcal{G}_c = \mathcal{d}_l(t_k) + m_s(\dot{\psi}^*_k - \beta),
\]

\[
\mathcal{T}_s = \text{sat}(k_1 \dot{s}_1^k + k_2 \bar{\Delta} u^k, \mathcal{F}_s),
\]

\[
\mathcal{G}_s = \text{sat}(k_3 \dot{s}_1^k + k_4 \bar{\Delta} \psi^k + k_5 \bar{\Delta} \beta^k, \mathcal{G}_s),
\]  

(11)

where \( T_k \equiv [t_k, t_{k+1}] \), \( t_k = kh, k = 0, 1, 2, \ldots, h \) is the control step; \( \mathcal{T}_c, \mathcal{G}_c \) are feedforward control terms aimed to cancel terms \( d_u, d_l \) in equations (9) and terms \( \beta, \dot{\psi}_F \) in the equation for \( \Delta r \equiv r + \beta - \psi \); \( \dot{\psi}^k \) is an estimate of acceleration \( \beta \) at \( t_k \) obtained using the dynamic model of the AUV (see [5] for details), \( \dot{\psi}_F = \bar{c}_\psi s + c_\psi \bar{c}_s \); \( \mathcal{T}_s, \mathcal{G}_s \) are feedback control terms, \( \mathcal{F}_s, \mathcal{G}_s \) are the shares of control resources reserved for stabilization, \( \text{sat}(\sigma, \bar{\sigma}) = \text{sign}(\sigma) \min(|\sigma|, \bar{\sigma}) \) is the saturation function; \( \dot{s}_1^k, \psi^k, \Delta u^k, \Delta \psi^k \) are measurements of \( s_1, y_1, \psi, \Delta u = u - u_d, \Delta r \) at time moment \( t_k \) that contain some additive errors:

\[
\begin{align*}
\dot{s}_1^k &= s_1(t_k) + \dot{s}_1(t_k), \quad |\dot{s}_1(t_k)| \leq \dot{s}_1^0, \\
\psi^k &= \psi(t_k) + \dot{\psi}_F(t_k), \quad |\dot{\psi}_F(t_k)| \leq \dot{\psi}_F^0, \\
\Delta u^k &= \Delta u(t_k) + \Delta \bar{u}(t_k), \quad |\Delta \bar{u}(t_k)| \leq \Delta u_0^0, \\
\Delta \psi^k &= \Delta \psi(t_k) + \Delta \bar{\psi}(t_k), \quad |\Delta \bar{\psi}(t_k)| \leq |\Delta \bar{\psi}|^0, \\
\end{align*}
\]

\( s_1^0, \psi_0^0, \Delta u^0, \Delta \psi^0 \) are positive constants; \( k_i \) are feedback coefficients to be determined \( i = 1, 5 \).

For synthesis of the feedback coefficients with the use of toolbox VLF-REDUCTOR, the dynamic model of the vehicle given by equations (9), (10) should be simplified. Using the Taylor expansion, neglecting the equation in sway and keeping in mind feedforward control terms, model (9), (10) can be rewritten as

\[
\begin{align*}
\dot{s}_1 &= \Delta u + c_i u_d y_1, \\
\dot{y}_1 &= u_d \psi - c_i u_d s_1, \\
\dot{\psi} &= \Delta r, \\
\end{align*}
\]

\[
\begin{align*}
m_u \Delta \bar{u} &= \mathcal{F}_s, \\
m_u \Delta \bar{\psi} &= \mathcal{G}_s,
\end{align*}
\]  

(12)

Model (12) combined with feedback control law (11) can be presented in terms of model (1), (3)-(6) of toolbox VLF-REDUCTOR:

\[
\begin{align*}
x &= \left[ \begin{array}{c} s_1 \ y_1 \ \psi \ \Delta u \ \Delta r \end{array} \right]^T, \\
u &= \left[ \begin{array}{c} \mathcal{F}_s \ \mathcal{G}_s \end{array} \right]^T, \\
J &= \left[ \begin{array}{cccccc} 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
\end{array} \right], \\
A &= \left[ \begin{array}{cccccc} 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
\end{array} \right], \\
B &= \left[ \begin{array}{c} 0 \\
0 \\
0 \\
0 \\
0 \\
0 \\
\end{array} \right], \\
G &= \left[ \begin{array}{c} 0 \\
0 \\
0 \\
0 \\
0 \\
0 \\
\end{array} \right], \\
\Theta &= \left[ \begin{array}{cccccc} 0 & 1 & 0 & 0 & 0 & 0 \\
1 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 1 & 0 \\
\end{array} \right], \\
U &= \left[ \begin{array}{c} u_d \bar{c}_\psi \\
0 \\
0 \\
0 \\
0 \\
0 \\
\end{array} \right], \\
D &= E_s, \quad \bar{\sigma} = \left[ \begin{array}{c} \mathcal{F}_s \ \mathcal{G}_s \end{array} \right]^T, \quad \eta_0 = \left[ \begin{array}{c} s_1^0 \ y_1^0 \ \psi^0 \ \Delta u^0 \ \Delta \psi^0 \ \Delta r^0 \end{array} \right]^T.
\]

The other matrices and vectors in model (1), (3)-(6) are assigned default values. Now, specifying the criteria for synthesis as

\[
J_f = \omega_1 \limsup_{t \to \infty} |s_1(t')| + \omega_2 \limsup_{t \to \infty} |y_1(t') + \omega_3 \limsup_{t \to \infty} |\psi(t')|,
\]

(\( \omega_i \) are the weight coefficients), the toolbox can compute feedback parameters \( k_i \).

C. Path-following Controller Design for Multi-AUV Formation

As mentioned above, the formation control strategy considered in the paper is based on the leader-follower approach. Assume that each leader can accurately estimate the value of its state variables \( \{x, y, \psi, \cdots\} \) at time instant \( t_{k+1} \) on the basis of its dynamic model and measurements of the state vector obtained at \( t_k \) \((t_{k+1} = t_k + h)\). Let the leader sends these estimates at every time moment \( t_k \) and its followers reliably receive them at \( t_{k+1} \). Moreover, we assume that the AUVs have their clocks synchronized and update their control signals at the same time moment \( t_k, t_{k+1} = kh, k = 0, 1, 2, \ldots \). Under these assumptions, the problem of communication delays can be left out.

In what follows, focusing on a given leader-follower pair, denote the leader as \( l \) and the follower as \( f \). Considering the leader as a virtual target for its follower, one can derive a
kinematic model of the leader-follower pair in coordinates \((s_1, y_1)\) as

\[
\begin{align*}
\dot{s}_1 &= v_{lf} \cos(\psi_{Wf} - \psi_W) - v_d + \dot{\psi}_W y_1, \\
\dot{y}_1 &= v_{lf} \sin(\psi_{Wf} - \psi_W) - \dot{\psi}_W s_1, \\
\psi_{Wf} &= r_f + \beta,
\end{align*}
\]

where \(\psi_W = \psi_a + \beta\).

Let a desired position of the follower with respect to the leader in coordinates \((s_1, y_1)\) be defined by vector \([s_1^*, y_1^*]^T\). The control law that provides stabilization of the desired position of the follower with respect to the leader can be defined as in (11) except for the feedback control terms given by

\[
\begin{align*}
\mathcal{F}_s &= \text{sat}(k_1 \Delta s^k_1 + k_2 \Delta \dot{s}^k_1, \overline{\mathcal{F}_s}), \\
\mathcal{G}_s &= \text{sat}(k_3 \Delta y^k_1 + k_4 \Delta \dot{y}^k_1 + k_5 \Delta \dot{\psi}^k_1, \overline{\mathcal{G}_s}),
\end{align*}
\]

where \(\Delta s^k_1, \Delta \dot{s}^k_1, \Delta y^k_1, \Delta \dot{y}^k_1, \Delta \dot{\psi}^k_1, \Delta r^k_f\) are estimates of \(\Delta s_1, \Delta \dot{s}_1, \Delta y_1, \Delta \dot{y}_1, \Delta \dot{\psi}_1, \Delta r_f\) at time moment \(t_k\) computed with some errors using measurements of the state vector of the follower and estimates of the state variables of the leader at \(t_k\), which are sent by the leader at \(t_{k-1}\) and received by the follower during time interval \(T_{k-1}\). As before, we need to design feedback coefficients \(k_i,i=1,5\).

Linearizing equations in (13) and (9) in the neighborhood of “unperturbed motion” \((s_1 = s_1^*, y_1 = y_1^*, \psi_{Wf} = \psi_{wf} = \psi_f, u_i = u_f = u_d, v_i = v_f = 0, r_f = \dot{\psi}_W = \dot{\psi}_L)\) and having in mind (14), one can derive the following error model for feedback control design:

\[
\begin{align*}
\Delta \dot{s}_1 &= \Delta u_{ff} + \dot{\psi}_f \Delta y_1 + y_1^* \dot{\psi}_t, \\
\Delta \dot{y}_1 &= u_d \Delta \psi_{lf} - \dot{\psi}_f \Delta s_1 - s_1^* \dot{\psi}_t, \\
\dot{\psi}_{lf} &= \Delta r_{lf}, \\
m_1 \Delta u_{ff} &= \mathcal{F}_s + m_1 \dot{r}_f, \\
m_2 \Delta \dot{r}_f &= \mathcal{G}_s + m_2 \ddot{r}_f.
\end{align*}
\]

There are two ways to synthesize the feedback control parameters for the follower AUV using toolbox VLF-REDUCTOR. The first way implies that the velocities of the leader \(\Delta v_f, \dot{\psi}_f\) and its accelerations \(\dot{u}_f, \ddot{r}_f\) are constrained and terms in equations (15) that contain these variables are regarded as bounded uncertainties, which can be accommodated in the toolbox model. In the second one, a full model of the multi-AUV system is built by aggregating error models (either (12) for the formation leader or (15) for the other AUVs) of all AUVs and then control design is performed for the full system. The first way gives more conservative results but it is less time-consuming compared to the second one. In practice, both approaches are used simultaneously.

IV. NUMERICAL COMPUTATION AND SIMULATION RESULTS

Numerical computations and simulations were conducted for a formation of four INFANTE underwater vehicles uniformly distributed around a circle of radius 5 m. We borrowed the AUV model parameters from [5], including \(m = 2234.5\) kg and \(I_z = 2000\) N m$^2$. The formation parameters are presented in Table I. The other parameters of the model used in control design and simulations are: \(v_d=0.6\) m s$^{-1}$, \(h=0.2\) s (control step), \(\mathcal{F}_s=200\) N and \(\mathcal{G}_s=100\) N m (constraints on the feedback control signals), \(\epsilon=0.12\) (constraints on the path curvature), \(\Delta s_{1}^0=y_{1}^0=0.1\) m, \(\psi_{0}^0=0.01\) rad, \(\Delta u_{0}^0=0.1\) m s$^{-1}$, \(\Delta \dot{\psi}_{0}^0=0.01\) rad s$^{-1}$ (estimation errors). Simulation results of the designed control system are depicted in Fig. 2-4.

Simulation results and analysis of model (15) show that the greater reference linear velocity \(u_f\) and the larger values \(s_1^*, y_1^*\) the more difficult for the follower to keep a desired position with respect to the leader. If these parameters are large enough, the proposed formation control algorithm does not
solve the path-following problem and other control schemes, for example, based on measurements of distance and bearing angles (see e.g. [17]) are preferable. However, the appearance of the follower’s trajectory generated by these algorithms may significantly differ from the appearance of the path to be followed, which is not acceptable in many applications.

It should be noted that the controller is designed for precise stabilization of the formation and works well only if the initial deviations from a desired configuration are small enough. However, for the case of large deviations, other formalizations of the desired formation behavior [18], [19] supported by VLF-REDUCTOR can be used.

V. Conclusion

In this paper, we presented a MATLAB-based software toolbox for analysis and synthesis of nonlinear control systems. Using the toolbox, a path-following digital controller for multi-AUV formations was designed taking account measurement errors, constraints on control actions, and the fact that only the formation leader holds information about the path to be followed. Simulation results illustrated the performance of the control system, which turns out to be acceptable for many cases, however, has the potential to be improved. The future work intention is in improving performance of the control system by including integral actions in the controller to reject constant disturbances and introducing extra controls for the virtual target to adjust its speed to the current errors of the followers.

Acknowledgment

The software toolbox designed for analysis and synthesis of continuous-discrete (digital) control systems using VLFs and the proposed multi-AUV formation model have been created under support of RSF (grant №16-11-00053). The reported study was also funded by RFBR according to the research projects №16-29-04238.

Abstract - This paper reviews ballast water treatment systems regarding functional and operational problems. Ballast water treatment systems (BWTS) could be in failure or under repair. New invented sensors based on flow measurement methodologies should report malfunctions utilizing satellites. This invention is the solution concerning the quality control of ship’s ballast water, and this is the system which would timely and with a higher degree of certainty establish the quality of ballast water treatment operations on ships. The system according to this invention is autonomous in relation to the ship’s crew and eliminates a possibility that the members of the ship’s crew influence the control of the ballast water, and it excludes the possibility of concealing a possible defect or irregular operation of the device for ballast water management.

Key words: Ballast water management; Flow measurement; Sensor; Communication; Evaluation; Innovation; Invention

I. INTRODUCTION

The technical problem being addressed in this article is the efficiency of BWTS and the necessity of supervising the results. There are various systems for the purification or neutralization of unwanted ingredients contained in ship’s ballast water [1][2]. The purification of ballast water implies the harmonization with the international laws on the allowed quantity of certain ingredients contained in ballast water [3]. The existing technologies do not provide a certification that a ship having entered a port has clean ballast water [4]. This problem is still tended to be solved by means of laboratory analyses of the samples taken on board a ship after it has entered a port. The solution concerning the quality control of ship’s ballast water should be found, and the system which would timely and with a higher degree of certainty establish the quality of ballast water on board a ship should be created [5]. Then, it could be established with certainty that certain ship would not create potential problems in the port of arrival from the legal or time aspects. In that way, any additional control by the sampling and laboratory analyses of the ship’s ballast water would not be necessary. A technical problem to be solved by this innovation relates to the question how to carry out the quality control of ballast water, as regards the compliance with international standards, before the ship enters a port and present such evidence to the port authorities [6]. The overall problem is that the ability of modern ships to cover long distances in a short amount of time, provides a means for non-native marine species, including algae, invertebrates, and pathogens to arrive in ports via ballast water [7]. The International Convention for the Control and Management of Ships' Ballast Water & Sediments was adopted by consensus at a Diplomatic Conference at IMO in London on Friday 13 February 2004 [8].

The today’s potential control of ship’s ballast water is provided for by the International Maritime Organization Convention according to which the port authorities are given a possibility to carry out laboratory analysis of ballast water, where the inspector working in that port orders so [8]. The ballast water samples are taken on board a ship, after the ship enters the port, and they are submitted to a long-term analysis in a laboratory. If the analysis of the ballast water shows deviation from the values specified by the Convention, the ship shall leave the port without the cargo operations being performed, and the total analysis cost shall be paid by the shipping company. If the results of ballast water laboratory analysis show to be negative, the total amount of analysis cost shall be paid by the port authorities located in the port in which the laboratory analysis has been carried out and the ship shall be granted permission to load the cargo and to discharge ballast water [9]. Ballast water treatment systems could have clogged filters (UV ballast water management systems), burned UV bulbs, improper function of de-chlorination unit (chlorination ballast water management system) and many other possibilities [10]. The operational efficiency of a BWTS is questionable considering the long number of years that these systems have to operate once installed on a ship. There were more than 60 existing certified treatment systems listed in year 2014 [11] and more new systems have been invented at this year 2016. Different technologies were suggested for ballast water treatment [12][13], such as disinfection with chlorine [14], adding biocides to ballast water for harmful microorganisms neutralisation [15],...
sterilisation with ozone [16], filtration with ultraviolet light [17], sonication [18], hydrodynamic cavitation [19], and many other technologies such as electro-ionization [20] and treatment by heat [21]. Contribution of this study is in proposed monitoring system which helps to exclude the possibility of concealing a possible unreported defect or irregular operation of a ballast water treatment system.

II. FAILURES AND MAINTENANCE OF BWTS

There are many ships already equipped with ballast water treatment systems today. Not all of them have a good operation performance of their certified treatment systems. Unsuitable function of automated ballast water management systems on board the ships could cause invasion to domestic waters. The ship’s movement in the storms combined with the salt exposure brings up a very big risk of damages or improper functionality of any device or parts of the systems of ballast water treatment [22]. Certain scientists have tried to prove the effectiveness and efficiency of a particular BWTS. A scientific paper and study results have proved the efficiency of BWTS on a very large passenger ship [23]. Most of the attention on these very large ships has been on passengers having the most stable journey possible. Everything possible is done so that the impact of waves and winds on the ship is kept to a minimum. These almost ideal conditions cannot be completely accepted as a measure of the quality of the operations and state of certain technologies for the treatment of ballast water. The operation and results of the BWTS after these conditions could be very different to those on mid-sized tankers that travel in difficult weather conditions of very high waves, as well as devastating and life threatening winds [22]. These working conditions for the BWTS are, from spring until autumn for example, quite frequent in certain areas when choosing the shortest possible route. These areas include the North Sea, the western coast of Algeria, the Bay of Lyon, Biscayne, the coast of Greece, the Adriatic Sea, the Aegean Sea, as well many other areas that are very difficult to travel in. Ships that transport liquid cargo, and usually travel in these areas the most, have a total load of between 25,000 and 50,000 tons DWT. These ships are far smaller than many large passenger ships. Due to the difficult weather conditions that these boats have to go through and after which their BWTS has to function perfectly, it is inappropriate to take into relevant consideration solely the results of BWTS operations in the best possible conditions, such as is the case in the largest passenger ships or cargo ships that travel in ideal conditions. Other scientists make no mention in their experiments of how long the BWTS, which was already installed on the boat, was used before their research, whether the water taken for analysis was during winter or in difficult weather conditions, and whether the installed system had already been under the influence of extreme weather and sea conditions.

A scientist has conducted a study related to consistency of BWTS operation. In certain study, the total calculated reliability of a particular ballast water treatment system on board ships which consists of the two computing subsystems as part of units of which one is software redundant, was 0.916 or 91.6% [22]. This means that for 8.4% of the operational time, any of the mentioned systems could be in failure or under repair. This is a significant risk for the operation of ballast water treatment systems. In same study, survey of operational experiences from ships has proven that more time would be needed for the maintenance of ballast water management systems. It can be clearly concluded from that survey result of 7.3% from all participants and interviews that ship officers by-pass ballast water treatment systems due to lack of time for rectifying malfunctions, failures, maintenance or spare parts replacement in ballast water treatment systems. [22]. This implies an unclear future for port environment protection management. Malfunctions occur and the reactions of the crew members can be loyal towards the shipping company [24][25]. When viewed from the aspect of making a profit, completing cargo operations and ballasting and then sailing towards the next port is of the utmost importance to a shipping company [26]. Ballast water treatment systems are not always in optimal operational condition and ships’ crew members by-pass them, as often occurred with automatic oil discharge content monitors in the past [25] [27]. Also, sensors of a system would inhibit the operation of the ballast water treatment system due to the TRO value being too high. It can take from three to three and a half hours to replace a UV bulb in a BWTS with a UV generator. Bulbs burn out often [10].

III. METHODS AND TOOLS FOR EVALUATION AND MONITORING

Efficacy of BWTSs was evaluated during certification tests [28] [29]. Evaluation of the treatment efficacy is based on the determination of living organisms after the treatment. Different methodologies were suggested for monitoring content of treated ballast water. Some methods that have been proposed regarding the supervision of ballast water have been the use of PAM fluorometry [30], flow cytometry [31] [32] [33] [34], FDA and ATP content [35] [36], as well as classic laboratory methods [37] [38].

Those methodologies use their detection tools. Significant difference of detection tools is coming from the aspect of time needed for ships’ ballast water sample analyses [4]. All the detection methods regarding the quality of ship ballast water have been proposed with the purpose of analysing the samples upon neutralisation. As such, depending on the analysis results of the treated ballast water samples, questions are raised regarding responsibility should the analysis results of this ballast water be such that it is not acceptable for unloading [9]. If the BWTS was monitored and it is action was taken...
immediately when treatment problems occurred, it would be easier to designate who is responsible for the poor operation of the BWTS. The existing technologies do not provide a certification that a ship having entered a port has clean ballast water. This problem is still tended to be solved by means of laboratory analyses of the samples taken on board a ship after it has entered a port. The system which would timely and with a higher degree of certainty establish the quality of ballast water on board a ship should be created. Then, it could be established with certainty that the detected ship would not create potential problems in the port of arrival from the legal or time aspects. In that way, any additional control by the sampling and laboratory analyses of the ship’s ballast water would not be necessary [39] [40]. The conclusion that can be drawn upon completing one of the best ballast water projects ever, the NSBWO (North Sea Ballast Water Opportunity) project, is that there should be no doubts regarding the capabilities of BWTS that has received all necessary working permits. These conclusions have also been drawn by many scientists in their studies. Biological scientists do not contest the obligatory installation of BWTS on ships, but confirm the repeated growth of numerous microorganisms upon treatment. Certain samples analyses after suitable BWTS function, showed re-growth of phytoplankton which represents risk of aquatic invasion and contamination [41] [42]. Growth of viable organisms can be assumed to occur cases where at least one cell keeps its viability after the treatment, and then, it is exposed to favorable conditions [43]. Fraction of organisms is expected to keep their viability after the treatment application [44]. Effects of the combination of UV irradiation and dark storage in ship's ballast water tank provide a framework for studies and research [30] [45] [46] [47]. However, the comments are always that the introduction of BWTS is good as it reduces the risk of the invasion of microorganisms in new areas. These interpretations leave too much room for discrepancies regarding treated ballast water compared to the prescribed standards. Overall, not one suggestion for compliance monitoring has been considered, let alone accepted, despite the efforts and lobbying of scientists. Drawing an indirect conclusion whether the treated ballast water has reached the required standard, which allows a certain number of microorganisms to remain in the water after treatment, is a debatable method. This is why not one suggestion has been accepted at any level. Despite the lobbying efforts of scientists from renowned institutes and universities worldwide that their monitoring method be accepted, the fact remains that lawyers can bail out the incriminated ship and company should any analysis show unacceptable results. Up to the present, not one suggested method has been seriously considered for the indicative monitoring of the quality and contents of ballast water. It is needed to have an information immediately after some failure happen in a ballast water treatment system during the operation [5].

The invention, as a result of this study, excludes the possibility of concealing a possible unreported defect or irregular operation of the ballast water treatment system, because the follow-up system results indicate this on time to the authorities of the port which the ship leaves. Figure 1 shows a block scheme of the system of the automatic measurement of ship’s ballast water, via satellite communication, which includes the assembly A of the system that is located on land, and the assembly B of the system that is located on board a ship. The function of this innovation is explained in further text.

IV. THE INNOVATION

Solutions that are suggested in this article reveal irregularities in the operations of BWTS immediately after they occur. In this way, the need for sampling and analysing ballast water is avoided as this type of supervision is not approved by the IMO in any case, even though it was the subject of analysis of many scientists. In this monitoring system, shown in Figure 1, the on duty operator is located at the ship terminal where the ship unloads its cargo and loads ballast water. He has contact with the ship via an internet connection or a cable and has immediate insight into any BWTS malfunctions. The indication is the amount of water that has gone through the treatment system. It is monitored and compared with the total amount of ballast water after loading the ballast. The method used in this system is flow measurement. There are several types of products and technologies that can be used to measure flow. The options for measuring flow include the use of magnetic and ultrasonic flow meters, and pressure transmitters. Magnetic flow meters can be affected by air in the pipe and can give false readings of the pipe if it is not kept full. They can also be affected by stray. Ultrasonic flow devices can be affected by solids in the flow, and if the pipe is not maintained full, they will not be able to read and report the flow. There are level measurement options in technology, such as radar. In USA, radar level technology has been partially approved. Meters are classified into two basic types: positive displacement and velocity. Meters that feature both positive displacement and velocity are known as compound meters. The unit of measurement could be in cubic meters. Positive displacement meters operate by filling and emptying a small compartment with a known volume of liquid which moves with the flow of water. The flow rate is calculated based on the number of times these compartments are filled and emptied. The movement of a disc or a piston drives an arrangement of gears that registers and records the volume of liquid. Velocity meters operate on the principle that water passing through a known cross-sectional area with a measured velocity can be equated into a volume of flow. Velocity meters are good for high flow applications. In this invention, two different meters
could be used: one for main ballast water pipeline flow measurement and the second one for treated ballast water flow measurement. The effectiveness of the proposed method has been proved by certain scientists [48] [49] [50] [51]. The tool and computed program measures flow of ballast water through main ballast water pipeline and flow just before and after the treatment [52].

The performance control of ballast water treatment system using the automatic alarm reporting system responsive to stoppage of ballast water treatment operation, starts in the port in which cargo will be loaded. The electronic devices 17, from the office 1 in the assembly A of the system that is located on land, start follow-up computed program, remotely, via satellite communication 2, through electronic devices 17 in the assembly B of the system that is located on board a ship 3, through the lines 16, and both flow meters 12. The ballast water is driven from the sea, through the pipes 15, via the valve 4, and pressure gauge 13 into the ballast water treatment system TS. By the automatic flow measurement of ballast water, the results of operation are obtained.

![Block scheme of the invented system](image)

Fig. 1. Block scheme of the invented system

The data are collected automatically in the electronic device 17, and are, after the filtration and archiving, sent as messages, via electronic devices 17 on board a ship and satellite communication 2, to the assembly A of the system that is located on land. It can be utilized hybrid communications that combine satellite connectivity with links to terrestrial mobile networks. The procedure is completed when the staff from the assembly A of the system that is located on land gives its statement on the performance and quality of the ballast water treatment system operation of the ship under control. That statement includes exact amount of ballast water loaded on board a ship and exact amount of treated ballast water driven through a treatment unit TS and measured on flow meter 12. The statement will be sent by email, using internet protocol (IP). This statement given by the staff from the assembly A of the system that is located on land is manifested in the issue of the Certificate of the Quality and Performance of the Observed Ballast Water that is filed to the port authorities. It will contain a comment of proper or improper ballast water treatment on a ship according to statement data sent by terminal operator. On the basis of such Certificate the port authorities decide to grant or to refuse to grant the ship’s permission to enter the next port, where the observed results indicated irregular operation of the ship’s ballast water neutralization system. In this monitoring system, the on duty operator is located at the ship terminal where the ship unloads its cargo and loads ballast water. He has contact with the ship via an internet and has immediate insight into any BWTS malfunctions. The tool and computed program measures flow of ballast water through main ballast water pipeline and flow just before and after the treatment. Measured data is transmitted through router, utilizing satellites. If there is a difference in the amount that had been treated and the total amount, this would then indicate the need to analyse the samples of treated ballast water. Should an alarm go off on his monitor regarding malfunctions (lack of flow) in the treatment of ballast water, the on duty operator has to contact the ship from the terminal and the ship has to be inspected. Records and notes of the event have to be made on the ship and it has to be photographed. Ballasting must not continue until the ship’s BWTS malfunction is fixed and the system works properly. The method of determining proper operations using a flow meter is rapid, preventative and the cheapest method for shipping companies owners. Pressure in the ballast system pipes is compared with pressure at the opening of the BWTS. In this way, the possibility of bypassing the BWTS when loading the ballast water is avoided. In addition, crew members cannot solve this problem in inventive ways so that the ship can continue its journey with untreated ballast. On the basis of the ship terminal operator’s report, the ship is either given permission or not given permission to sail to the next planned port for cargo operations. If a failure in the operation of the BWTS occurs that is difficult to fix, the ship would need to terminate cargo operations and anchor in front of the port. The next planned ship enters and moors itself to the port terminal and undertakes loading or unloading cargo operations and water ballast. Responsibility and expenses are determined according to the current law that is related to these situations. The advantages of this system above others in the quality detection of ship ballast are that it is a timely, economical and simple procedure, accurate and the cost of the flow meter device is very low, as is its installation and maintenance. The essence of this invention is the system of automatic detection of ship’s ballast water operation stoppage. The system is
composed of the following assemblies: an assembly A of the system that is located on land and an assembly B of the system that is located on board a ship. The assembly A of the system that is located on land and the assembly B of the system that is located on board a ship mutually communicate remotely, via satellite communication. The aim of the invention is to establish the quality and purity of ship’s ballast water, via satellite communication, before the ship leaves the port, and to deliver a certificate containing the received information to the port authorities that grant the ship permission to enter the next port. In this way, an additional sampling of the ballast water after the ship enters the next port is avoided, at the same time avoiding the possibility of having to send the ship back from the local waters due to unwanted ingredients contained in the ballast water. The system is autonomous and does not depend on the ship’s crew influence. This invention also eliminates the possibility that the members of the ship’s crew influence, in any manner whatsoever, the ballast water control [53]. The invention excludes the possibility of concealing a possible unreported defect or irregular operation of the device for the purification and neutralization of ballast water, because the results indicate this on time to the authorities of the port which the ship leaves [54]. It can be implemented through maritime remote maintenance protocols [55]. The system which is presented by this innovation is proposed to be implemented in the world maritime legislation, since it provides for a frequent taking of observation of the ship’s ballast water management operation order that it could be asserted with high credibility whether the ballast water is acceptable for discharge in the port of arrival or not. The system presented by this invention may be applied in the control of the water used for washing cargo tanks after unloading chemical substances. The system according to this invention may be applied in the remote control and management of the water supply and sewage systems.

V. CONCLUSION

The suggested methods of monitoring the operations and functionality of a particular BWTS unify the analysis results of previous research and suggestions for monitoring and controlling the operations of BWTS. The methods suggested in previous research were based on controlling the contents of treated ballast water. Not one of these methods has been accepted at a worldwide level nor implemented in the shipping industry worldwide. The reasons for this are, among others, due to the interests and profits of large shipping companies who would not like their ship to be stopped in future due to malfunctions in the BWTS. As such, there is a large risk of the invasion of sea microorganisms. One could say that the 2004 Convention has not fulfilled it task. Automatic alarm reporting system responsive to stoppage of ballast water treatment operation on ships continues the fight to protect the marine environment and endemic species in local seas. The advantages of this system are that it is simple, economic, harmless technology and there is no need for additional training of the ship’s crew as would be the case in using other methods. In this system, the port terminal has immediate insight into the proper operation of the BWTS and should its monitoring and supervision program malfunction – an alarm is activated. In this way, should the flow of the ballast water (treated or untreated) not be shown on the sensors that are monitored at the port terminal, they have to personally go to the ship and record the reasons for this. The best characteristic of this system is its timeliness as the ship should not continue cargo operations until the ballast water can be unloaded as per the regulations of the 2004 Convention.

Abstract — Circuit Breakers are one of the most important elements in the transmission and distribution of electrical energy, and assessing their condition is of the utmost importance regarding the health and safety of the transmission and distribution system. Numerous procedures and parameters exist that directly reflect the state of the circuit breaker, but this paper focuses on a relatively new procedure that measures and estimates the states of the arcing contacts of the circuit breaker. The state of the arcing contacts is in a direct correlation with the health of the circuit breaker and it is assessed by applying test called the Dynamic resistance measurement. The important parameters during this Dynamic Resistance test will be explained. The results obtained using developed algorithm are demonstrated in the field on a real circuit breaker, completing thus all necessary steps for the assessment of the arcing contacts.

Keywords — High Voltage Circuit Breaker; Dynamic Resistance Measurement; Arcing Contacts;

I. INTRODUCTION

The design of modern high-voltage SF6 gas circuit breakers (HVCB) is based on the switching of two parallel contact sets. The first ones are the low-resistance contacts – main contacts which are specifically designed to carry the load current without excessive temperature rise. The second set, arcing contacts with tungsten – copper tip operate (as standalone contacts in the circuit for a few milliseconds) at the breaker opening following the main contact part. The electrical arc starts after the separation of the arcing contacts. The tungsten-copper material is designed to carry the arc until it is cleared at the next current zero-crossing.

Measurement of the dynamic resistance of the contact system (DRM) was presented in 1993 [1][2] as a tool to diagnose the condition of the arcing contacts. The method consists of applying constant current through the circuit breaker contact system, measuring the voltage drop over the contacts and plotting the resistance waveform during open or close operation of the HVCB. Since arcing contacts have higher resistance than the main contacts, during opening operation increasing of the voltage drop will appear at the moment of the main contacts separation. Relevant information related to contact condition, wear and/or misalignment can be obtained by analyzing resistance waveform together with the waveform of the motion of the contact system.

Beside the waveform shape, there must be numerical values that are comparable and that determine the condition of the arcing contacts - if they are in a good or bad condition or fall into the “gray zone”. Arcing contacts degradation due to thermal stress can be determined using two parameters: - Arcing contact overlapping time - Arcing contact wipe (overlapping distance) length

Those two parameters might be calculated manually, or automatically extracted from the resistance and motion waveforms using an appropriate algorithm.

II. IMPORTANCE OF PARAMETERS FOR ARCING CONTACT CONDITION ASSESSMENT

The arcing contacts are the most important part of the high voltage circuit breaker. During the trip operation the main contacts open first and arcing contacts open after a few milliseconds. The electrical arc starts after the separation of the arcing contacts, and is cleared at the next current zero – crossing. During the closing operation the arcing contacts close first and main contacts close after a few milliseconds. The electric arc starts before arcing contacts are closed. Therefore, any electrical arc formed during breaker operation will appear on the arcing contacts.

During each opening and closing operation, a fraction of the arcing contact material burns away since temperature at the center of the arc is around 25,000° C [4]. This temperature is four times higher than the temperature of the surface of the Sun, there is no material which can withstand such a high temperature. The standard operation for circuit breakers requires a test in a high power laboratory under rated short circuit current condition and there are three opening operations O – t1 – CO – t2 – CO. The standard operation practically represents the life span of a circuit breaker and is directly connected to the shape of the arcing contact. The life span of a circuit breaker, and the life span of the arcing contacts, is represented graphically (Figure 1).
Figure 1 show the number of interruptions versus short-circuits current that the arcing contacts in a circuit breaker can withstand before they must be replaced.

Each circuit breaker type has its own permissible electrical wear curve. In most designs, a minimal number of circuit breaker operations under rated short circuit conditions are from 3 to 10 [4].

One of the consequences of material loss at the arcing contacts is the shortening of the arcing contacts and thus shortening time difference between the separation of the main contacts and the separation of arcing contacts. This time difference is called the contact overlapping time. In accordance with this, arcing contact wipe is shorter. Other characteristics of material loss is the change the arcing contact surface (Figure 2.), which will result in the changing of the dielectric strength of space between the arcing contacts.

The shape of the arcing contacts is probably their most important characteristic. At some point during an arc the alternating current which forms the arc will pass through zero; this is the instant at which current is zero. At that moment a transient voltage will be present across arcing contacts. According to circuit breaker design, the distance between the arcing contacts has to be sufficient to withstand the transient voltage to perform the opening operation successfully. If the voltage is greater, the arc will “re-strike” and alternating current begins to flow again.

Assuming a sufficient distance is reached at the zero crossing to withstand the transient voltage presumes the shape of the arcing contacts is unchanged, according to the design, the contacts are undamaged and the breaker separates the contacts at a given velocity. In the case where arcing contact shape has changed, through wear from previous arcs for example, dielectric strength has decreased and it is probable that this planned distance will not be sufficient to withstand transient voltages. Breaking time will increase as the contacts must now travel further at a finite velocity to reach next current zero-crossing. If the opening velocity of the contacts is not increased the breaker will not clear the current within the specified time; this leads to a longer arcing time and consequently more material wear. Clearly, the performance of the arcing contacts is critical to the performance of the breaker.

Change of the arcing contact shape will most likely affect the main parameter values used for arcing contact assessment (Contact overlapping time, arcing contact wipe).

III. MEASUREMENT PRINCIPLES

Dynamic resistance measurement is performed using a Circuit Breaker Analyzer and Timer instruments (CAT) and software solution for the acquisition and analysis of the obtained results [6]. The device has the ability to generate true DC ripple free current up to 500 A and it has the channel for recording motion of the contact system.

Measurement and calculation of the resistance of the current path is based on the 4 wire Kelvin method (Figure 3).

This principle of resistance calculation has been chosen since the cables have the resistance in the range of mΩ and the contact resistance is in the range of μΩ thus the measurement error using classical two wires method would be significant.
IV. MEASURED VALUES AND PRESENTATION

The result of the DRM consists of:
- Resistance waveform
- Motion waveform
- Voltage drop waveform
- Numerical results

Figure 4 DRM result presentation

The resistance change of CB main circuit during opening operation can be seen the best in the resistance waveform (blue plot). For the interpretation of the result, the most interesting part is the moment in time where the arcing contacts are engaged.

Prior to point A in the Figure 5 the contact system is still in idle state. At point A the contacts starts moving, at point B main contacts separates, at point C the arcing contacts separates and the HVCB changes its role from ideal conductor to ideal insulator. The time difference between points C and B on the time axis represents the arcing contacts overlapping time. Arcing contact overlapping length is extracted from the motion plot, correlating it with previously mentioned points on the time axis.

Figure 5 Period in time (B-C) of the arcing contacts engadement

V. ALGORITHM

Even if points B and C can be obtained manually using cursors, it is highly important to provide the test engineer with the fully automated measurement system and shorten the time of the testing and analysis.

Resistance waveform in an ideal case does not have any superposed noise and points B and C are clearly emphasized. However, depending on a large number of factors, the waveform of the real results contains noise. Also, depending on the state of the contact system, waveform shape in the arcing area varies for different HVCB. All those factors influence the algorithm for determining points B and C on the time scale.

The assumed premise is that in point B and C the waveform has its highest gradient. However, using only this premise to determine points B and C is not enough due to noise and waveform shape differences caused by contact system itself. Because of this, the resistance waveform is filtered.

Figure 6 shows the interesting section of a typical Dynamic Resistance operation and a comparison between the filtered and the raw signal. The purpose of the filter is to "smooth out", to a reasonable amount, the aggressive rate of change of the signal but still keep the qualitative form of the signal intact. This will result in a signal more suitable for certain numerical analysis procedures required to obtain the arcing contact overlapping time. For the smoothing of the signal it has been used classical moving average filter of the order 5.

Figure 6 - Comparison between the filtered (dashed red line) and the raw signal (blue line).

As previously explained, the arcing contact overlapping time from the signal point of view, can be defined as the time difference between the point in time where the signal shows its first "significant" change and the point where the signal displays a final jump. The former point signifies the initial opening of the main contacts and the latter signalizes the completion of the opening process (arcings contacts separation). In other words, we are actually interested in the rates of change of the signal, and by straight forward numerical differentiation of the filtered signal, the key points such as in Figure 7 are obtained:
Using the previously described algorithm, numerical results calculated are shown in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Overlapping time</td>
<td>3 ms</td>
</tr>
<tr>
<td>Overlapping length</td>
<td>2.52° ≈ 8.4 mm</td>
</tr>
</tbody>
</table>

To verify the validity of the algorithm, a manual calculation is performed using the waveforms and cursors, as shown in the Figure 9.

As can be seen in the Figure 9, the moment when main contacts separate is the moment when the resistance changes (significantly increases) for the first time (23.6 ms). The moment when the arcing contacts separate finally is the moment when the resistance goes (theoretically) to infinity (26.6 ms). The time difference (3 ms) between these two moments is the arcing contact overlapping time.

Based on these two moments and motion curve the arcing contact wipe is calculated (2.52°). Since motion is measured with rotary transducer, it is expressed in degrees. When this value is converted into contact motion (60° corresponds to 200 mm), it corresponds to 8.4 mm.

Arcing contacts overlapping distance should not be less than 12 mm for this circuit breaker, so calculated parameters indicate that arcing contacts are worn and should be considered to be investigated or replaced.

Validation of this method will be demonstrated on one more example. This time it is shown on GIS type of circuit breaker. Data about circuit breaker used for this example are given in the table 3.
Table 3. – HVCB data sheet

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>SFT 11 I K (GIS)</td>
</tr>
<tr>
<td>Manufacturer</td>
<td>Energoinvest</td>
</tr>
<tr>
<td>Number of breaks per phase</td>
<td>1</td>
</tr>
<tr>
<td>Rated voltage</td>
<td>123 kV</td>
</tr>
<tr>
<td>Rated short circuit current</td>
<td>31.5 kA</td>
</tr>
<tr>
<td>Rated short circuit duration</td>
<td>3 s</td>
</tr>
<tr>
<td>Operating mechanism</td>
<td>Pneumatic</td>
</tr>
<tr>
<td>Control type</td>
<td>Three pole control</td>
</tr>
<tr>
<td>Medium</td>
<td>SF6</td>
</tr>
</tbody>
</table>

As can be seen in the Figure 10, the moment when main contacts separate is 21.7 ms. The moment when the arcing contacts finally separate is 28.1 ms. The time difference (6.4 ms) between these two moments is the arcing contact overlapping time.

Based on these two moments and motion curve the arcing contact wipe is calculated (26.6 mm). Calculated parameters indicate that arcing contacts are in good conditions since minimum required overlapping distance (contact wipe) of the arcing contacts for this type of CB is 20 mm.

VII. CONCLUSION

Measuring dynamic resistance of the CB main circuit is highly important to assess the condition of the arcing contacts. Also, the automation of the testing procedures is crucial for saving test engineers valuable time. The important parameters of Dynamic Resistance testing have been explained in this paper, and the algorithms and procedures for the extraction of key information about the arcing time and distance have been demonstrated.

Abstract—The distribution power networks are growing in complexity due to the increasing penetration of the distributed power generation such as from wind and solar plants, and distributed resources such as electric vehicles and batteries, which are making the operation of the system more and more challenging. The first step towards more efficient operational capabilities is to introduce an observability of the system. Power system is considered observable, when all its system variables are known, in other words, system variables are chosen in such a way that when known, they allow computation of all other physical quantities in the system. In this paper a State Estimation (SE) software that considers bus voltage magnitudes and phase angles as state variables is presented. To deduce the state of the system from measurements a non-linear relation between measurements and state variables is used. The system is also overdetermined, i.e. there are more measurements then state variables. A non-linear Weighted Least Square (WLS) approach is used to solve the problem at hand with the final goal to demonstrate how quality of measurements affects the quality of power system state awareness. The results are presented in terms of statistical information about the state variables estimated with presented state estimator using generated measurements with added zero-mean Gaussian noise. We show that noise propagation through the SE algorithm is greatly influenced by the selection and placement of measurement devices.

I. INTRODUCTION

A. Motivation

In recent decade it became apparent that global climate change is a man-caused phenomena and consequently a vast societal consensus for shift to low carbon energy sources and transportation appeared [1]. One aspect of this shift are increased investments into the solar and wind power plants, and increased adoption of electric vehicles. Since the nominal powers of these are typically less than 1 MVA, they are normally connected to distribution networks. The distribution networks are thus growing in complexity and their operation is more and more challenging [2], [3]]. It is expected that in less than 10 years the complexity of the system will overgrow current operational capabilities and therefore make safe and stable operation of the system impossible without a real-time regulation of assets in the system. The first step towards more efficient operational capabilities is to introduce the observability of the system, which can be achieved in various ways. The most economically feasible is a combination of special measurement devices (Phasor Measurement Units - PMUs) and real-time SE algorithms [2].

The SE tool has been used in transmission systems for decades, but it’s straightforward application to distribution systems is not possible due to some inherent differences between the two systems. This differences are:

- Load imbalance - distribution systems have many single phase loads and therefore all three phases of the system need to be modelled
- Low line X/R ratio - since the lines are smaller in diameter and shorter in length, their inductance is smaller, which in turn means that phase displacement is smaller and harder to measure.
- High number of nodes - this poses a demand for high number of measurements and increases computational burden.
- Network model uncertainty - network parameters such as series impedances or shunt admittances may be incorrect as a result of inaccurate measurement campaigns. Measurement devices can become inaccurate also due to ageing. All these errors impact the results of the SE.

In this work we present a WLS based SE and attempt to provide an answer about how the measurement errors propagate through state estimation algorithm into its results.

B. Literature review

The existing literature describes several different methods for evaluation of noise propagation. In [4] authors presented a method that compares the covariance matrices of the true state vector based on the error free model and a state vector that is based on a model with a known error. The drawback of this method is that the complete calculation has to be repeated for every measurement in the system. Comparison of two statistical measures namely bias and variance gives a good indication for evaluation of measurement errors. In [5] Macii et al. propose a similar technique that allows computation of noise propagation properties for the complete measurement set. In [6] a two-step method for noise propagation evaluation is proposed. In the first step a WLS estimate is calculated and
the lower and upper bounds are computed for the specified range of the measurement error using linear programming.
In the second step, the method specifies an uncertainty range within which we can be certain that the true value lies.

In [7] authors use the Monte Carlo (MC) method for the evaluation of noise propagation properties in a one phase model. This paper extends [7] with application on a novel unified three-phase branch model.

C. Paper organization

This paper is organized as follows. Section II describes the underlying state-estimation problem and its WLS solution. Section III presents the three-phase branch model and relationships between SE variables and measurements. Section IV describes the simulation framework and demonstrates the results. Section V concludes the paper.

II. State estimator

Power system is considered observable, when all system variables are known, in other words, system variables are chosen in such a way that when known, they allow computation of all other physical quantities in the system. Bus voltage magnitudes and phase angles (commonly referred to as voltage phasors) or branch current magnitudes and phase angles, i.e. current phasors, are most commonly chosen as state variables.

State of the system can be deduced from sufficient number of measurements deployed in the system. Generally we divide measurements into two groups, namely real measurements, i.e. the measurements from the actual devices in the network, and pseudo measurements that are derived from other, typically less accurate, data about the system, e.g. customer load profiles. In order to deduce the state of the system from measurements, we need to establish a relation between the measurements and state variables. In general this relation is non-linear and can be written as

\[
\begin{bmatrix}
  f_1 \\
  f_2 \\
  \vdots \\
  f_m
\end{bmatrix} = 
\begin{bmatrix}
  h_1(x_1, x_2, \ldots, x_n) \\
  h_2(x_1, x_2, \ldots, x_n) \\
  \vdots \\
  h_m(x_1, x_2, \ldots, x_n)
\end{bmatrix} +
\begin{bmatrix}
  w_1 \\
  w_2 \\
  \vdots \\
  w_m
\end{bmatrix}
\]

where \( f_k \) is a measurement of the system’s output, \( h_k(x_1, x_2, \ldots, x_n) \) are the nonlinear functions relating measurement \( k \) to state variables, and \( w \sim \mathcal{N}(0, \mathbf{R}) \) is a Gaussian, zero mean, with covariance matrix \( \mathbf{R} = \text{diag}(\sigma_1^2, \sigma_2^2, \ldots, \sigma_m^2) \) noise contribution to measurement \( k \).

To construct a robust method that tolerates failure or inaccuracy of certain number of measurements, the system (1) needs to be overdetermined, i.e. \( m > n \) where \( n \) is the number of nodes in the system, and \( m \) is the number of real and pseudo measurements; typically \( m \approx 2n \) should hold.

There are various ways to solve such overdetermined systems, i.e. Weighted Least Squares (WLS) [8], variations of Kalman filter (KF) [9], and Bayesian Estimation (BLSE) [10]. Since the problem is overdetermined \((m > n)\), we define the residual function:

\[
 r_i = \frac{f_i - h_i(x)}{\sigma_i}
\]

and write the cost function as a minimization of the weighted least squares (WLS):

\[
 J(x) = \sum_{i=1}^{m} R_{ii}^{-1} r_i^2 = (f - h(x))^T \mathbf{R}^{-1} (f - h(x)).
\]

It can be shown that the WLS approach is a minimum-variance unbiased estimator (MVUE) if the stated noise assumptions hold true [11].

Since the problem has no direct solution, the Newton-Gauss method can be used to solve it iteratively. Starting with an initial guess \( x^{(0)} \), the method proceeds with:

\[
 x^{(k+1)} = x^{(k)} - (J^{(k)}J^{(k)})^{-1} J^{(k)} r^{(k)}
\]

where \( J^{(k)} \) is a Jacobian matrix with the elements:

\[
 J_{ij}^{(k)} = \frac{\partial R_{ii}^{-1}(f_i - h_i(x^{(k)}))}{\partial x_j}
\]

The method terminates when the difference between two successive approximations falls below a selected threshold:

\[
 |x^{(k+1)} - x^{(k)}| < \epsilon.
\]

The first partial derivatives of the measurement functions with respect to the state variables (Eqn. 6) required by the Gauss-Newton method can be found in [12].

III. Three-phase Branch Model

A three-Phase Branch Model [13], considered in this paper (Fig. 1), is symmetrical and establishes a relationship between the voltages and currents between the nodes \( k \) and \( m \). The node voltage phasors are denoted as:

\[
 E_m = |V_m|e^{j\phi_m},
\]

where \(|V_m|\) represents the phasor magnitude, and \( \phi_m \) represents a phase angle at the node \( m \) on phase \( a \). The self and mutual series impedances are denoted as \( z_{km}^s \), and \( Y_{km,sh} \) is the matrix of self and mutual shunt admittances. The elements \( T_{km} \) and \( T_{mk} \) are presented as matrices and are used for the modeling of voltage regulators or tap changers.
Line current equations that follow from the model are:

\[ I_{km} = \sum_{j \in \Omega_p} \sum_{n \in \Omega_p} \left( y_{km}^{j,n} + y_{km,sh}^{j,n} \right) I_{km}^j I_{km}^n \]
\[ I_{mk} = \sum_{j \in \Omega_p} \sum_{n \in \Omega_p} \left( y_{km}^{j,n} + y_{mk,sh}^{j,n} \right) I_{mk}^j I_{mk}^n \]
\[ T_{km} = \sum_{j \in \Omega_p} \sum_{n \in \Omega_p} \left[ (y_{km}^{j,n} + y_{km,sh}^{j,n}) I_{km}^j I_{km}^n E_m^j \right] \]
\[ T_{mk} = \sum_{j \in \Omega_p} \sum_{n \in \Omega_p} \left[ (y_{km}^{j,n} + y_{mk,sh}^{j,n}) I_{mk}^j I_{mk}^n E_m^j \right] \]

(9)

where \( \Omega_p = \{a, b, c\} \) denotes the phases. A matrix form of the equations can be obtained as shown in [13] which is more convenient for computer implementation.

Formulation of the state-estimation problem usually includes active and reactive line-power flow and active and reactive node power injection measurements, as well. Expressions for them are provided in Eqs. 11, Eqs. 12, Eqs. 13, and Eqs. 14 respectively, where \( y_{km}^{a,p} = g_{km}^{a,p} + j b_{km}^{a,p} \) is the branch series admittance, and \( G_{km}^{a,p} \) and \( B_{km}^{a,p} \) respectively, represent the real and imaginary components of the \((a, p)\) element of the \((k, m)\) system-admittance submatrix, and \( \kappa \) is the set of buses adjacent to bus \( k \), including bus \( k \).

IV. UNCERTAINTY PROPAGATION

The quality of estimated state variables is reflected from the noise in the measurement. We are interested in how the noise propagated through the SE algorithm into the state variables, i.e. we attempt to evaluate how the uncertainty of different types of measurements in different measurement configurations in the network is transmitted into the estimated state variables. This is done by means of MC simulations on several different measurement configurations. In each particular experiment noise is added to a single selected measurement, while other measurements are assumed to be perfectly accurate, without added noise. The measurements are generated from the load-flow results for the reference feeder loading provided by the IEEE [14], more precisely the methodology was tested on the 13-bus IEEE distribution test feeder [14] presented in Fig. 2 (labels on branches represent phasing sequence, labels near spot loads represent load type and connection). Measurement that has added noise is calculated as follows:

\[ X_{\text{meas}} = N(X_{\text{refVal}}, X_{\text{refVal}} X_{\text{acc}}/2). \]

(10)

For each experiment 500 MC runs were performed. The result sets were then processed to evaluate their statistical behaviour.

Uncertainty propagation was evaluated for several measurement configurations, namely:

1) All buses were equipped with injection active and reactive power measurements. No other measurements were installed.
2) All buses were equipped with voltage PMU measurements. No other measurements were installed.
3) All branches were equipped with active and reactive power flow measurements. No other measurements were installed.
4) All buses but the selected one were equipped with voltage PMU measurements. The selected bus was equipped with active and reactive power injection measurement.

Measurement device accuracies were selected as 2 sigma values for the Gaussian random generator, and the values for different devices were selected as follows:

- 10% of the reference value for active and reactive power flow measurements.
- 50% of the reference value for active and reactive power injection measurements.
- 1% of the reference value for the PMU magnitude.
- 0.005° for the PMU angle.

Fig. 2. The 13-bus IEEE test feeder

1) Measurement configuration 1: In this measurement configuration noise is added to the measurement on the first phase of active power measurement on bus 671. All other measurements have no noise added as shown in Fig. 3. The results of SE for buses 634 and 675 are shown in Fig. 4 and Fig. 5 respectively. It can be observed that the distribution of the results is also Gaussian, and that the noise spreads to other two phases. Bias and variance for all buses for both experiments are shown in Table I. It can be observed that added noise in single measurement spread across all buses in this measurement configuration.

2) Measurement configuration 2: In this measurement configuration, noise was added to the phase measurement on the bus 632 as shown in Fig. 6. Since the SE problem for this measurement configuration is linear (the configuration consists solely of PMU measurements), the noise does not spread across other buses in the SE results. The results for bus 632 are shown in Fig. 7, since there is no influence on the other buses the results for them are not presented.

3) Measurement configuration 3: In this measurement configuration, noise was added to the flow measurement between buses 671 and 684. Similarly to measurement configuration 1, the noise due to the non-linear formulation of state estimation problem spreads across all buses. Results for all buses are presented in Table II.

4) Measurement configuration 4: In this measurement configuration all the buses, except bus 671, were equipped with the voltage PMU measurements. Bus 671 was equipped with a real/reactive power injection measurement. Noise was added
\[ P^a_{km} = |V_k^a| \sum_{i \in \Omega_p} \sum_{j \in \Omega_p} \sum_{m \in \Omega_p} \left\{ \begin{array}{l} t^m_i t^j_k [V^i_j] \left[ (g^m_{km} + g^m_{km,sh}) \cos(\phi^a_k - \phi^i_k) + (b^m_{km} + b^m_{km,sh}) \sin(\phi^a_k - \phi^i_k) \right] \\ - t^m_i t^j_k [V^i_j] \left[ g^m_{km} \cos(\phi^a_k - \phi^i_k) + b^m_{km} \sin(\phi^a_k - \phi^i_k) \right] \end{array} \right\} \] (11)

\[ Q^a_{km} = |V_k^a| \sum_{i \in \Omega_p} \sum_{j \in \Omega_p} \sum_{m \in \Omega_p} \left\{ t^m_i t^j_k [V^i_j] \left[ (g^m_{km} + g^m_{km,sh}) \sin(\phi^a_k - \phi^i_k) - (b^m_{km} + b^m_{km,sh}) \cos(\phi^a_k - \phi^i_k) \right] \\ - t^m_i t^j_k [V^i_j] \left[ g^m_{km} \sin(\phi^a_k - \phi^i_k) - b^m_{km} \cos(\phi^a_k - \phi^i_k) \right] \right\} \] (12)

\[ P^a_k = |V_k^a| \sum_{m \in \Omega_p} \sum_{p \in \Omega_p} |V_p^m|^2 \left( G_{km}^{op} \cos(\phi^a_k - \phi^p_m) + B_{km}^{op} \sin(\phi^a_k - \phi^p_m) \right) \] (13)

\[ Q^a_k = |V_k^a| \sum_{m \in \Omega_p} \sum_{p \in \Omega_p} |V_p^m|^2 \left( G_{km}^{op} \sin(\phi^a_k - \phi^p_m) - B_{km}^{op} \cos(\phi^a_k - \phi^p_m) \right) \] (14)

V. CONCLUSION

In this paper measurement noise propagation in distribution-system SE was evaluated through means of MC simulation. It has been shown that configuration of measurements has a large influence on noise spread in the SE variables. It has also been shown that in the configuration consisting solely of PMU measurements, the noise stays localized to a particular node, as a result of linear formulation of SE problem. However, using other measurement types with non-linear measurement functions, the noise of a particular measurement spreads into the adjacent phases and into other buses. This effect is most severe in the configuration with power injection measurements.

The main drawback of presented analysis is the computational inefficiency, which renders it useless for larger networks. The future work will be therefore focused on the formulation of more computational effective techniques for sensitivity analysis of SE algorithms.

Summary - Simultaneously with the development of modern industrial plants there are also increasing demands for more powerful industrial automation systems in terms of safer and more reliable process. Failure or malfunction of specific component of the system can result in fatalities or negative effects on the equipment and/or the environment. Apart from this, a downtime of a plant can cause big financial losses. However, the implementation of fail-safe (FS) technology and fail-safe programmable logic controllers (PLC) prevents above-mentioned harmful consequences. This paper focuses on the implementation of fail-safe technology in a gas pressure reducing station. It generally describes how fail-safe system of boiler room directly affects on the reliability of natural gas distribution.

I. INTRODUCTION

Recently, there has been a growing interest in fail-safe technology based on fail-safe PLC systems. With the development of fail-safe programming logic controllers, industrial automation has made a significant step forward with application of high-level safety and reliability. Fail-safe technology is present in industries such as oil and gas, manufacturing, chemical, automotive, food and beverage, health-care, and nuclear power industry, as well as in many other industries. In addition, it provides safety and reliability of highly sophisticated systems and machines like railway crossings systems, robotic surgery systems, demining machines, management and control of airport traffic and so on [1][2][3][4][5]. It is also important to note that in the given examples the smallest irregularity or malfunction can have harmful consequences. There are many advantages of integrated FS PLC safety: only one programming tool is necessary for the development of standard and safety automation; implementation of a fail-safe system is easier and faster due to the unique engineering techniques; only one cable is used for standard and safety communication; changes to the standard program do not have any consequences for the safety program; fault detection is much faster. All of the above ensures that this is a high quality solution in industrial safety, and it is more economical than standard fail-safe solutions [6][7].

In the recent years, many commercial projects and research studies have focused on the implementation of fail-safe technology in order to ensure more reliable and safer industrial systems. Although considerable projects have been aimed at high representation of fail-safe technology, less attention has been paid to implementation of fail-safe technology in secondary gas distribution systems. A typical example of a secondary system in which a high level of safety can be neglected is a gas boiler room, which is an integral part of the gas pressure-reduction station (Fig. 1). Considering that there is no permanent staff present at the gas pressure-reduction station, in the event of failure or malfunction, the FS integrated PLC system must automatically, safely and reliably ensure a safe state of the boiler plant. The purpose is to prevent major damage to special equipment or fatalities and to ensure that natural gas distribution and delivery is highly reliable.

The aim of this paper is to illustrate the application of FS PLC and other advanced technical solutions on the example of the gas pressure-reduction station system. The goal is to ensure a high level of safety of personnel, machinery and work equipment. The paper generally explains the role of the pressure-reduction station and the method of pre-heating natural gas at gas pressure reduction stations.

Figure 1. Pressure-reduction station, gas reduction lines.

II. INTEGRATED SAFETY FEATURES OF MODERN PLCS

For a better understanding of this paper, it is important to realize the difference between the two key terms: “Available System” and “Safe System”. Availability prevents process downtime. Ideal availability of 100% cannot be reached in practice. However, the purpose of high-availability (H) systems is to minimize the probability of unwanted breaks within the system. It means that the economic effectiveness directly depends on the availability of the system [8]. The
ideal safety of 100% also cannot be reached, but fail-safe, as a high-level safety feature, prevents accidents and damage caused by faults in machines or industrial systems with above the average effectiveness. In the event of failure it reacts in the way that can cause minimum harm to people, equipment or the environment [9].

Before the modern PLC devices with integrated characteristics of safety and availability came into existence, it was only possible to combine two or more standard PLCs to achieve high availability and/or fail-safety of industrial automation systems. Implementation of two or more standard PLC devices enables mutual supervision. At the moment of failure of one of these, in case of a system that requires high availability a backup PLC allows the execution of the system to function without any interruption. For systems that require fail-safety, a backup PLC brings the system into a safe state. The required aspects of availability and safety are achieved with certain features of standard PLCs, but the lower cost of implementation and maintenance, as well as a less complex system design that reduces the possibility of error are demands placed upon the new generation devices and systems. Because of the abovementioned, today we have modern PLCs with integrated features of safety and availability. We call it fail-safe PLCs and high availability PLCs. They ensure safety and availability just like complex redundant standard systems, but in comparison to them, they have many more advantages.

This paper focuses on PLC devices that provide a high overall level of safety. As mentioned before, standard PLC controllers used in safety applications are typically configured in pairs. The backup controller is used to support the safe controller and automatically shuts down the system if the primary controller fails (Fig. 2). The goal is to prevent major damage or fatalities. Safety systems and their applications that are designed by standard PLCs use additional inputs to supervise safety system output signals. Design of safety systems by use of standard PLCs requires additional engineering time, hardware, wiring, etc. [10].

To sum up, a fail-safe system based on FS PLC has to be designed in a way that it, in the event of failure of any FS function with a high level of reliability, detects the fault and responds with a predetermined action. Predetermined action for a result must have safe state of system or machine. Once a failure or a fault has been detected, FS PLC executes a prepared FS action. For example, it shuts down the plant and starts the alarm. Next, the operator has to acknowledge that FS detected a fault, repair this fault and then, the plant can finally be put into operation again.

Integrated programmable logic controllers safety has many technical specificities. All of the hardware is in one housing, and only one CPU is required to handle standard and safety automation. It is possible for the safety and standard automation application to exist in the system simultaneously. Standard and safety communication can be established through only one bus cable. Only one distributed input/output configuration is necessary. There is a unique procedure for standard and safety engineering which reduces implementation time. Safety logic is software-based and other specificities [11].

When designing and installing high-safety integrated PLC systems, additional attention should be paid to the selection of sensors and actuators. They have to meet the strict requirements of safety standards. The safety category level depends on the sensor and actuator quality, the probability of failures and the mean time between failures of used equipment should also be considered. The way of connecting the sensors and actuators to I/O modules also affects the level of safety. An actuator has to be able to tolerate fail-safe testing impulses etc. [7].

In general, fail-safe PLCs represent a unique system of integrated safety and standard automation features (Fig. 3). PLCs with safety-integrated features have many advantages as follows: safety functions can be programmed instead of wiring; only one software development tool is necessary for programming; shorter downtime thanks to a less complex design of the system; and due to a less complex design, the engineers have to devote less time and they need to provide less support to the operation of the system [9][11]. Moreover, all of the mentioned advantages drastically reduce the engineering time in designing, programming, implementation and operation of high-level safety systems. More specifically, PLCs with safety-integrated features are much more economical than other safety solutions.

Generally speaking, most of the modern manufacturers of fail-safe controllers certify their products in accordance with IEC 61508 Functional Safety and are suitable for use in safety-related applications according to IEC 62061 and ISO 13849 [12][13].

III. NATURAL GAS METERING AND REDUCTION STATION

A pressure-reduction station is one of the crucial parts of the natural gas pipeline transmission system. It connects the high-pressure gas transmission system to the lower-pressure gas distribution. The primary technological task of a pressure reduction station is to reduce pressure in accordance with the needs of distributors and users. Apart from this, a pressure-reduction station also carries out additional tasks: it filters natural gas in order to provide gas without impurities, it preheats gas, regulating the flow rate in accordance with its flow capacity and it perform various measurements, the role of which is to optimize and

---

**Figure 2. Safety and standard automation as divided systems [9].**

**Figure 3. FS PLC with integrated safety [9].**
supervise the pressure-reduction station (PRS) system. The boiler system ensures that natural gas is preheated, thereby ensuring the validity of the pressure regulation line’s special equipment, as well as the reliability of natural gas delivery.

For the Plinacro d.o.o. company, a natural gas transmission system operator in Croatia, a gas pressure reducing station is one of the integral parts of its transmission system. Currently, there are around 150 more or less complex pressure-reduction stations in Croatia [14][15].

In high-pressure pipelines, natural gas comes to the pressure-reduction station at the pressure-reduction line (Fig. 4). Having passed through the inlet valve, it goes through filtering and preheating processes. After these two steps, it goes into the pressure regulator, where pressure reduction is performed. The pressure reduction process has an unwanted side effect rapid cooling of the gas. If safe and reliable preheating of the reduction-line is not ensured, there is a high possibility of the gas freezing and damaging the equipment and the fittings. As a result, a disruption of gas delivery to distributors and their end users is very likely.

Natural gas pressure-reduction stations supply households, industrial plants and other important facilities. In certain cases, interruptions to the supply of industrial plants may cause production downtime and, as is to be expected, significant, sometimes multimillion financial losses.

For the purpose of technical functionality of the system, prior to the pressure-reduction process, natural gas has to go through the process of preheating. This process is usually carried out with the help of hot water filter-exchangers, which have two roles: the role of filtering and the primary role of preheating. The boiler room, which is an integral part of PRS (Fig. 5), provides the necessary heating energy for the exchangers. Modern condensing boilers can achieve high efficiency, which is typically greater than 90%. Circulator pumps are responsible for heat transmission and circulation of the antifreeze fluid from the boilers at the boiler room to the heat exchangers in the reduction room (Fig. 6). There are also systems in which preheating is performed by heating cables. In such cases, the heating cables and their installation have to meet strict requirements of protection against explosions. The main role of the boiler room of the PRS is to maintain the output gas temperature above 0 °C. Considering that the temperature directly affects the gas volume and quality, usually the temperature setpoint is between 10 °C and 15 °C. Electromotor control valves regulate the amount of heated fluid, which maintains the desired output gas temperature (Fig. 6). For the purpose of automated control of electromotor valves, it is necessary to form a software-related PID (Proportional-Integral-Derivative, PID) controller block. Accordingly, when the gas output temperature rises (temperature after reduction), a power-operated valve actuator slowly closes hot fluid flow, and when it drops, it slowly opens and increases hot fluid flow. Depending on the temperature deviation control in comparison to the setpoint value, the pulses for opening or closing the valve can be longer or shorter.

A. The high overall level of safety in the boiler room of a gas pressure-reduction station

At the very beginning of industry development, safety aspects of industrial facilities were ignored, but industrial facilities gradually become not only more sophisticated, but also more dangerous for their personnel and the environment surrounding them. Therefore, the number of injuries and fatalities at the workplace gradually grew in industrial facilities. A result, more attention is given to the safety of the workplace and personnel now than ever before. As stated above, safety of personnel, machinery and the environment in modern industrial plants is a very important requirement, which all modern facilities have to satisfy.
Alongside the individual engineering solutions, which ensure high-level safety of complex industrial systems, significant progress has been made regarding the safety aspects of industrial automation. Now we have industrial PLC controllers with integrated high-level safety features. Such a PLC device is the heart of the automation system of a gas pressure-reduction station’s boiler room. A very important task when designing high-safety systems is to properly define the safety integrity level (SIL) which the system must to satisfy. Designing safety aspects of automated regulation and control of gas pressure-reduction station’s boiler room has to be performed in accordance with the valid industrial safety standards like IEC 62061, IEC 61508 and ISO 13849.

Through detailed analysis, it has been established that the safety aspects of the boiler room have to meet the safety category SIL 2. For this reason, safety in PRS boiler rooms is ensured in accordance with the specified requirements [16]. To assist in designing fail-safe systems, IEC standards recommend the requirements shown in Fig. 7, as well as Table 3 [6][17]. All elements of the designed and implemented safety systems, as well as the entire system with all of its integral parts and features must satisfy the requirements shown in Table 2 [17].

Typically in Croatia, the PRS boiler room in an electrical control panel has a built-in FS PLC controller with a central processor unit (CPU) and modules with integrated SIL safety features. Most commonly, Configuration of FS PLC at a PRS is based on the CPU type 315F-2DP with the appropriate modules of both standard and safety automation. It should be noted that the PLC architecture and programming interface of modern FS PLC devices integrated in boiler rooms of pressure-reduction stations meet the requirements of valid safety standard.
As mentioned, the analog FS input modules of the PRS’s boiler room are connected and implemented in compliance with SIL 2 category. At its input terminals, they accept analog process data regarding the boiler temperature (PT100 temperature-probes); exhaust smoke temperature (PT100 temperature-probes) and fluid pressure (4–20 mA, pressure-transmitter). These analog values, which are well-known for their role of supervision, ensure the function of the boiler room’s safety signals. They are implemented in the FS PLC software application and included into process shutdown (PSD) safety function. When PSD conditions are met, fail-safe PLC currently and automatically bring the boiler system into a safe state! To summarize, the following data is used as critical analog input values which fail-safe PLC use for activation of PSD actions: very high boiler temperature; very high boiler exhaust smoke temperature; and very high or very low value of pressure inside the pipes of the boiler room preheating system. In addition, a PSD alarm can be activated manually if the operator detects a threat in the system or in the event of failure of any integral part of the FS function. The alarm limits of the mentioned critical values are determined by many factors. For the most part, they depend on the technical characteristics of installed machinery and system design, but the location and construction of the facility can also affect the limits.

The FS modules of the FS PLC controller receive the aforementioned signals and include them into the PSD software application. FS PLC must also join execution elements in order to fully fulfill its role of integrated safety of the boiler room's machinery. Operating personnel is not present at most of the metering/pressure-reduction stations and other objects within gas transmission system in normal operation mode. Therefore, attention should be paid to the quality of installed equipment and machinery, and especially to the quality of installation of the safety equipment. FS digital output module executes important output actions. In the case of PSD state, use of digital FS output modules and certified safety relays, a high level of overall safety can be reached. When a PSD state has been detected, the PSD functionality immediately turns the gas burner off. The PSD system, which has a very high level of safety integrity, detects a fault or a failure in the boiler room and returns it to a safe state in the above mentioned way. In most cases, it prevents the destruction of an expensive, highly sophisticated installation, equipment and machinery. It is important to note that emergency shut down hand-activators, faults of process boilers (heaters), boiler’s maintenance mode, etc. also activate FS output signals. Their main role is reliable supervision; they have nothing to do with the PSD functioning. With regard to a higher level of safety, implementation of those signals in such a way so as to achieve a higher level of reliability should be taken into consideration. Activation of any ESD element activates an FS alarm that triggers the local executive signal elements: a signal horn and a signal light placed outside, at the entrance to the boiler room. At the same time, a general alarm signal is transmitted through a modern telemetry system to the monitor center of the main gas transmission system. All elements of the FS chain are constantly tested regarding their functionality. To conclude, in case a fault or a failure of any FS PSD component is detected, the PSD function returns the boiler system into a safe state. The FS PLC device represents the heart of the automated regulation and supervision of the heating system of the gas pressure-reduction station, showing the advantages of integrated standard and safety automation as a unified system.

As one can realize, setting the boiler room system in a safe state has a direct negative effect on the reliability of natural gas delivery. When the preheating process is terminated there is a possibility of a breakdown and/or malfunction of reduction line system. The current performance of the system and the supervision and maintenance procedures of the PRS facility pose a very low level of risk. But why the PSD safe state does not negatively affect delivery of natural gas? This is why the level of risk is low: immediately, when PSD alarm state detected; a modern telemetry system sends alarm information about downtime of the boiler system to the main control center. The control center continuously monitors all alarms and relevant process data of the pressure-reduction station 24/7. In order to meet the PRS system’s demands, experienced employees with extensive knowledge and wide experience are available 24/7, both in the monitoring room and out in the field. Considering the system’s inertia, changes in the output gas temperature are mostly gradual (in most cases it takes hours for the reduction machinery to freeze). Furthermore, experienced personnel have enough time to arrive at the facility, eliminate the minor fault and put the boiler system back into the operating mode again. Therefore, the implementation of a fail-safe programmable logic controller at the pressure-reduction station's boiler room provides a high level of overall safety. It prevents major damage to the pressure-reduction system and ensures the reliability of natural gas delivery [18].

B. Technical concepts of explosion protection inside the gas pressure-reduction station

The basic concept of preventing the occurrence of technological explosions is based on prevention of simultaneous occurrence of an explosive atmosphere and a source of ignition. Explosive atmospheres can be created by flammable gases, mists or vapors or by combustible dusts. Explosions can lead to fatalities or serious injuries as well as major damage to the machinery or the whole industrial plant. A source of ignition can, for example, be: an electric spark caused by a short circuit, mechanical spark, hot surfaces, flame, static electricity, electromagnetic radiation, lightning strike, leakage currents, etc. [19][20]. The temperature and pressure affect the lower and upper limit of explosion. High temperatures affect the reduction of lower explosion level (LEL) and increase of upper explosive level (UEL). High pressure results in both values increasing. Potential releases of natural gas outside the pipeline in the reduction room can result in a flammable atmosphere. Under normal atmospheric conditions, LEL is 5% while UEL is 13% [21].

Considering the area endangered by explosion, and the probability of occurrence of an explosive atmosphere, areas of the pressure-reduction facility are classified as Zone 1 IIA T1 (gas dischargers outside, on the roof of PRS) and Zone 2 IIA T1 (inside the reduction room). A detailed hazardous area classification is shown in hazardous area studies (Fig. 8). Installation, maintenance and repair of
explosion-proof equipment (Ex equipment) must be carried out in accordance with IEC 60079-14, IEC 60079-17 and IEC 60079-19 standards.

Temperature sensors (usually PT100 probes) are immersed in the low-pressure gas collectors after the heat exchanger and after pressure regulator. They are installed as intrinsically safe (Exi), and their associated Exi interfaces are installed outside the classified zone, at the main electrical control cabinet of the boiler room. Their function is very important, because it is used for precise regulation of the natural gas output temperature. Temperature values indirectly determine the required amount of heat necessary for the preheating process. It is important to note that the intrinsically safe circuits must be installed in accordance with the strict rules of explosion protection.

Table 4. Protection against explosion—explanation of used terms [20].

| Zone 0 | Explosive atmosphere present continuously or for long periods or frequently. |
| Zone 1 | Explosive atmosphere is likely present in normal operation. |
| Zone 2 | Explosive atmosphere is unlikely in normal operation and, if it occurs, will be present for only a short period. |
| IIA | A group of gases that can occur within the classified Ex zones (IIA-hydrocarbon, methane, etc.). |
| T1 | Represents equipment temperature limit which has to be < T, and the ignition temperature which has to be > T (for T1 category = 450 °C). |
| Intrinsic safety | Type of explosion protection, based on limiting the power of circuits below the minimum ignition energy of the observed explosive atmosphere. |

To summarize, modern technical solutions of explosion protection are contributing to the safety of the entire PRS facility. They significantly reduce the possibility of damage, fatalities, environmental pollution and downtime of natural gas distribution. It is very important to keep in mind that an explosion can cause complete destruction of the pressure-reduction facility. Modern PLC devices in contain modules that are manufactured to meet the special requirements of explosion protection (Ex) and the safety integrity level (SIL) conditions in their configuration. Ensuring an additional level of safety and reducing the cost of the system design and integration entails an unique combination of high standards of explosion protection and the high standards of the safety integrity level.

Figure 8. PRS facility - hazardous area classification.

IV. CONCLUSION

Implementation of fail-safe technology on a pressure-reduction station’s boiler room drastically reduces the possibility of damage to the machinery and ensures reliability of natural gas distribution. Integrated FS programmable logic controllers significantly simplify the design, implementation and maintenance of the system. Accordingly, modern pressure-reduction stations are more advanced and more economical than they used to be. Likewise, there is still room for improvement in the area of inspection and joint implementation of the safety integrity level and technologies aimed at explosion protection in order to obtain a contemporary system.

LITERATURE

Brief Review of Self-Organizing Maps

Dubravko Miljković
Hrvatska elektroprivreda, Zagreb, Croatia
dubravko.miljkovic@hep.hr

Abstract - As a particular type of artificial neural networks, self-organizing maps (SOMs) are trained using an unsupervised, competitive learning to produce a low-dimensional, discretized representation of the input space of the training samples, called a feature map. Such a map retains principle features of the input data. Self-organizing maps are known for its clustering, visualization and classification capabilities. In this brief review paper basic tenets, including motivation, architecture, math description and applications are reviewed.

I. INTRODUCTION

Among numerous neural network architectures, particularly interesting architecture was introduced by Finish Professor Teuvo Kohonen in the 1980s, [1,2]. Self-organizing map (SOM), sometimes also called a Kohonen map use unsupervised, competitive learning to produce low dimensional, discretized representation of presented high dimensional data, while simultaneously preserving similarity relations between the presented data items. Such low dimensional representation is called a feature map, hence map in the name. This brief review paper attempts to introduce a reader to SOMs, covering in short basic tenets, underlying biological motivation, its architecture, math description and various applications, [3-10].

II. NEURAL NETWORKS

Human and animal brains are highly complex, nonlinear and parallel systems, consisting of billions of neurons integrated into numerous neural networks, [3]. A neural networks within a brain are massively parallel distributed processing system suitable for storing knowledge in forms of past experiences and making it available for future use. They are particularly suitable for the class of problems where it is difficult to propose an analytical solution convenient for algorithmic implementation.

A. Biological Motivation

After millions of years of evolution, brain in animals and humans has evolved into the massive parallel stack of computing power capable of dealing with the tremendous varieties of situations that it can run into. The biological neural networks are natural intelligent information processors. Artificial neural networks (ANN) constitute computing paradigm motivated by the neural structure of biological systems, [6]. ANNs employ a computational approach based on a large collection of artificial neurons that are much simplified representation of biological neurons. Synapses that ensure communication among biological neurons are replaced with neuron input weights. Adjustment of connection weights is performed by some of numerous learning algorithms. ANNs have very simple principles, but their behavior can be very complex. They have a capability to learn, generalize, associate data and are fault tolerant. The history of the ANNs begins in the 1940s, but the first significant step came in 1957 with the introduction of Rosenblatt’s perceptron. The evolution of the most popular ANN paradigms is shown in Fig. 1, [10].

B. Basic Architectures

An artificial neural network is an interconnected assembly of simple processing elements, called artificial neurons (also called units or nodes), whose functionality mimics that of a biological neuron, [4]. Individual neurons can be combined into layers, and there are single and multi-layer networks, with or without feedback. The most common types of ANNs are shown in Fig. 2, [11]. Among training algorithms the most popular is backpropagation and its variants. ANNs can be used for solving a wide variety of problems. Before the use they have to be trained. During the training, network adjusts its weights. In supervised training, input/output pairs are presented to the network by an external teacher and network tries to learn desired input/output mapping. Some neural architectures (like SOM) can learn without supervision (unsupervised) from the training data without specified input/output pairs.

Figure 1. Evolution of artificial neural network paradigms, based on [10]

Figure 2. Most common artificial neural networks, according to [11]
III. SELF-ORGANIZING MAPS

Self-organized map (SOM), as a particular neural network paradigm has found its inspiration in self-organizing and biological systems.

A. Self-Organized Systems

Self-organizing systems are types of systems that can change their internal structure and function in response to external circumstances and stimuli, [12-15]. Elements of such a system can influence or organize other elements within the same system, resulting in a greater stability of structure or function of the whole against external fluctuations, [12]. The main aspects of self-organizing systems are increase of complexity, emergence of new phenomena (the whole is more than the sum of its parts) and internal regulation by positive and negative feedback loops. In 1952 Turing published a paper regarding the mathematical theory of pattern formation in biology, and found that global order in a system can arise from local interactions, [13]. This often produces a system with new, emergent properties that differ qualitatively from those of components without interactions, [16]. Self-organizing systems exist in nature, including non-living as well as living world, they exist in man-made systems, but also in the world of abstract ideas, [12].

B. Self-Organizing Map

Neural networks of neurons with lateral communication of neurons topologically organized as self-organizing maps are common in neurobiology. Various neural functions are mapped onto identifiable regions of the brain, Fig. 3, [17]. In such topographic maps neighborhood relation is preserved. Brain mostly does not have desired input-output pairs available and has to learn in unsupervised mode.

A SOM is a single layer neural network with units set along an n-dimensional grid. Most applications use two-dimensional and rectangular grid, although many applications also use hexagonal grids, and some one, three, or more dimensional spaces. SOMs produce low-dimensional projection images of high-dimensional data distributions, in which the similarity relations between the data items are preserved, [18].

C. Principles of Self-Organization in SOMs

Following three processes are common to self-organization in SOMs, [7,19,20]:

1. Competitive Process
   For each input pattern vector presented to the map, all neurons calculate values of a discriminant function. The neuron that is most similar to the input pattern vector is the winner (best matching unit, BMU).

2. Cooperative Process
   The winner neuron (BMU) finds the spatial location of a topological neighborhood of excited neurons. Neurons from this neighborhood may then cooperate.

3. Synaptic Adaptation
   Provides that excited neurons can modify their values of the discriminant function related to the presented input pattern vector by the process of weight adjustments.

D. Common Topologies

SOM topologies can be in one, two (most common) or even three dimensions, [2-10]. Two most used two dimensional grids in SOMs are rectangular and hexagonal grid. Three dimensional topologies can be in form of a cylinder or toroid shapes. 1-D (linear) and 2-D grids are illustrated in Fig. 4, with corresponding SOMs in Fig. 5 and Fig. 6, according to [19].

![Figure 4. Most common grids and neuron neighborhoods](image)

![Figure 5. 1-D SOM network, according to [19].](image)

![Figure 6. 2-D SOM network, according to [19].](image)

IV. LEARNING ALGORITHM

A. Measures of Distance and Similarity

To determined similarity between the input vector and neurons measures of distance are used. Some popular distances among input pattern and SOM units are, [21]:

- Euclidian
- Correlation
- Direction cosine
- Block distance

In a real application most often squared Euclidean distance is used, (1):

\[ d_j = \sum (v_i - w_i)^2 \]  

(1)
B. Neighborhood Functions

Neurons within a grid interact among themselves using a neighbor function. Neighborhood functions most often assume the form of the Mexican hat, (2), Fig. 7, that has biological motivation behind (rejects some neurons in the vicinity to the winning neuron) although other functions (Gaussian, cone and cylinder) are also possible, [22]. Ordering algorithm is robust to the choice of function type if the neighbor radius and learning rate decrease to zero. The popular choice is the exponential decay.

\[ h_r(w_i, w_m, r) = e^{-\frac{(r^2 - d^2)}{2}} \]  

(2)

Figure 7. Mexican hat function

C. Initialization of Self-Organizing Maps

Before training SOM, units (i.e. its weights) should be initialized. Common approaches are, [2,23]:
1. Use of random values, completely independent of the training data set
2. Use of random samples from the input training data
3. Initialization that tries to reflect the distribution of the data (Principal Components)

D. Training

Self-organizing maps use the most popular algorithm of the unsupervised learning category, [2]. The criterion \( D \), that is minimized, is the sum of distances between all input vectors \( \mathbf{x}_i \) and their respective winning neuron weights \( \mathbf{w} \) calculated at the end of each epoch, (3), [21]:

\[ D = \sum_{i=1}^{n} \sum_{j=1}^{m} (x_{ij} - w_{ij})^2 \]  

(3)

Training of self-organizing maps, [2,18], can be accomplished in two ways: as sequential or batch training.

1. Sequential training
   - single vector at a time is presented to the map
   - adjustment of neuron weights is made after a presentation of each vector
   - suitable for on-line learning
2. Batch training
   - whole dataset is before any adjustment to the neuron weights is made
   - suitable for off-line learning

Here are steps for the sequential training, [3,7,19,22]:
1. Initialization
   - Initialize the neuron weights (iteration step \( n=0 \))
2. Sampling
   - Randomly sample a vector \( \mathbf{x}(n) \) from the dataset
3. Similarity Matching
   - Find the best matching unit (BMU), \( c \), with weights \( \mathbf{w}_{m_{BMU}} \), \( \mathbf{w}_c \), (4):
   \[ c = \arg \min \| \mathbf{x}(n) - \mathbf{w}(n) \| \]  

(4)

4. Updating
   - Update each unit \( i \) with the following rule:
   \[ \mathbf{w}_i(n+1) = \mathbf{w}_i(n) + \alpha(n) h_r(w_{i}, w_{c}, r(n)) \| \mathbf{x}(n) - \mathbf{w}_i(n) \| \]  

(5)

5. Continuation
   - Increment \( n \). Repeat steps 2-4 until a stopping criterion is met (e.g. the fixed number of iterations or the map has reached a stable state).

For the convergence and stability to be guaranteed, the learning rate \( \alpha(n) \) and neighborhood radius \( r(n) \) are decreasing with each iteration towards the zero, [22].

SOM Sample Hits, Fig. 8, show the number of input vectors that each unit in SOM classifies, [24].

Figure 8. SOM Sample Hits, [24]

During the training process two phases may be distinguished, [7,18]:
1. Self-organizing (ordering) phase:
   - Topological ordering in the map takes place (roughly first 1000 iterations). The learning rate \( \alpha(n) \) and neighborhood radius \( r(n) \) are decreasing.
2. Convergence (fine tuning) phase:
   - This is fine tuning that provides an accurate statistical representation of the input space. It typically lasts at least (500 x number of neuron) iterations. The smaller learning rate \( \alpha(n) \) and neighborhood radius \( r(n) \) may be kept fixed (e.g. last values from the previous phase).

After the training of the SOM is completed, neurons may be labeled if labeled pattern vectors are available.

E. Classification

Find the best matching unit (BMU), \( c \), (5):
\[ c = \arg \min \| \mathbf{x} - \mathbf{w}(n) \| \]  

(5)

Test pattern \( \mathbf{x} \) belongs to the class represented by the best matching unit \( c \).

V. Properties of SOM

After the convergence of SOM algorithm, resulting feature map displays important statistical characteristics of the input space. They are also able to discover relevant patterns or features present in the input data.

A. Important Properties of SOMs

SOMs have four important properties, [3,7]:

1. Approximation of the Input Space
   - The resulting mapping provides a good approximation to the input space. SOM also performs dimensionality reduction by mapping multidimensional data on SOM grid.
2. Topological Ordering
   - Spatial locations of the neurons in the SOM lattice are topologically related to the features of the input space.
3. Density Matching
   - The density of the output neurons in the map approximates the statistical distribution of the input space. Regions of the input space that contain more training vectors are represented with more output neurons.
4. Feature Selection
   Map extracts the principal features of the input space. It is capable of selecting the best features for approximation of the underlying statistical distribution of the input space.

B. Representing the Input Space with SOMs of Various Topologies

1. 1-D
   2D input data points are uniformly distributed in a triangle, 1D SOM ordering process shown in Fig. 9.

   Figure 9. 2D to 1D mapping by a SOM (ordering process), [2]

2. 2-D
   2D input data points are uniformly distributed in a square, 2D SOM ordering process shown in Fig. 10.

   Figure 10. 2D to 2D mapping by a SOM (ordering process), [3]

3. Torus SOMs
   In conventional SOM, the size of neighborhood set is not always constant because the map has its edges. This problem can be mitigated by use of torus SOM that has no edges. [25]. However torus SOM, Fig. 11, is not easy to visualize as there are now missing edges.

   Figure 11. Torus SOM

4. Hierarchical SOMs
   Hierarchical SOMs should also be mentioned. Hierarchical neural networks are composed of multiple neural networks concreted in a form of an acyclic graph. The output of one SOM can be used as the input for another SOM, Fig. 12. [10]. Such input can be formed of several output vectors coming from Best Matching Units (BMU) of many SOMs.

   Figure 12. Hierarchical SOM. The topmost SOM takes input from the best matching units of the three lower level SOMs, [10]

VI. Applications

Despite its simplicity, SOMs are used for various applications, [2,26,27]. This in a broad sense includes visualizations, generation of feature maps, pattern recognition and classification. Kohonen in [2] came with the following categories of applications: machine vision and image analysis, optical character recognition and script reading, speech analysis and recognition, acoustic and musical studies, signal processing and radar measurements, telecommunications, industrial and other real world measurements, process control, robotics, chemistry, physics, design of electronic circuits, medical applications without image processing, data processing linguistic and AI problems, mathematical problems and neurophysiological research. With such an exhaustive list provided here, as space permits, it is possible only to mention some of them that are interesting and popular.

A. Speech Recognition
   The neural phonetic typewriter for Finnish and Japanese speech was developed by Kohonen in 1988, [28]. The signal from the microphone proceeds to acoustic preprocessing, shown in more detail in Fig. 13, forming 15-component pattern vector (values in 15 frequency bands taken every 10 ms), containing a short time spectral description of speech. These vectors are presented to a SOM with the hexagonal lattice of the size 8 x 12.

   Figure 13. Acoustic Preprocessing

   After training resulting phonotopic map is shown in Fig. 14. [7]. During speech recognition new pattern vectors are assigned category belonging to a closest prototype in the map.

   Figure 14. Phonotopic map, [7]

B. Text Clustering
   Text clustering is the technology of processing a large number of texts and gives their partition. Preparation of text for SOM analysis is shown in Fig. 15, [29], and

   Figure 15. Preparation of text for SOM analysis, according to [29]
C. Application in Chemistry

SOMs have found applications in chemistry. Illustration of the output layer of the SOM model using a hexagonal grid for the combinatorial design of cannabinoid compounds is shown in Fig. 18, [11].

D. Medical Imaging and Analysis

Recognition of diseases from medical images (ECG, CAT scans, ultrasonic scans, etc.) can be performed by SOMs, [21]. This includes image segmentation, Fig. 19, [31], to discover region of interest and help diagnostics.

E. Maritime Applications

SOMs have been widely for maritime applications, [22]. One example is analysis of passive sonar recordings. Also SOMs have been used for planning ship trajectories.

F. Robotics

Some applications of SOMs are control of robot arm, learning the motion map and solving traveling salesman problem (multi-goal path planning problem), Fig. 20, [32].

G. Classification of Satellite Images

SOMs can be used for interpreting satellite imagery like land cover classification. Dust sources can also be spotted in images using the SOM as shown in Fig. 21, [33].

H. Psycholinguistic Studies

One example is the categorization of words by their local context in three word sentences of the type subject-predicate-object or subject-predicate-predicative that were constructed artificially. The words become clustered by SOM according to their linguistic roles in an orderly fashion, Fig. 22, [18].

I. Exploring Music Collections

Similarity of music recordings may be determined by analyzing the lyrics, instrumentation, melody, rhythm, artists, or emotions they invoke, Fig. 23, [34].
J. Business Applications

Customer segmentation of the international tourist market is illustrated in Fig. 24, [35]. Another example is classifying world poverty (welfare map), [36]. Ordering of items with the respect to 39 features describing various quality-of-life factors, such as state of health, nutrition, and educational services is shown in Fig. 25. Countries with similar quality of life factors clustered together on a map.

VII. CONCLUSION

Self-organizing maps (SOMs) are neural network architecture inspired by the biological structure of human and animal brains. They become one of most popular neural network architecture. SOMs learn without external teacher, i.e. employ unsupervised learning. Topologically SOMs most often use a two-dimensional grid, although one-dimensional, higher-dimensional and irregular grids are also possible. SOM maps higher dimensional input onto the lower dimensional grid while preserving topological ordering present in the input space. During competitive learning SOM use lateral interactions among the neurons to form a semantic map where similar patterns are mapped closer together than dissimilar ones. They can be used for broad type of applications like visualizations, generation of feature maps, pattern recognition and classification. Humans can’t visualize high-dimensional data, hence SOMs by mapping such data to two-dimensional grid are widely used for data visualization. SOMs are also suitable for generation of feature maps. Because they can detect clusters of similar patterns without supervision SOMs are a powerful tool for identification and classification of spatio-temporal patterns. SOMs can be used as an analytical tool, but also in myriad of real world applications including science, medicine, satellite imaging and industry.
Fault Detection for Aircraft Piston Engine Using Self-Organizing Map

Dubravko Miljković
Hrvatska elektroprivreda, Zagreb, Croatia
dubravko.miljkovic@hep.hr

Abstract - Aircraft piston engine can be monitored using an advanced graphic engine monitor. Such engine monitor can supply a large amount of data containing evolution of engine parameters through the time. Analysis of a vast amount of multidimensional temporal data by a self-organizing map may aid in data visualization, but also in detection of engine parameter deviations from normality indicating potential problems in operation of aircraft piston engine. For determination of engine parameter space that corresponds to normal engine operation quantization error of the self-organizing map is used.

I. INTRODUCTION

Piston engine is a heat engine designed to convert energy into rotational mechanical motion. It uses reciprocating pistons to convert pressure into a rotating motion, [1]. The chances for an engine failure are pretty remote, but do happen. Piston engine reliability depends on the complexity of the engine (number of cylinders, turbocharging), use (private or club aircraft) and maintenance. Piston engine has a lot of moving parts and in comparison to a turbine engine its reliability is significantly lower (about seven times), yet low cost of such engines makes them a popular choice among most general aviation airplanes. An engine failure is a serious situation, both in single and twin engine aircrafts. Single engine aircraft can attempt to glide to a nearest airport (if altitude and winds permit) or perform an off airport landing (challenging situation if over inhospitable terrain, at night, low cloud ceiling and low visibility). Twin engine (particularly piston engine) aircrafts encounter an asymmetric thrust situation that pose increased risk during take-off, initial climb and possible go-around (that should be avoided altogether). Single engine climb rate is severely reduced and is only about 20% of climb rate available when operating on both engines (not 50% as one would expect). Failures further complicate the fact that it can be partial power loss instead of full power loss.

II. ENGINE MONITOR

Engine monitors (also called engine analyzers or engine management system) provide monitoring of vital engine parameters, [1]. These parameters are measured, by engine probes, recorded and presented on a graphic display with parameters usually shown as vertical bars. Cylinder head temperatures (CHTs), Exhaust gas Temperatures (EGTs) for each cylinder and Turbine inlet temperatures (TITs) are shown graphically as bars on the display of an engine monitor, [2,3], as shown in Fig. 1. Some additional engine parameters like engine rotational speed (RPM), calculated % of maximal horsepower (% HP), etc. are also shown. All parameters are logged and can later be analyzed on the ground. Such an advanced piston engine-monitoring instrument helps pilots to better manage engine operation and detect engine problems in real time (while the engine is running). It is also of great value to maintenance personnel. Logged data are available for post-flight analysis helping to detect impending problems and suggest appropriate preventive actions. Engine parameters that are most commonly monitored in engine monitors are listed in Table I, [2,3].

*optional, †fastest cooling cylinder, ‡difference between the hottest and coolest EGT
An engine monitor typically has two modes: monitoring and lean operation mode (for accurate adjustment of fuel mixture). Various engine problems can be detected using an engine monitor by spotting characteristic EGT/CHT bar patterns, [4]. Such patterns are catalogued and included in a technical documentation accompanying an engine monitor, [2].

III. VISUALIZATION OF ENGINE PARAMETERS

Engine parameters recorded during each flight can later be visually presented using specialized plotting software, e.g. the EzTrends2, [5]. Graphical representation of engine parameters (multidimensional data) through the duration of the whole flight as presented by JPI EZTrends2 is shown in Fig. 2 (upper curves represent EGTs and lower CHTs, inverted colors and background).

![Figure 2. Engine parameters plot](image)

As can be seen from the figure, EGT and CHT curves from the engine with no faults present group together. Another, simpler, representation of engine operation that doesn’t include evolution of parameters during a time is use of flight summaries, Fig. 3. Temperature ranges and average temperatures are shown in summary table. Discrepancies from the symmetry between temperatures of various cylinders can also be easily spotted in accompanying graphical representation. Engine monitor data can also be analyzed statistically, one such analysis is given in [6].

Despite interesting graphical representations of engine parameters, both in real-time on engine monitor display during a flight and later on computer using specialized accompanying software, more subtle engine problems are not so easy to discern and process require trained maintenance personnel with the experience in engine diagnostics from available recorded engine parameters. Catalogued patterns of various engine problems are commonly supplied with the engine monitor documentation, [2].

IV. SELF-ORGANIZING MAPS

Self-Organizing Map (SOM) is a type of neural network architecture that is trained using unsupervised training and produces a low-dimensional (most common 2D) discretized representation of the input space of the presented training samples. It provides dimensionality reduction of available multidimensional training data. The map is used in two modes: training mode and mapping mode. During the training mode a two-dimensional discrete representation of input space is formed. In the mapping mode input sample is assigned to the closest member of a map, thus classifying newly presented input vector. The most common two dimensional SOM lattice with neuron neighborhood is shown in Fig. 4. SOM uses competitive learning with lateral inhibition function. The most often used neighborhood function is the Mexican hat. An engine monitor with its parameters can form an input vector that is simultaneously fed to all SOM neuronal units. The input vector is mapped to the winner node (node with highest activation). More on SOM and learning algorithm could be found in [7,8].

![Figure 4. Self-organizing map (SOM) with hexagonal lattice and the local neighborhood of the one particular neuron](image)

V. FAULT DETECTION USING SOM

SOMs could be used for the visualization of engine and equipment parameters, [9,10]. Sometimes further step is taken with the application of the SOM to fault detection and condition monitoring, [11,12]. Fault detection using SOM is based on the assumption that a SOM (or its parameters like quantization error or SOMs hits map) that belongs to the normal engine operation differs from one that belongs to a faulty engine. The main problem is that SOMs trained on similar data may not always give quite similar results (e.g. occurrence of data shift in a map), [13]. Resulting self-organization is influenced by the various initial conditions: SOM initial
weights, [14], the choice of the neighborhood function, data normalization, the learning rate and the order of presentation sequence of training vectors. One analysis of statistical measures to assess the stability of the results of SOM training is given in [15].

A. Methods for Fault Detection

Some ideas how to compare SOMs are listed below:

1) Comparison of SOM maps

Comparison of SOM maps (test and reference) is done by comparing weights belonging to SOM planes, Fig. 5. These maps can be compared visually, an analytical approach is, however, more difficult, [13,16].

\[ \epsilon_{MQE} = \frac{1}{N} \sum_{i=1}^{N} \min_{k \in K} ||z_i - w_k|| \]  \hspace{1cm} (3)

where \( N \) is the number of patterns in a dataset, and \( z \) is the \( i \)th pattern vector in a dataset. The accuracy of a SOM in representing its inputs can be validated using the mean quantization error (MQE). It quantifies how well a previously trained SOM approximates the presented data items. Low values for MQE show that the data set is well represented by the SOM.

B. Method Used in This Paper

Method with MQE is applied in this paper. MQE is a more robust measure than a comparison of SOMs as it is resistant to data shift in a map.

1) Training Phase

During the training phase SOM captures the statistical distribution of the input space, Fig. 7.

\[ \epsilon_{MQE} = \frac{1}{N} \sum_{i=1}^{N} \min_{k \in K} ||z_i - w_k|| \]  \hspace{1cm} (3)

2) Monitoring Phase

During the monitoring phase input vectors are classified to the Best Matching Unit (BMU) and Mean Quantization Error (MQE) is determined, Fig. 8.

C. Off-Line and On-Line Detection

Method for fault detection can be performed as off-line detection (compares complete engine log with the SOM after the flight) and on-line detection (compares each new vector with the SOM).

1) Off-Line Detection

- Normal condition
  The new engine log is classified as normal if \( \epsilon_{MQE} \) (mean quantization error) is less than the threshold \( L \), (4):

\[ \epsilon_{MQE} < L \]  \hspace{1cm} (4)
• Suspicious condition
The new engine log is classified as suspicious if $e_{MQR}$ is greater than the threshold $L$, (5):

\[ e_{MQR} \geq L \]  

(5)

2) On-Line Detection
• Normal condition
The new vector is classified as normal if $e_{QE}$ (quantization error) is less than the threshold $L$, (6).

\[ e_{QE} < L \]  

(6)

• Suspicious condition
The new vector is classified as suspicious if $e_{QE}$ is greater than the threshold $L$, (7).

\[ e_{QE} \geq L \]  

(7)

In real applications additional filtering will be required (e.g. minimal number of threshold violations in a specific period of time).

VI. EXPERIMENT

The SOM was trained using engine parameters from available engine monitor logs.

A. Available Data

An experiment was performed using engine logs accompanying the EzTrends2 software, belonging to a six cylinder engine, with no known faults present, [5]. Available experimental data were flight logs Flt#192 (duration 1.49h) and Flt#193 (duration 1.23h). As these files belong to twin engine aircraft, only one (left) engine was selected for analysis. Engine parameters are logged every 6 seconds. Part of engine log Flt#192 is shown in Fig. 9, (left engine EG Ts: LE1-6 and CHTs: LC1-6).

B. Synthetic Faults

Because it is difficult to obtain data logs from faulty engines (as they are still quite reliable) and one has rarely access to large maintenance facility, testing datasets were created artificially by modifying existing engine data log (Flt#193) according to common descriptions of engine problems that include EGT and CHT temperature deviations. Examples of two patterns corresponding to problems in engine operation are shown in Fig. 10 and Fig. 11. Such patterns are often catalogued in documentation belonging to an engine monitor. Detailed description of fault indications as EGT/CHT bars on the engine monitor with temperature differences is given in [2]. This gives following datasets, as shown in Table II.

![Figure 10. Example of fault pattern, failure 1, EGT rise for one cylinder](image)

![Figure 11. Another example of fault pattern, failure 2, loss of EGT for one cylinder](image)

C. Selection of Input Parameters

Engine monitors are primarily designed to monitor engine temperatures EGTs and CHTs as they reflect a combustion process that is happening in engine cylinders. The other parameters were added to most monitors later as additional information about engine operation. Parameters, not directly related to a combustion process, are not considered in this experiment. Selected input parameters are:

• Exhaust Gas Temperatures (cylinders 1-6):
  - EGT1, EGT2, EGT3, EGT4, EGT5 and EGT6

• Cylinder Head Temperatures (cylinders 1-6):
  - CHT1, CHT2, CHT3, CHT4, CHT5 and CHT6

Input vector $z$ to SOM that consists of EGT and CHT temperatures is given in (8), (static, current state, neighborhood for time evolution analysis is not included):

\[ z = [ \text{Temp}_1, \text{Temp}_2, \text{Temp}_3, \ldots, \text{Temp}_6 ] \]  

(8)
Software used for analysis is the SOM Toolbox for MATLAB 5,[17]. Initialization was linear. Training was performed using a batch algorithm.

D. Sizing of SOM

The size of the SOM was determined according to (9), where $M$ denotes number of SOM units and $N$ is the number of samples,[12]:

$$M \approx 5\sqrt{N} \tag{9}$$

Most flights last about an hour. One hour flight consists of 600 frames. For 600 frames $M \approx 123$. In case of SOM lattice with equal number of rows and columns it is a 11x11 lattice.

E. Normalization of Parameters

Due to various ranges of values for EGT and CHT parameters should be normalized (as parameters are features it is also feature scaling) before applying to SOM. One interesting analysis of data normalization applied to SOMs is given in [18].

Two methods for feature scaling are popular:

- Rescaling (normalization): rescales the values into to a [0, 1] range. This is useful in cases where all parameters must belong to the same range. The disadvantage of this method is that the outliers from the data set are lost, (10):

$$x' = \frac{x - x_{\text{min}}}{x_{\text{max}} - x_{\text{min}}} \tag{10}$$

- Standardization (variance method): rescales data to have a zero mean ($\mu$) and standard deviation ($\sigma$) of 1 (unit variance), (11):

$$x' = \frac{x - \bar{x}}{\sigma} \tag{11}$$

Standardization method is recommended for most applications. It was also chosen for SOM visualizations, partially because it was already included in the SOM Toolbox.

Previous normalization methods are single-variable operations suitable for visualization of isolated parameter planes. However, for preserving multivariate anomalies and comparisons of MQEs of test datasets classified by a SOM produced by a normal dataset with the threshold for the purpose of fault detection, following normalization is applied to the CHT data instead, (12). Considering that the average EGT value is approximately 3.8 times greater than the average CHT value this puts normalized CHT values in the same range with EGT for each cylinder $i$:

$$T_{S,\text{CHT}_i} = 3.8T_{\text{CHT}_i}, \quad i = 1, \ldots, 6 \tag{12}$$

F. Data Visualization

Following are three examples of visualization of engine logs using SOMs. The training process is accomplished with normalized vectors, however legend corresponds to real temperatures. SOM corresponding to training data from a normally operating engine is shown in Fig. 12. In Fig. 13 there is another example of a normally operating engine, similar to one in Fig. 12, and in Fig. 14 is an example of faulty engine operation (see EGT4 plane).

- SOM Training data (normal engine operation, Flt#192)

SOM Test data (example of problematic engine operation, artificial data: Failure 3)

- SOM Test data (example of problematic engine operation, artificial data: Failure 3)

## G. Fault Detection of Failure Datasets

Artificial data and MQEs for abnormal engine operation (eight different failures) were also analyzed. Examples of eight different engine problems were included in eight test datasets. Example of visualization of abnormal engine operation for one failure (Failure 3) is shown in Fig. 14. MQEs ($e_{MQE}$) were calculated for different data sets and results are shown in Table III, including the original, non-normalized data and data normalized according to (12). These values could be used for determination of the threshold $L$ by multiplying with a constant $\alpha$ for the safety margin (e.g. $\alpha = 0.8$), (13). More failure examples are needed for more precise value of $L$.

</table>

*non-normalized data* normalized data according to (12)

$$L = \alpha \min(e_{MQE,k})$$  
$k = 1, 2, \ldots, 8$  
(13)

In previous experiment one SOM is used for all engine operating regimes. Better accuracy could be achieved if separate SOM is prepared for each particular operating regime. Methods for regime selections are given in [16].

## VII. Conclusion

Engine monitors for aircraft piston engines record large amount of data that may be difficult to visualize and analyze. SOMs with its unsupervised learning algorithm are able to produce the two-dimensional mapping of multivariate data. This provides dimensionality reduction while topologically preserving similarities in the input space. Such two-dimensional representation is suitable for visualization. Resulting SOM can be further analyzed and used for the fault detection. Use of SOM for monitoring of aircraft piston engine operation is proposed. By comparing MQE of engine logs from engines under the test with the threshold it is possible to detect suspicious engine operation. On-line detection is also possible by comparing input vector to best matching unit (BMU) and comparing quantization error with the predetermined threshold.

Sažetak – U ovom radu je prikazano poboljšanje standardnog rješenja relejnog upravljačkog kruga hlađenja energetskog transformatora uvođenjem dodatnog sekundarnog računalnog upravljačkog kruga. Kod OFAF i OFWF načina hlađenja transformatora pomoću standardnog upravljačkog kruga, i u ručnom i u automatskom načinu rada prva grupa hlađenja je stalno uključena, dok se ostale grupe povremeno uključuju ili porastom temperature ulja ili namota. Posljedica takvog nejednolikog rada su češći kvarovi u prvoj grupi hlađenja te zatajanje ostalih grupa uslijed povremenog rada. Redundantni računalni sustav upravljanja temeljen na PLC uređaju bi u slučaju neprekidnog rada jedne grupe hlađenja određeno vrijeme ili njenog zatajanja rada, automatski isključio standardni relejni upravljački sklop i po vremenskom algoritmu izmjenjivao grupe hlađenja u radu. U slučaju kvara ili prestanka rada računalnog sustava, sustav bi se vratio na relejno upravljanje. Očekivana korist ovakvog kombiniranog rješenja je podjednako trošenje hladnjaka, povećana pouzdanost sustava hlađenja te smanjenje potrebe fizičke prisutnosti osoblja održavanja u transformatorskom postrojenju.

I. UVOD

Kod transformatora u radu, gubici u željezu zagrijavaju jezgru transformatora, a gubici u bakru zagrijavaju primarne i sekundarne namote. Kako bi se spriječilo pregrijavanje, toplina treba neprestano odvoditi. Kod energetskog transformatora se koristi ulje kao medij za odvođenje topline iz jezgre i namota. Do pregrijavanja transformatora može doći zbog preopterećenja, slabog hlađenja ili previsoke temperature okoline.

OFAF hlađenje je hlađenje prisilnim strujanjem ulja i zraka. Ova vrsta hlađenja uključuje pumpe (prisilno ili dirigirano strujanje ulja) i ventilatore (prisilno strujanje zraka). OFWF je hlađenje prisilnim usmjerjenim strujanjem ulja i prisilnim strujanjem vode. Pumpe služe za strujanje ulja u kotlu transformatora, a prisilno strujanje vode se koristi u sekundarnom rashladnom krugu.

Kod OFAF hlađenja uz pomoć OFAF hladnjaka, te kod OFWF uz pomoć vodenih hladnjaka, uobičajeno je da se sa uključenjem transformatora u ručnom i u automatskom načinu upravljanja uključuje jedan ili više hladnjaka. Porastom temperature namota ili ulja na određenu vrijednost uključuje se sljedeći stupanj hlađenja.

Uređaji kojima se motri temperatura namota i ulja su termoslika i kontaktni termometar. Najčešće su izvedbe 4 izmjernička kontakta, od kojih se prva dva koriste za upravljanje hlađenjem, a treći i četvrti kontakt za signal alarma i isključenja.
Prema tablici 3. se podešavaju temperature na kontaktima termoslike i kontaktognog termometra za OFAF hladenje.

Kontakte termoslike i kontaktognog termometra je potrebno postaviti tako da ne dođe do interferencije u paralelnom radu dvaju sustava. Moguće je podešavanje zastavicama (kontakt zatvori kad kazaljka dotakne zastavicu) ili direktn odabir na okretnom brojčaniku.

Slika 1 Podešavanje temperature na kontaktnom termometru

II.RELEJNA SHEMA UPRAVLJANJA HLADENJEM

Kad je riječ o upravljanju hladenjem transformatora, prevladava korištenje relejnih sklopova. Postoje standardizirani tipovi hladenja transformatora i za svaki od njih tipizirane sheme upravljanja. Korisnici i proizvođači transformatora su navikli na takav pristup upravljanja i teško mijenjaju navike u upravljanju ili u održavanju sustava hladenja.

Slika 2 Primjer paralelnog rada kontaktognog termometra i termoslike

Kod većine krugova upravljanja princip je sličan, kad temperatura ulja ili temperatura namota dosegne zadano vrijednost, pobudi se elektromagnet sklopika koji potom preko pomoćnih kontakata uključuju ili isključuju grupe hladenja. Kod velikih transformatora, direktno sa uključenjem transformatora na mrežu uključuje se prva grupa hladenja. Na taj način se smanjuje zagrijavanje ulja koje nastaje već pri malim opterećenjima. Ostale grupe hladenja se uključuju prema granicama postavljenim na termoslici ili kontaktnom termometru.

Na slici 2. je prikazana shema izmjeničnih kontakata termoslike i kontaktognog termometra u paralelnom radu. Temperature se za svaki stupanj hladenja postavljaju prema tablici 3.

Izabran je primjer OFAF hladenja sa šest hladnjaka koji rade u 3 stupnji, pri čemu svaki stupanj uključuje 2 hladnjaka. Prvi stupanj hladenja se uključuje čim se uključi transformatorska glavna sklopka i tako pobudi relej K31. Kako su sa uključenjem transformatora u rad usla dva hladnjaka, kad proradi prvi kontakt termoslike ili kontaktognog termometra, uključit će se druga grupa hladenja. Ako temperatura nastavi rasti, te temperatura namota dosegne 70°C ili ulja 60°C, uključit će se treća grupa hladenja (preostala 2 hladnjaka).

Upravljanje se vrši uz pomoć grebenastih sklopki i to sklopkom S3 za izbor ručnog ili automatskog načina rada i sklopkom S4 koja određuje redoslijed uključivanja hladnjaka u automatskom načinu rada. Logika uključivanja je dana u dijagramu toka na slici 3.

Slika 3 Dijagram toka relejnog sustava upravljanja hladenjem

Ako je sklopkom S3 (slika 4) u položaju „ručno“, tada se uz pomoć grebenastih sklopki S5 do S10 određuje koji će hladnjak biti uključen.

Slika 4 Sklopk S3 za izbor automatski ili ručno
Sklopka S5 služi za ručno uključenje ili isključenje prvog hladnjaka koji se sastoji od jedne pumpe i jednog ventilatora (MZS Q1 i Q7).

U ručnom načinu upravljanja mogu biti uključeni pojedini hladnjaci prema izboru, od hladnjaka 1 do hladnjaka 6. Isto tako se može izabrati da svi hladnjaci rade ili da ne radi ni jedan. Posljednja opcija se koristi kod održavanja rashladnog sustava.

Ako je sklopka S3 u položaju „automatski“, tada se prema tablici 4. prorade sklopke S4 (slika 6) određuje koja grupa hlađenja proradi prva.

Ako je sklopka S4 u položaju 1, radni kontakti 13,14 i 23,24 releja K31 će prvo uključiti hladnjak 1 i hladnjak 2.

III. PROBLEMI KOJI NASTAJU U RELEJNOM NAČINU UPRAVLJANJA

Nedostaci relejnog sklopa u upravljanju hlađenjem mogu se svesti na:

1. Pogreške u upravljačkoj logici i promjena funkcije upravljanja mogu se ispravit samo prepravkama u ožičenju.
2. Dodavanje uređaja ima za posljedicu naknadno ožičenje i promjenu shemu upravljanja.

Ovo su općeniti problemi koji bi se mogli preslikati na gotovo svaki upravljački krug. Konkretan slučaj koji se pojavljuje kod onih vrsta hlađenja u kojima se odmah sa uključenjem transformatora uključuje jedan ili više hladnjaka pokazuje mogući veliki nedostatak u relejnog načinu upravljanja. Grupa hlađenja koja ulazi u rad prva, radi će stalno dokle god se ručno ne prebaci položaj na sklopci S4. Ako transformer radi u hladnijoj klimi ili ako ne radi pod opterećenjem, sasvim je izvesno da grupa hlađenja koja ulazi u najvišem stupnju neće uopće ući u rad, ako netko ne okreće položaj na izbornoj sklopci S4. Iz tog je razloga moguć kvar ventilatora u drugoj ili trećoj grupi hlađenja uslijed korozije. Isto tako ventilator koji ulazi u prvoj grupi hlađenja radit će neprestano dok ne ispadne motorna zaštita sklopka ili ne nastupi neka druga vrsta kvara. Dakle, korištenjem samo relejnog sklopa, bilo kakva promjena stanja hladnjaka zahtjeva fizičku prisutnost osoblja u transformatorskom postrojenju, dolazak do upravljačkog ormarca, te ručno mijenjanje položaja izbornih sklopk i tipkala.

IV. IDEJA SPAJANJA PLC RAČUNALA NA RELEJNI SUSTAV

PLC računalo treba raditi paralelno sa relejinim skloptom, a da ničim ne ometa relejni logiku upravljanja. To se postiže pravilnim odabirom radnih i mirnih kontakata sklopnika i releja u upravljačkoj shemi. Šest grupa hladnjaka treba hlađiti prema standardnoj relejnij shemi. Paralelno njoj treba spojiti PLC računalo koje će isključiti relejnju logiku u slučaju da bilo koji hladnjak neprekidno radi duže od 48 sati. Relativno složen upravljački krug se može zasnimiti kao skup jednostavnih logičkih operacija gdje se svaka operacija može raščlaniti na jednu ili više ON/OFF funkcija ili stanja u procesu. Stanju ON odgovara logička 1, a stanju OFF logička 0. Sekvencionalno uključivanje grupa hlađenja u slučaju kada se zahtijeva OAF hlađenje sa 6 grupa hladnjaka, nije jednostavno niti pouzdano izvesti.
Rješenje sekvencionarnog uključenja pojedinih grupa hlađenja se jednostavno može izvesti pomoću PLC računala. Vremenski releji koji bi bili potrebni u relejncom sklopu, mogu se zamijeniti sa virtualnim relejima u PLC računalu uz programsku logiku.

PLC je moguće proširiti digitalnim i analognim signalnim modulima. Signalni moduli se odabiru prema broju ulaza i izlaza, te prema naponu. Služe za prilagodbu digitalnih i analognih procesnih signala. Modularnost je vrlo korisna osobina PLC računala, jer promjenom upravljačke logike ili dodavanjem novih uređaja u upravljački sustav, ne treba kupiti novi PLC. Dovoljno je dodati jedan ili više signalnih modula.

Signalni moduli se spajaju sa desne strane CPU pomoću ugrađenog konektora (komunikacijski moduli se spajaju sa njegove lijeve strane).

U najsloženijem primjeru upravljanja hlađenjem transformatora pomoću OFAF hladnjaka u kojem se ono izvodi sa 6 hladnjaka, potreban je PLC sa 21 digitalnim ulazom i 8 digitalnih izlaza. Napon napajanja je 24 V DC, stoga je izabrana samostalna upravljačka jedinica CPU S7-1200 1214C (6ES7 214-1AG40-0XB0) DC/DC/DC.

Kako je izabrana CPU sa 14DI i 10 DO, nedostaje 7DI za ostale ulazne signale. Izabran je digitalna ulazna kartica SIMATIC S7-1200, DIGITAL INPUT SM 1221 (slika 8), 16 DI, 24VDC, SINK/SOURCE INPUT, 6ES7221-1BH32-0XB0.

Razmatra se slučaj kada je sklopka S4 u položaju 1. Tada se uključenjem releja K31 uključuje prvi i drugi hladnjak – pobudi se sklopnik K1 koji pokreće pumpu 1 i ventilator 1, i sklopnik K2 koji pokreće pumpu 2 i ventilator 2.
Prema relejni shemi, hladnjak 1 i hladnjak 2 će raditi sve vrijeme dok netko na sklopci S4 ručno ne promjeni položaj 1 u neki drugi.

Sviti releja K105-K110 su spojeni na digitalne izlaze CPU 1214C DQa:0/0-DQa:0/5.

Kada K111 proradi (slika 13), sasvim je svejedno u kojem položaju je grebenastu sklopka S4. PLC će preuzeti automatiku upravljanja hlađenjem i u zadanom vremenskom ritmu uključivati slijedeći hladnjake jednog za drugim, kako bi svaki od njih radio jednako vrijeme. Ova logika se može primijeniti za bilo koji položaj sklopke S4, pa ju nije potrebno posebno objašnjavati za svaki položaj.

Čim PLC preuzme upravljanje, isključuje se logika ostvarena izbornom sklopkom S4. U slučaju da se želi vratiti stanje natrag na relejno upravljanje hlađenjem, dovoljno je grebenastu sklopku S3 prebaciti na ručno. Tada se sve vraća na početne uvjete.

Oprema potrebna u redundantnom sustavu je CPU 1214C, napajanje 24V DC i jedan signalni modul SM1221. Uz PLC je dodano 7 releja 3RH2122-1BB40. Analogni ulazni signali se ne koriste, jer su za proradu termoslike i kontaktog termometra iskorišteni rezervni radni kontakti releja K32 i K33. Isto tako, iskorišteni su slobodni kontakti postojećih sklopnika i releja za digitalne ulaze u PLC, te se tako uštedjelo na opremi i prostoru u upravljačkom ormaru.

V. ZAKLJUČAK

Redundantni sustav koji sadrži PLC računalo i relejni sklop ima smisla kod onih vrsta hlađenja kod kojih se s uključenjem transformatora u pogon direktno uključuje jedan ili više hladnjaka. Postoji vjerojatnost da će taj hladnjak stalno raditi, a hladnjak koji dolazi u nekom od viših stupnjeva hlađenja će vrlo rijetko ući u pogon. Na taj način se oni nejednoliko troše i velika je mogućnost kvara.

Način na koji je PLC spojen, dozvoljava mogućnost da ga se fizički potpuno ukloni, a da se ne promijeni logika upravljanja relejnog sklopa. Redundantni sklop sa PLC računalom je skuplji od relejnog sklopa, ali ako se uzme u obzir cijena hladnjaka i troškovi njihove zamjene, svakako je isplativ.

Poboljšanje procesa se ogleda u automatizaciji sekvenci koji se u standardnom načinu hlađenja obavljaju ručno, te u povećanoj sigurnosti cijelog sustava.
Redundantni sklop sa PLC računalom daje dodatne pogodnosti kao što su mogućnost spajanja na SCADA sustav, daljinsko uključenje/isključenje hladnjaka, te bržu izradu dokumentacije.

Svrha redundантnog upravljanja hlađenjem energetskog transformatora uz pomoć PLC računala je povećanje pouzdanosti sustava, te produžen radni vijek pumpi i ventilatora zbog cikličke zamjene grupa hlađenja.

Platforma za izradu korisnički specifičnih uređaja

Luka Kapraljević, Goran Kemfelj, Danijel Maršić i Goran Mulčić
Tehničko veleučilište u Zagrebu / Elektrotehnički odjel, Zagreb, Hrvatska
danijel.marsic@tvz.hr

Sažetak - Primjenom mikroupravljačkih struktura u elektroničkim sklopovima moguće je ostvariti specifične funkcije pojedinih sklopova i projektirati ih kao zasebne uređaje te ih zatim povezati u funkcionalne cjeline čineći time modularno računalo. Gledajući standardna rješenja na tržištu koja se sastoje od Funkcijskih objekata, uočeno je da se pomoću takve objektne strategije izrade elektroničkog sklopovlja postiže veća fleksibilnost prilikom same izrade, a posebno daljnjeg proširenja uređaja. Temeljem te ideje, u ovom radu prikazan je projekt sklopovskog i programskog rješenja platforme za izradu korisnički specifičnih uređaja.

I. UVOD
Mikroupravljački sustavi postaju sve pogodniji za brz razvoj novih uređaja koji nalaze široku primjenu. Brz i učinkovit razvoj omogućuje povezivanje računalne aplikacije i mikroupravljačkog sustava u cjelinu koja je fleksibilna i laklo programirljiva te kao takva omogućava uključivanje sve većeg broja korisnika takvih uređaja.

Na tržištu se nalazi velik broj razvojnih platformi koje se programiraju, ali povezivanje računala i izgrad jednostavne računalne aplikacije ne koriste što smanjuje fleksibilnost sustava. Prednost u odnosu na ostale sustave na tržištu je jednostavno programiranje sklopovlja i računalne aplikacije.

Cilj rada je pokazati mogućnosti razvoja korisnički specifičnih upravljačkih platformi koje bi služile za obrazovne svrhe i robotiku, upravljanje pametnih kuća, automatiziranih linija, mobilnim sustavima za nadzor i upravljanje, upravljanje vozilima i strojevima i njihovo međusobno povezivanje u upravljačko nadzornu strukturu.

II. IDEJNO RJEŠENJE
Uređaj koji se modularno i jednostavno povezuje i programira, nadograđuje i proširuje pomoću novog sklopovlja ili aplikacija razvijen je i izrađen kao platforma sa funkcijama objektima (Slika 1.). Takav uređaj ima za cilj da se koristi kao razvojna platforma bez programske podrške, s programskom podrškom kao podatkovno distributivni upravljan pomoću vanjskog računala ili samostalni uređaj specifične namjene programiran od krajnjeg korisnika pomoću aplikacije za programiranje.

Specifični moduli, što su u ovom radu funkcijski objekti, čija funkcionalnost može biti različita (očitavanje senzora, obrada informacija, komunikacija, upravljanje aktuatorima i sl.), izrađeni su od kompatibilnih mikroupravljačkih struktura koje pomoću različitih programa obavljaju određenu funkciju. Objekti se međusobno povezuju pomoću zajedničke sabirnice, komunikacijski i energetski.

Odabir komunikacijski energetska sabirnica postiže se međusobno povezivanje funkcijalnih objekata uređaja, a programaška podrška pomaže jednostavno upravljanje i korištenje. Također programaška podrška ima nekoliko mogućnosti pristupa funkcijom objektu. Korištenjem fizičkog odabira opređenog funkcijalnog objekta kao i programske podrške postiže se mogućnost plivanja fizičkog funkcijalnog objekta koji nije nužno fizički vezan za određenu počitnicu u sabirnici. Također pomoću programske podrške moguće je multipliciranje istih funkcijalnih objekata, režim paralelnog rada funkcijalnih objekata.

III. SKLOPOVSKO RJEŠENJE
A. Komunikacijsko energetska sabirnica
Komunikacijsko energetska sabirnica služi za međusobno povezivanje funkcijalnih objekata. Na njoj se nalaze podatkovna sabirnica, adresna sabirnica i napajanje za sve funkcijalne objekte. Izvedena je tako da se na tiskanoj pločici nalazi 8 priključka u koje je moguće
spojiti funckijaške objekte. Prikljućci su međusobno paralelno povezani komunikacijskim, podatkovnim i energetskim linijama [1].

Na slici 2 je prikaz svih podatkovnih in energetskih linija koje postoje na komunikacijsko energetskoj sabirnici. U izrađenom uređaju se za komunikaciju između funkcijskih objekata koristi SPI (eng. Serial Peripheral Interface, SPI) sabirnica, za adresiranje „FIZIČKA ADRESA” a od napajanja se koriste 3V3, 5V i 12V. Svaki funkcijski objekt se automatski prijavljuje glavnom procesoru sa svojim identifikacijskim kodom (ID) te prema tom kodu glavni procesor zna koji je to funkcijski objekt (DI, DO, AI, AO, PS), koliko ulaza odnosno izlaza ima, koja su mu napajanja i ostale bitne informacije za upravljanje s tim objektom.

B. Napajanje

Da bi funkcijski objekti radili ispravno potrebno je osigurati adekvatne napone za napajanje preko komunikacijsko energetske sabirnice. Napajanje PS3512 je izrađeno isključivo za napajanje funkcijskih objekata, a ne za napajanje trošila, te je stoga potrebno za napajanje trošila i kao ulazni napon za PS3512 koristiti komercijalno dobavljačko napajanje.

C. Glavni procesor

Za izvršavanje korisničkog programa brine se funkcijski objekt Glavni procesor koji se sastoji od mikroupravljača Atmel AT32UC3A1128, radne memorije High speed SRAM 32 kB i servisne flash memorije (Slika 3).

Funkcijski objekt glavni procesor je spojen na komunikacijsko energetsku sabirnicu. Od komunikacije koristi dva SPI kanala (SPI0 i SPI1), a za napajanje koristi 5V sa funkcijskog objekta napajanje. SPI0 koristi za komunikaciju sa svim funkcijskim objektima osim s komunikacijskim procesorom. Prijenos podataka između glavnog procesora i komunikacijskog procesora odvija se na SPI1 kanalu. Brzina prijenosa podataka po SPI kanalu iznosi 200 kb/s. Rad uređaja (platforme) je podijeljen u radne cikluse koji obuhvaćaju slijedeće operacije: čitanje ulaza, izvršavanje korisničkog programa i postavljanje izlaza (Slika 4.).

D. Komunikacijski procesor

Komunikaciju s računalom obavlja funkcijski objekt komunikacijski procesor. Njegovi zadaci su pohranjivanje korisničkog programa na Micro SD karticu i prijenos korisničkog programa glavnom procesoru.

Komunikacija s glavnim procesorom se odvija preko komunikacijsko energetske sabirnice SPI1 kanalom. Za upravljanje memorijom kod prijenosa podataka brine se DMA upravljač koji bez opterećivanja komunikacijskog procesora razmjenjuje podatke sa glavnim procesorom (Slika 5.).

E. Digitalni ulazi

Da bi uređaj mogao primiti digitalne informacije iz procesa koji upravlja potreban mu je funkcijski objekt koji ima mogućnost očitati digitalni signal. Tome služi funkcijski objekt sa osam digitalnih ulaza. Na slici 6. vidljiv je blok prikaz funkcijskog objekta digitalni ulazi na kojem se nalazi unutarnja struktura objekta. Ulazi su izvedeni tako da imaju zaštitnu diodu protiv krivog spajanja (obnutog polariteta). Ujedno su i galvanski
odvojeni od mikroupravljača, a tako i od ostatka uređaja. Galvanska odvojenost služi, ukoliko dođe do povećanog napona na pojedinom ulazu, da zaštići ostatak tog funkcionalnog objekta od previsokog napona.

**F. Digitalni izlazi**

Da bi izrađeni uređaj mogao upravljati sa procesom potreban mu je funkcionalni objekt sa 8 digitalnih izlaza na koje je moguće spojiti induktivno i otporno trošilo. Svaki digitalni izlaz je galvanski odvojen (koristeći optoizolator) od mikroupravljača te od ostalih izlaza kako bi se funkcionalni objekt zaštitio od neželjenih napona i struja (Slika 7.). Maksimalna struja po izlazu iznosi 500 mA dok je maksimalna ukupna struja po svim izlazima 2,5A.

**G. Analogni ulazi**

Za očitavanje analognih vrijednosti brine se funkcionalni objekt analogni ulazi čija dva ulaza mogu prema potrebi biti naponski ili strujni (Slika 8.). Vrsta ulaza odabire se programski, koristeći aplikaciju za konfiguriranje uređaja.

Kada je odabrani naponski ulaz, raspon napona kojeg može mjeriti je od -10V do 10V. Uz klasične analogne senzore (naponski) na naponski ulaz moguće je spojiti K-tip i T-tip termopara. Prilikom odabira strujnog ulaza funkcionalni objekt mjeri struju od -20 do 20 mA. Vrijednost struje odnosno napona se mjeri pomoću 16 bitnog ADC (eng. Analog to Digital Converter).

pretvornika. Na taj način moguće je ostvariti digitalne vrijednosti napona od -32768 do 32767.

**H. Analogni izlazi**

Funkcionalni objekt analogni izlazi zamišljen je tako da ima dva izlaza koji se mogu neovisno odabrati da li će biti naponski ili strujni.

Na slici 9. vidljiv je blok prikaz unutarnje strukture funkcionalnog objekta analogni izlazi. Prikazan je samo jedan analogni izlaz, a funkcionalni objekt sadrži dva izlaza. Nije moguće istovremeno imati i naponski i strujni izlaz na jednom kanalu (VOUT1 i IOUT1 ili VOUT2 i IOUT2). Na naponski izlaz moguće je spojiti trošilo sa 2 žice (bez kompenzacije impedancije spojnih vodova) ili sa 4 žice (sa kompenzacijom impedancije spojnih vodova). Raspon napona odabire se (za svaki izlaz zasebno) koristeći aplikaciju za konfiguriranje u rasponima 0 do 5V, 0 do 10V, ±5V i ±10V s mogućnošću 20% nadišenja.

Na strujne izlaze trošila se spajaju samo na jedan način, a to je između stezaljki IOUT+ i IOUT-. Raspon izlazne struje odabire se koristeći aplikaciju za konfiguriranje u rasponima 0 do 20mA, 4 do 20mA, 0 do 24mA, ±20mA i ±24 mA s mogućnošću 2% nadišenja. Na strujne izlaze spajaju se otporna trošila otpora do 300Ω.
I. Procesor za proširenje

Na jednu komunikacijsku sabirnicu može se priključiti maksimalno osam funkcionalnih objekata, što je dovoljno za neki manje složeni proces. Iz toga razloga razvijeni su i dodatni funkcionalni objekti za proširenje sustava. Proširenje sustava zamišljeno je u dva smjera, proširenje sa dodatnom komunikacijskom energetskom sabirnicom i proširenje sa dodatnim funkcionalnim objektima.

Proširenje sa dodatnom komunikacijskom energetskom sabirnicom izvodi se na način da se u obje komunikacijsko energetske sabrinice priključi po jedan dodatni funkcionalni objekt za proširenje koji se meĎusobno povezuju kablom koristeći SPI komunikacijski kanal. Na taj način glavni procesor očita oba dodatna funkcionalna objekta za proširenje i automatski prepoznaje funkcionalne objekte priključene na dodatnoj komunikacijsko energetskoj sabirnici.

Proširenje sa dodatnim funkcionalnim objektima izvodi se na način da se u komunikacijsko energetsku sabirnicu priključi funkcionalni objekt za proširenje na kojega se kablom priključuju dodatni funkcionalni objekti koristeći SPI komunikacijski kanal.

Na slici 10. prikazana su gore opisani načini spajanja dodatnih funkcionalnih objekata. Uz tu dva načina moguća je i kombinacija spajanja, što znači da se istovremeno mogu spojiti dodatna komunikacijska energetska sabirnica i zasebni funkcionalni objekti. Naravno, potrebno je koristiti dodatno napajanje kod svakog gore navedenog načina spajanja.

Slika 10. Princip spajanja dodatnih funkcionalnih objekata

IV. PROGRAMSKA PODRŠKA

Programsku podršku čini šest nezavisnih aplikacija. To su aplikacija za konfiguriranje, uređivanje, preglednik, programiranje, prevođenje i testiranje. Na slici 11. je prikaz aplikacija i njihovo meĐusobno djelovanje.

B. Aplikacija za testiranje

Aplikacija za testiranje koristi se za ispitivanje priključene sklopovske opreme u svrhu podešavanja ulazni i izlaznih funkcionalnih objekata. Aplikacija koristi Windows sučelje i naziva se Corebus config v5.1.

Nakon spajanja, u statusnom prozoru postavlja se status Connected nakon čega se mogu očitati funkcionalni objekti uređaja pritiskom na tipku Scan. Po završetku očitavanja funkcionalnih objekata prikazuje se slika uređaja s funkcionalnim objektima. Vidljive se pozicije funkcionalnih objekata priključenih u komunikacijsku energetsku sabirnicu, programska adresa objekata i pozicija promjenljivog fizičkog priključka koji se postavlja u režimu paralelnog rada [2].

Slika 12. Prikaz konfiguriranog uređaja

Na slici 12. je prikazano u kojem se dijelu nalazi promjenljiva fizička adresa, a u kojem programska adresa. Iz slike je vidljivo da se na poziciji broj 4 (pozicije su od 0 do 7) nalazi objekt digitalni ulazi i dodijeljena mu je oznaka I kao Input na poziciji 4, a njegova programska adresa označena s ADRI kao Address Input i iznosi 0 (koristi se 8 bitni izbor, odnosno raspon od 0 do 255). Promjenljiva fizička adresa je označena s CS i iznosi 6 (mogućnosti su od 0 do 7). Jednako tako funkcionalni objekt digitalni izlazi s oznakom O kao Output na poziciji 5. Ukoliko je u konfiguraciji pronađen komunikacijski funkcionalni objekt s programskom memorijom (Micro SD memorija kartica) moguće je formatirati memoriju na format za uređaj. Takav format nije čitljiv u drugim sustavima. Formatiranje se obavlja pritiskom na tipku Format. Po završetku formatiranja pojavljuje se skočni prozor koji obavještava korisnika da je formatiranje obavljeno.

C. Aplikacija za uredivanje

Aplikacija za uredivanje koristi se za izradu korisničkog grafičkog sučelja preglednika. Aplikacija koristi Windows sučelje i naziva se Corebus edit v5.1. Objekti se postavljaju obdariom na alatnoj traci koja je prikazana na slici 13. i svaki sadrži određena svojstva. Objekti su linija, krug i kružni isječak, tipka, prekidač, indikator, analogni pokaznik, digitalni pokaznik, analogni...
davać, osciloskop, dnevnik za podatke, animacija, tekst, geometrijski oblik, gumb stranice, pozadina stranice, prazni element za izradu.

Slika 13. Alatna traka objekata

Svojstva jednog objekta prikazana su na slici 14. Svojstva objekta uključuju dimenziju, oblik, poziciju, negativnu logiku, početno stanje, boju naziva, boju vanjskog ruba, unutarnjeg dijela, pokazivača, pomoćnih linija, naziv za uključeno stanje, naziv za isključeno stanje, povezivanje, ispis greške, boju uključenog naziva, boju isključenog naziva, minimalna vrijednost, maksimalna vrijednost, broj podjela, stranica na kojoj se nalazi objekt, a neki od objekta sadrže veličinu slova, naziv datoteke prilikom pohranjen podataka, uzorkovanje i vremensku odgodu.

Slika 14. Svojstva objekta

Veza između objekta i podatka sa funkcijskog objekta, ostvarena je pod nazivom link, odnosno povezivanje, gdje je potrebno upisati fizičku adresu s oznakom, brojem pozicije i izvodom (npr. I4.5, O5.7, A10.1), programsku adresu (npr. ADR10.5, ADRO6.7, ADRA10.1) vidljivu iz aplikacije za konfiguriranje ili gotovu naredbu (FILEmoj_file, MEM4.9.5, PAGE1, NEXTPAGE, PREVPAGE, TIME, DATE, DAY).

Na slici 15. prikazan je početni izgled nekih od objekata kojima je moguće mijenjati gore opisana svojstva.

Slika 15. Početni izgled objekata

Ova aplikacija ima za cilj jednostavno i brzo izraditi upravljačku ploču za specifičnu korisničku namjenu.

D. Aplikacija za preglednik

Aplikacija se koristi za pregled, promjenu i pohranu podataka u realnom vremenu. Upotrebljava datoteku koja je predložak izradi objekata korisničke upravljačke ploče pripremljena u aplikaciji za uređivanje. Aplikacija koristi Windows sučelje i naziva je Corebus view v5_1.

Na slici 16. prikazan je izgled pokrenute aplikacije s izrađenom upravljačkom pločom. Promjenu stanja nekih objekata moguće je ostvariti pritiskom na isti ili povlačenjem određenog kliznog dijela objekta.

Slika 16. Aplikacija preglednika s izrađenom upravljačkom pločom

E. Aplikacija za programiranje

Aplikacija za programiranje koristi se za izradu programskog sadržaja. Korisnik postavlja operacije, funkcije i njihovu vezu sa funkcijskim objektima i memorijski koji se nalaze unutar funkcijskog objekta. U tablici I prikazane su naredbe koje se koriste.

Napisani korisnički program pohranjuje se u programsku memoriju (Micro SD memorijska kartica) i koristi se za glavni procesor koji ima ugrađeni prevoditelj.

**F. Aplikacija za prevaljenje**

Aplikacija za prevaljenje pretvara napisani program u kod za funkcionski objekat glavni procesor koji ima u dijelu svoje memorije programski prevoditelj koji očitava i izvršava korisnički program. Pritisnom na tipku Compile aplikacija pretvara korisnički program u podatkovne pakete koji se izvode slijedno. Pritisnom na tipku Prog programska paket se učitava u memoriju uređaj, a na tipku Restore preuzima se korisnički program iz memorije uređaja.

**V. ZAKLJUČAK**

Platforma za izradu korisničkih specifičnih uređaja je uređaj kojim se učinkovito može nadzirati i upravljati odabranim procesom. Što je proces složeniji to je potrebno više ulazne i izlazne funkcionalne objekata. Izrađena platforma podržava do 256 funkcionih objekata što može zadovoljiti i veće korisničke procese.

Kod obrade korisničkog programa bitna je brzina procesora i količina radne memorije. Ovakva modularna struktura omogućava da se ne izakvanih modifikacija u korisničkom programu i ostalim funkcionih objektima priključi drugi funkcionni objekt glavni procesor koji ima brži procesor i više radne memorije. Isto vrijedi i za primjerice komunikacijski procesor. Ukoliko je potrebna komunikacija preko Etherneta ili GSM-a ili slično, jednostavno se priključiti potrebn funkcijni objekt i rad uređaja se nastavlja sa tom novom funkcijom.

Podatkovni paketi prilikom komunikacije između glavnog procesora i ostalih funkcionih objekata su standardizirani i univerzalni te omogućuju dodatna proširenja kao na primjer dodatni funkcijni objekt za upravljanje istosmjernim elektromotorima (H-most), upravljanje stop motorima, PWM izlaz funkcionih objekti, brojači i slično.

Programiranje funkcionih objekata je univerzalno i kao takvo se može primijeniti u budućnosti na bilo koji bolji procesor ili računalnu komunikaciju. Odabir odvojenih funkcionih objekata dovelo je do lakšeg razvoja aplikacija koje su se razvijale postepeno sa svakim objektom.

Moguće je ubrzati rad komunikacije, dohvata podataka i slanja podataka na strani računala i funkcionih objekata pomoću direktnog brzog adresiranja koje još nije do kraja razvijeno. Također dio aplikacije za prevaljenje i programiranje se nadagradje i poboljšava za uporabnu verziju.

INVITED PAPERS
Automatic Construction of Ontologies from Petri Nets for the Semantic Web

Zongmin Ma, PhD & Professor
Nanjing University of Aeronautics and Astronautics, China
zongmin_ma@yahoo.com

Abstract
Petri nets have been a kind of popular modeling tool, and have been widely studied and successfully applied in modeling of software engineering, database and artificial intelligence. In particular, Petri net Markup Language (PNML) has been a part of ISO/IEC Petri nets standard for representing and exchanging data on Petri nets. Currently, being a formal representation method of domain knowledge, ontology plays a particular important key role in the Semantic Web. How to construct ontologies has become a key technology in the Semantic Web, especially constructing ontologies from existing domain knowledge.

In the talk, we will investigate how to construct ontologies from PNML model of Petri nets for the Semantic Web. We will give a formal definition and the semantics of PNML models of Petri nets. On this basis, we will present a formal approach to transform Petri nets (including PNML model and PNML document of the Petri nets) into OWL (Web Ontology Language) ontologies at both structure and instance levels. We will discuss the correctness of the transformation also. A prototype construction tool has been developed to transform Petri nets models into OWL ontologies automatically.
PicoAgri. Realization of a Low-cost, Remote Sensing Environment for Monitoring Agricultural Fields Through Small Satellites and Drones

S. Marsi *, A. Gregorio **, M. Maris *** and M. Puligheddu **

*** INAF – Istituto Nazionale di AstroFisica, Osservatorio Astronomico di Trieste, Trieste, Italy

Abstract - In this paper, we analyze the accomplishment of a study for a low cost system, named PicoAgri, to monitor the status of agricultural fields. We here deal with the small detection system we are developing representing the first element to build the final PicoAgri concept: a system consisting of two elements, an array of small satellites coupled to drones. The array of CubeSat small satellites will provide data for an initial multispectral analysis with a resolution at ground of 30 m; when required a well localized area will be explored employing suitable drones capable of analyzing the territory with a resolution at least two orders of magnitude higher.

I. INTRODUCTION

Small satellites represent a new generation of satellite platforms that are opening their own market niche expanding extremely quickly. Particularly interesting is the Earth Observation and remote sensing field with practical applications for agriculture.

The “PicoAgri” concept will consist of two elements, an array of small satellites coupled to drones. The array of small satellites will be orbiting at a height of 400 km to provide data for an initial multispectral analysis with a resolution at ground of 30 m. When required a well-localized area will be explored employing suitable drones capable of analyzing the territory with a resolution at least two orders of magnitude higher.

In this context, the University of Trieste is developing a new low cost detector system dedicated to agriculture monitoring based on an array of CubeSats [1]. The PicoAgri system is mostly based on COTS (Commercial Off The Shelf) devices that are being adapted to the requirements of the full system aimed at monitoring the status of agricultural fields.

In this paper we briefly presents a feasibility study of the PicoAgri system and in particular we will focus the attention on the detection system, composed by the optical environment and by a suitable sensor.

II. SMALL SATELLITES

From the late 90s, with the construction of the first small satellites with very compact mass and size, space technology, prerogative of large companies specialised in the aerospace field, wants to become a technology available to small companies, facilities and research institutes, historically smaller and less rich. The design can be complex, given the environment in which such systems have to operate, but it is clear that the CubeSats small satellite systems [1], initially designed for educational purposes [2,3], are being brought to the daily technological and scientific use [4,5,6,7]. Over the last decade, more than one hundred CubeSats, modular small satellites whose basic element is an Aluminium cubic structure of 10 cm side, have been launched. This number will double very soon and in recent years interest for small satellites has grown considerably also for commercial applications further expanding the potential use of these systems.

Particularly interesting is the Earth Observation [8] and remote sensing field segment, that has large potential applications for safety issues or even more practical applications for agriculture. In this context the University of Trieste, with the two departments of Physics and Engineering and Architecture, in Collaboration with the Astronomical Observatory of Trieste, is developing the PicoAgri detection system dedicated to agriculture monitoring.

Figure 1. A picture of the CubeSat mechanical prototype produced by PicoSaTs

The University of Trieste started a CubeSat program that finally converged in the creation of a spin-off company, PicoSaTs S.R.L. [9], that is developing its own CubeSat satellite to be used as platform for this system. Figure 1 shows a picture of the mechanical prototype.
A. Remote Sensing and Earth observations

Remote sensing from Low Earth Orbit (LEO) satellites can significantly contribute to provide a timely and accurate picture of the agricultural sector [10,11], as it is suitable to gather information over large areas with high revisit frequency. The increase in agriculture production, required to cope with the foreseen increased worldwide population, must be achieved while minimizing the environmental impact of agriculture. Agriculture must cope with climate change and compete with land users not involved in food production (e.g., biofuel production, urban expansion). The necessary changes and transitions have to be monitored closely to provide decision makers with feedback on their policies and investments. In particular remote sensing studies of vegetation, adopting spectral radiance data from three bands has been proved to be suitable to gather properties related to pigment absorption, leaf density, and the canopy leaf water content[12,13,14] and eventually to the vegetation health.

The rapid wide coverage capability of satellite platforms allows monitoring of rapidly changing phenomena. Sensors on board satellites [15] can provide prompt information about global patterns on Earth (surface vegetation cover and its time and seasonal variations, surface morphologic structures, ocean surface temperature, near-surface wind), and in the atmosphere (dynamics of clouds).

B. The market view

There are a number of scientific satellites whose data are available to scientists but typically not suitable for commercial use. On Europe side, the European Space Agency (ESA) GMES (Global Monitoring for Environment and Security) Sentinel family and in particular Sentinel-2 [16], a multispectral high-resolution imaging mission for land monitoring to provide, for example, imagery of vegetation, soil and water cover, inland waterways and coastal areas, represents the status of the art of Earth Observation from space.

On business side, according to Euroconsult [17] more than 150 satellites (class larger than 50 kg) were launched providing ad hoc services for civil and Earth observation over 2006-2015. According to similar analysis by Pixyalytic Ltd [18], the fleet is even larger, almost 200 satellites overall, of which about 6% are commercial satellites. About 15% of the fleet belongs to Europe, demonstrating once more that Earth Observation is one of the most promising commercial space applications. A number of market and economic studies can be analysed [19,20,21], but it is clear that services varies according to the type of system and on board sensors. In this context we think that state of the art technology, as hyper-spectral imaging, is now ready for miniaturization. High resolution can be achieved also by small satellite systems, well below 50 kg, by using dedicated detection systems as the one proposed here, definitely at lower costs with respect to actual large space Earth Observation missions.

III. Vegetation Remote Sensing

Remote sensing studies of vegetation use specific wavelength bands that enhance leaf optical properties (scattering and absorption) providing spectral contrast with respect to background. Figure 2 gives the typical reflectance curve of green leaves, enhancing the dominant reflectance factors. Five primary regions are typically identified in the 0.4-2.5 μm band:

- **B1. 0.4-0.5 μm.** Strong spectral absorption by chlorophylls and carotenoids;
- **B2. 0.6-0.7 μm.** Strong chlorophyll absorption;
- **B3. 0.7-1.1 μm.** Minimum absorption, leaf scattering mechanisms resulting in high levels of spectral reflectance, especially for dense canopies;
- **B4. 1.1-1.3 μm.** Increase of water absorption coefficients;
- **B5. 1.3-2.5 μm.** Absorption by liquid water.

The amount of green biomass also affects the reflectance signature of biologic materials. As the vegetation grows, vegetation spectral signature becomes dominant; this signature can be observed in Figure 3. In principle, the biomass can be measured by comparing the reflectance in the 0.8-1.1 μm region to the reflectance near 0.4 μm.

IV. The PICOAgri System

A. The satellite system

Very simple considerations are given here for what regards satellite requirements since the full system...
concept is still preliminary; requirements are related on one side to the system size and on the other to the orbital characteristics. For what regards the attitude control system, it is assumed the satellite is controlled on three axes and the instrument will be pointing in the nadir direction.

For what regards the size, the system shall fit within a so-called 3U CubeSat, a parallelepiped satellite of 10 cm side and 30 cm length and maximum power consumption of the order of a few tens W. The optical system will be aligned with long side of the parallelepiped satellite whose size limits the optical system diameter to 10 cm and length to less than 30 cm if one consider that there should be enough room to host the PicoAgri detection system and all the other satellite systems.

Satellites will be in Sun-Synchronous1 (SS) orbits at 400 km altitude corresponding to an inclination of 97° (polar regressive orbits): the surface illumination angle will be nearly the same every time the satellite is overhead, being almost in constant sunlight, useful for imaging, and for Earth Observation in particular.

About the data acquired by the satellite, we have to consider that all the acquired data can be downloaded, of course, only when the satellite orbit passes near the ground station. Since the time during which the satellite and the ground station can communicate is very limited (few minutes) and moreover it depends by the available communication bandwidth, the information provided by satellite should thus be quite limited. However, it could be noted that even if the satellite will scan the entire earth surface, the data we are interested to acquire is typically limited to some predefined targets, where every target would have the dimension of one or more agricultural field. Thus, the strategy we suggest to adopt is the following: When the satellite is near to the target, the acquisition system will be turned on and all the data acquired will be stored inside a proper memory device, on the opposite if the target is outside the field of view, the satellite acquisition system remains in stand-by and no further acquisition is performed. A suitable on board control system will control both the acquisition system and the transmission procedure according to the data provided by the GPS system and to the current time. The acquired data will eventually be analyzed by the ground station which would provide several processing steps: Mapping, mosaicking, cloud and shadow detection, lens distortion correction, atmospheric correction, compositing procedure, etc. [26].

B. Mission Analysis

With the aid of the STK commercial software [24] we analysed possible CubeSaT constellations that use the SS orbit. Five test constellations were analysed:
1. One satellite;
2. Two satellites on the same orbit plane;
3. 12 satellites orbiting on two planes (six on each plane). The angle between the orbital planes is 90°;
4. 24 satellites orbiting on two planes (12 each orbit). The angle between the orbital planes is 90°;
5. 36 satellites orbiting in three planes (12 each orbit). The angle between the orbital planes is 45°.

The parameter that best ranks the different configurations is the revisit time, defined as the time elapsed between two consecutive observations of the same point on Earth. To calculate it, we used a grid of 33 target points placed at different latitudes (but with the same longitude) and run the simulation over three months. Figure 4 shows the result. One or two satellites do not provide a good revisit time, from 100 to 1000 hour to see the same point on Earth (according to their latitude). To improve this result the overall number of satellites should be increased, a constellation made of 12 satellites distributed into two planes can provide good coverage, with a worst case of about one week at the equator. The constellation performance grows almost linearly at the beginning as a function of the number of satellites in the constellation, but after about 30 satellites the performance reaches a plateau.

![Figure 4. Average Revisit Time simulated at different latitude](image1)

C. Communication Time

In a Low Earth Orbit (LEO), the time during which the satellite and the ground station can communicate is very
limited. With STK we analysed the satellite connections with a ground station placed in Trieste (Italy). On average two links per day are available, the mean duration is 236 seconds (minimum elevation angle of 15°), ranging from a minimum of 25 s to 302 s.

D. Detection System

The detection system is made of an optical system and a sensor, the processing unit used by now is an Arduino 1, that have been already demonstrated to work in flight [25] although we are analysing the possibility of using a more powerful unit.

For what regards both the optical and sensor systems, we analysed possible COTS optical and detection systems and linear CCD systems.

1) Working Principle

The acquisition of the satellite image is performed via a multispectral sensor that cover three spectral bands simultaneously:

1. Blue 459-479 nm
2. Red 620-670 nm
3. Near Infra-Red (NIR) 841-875 nm

The satellite acts as an along track scanner (push-broom scanner) (Fig.5) to obtain the spectroscopic image. A push-broom camera consists of an optical system projecting an image onto a linear array of sensors, typically a CCD array, arranged perpendicular to the flight direction of the spacecraft. At any time only those points are imaged that lie in the plane defined by the optical center and the line containing the sensor array. This plane is called the instantaneous view plane or simply view plane. The push-broom sensor is mounted on a moving platform, a satellite in our case, and as the platform moves, the view plane sweeps out a region of space. At regular intervals of time, 1-dimensional images of the view plane are captured. The ensemble of these 1-dimensional images constitutes a 2-dimensional image.

PicoAgri uses three different linear sensors, one for each spectral band, to reconstruct an approximate spectral image of the soil. The three sensors lay parallel on the focal plane perpendicular to the satellite flight direction so that they are scanning quasi simultaneously the view plane on Earth. In such a device the size of detectors (in our case the physical dimension of pixels) determines the size of each ground resolution cell. Another parameter that determines the instrument resolution is the acquisition time: the satellite is moving at a speed of approximately 8 km.s⁻¹ with respect to the ground, this has an impact on the image resolution along the satellite moving direction.

A desired resolution of 30 m corresponds to a maximum sampling time of 4 ms, a value easily achievable with Arduino or with any other acquisition systems. The main advantage of this type of sensors is the lack of mechanical components, preventing from malfunctions and extending satellite lifetime. The requirements of the detection system are summarized in Table I.

2) Feasibility Study

Requirements for optics and optoelectronics can be derived from analysis of mission requirements. In this section we want to determine the most important parameters for the optical system: the effective focal length F, the plate scale S, the diameter D or the F/D ratio. For what may concern the optoelectronic part of the device, relevant parameters are: the sampling frequency fₛ, the pixels size Pₛ and the detector number of pixels Nₛamp.

With the figures given in Table I, the angular resolution rₑ is:

\[ rₑ = r/h = 7.5 \cdot 10^{-5} \text{ rad} \]  \hspace{1cm} (1)

The diameter of the lens has to be large enough to assure proper resolution for a diffraction limited system. Since the typical resolution rₒ is:

\[ rₒ = 1.22 \lambda / D \]  \hspace{1cm} (2)

The constrain becomes:

\[ D > 1.22 \lambda / rₑ = 16 \text{ mm} \]  \hspace{1cm} (3)

The fov required to accommodate w is:

\[ \text{fov} = w/h > 6.2 \cdot 10^{-2} \text{ rad} \]  \hspace{1cm} (4)

This puts a limit for the F/D ratio:

\[ F/D < h/w < 16 \]  \hspace{1cm} (5)

![Figure 6. Optical instruments constrains](image-url)
Figure 6 depicts the allowed $F$ and $D$ for the optical instrument. Suitable $F$ and $D$ combinations are those included in the white area. Tilted lines represent the geometric locus with a constant $F/D$. The $D$ is limited on the lower side by the Airy disk as reported by eq. (3) and on the upper side by the satellite dimensions.

For a single lens or mirror optics, the upper limit for $F$ would be the satellite size itself which is 300 mm, however more sophisticated optical configurations allows a compression of the telescope size till a factor of five, leading to a maximum $F$ of about $1.5 \times 10^{-4}$ mm. The $F/D$ ratio is limited on the right side by eq. (5) while on the left side there is not a real physical limit, but COTS objectives have typically $F/D > 2$.

The pixel size $P$, of the detector fixes the scale $S$ of the optics. If $O$ is the oversampling factor i.e. the number of pixels corresponding to a single element of image with an $r$ size on ground, the scale is:

$$S = r_{ang}(O \times P) = 1/F$$

(6)

In our simulation we assumed two possible pixel sizes: $7 \mu m$ and $63.5 \mu m$ as representative of typical commercial sensors, and we also assumed $O = 1$. We then obtain $S = 1.1 \times 10^{-2}$ rad/mm in the first case and $1.2 \times 10^{-2}$ rad/mm in the second case. These values correspond to a focal length $F$ respectively of 93 mm and 847 mm. While the first can be easily accommodated in the satellite, the second actually exceeds the satellite size, but it can be accommodated using a two lens objective, one for instance with an objective 180 mm lens, with a scale $5.5 \times 10^{-3}$ rad/mm and a 36 mm camera lens suitable to magnify a portion of the image of about a factor 5.

The minimum sampling rate for the sensor is determined by the scanning speed of the satellite to limit motion blurring. The fov scans the Earth surface at a linear rate given by:

$$rate_{scan} = 2 \pi R_{earth} / P_{sat}$$

(7)

with $R_{earth}$ the Earth radius and $P_{sat}$ the orbital period of the satellite (~90 min), the $rate_{scan}$ is ~ 7.4 km/s.

The crossing time for resolution element $r$ is

$$t_{res} = P_{sat} / 2 \pi R_{earth} \approx 4 \times 10^{-3}$$

(8)

Assuming we accept a motion blurring of at most 50% of an image element, the maximum integration time for the detector is:

$$t_{exp} < t_{res} / 2 = 8 \times 10^{-3} s$$

(9)

The $w$ is equivalent to $N_{samp} = w / r > 833$ samples the minimal sampling rate for a linear detector is then:

$$f_s > N_{samp} / t_{res} \approx 500 kHz$$

(10)

Commercially available linear detectors allows sampling rates larger than few MHz, with frame formats equivalent to 256, 512, 1024 pixels per line or even larger, and pixel sizes in the range 7–63.5 $\mu m$. In order to reduce the size of the camera, small pixel sizes should be preferred. However low cost linear detectors are more easily available with large pixel sizes. So we consider two basic figures schemes for the camera as summarized in Table II.

Scheme 1 has been the first developed since it is based on on-the-shelf optics available, as describe in the next section while Scheme 2 is under development since it could be a good solution for a more compact optical system, suitable to be installed on smaller satellite.

### V. HARDWARE DEVICES

#### A. Optical System

We acquired two telescopes for amateur astronomical observations, namely “Skywatcher Makinuto MC 90/1250 SkyMax OTA” and “OmegaMakutov MightyMak 60”. Their characteristics are summarized in Table III together with the minimal characteristics of the detection system to be placed on the focal plane. Both the telescopes have a

Maksutov design, a catadioptric telescope design that combines a spherical mirror with a weakly negative lens placed at the entrance pupil of the telescope.

In figure 6 the parameters of the two telescopes under test are marked with a circle for the 60 mm and a square for the 90 mm. It can be noted in particular that vertical dashed lines represent the required focal lengths for a pixel size of 63.5 $\mu m$ to have a resolution at ground of respectively 20, 30 and 40 m.

It could be interesting to compare how the two proposed instruments copes with the required resolution at ground. Assuming a 63.5 $\mu m$ pixel size, the 90 mm focal length allows a resolution at ground of about 20 m. On the other side the 60 mm focal length allows a resolution at ground of about 37 m. While the first case represents a slight oversampling, the second represents a slight degradation of performance. A better match can be

**TABLE III. CHARACTERISTICS OF THE CHOSEN TELESCOPES**
obtained either using a sensor with different pixel sizes, or adding a camera lens to properly match the required scale.

B. Sensor

The first sensor that is being proposed is a linear CCD sensor, the TSL 1410R. The TSL 1410 linear sensor array consists of two sections of 640 photodiodes each and associated with achiaper amplifier circuitry, aligned to form a contiguous 1280×1 pixel array. The pixels measure 63.5 μm by 55.5 μm, with 63.5 μm center-to-center spacing and 8 μm spacing between pixels. This sensor reasonably fits on the two optical systems by coupling three sensors.

VI. CONCLUSION

We have proved the feasibility of a hyper-spectral system to be placed on board a small satellite, the first element of a low cost system, named PicoAgri, to monitor the status of agricultural fields at low costs.

At this level we verified the existence of COTS devices that are suitable for the system and acquired them, we designed and produced a box to contain a single detection sensor interfaced with an Arduino processing unit for the readout. The black box allows simulating the detection system since light comes from a slit and can be mounted on an optical bench that is used for all the measurements. We are calibrating the system by performing flat field, dark current and sensitivity of linear device exposures to properly characterize the system.

As a second step in the next future we are going to simulate and produce a prototype of the full scanning system, coupling the detection to the optical system, first as a monochromatic device, followed by a set of three linear cameras with ad hoc filters.

Abstract - There has recently been a strong push by environmental protection and research institutions for increased efforts in ecology, especially in the domain of water quality. Ecologists monitor and gather samples from thousands of locations around Europe yearly, but information technology penetration in their field is shallow, especially in freshwater macroinvertebrate monitoring. We propose a system that improves some common sampling techniques by increasing the precision of the sampling location description, makes it easier to find and tag sampling microlocations, improves sample gathering by reducing disturbance of debris in the lake bottom and increases the speed of sample analysis.

I. INTRODUCTION

In October 2000, the European Commission adopted the "Directive 2000/60/EC of the European Parliament and of the Council of 23 October 2000 establishing a framework for Community action in the field of water policy" or in short, the “Water Framework Directive”, as a legislative guideline for governing and managing water resources of all the European Union member-states [1]. The reasoning behind its adoption was the concern not only for the quality of drinking water (as a basic human right), but also for the quality of all water bodies due to increasing pressures due to pollution, climate change and population growth. One of the most difficult parts of the Water Framework Directive in the implementation sense is the required monitoring.

The number of surface water locations for which chemical and ecological monitoring was reported as of 2009 is more than 54000 [2]. The number of lakes for which monitoring is required as of February 2017 is at least 18859 [3]. The process for sample collection is currently inefficient from a duration and work power standpoint, mostly due to lack of penetration of information technology and reliance on manual techniques for the entire procedure.

This article focuses on the methodology for ecological sampling of lakes, more specifically reservoirs, through biological indicators (counts of various species of macroinvertebrates), and the possibilities for improvement on the current way of working. The sampling procedure for each location can be divided into three stages – planning, gathering and analyzing the sample.

In the planning stage, ecologists locate the sampling area on a map and plan a route to reach it. It is important to estimate the characteristics of the area in order to prepare the applicable equipment and its transport to the site (e.g. if a boat is required).

The gathering phase starts by finding a representative and accessible microlocation for sampling. This can be difficult due to vegetation, ground composition, steep inclines and other geological features. Once a microlocation is selected, the pH and temperature value is measured and alkalinity is manually calculated. Plant ecologists document the abundance of various types of vegetation which is a strong indicator of water quality and the status of the habitat [4]. A 10 - 25 meter stretch is marked along the shore (width is customized to lake characteristics). At each end of this stretch, a perpendicular line to the shore is followed towards the water across its surface and depths are marked at 0.25, 0.5, 0.75 and 1 meter or up to 10 meters of distance from the shore, whatever comes sooner (Picture 1). This is done using by using a rod to measure the depth of the water. The distance between the shore and these four pairs of points marks four quadrilateral areas on the water surface. Ten subsamples are gathered using a Surber sampler from these zones so that the number of subsamples taken in each of them is proportional to its share of the total surface area. Ideally, the surface area of the lake bed would be used, but this method provides an estimate which is easier to calculate [5][6]. The subsamples are run through a sieve to remove as much debris as possible, fixed in ethanol and combined into a representative sample for that location.

![Figure 1 Ecologists measuring distance from shoreline](image-url)
The samples are brought into the laboratory environment where the organisms from the sample are all collectively separated from the rest of the debris such as vegetation, sand, and sludge. They are then manually separated by species and finally individuals from each macroinvertebrata species are counted and their number is compared to referent indices, reported and entered into geographic information system (GIS) software. The analysis part of the process is very intensive in manual labor.

Adoption of certain computer, information and communication technologies could improve the sampling process by increasing efficiency, reducing the required number of workers on the field, reducing strain of the laboratory workers, and raising the quality of the gathered data while keeping cost flexibility in mind.

II. INFORMATION SYSTEM ARCHITECTURE

The proposed system architecture is planned trying to use as much of the toolset that ecologists executing the monitoring tasks already have at their disposal today as possible. It is intended to be modular and each added element is justified through an increase of either speed, ease of work, expansion of capabilities or cost reduction.

A. Integrated water quality sensor solutions

Already on the market, a wide array of water quality monitoring sensors exists [7]. Industrial complete solutions such as Libelium Smart Water and Smart Water Ions offer the possibility for users to measure in real time all of the required parameters with many additional ones. Such solutions do not need to be permanently fixed to one location, but may instead be used as mobile devices that would quickly measure the water condition while sampling equipment is being prepared [8]. A lot of research exists on the topic of automated water quality monitoring using sensors specifically targeting the Internet of Things concept. However one of the challenges of that approach is the balance between cost, from the acquisition, installation and maintenance standpoint and sensing capability [9]. Since field work and physical sample gathering is a prerequisite of this monitoring methodology, it is sufficient to acquire one sensor solution with adequate capabilities and utilize it repetitively. Private development of a customized solution is likely to bring the acquisition cost of a sensor system for this purpose down significantly and would allow targeting the parameters that are the most interesting to ecologists when monitoring lakes specifically.

B. Unmanned aerial vehicles

There are several use cases for unmanned aerial vehicles (drones) in ecological sampling.

The first scenario for which a drone could be used is to search for suitable microlocations, primarily from an accessibility and practicality standpoint. As soon as a sampling area is reached, a drone could be flown to find an approachable location without the need for the team to drive around the site in hopes of finding a convenient access point. The average of the area of all monitored lakes in the European Union is 4.7 km² [3]. Since locations are required to be visited every one to three years, vegetation and area characteristics could change so significantly that a previously accessible microlocation becomes unreachable [6]. This makes drones a valuable tool to be used throughout the monitoring process, and not just once per location (Picture 2).

Drones are already used in ecology for vegetation mapping [10]. Image resolution is sufficient for precise recognition of species with added practicality of access to heavily vegetated areas, reduction of costs and an increase in safety when compared to using manpower on the field, and a detection quality increase and cost reduction when compared to aerial photography [11]. Automated systems use image-based recognition techniques. Their use can significantly increase the detection accuracy and speed compared to manual methods using GPS for marking (several hundred hours for a 16 hectare area) [10]. Implementation of a customized computer vision algorithm for detection of species on which this method relies is likely to further increase the efficiency of the monitoring process.

The third possibility for use of drones is for mapping of the lake bed. The unmanned aerial vehicles that would be used for such a purpose would need to have mounted ground-penetrating radars which increases the complexity of the system. Conventional radar and LIDAR systems are highly attenuated by water and ground and would not be reliable in this situation. Use of drone-mounted ground penetrating radar solutions is already explored in the archaeological field, search and rescue, minefield clearing efforts and urban planning and maintenance, with several tailored solutions not only feasible, but precise enough and available on the market [12][13][14]. A custom solution should be developed for lakebed mapping. Depending on the desired price-precision ratio of the system, it could be used for either just measuring the incline of the lake bed or in addition measuring the granularity of the materials of which the lake bed surface is composed (sand, gravel, large stones, sludge). Incline measurements themselves would allow for more precise determination of representative sampling belts while...
composition measurements are a valuable habitat descriptor whose significance increases if measured before a person enters the water and disturbs the bottom. Due to the successful use of ground-penetrating radar with drones in other fields, the main challenges in the implementation of this solution would likely be in the software development, calibration and integration domains, while the hardware portion is not expected to create problems.

C. Radiocommunication technology

If a solution using an unmanned aerial vehicle is unfavorable due to cost or other reasons, a radiocommunication solution can be used to improve the depth segmentation surveying part of the methodology. An additional rod is used, and a pair of class 1 Bluetooth transceivers connected to microcontrollers is installed on the two rods. One of the rods is held at the edge of the water while the second rod is moved away to the depths required by the sampling methodology. At each depth, a button is pushed and the distance between the rods is determined by measuring received signal strength using the Friis equation, where $P_G$ is path gain or path loss in decibels compared to the permitted maximum transmitting strength for a class 1 Bluetooth device of 100 milliwatts (usually stated as 20 dBm), $\lambda$ is the wavelength of the signal, and $d$ is the distance being calculated (1).

$$P_{G_{dB}} = 10 \log \left( \frac{\lambda}{4\pi d} \right)$$ (1)

This procedure is then repeated for the second set of points. The Friis equation is precise in this situation as the environment can be described as having free-space qualities — it is highly unlikely to find objects that can have a significant influence on signal strength in the sampling microlocation bounds as such objects would impede the ecologist’s work and locations containing them are not selected for sampling. The forms of vegetation that would not be avoided at location selection do not impact signal strength measurably [15][16]. Since it is known in advance that the distance between the two rods will never be more than 10 meters, Bluetooth’s free-space range of 100 meters is sufficient for any measurement scenario [17]. The distances are sent using Bluetooth to an Android mobile device where the areas of the four quadrilaterals are automatically calculated and reported to the personnel operating the system. This solution is cost-efficient (currently around 30 EUR, depending on current module and microcontroller prices), does not require additional training of staff, makes the calculation process easier to execute in rainy and windy conditions where writing values on paper during calculations is difficult and saves around 10 minutes per location in calculation time while maintaining precision.

D. Computer vision and image analysis

The most time consuming part of the sampling process is the species separation, determination and counting. Algorithms are being developed for macroinvertebrates determination using computer vision and image analysis techniques. This methodology is apparently limited to determination to family level by lack of visually discernable features between species of the same genus while the manual form of this analysis involves mechanically changing the individual animals [18][19]. The maximum automated level of determination does not result in a sufficiently precise verdict to be helpful with fulfilling European Commission requirements which demand species-level determination. Further work is planned with the goal of ascertaining the value of determining various families visually without the possibility to separate them physically for manual determination on the species level and further exploring mechanical separation techniques such as sieves and centrifuges.

When the domain data is a sample in which the individuals are already separated by species (Picture 3 and 4), a neural algorithm-based program trained using Levenberg–Marquardt back-propagation optimization counted the individuals reliably, with omission and commission differential rates of between 0 and 4.85% depending on the genus. It is likely that the program could be improved further if more images are available during the training process [20].

Using image analysis just for counting individuals of each species saves an estimated 30 to 45 minutes per sample with the advantage of having the possibility to queue multiple sample analysis jobs to execute during the night.

![Figure 3 Individual from the chironomidae family](image3)

![Figure 4 Segment of collected sample with multiple species and debris](image4)
E. Data analysis and GIS

Use of GIS solutions is a prerequisite for monitoring projects. The gathered data is input into the GIS software which allows for database storage of data points with added functionality of it being tied to a geographical location with the corresponding context. Almost all GIS solutions have a programming interface enabling use of either Python or R, or JavaScript in web-based solutions, which allows for easy and powerful statistical analysis. The breadth of gathered data is determined by European Commission requirements and the data owners are government bodies responsible for water quality in each country who initiate and finance the monitoring. The data is disseminated to the public through European Commission and European Environment Agency databases such as the WISE WFD database (The Water Information System for Europe). This is a potential impediment if researchers on the local level want to expand the data domain to include a broader dataset. Finding correlations between unexpected or unapparent data points is a likely outcome of data analysis based on machine learning or big data algorithms.

The dataset gathered through this project can be considered multidimensional considering it contains at least a biological, a chemical, a geological and a geographical component which is tracked temporally and spatially. Multiple promising ecological discoveries have been achieved over multidimensional data in the recent past using machine learning [21]. In general, ecological data is favorable for machine learning techniques such as the Random Forest algorithm family for prediction of ecological phenomena. A lot of value can be found in using machine learning in information systems operating over ecological data as long as the data ownership is clear and its use is unimpeded [22][23]. Reluctance of ecologists to rely on machine learning for research in the past decade when compared to other scientific branches emphasizes this point [21][22].

F. System modularity

Most of the system components listed in this chapter are not reliant on other ones, which is convenient because it allows researchers to adapt the system to their specific needs. The GIS database can be considered to be the nexus of the system. The rest of the functions mostly report various measurements to the database. Its architecture was designed with the intention of automating as much of the sampling process as possible. This system structure is flexible for possible future expansions or changes as well. Figure 5 shows how there are only a few causal links in the system, so removing or including subsystems does not impact the others significantly.

III. DISCUSSION

There are a few remaining open questions with regards to technology options that if explored might become useful further improvements to the system.

The longest part of the analysis work that remains as a fully manual effort in this design is the species determination. Extensive research and development would be required in order to find a quality solution to this challenge. It might be worthwhile to look into chemical and other forms of detection of macroinvertebrates other than through computer vision and possibly combine it with robotics in the future. This would remove the largest bottleneck of the methodology other than the actual sample gathering in the field (determination of a single sample lasts between 8 hours and a week).

Another avenue that was not explored in this article is the use of floating or underwater drones. While unifying all three mentioned functions into a single unmanned aerial vehicle is appealing for lowering the system complexity and possibly cost, it is possible that mounting the ground-penetrating radar function on a small unmanned vessel might provide higher quality data or might make possible use of other detection technologies such as sonar.

IV. CONCLUSION

This article overviews technological advances from the recent several years that have achieved commercial and practical availability and are seldom used in ecology. Even maintaining very high cost awareness during selection of the proposed subsystems, the workflow of a team working on ecological monitoring of a lake or reservoir could be reduced by a few hours and at least made easier. For researchers, it offers a way to gather more data and data of higher quality allowing new discoveries and development of new ecology techniques with the goal of achieving better water quality in the future. Commercial options for a lot of the suggested tools are available on the market, but many of the solutions can also be developed independently. This distinction is important to maintain the flexibility of the system. Further research, implementation of an integrated system and empirical testing is planned to be executed in the near future, but we estimate that the system will achieve its goals in increasing efficiency of the ecological monitoring flow.

Abstract—Some experiments on a face verification tool based on FaceNet are presented in this paper. The task of the system is to perform face verification in a real-time assistive system aiming at facilitating the approach between a blind person and a presel ected acquaintance of his/her who enters the field of view. Face detection is made easier by the fact that an almost frontal view of the face is highly probable; verification on the contrary is difficult due to the poor quality of the acquired images and to the necessity of achieving a very low error rate. A custom database consisting of subjects required for verification is populated with face images provided by a suitable detection tool. The cascade of FaceNet and a Bayesian Classifier proves to be an effective tool for this unconstrained face verification task.

Index Terms—face detection, face verification, convolution neural network, face recognition

I. INTRODUCTION

We are developing a system for facilitating a blind person to interact with other people in a way similar to the one of a person with normal vision [1], [2]. The scenario we have agreed upon with the users is the one of a blind person who needs to meet one of his/her acquaintances in a public place, and is not willing to wait for the acquaintance to engage interaction e.g. by speaking: the users prefer to autonomously recognize the person they are meeting, in order to be able to behave consequently. In computer vision, this is a problem of face verification. To enable such a scenario, the system has to access the visual information of the surrounding environment and process it to extract information which gives an understanding of different non-verbal communication cues. Some of them may include the number of people in the scene, distance and position of identified people, physical appearance, gesture and expression of known people. This research devises the various steps needed to verify the presence or absence of particular people in the scene captured by the blind user, i.e. video acquisition, face detection, preprocessing, feature extraction and finally classification for end use.

The scene is simultaneously recorded by two commercial devices: one camera is mounted on the bridge of a pair of sunglasses, another is held by a short necklace on a light support. The glasses-mounted camera has a resolution of 1280 \times 720 pixel and an angle of view of 135 deg.; the resolution and angle of view of the necklace-mounted camera are 1920 \times 1080 pixel and 124 deg. respectively. In order to keep the prototype system close to its final goal, several test videos used for experimentations and validations are actually recorded by users who are fully blind from birth. Consequently, the acquired video data suffer from geometrical distortion due to wide angle camera optics, back-lighting, and disturbances due to fast and wide movement of the blind person. As the user of course lacks any feedback about the subjects in the field of view of the cameras, faces can be partially occluded or partially outside the frame. Moreover, the field of view of both cameras may be partially occluded, typically by a tuft of hair or by a lapel of the dress.

The video sequences are acquired in different indoor and outdoor environments where it may be required to identify subjects. These include a university library, a coffee shop, the hall of a public building, the neighborhood of a bus stop. These scenes reflect some typical scenarios in terms of natural and artificial lighting and crowd where the user may have to find and approach his/her acquaintance [3]. Our research focuses on preprocessing detected faces from these video sequences and feeding a feature extractor which provides face representation embeddings for classification.

The performances of face recognition tools have gradually increased even in unconstrained situations with the application of biologically-inspired Deep Neural Networks (DNN), which have been shown to largely outperform shallow nets. The literature reports both the existence of standard DNNs trained with millions of face images and the continuous evolution in layer architecture and patch selection [4], [5], [6], [7], [8], [9], [10], [11].

The performance of recognition or verification is greatly influenced by the preceding face detection and preprocessing steps. In our system, faces are detected using PICO [16]; they are validated based on a quality parameter, preprocessed and then passed on to pretrained networks which are variants of FaceNet, developed by Google for feature extraction. The features extracted from the second last layer of the network are fed into a Bayesian classifier for the face verification tasks. The method is hence able to exploit the deep layered feature extraction of FaceNet and adapt it for recognition or verification with a classifier-training phase which uses a customized dataset. Moreover, we also analyse verification results of Euclidean distance classifiers on the two different FaceNet versions [11] and [4].

Novel contributions of this paper are related to the usage of truly-in-the-wild video data acquired by a blind user, a refined...
method for region of interest (RoI) preprocessing, and a study of intensity preprocessing methods and their effects. The rest of the paper is organized as follows. Section II discusses face detection and RoI processing; the feature extraction models are discussed in III, while classification results are given in Section IV; section V provides the conclusions and future directions of the current research.

II. FACE DETECTION AND ROI PROCESSING

A lot of datasets have been reported in the literature for face detection. These differ in their level of annotation detail, which may vary from a simple bounding box to few or more facial landmarks such as eyes, nose, lips etc. The use cases considered in our project require to work on video sequences and hence the need to cope with larger amounts of data. Moreover, the final deliverable in this respect includes eye-related detections for gaze estimation and pose modifications between successive frames as a suggestion of an intention to communicate; although this counts as a future direction and is not in the scope of the work discussed here, the currently used face detector is chosen to accommodate this scope as an add-on without major modifications.

Popular face detectors like Viola Jones [12], Visage [13], NPD [14], FaceID [15], PICO [16], and GMS Vision [17] were tested to get an idea of which works best for the current dataset. Indeed, as elaborated in [18], all the face detectors performed poorly in the considered sequences. PICO and NPD, however, provide a confidence value which can be utilized to successfully refine the outcome by discarding the detected regions for which a low confidence is obtained. PICO is chosen in our experiments as it gives a higher average precision compared to NPD for the data under consideration.

The PICO software reports a rectangular RoI and a score for each object found. When a face is actually present, PICO reports several RoIs in slightly different positions for the same face in each frame; these RoIs are reported in subsequent frames as long as the face is inside the scene. In turn, for false positive results PICO often reports only one or two RoIs in isolated frames. To get rid of false positive results we implement a filter that uses the RoIs and their scores as well as their occurrence in subsequent frames. For each RoI reported by the detector we test if this RoI belongs to an already existing face object of our filter by calculating the distance using PCA and Joint Bayesian Model; [20] combines the responses of 25 networks and predicts the distance using PCA and Joint Bayesian Model; [20] uses SVM to combine the predictions of three networks using different face alignments.

The input to the network is an aligned or frontalized face. DeepFace uses 3D frontalization to align the face, whereas OpenFace utilizes a 2D affine transform to align and get a tight crop of the face. Different networks on different face patches or alignments are computed and their responses are combined. [21] combines the responses of 25 networks and predicts the distance using PCA and Joint Bayesian Model; [20] uses SVM to combine the predictions of three networks using different face alignments.

The network is trained with a combination of classification and verification loss [4], [22]. This also avoids the extra dimension reduction and the nonlinear classification tasks.

According to an analysis of popular networks in [23] the following facts are highlighted:

- Large fully connected layers are inefficient for small batches of images as the operations are better optimized over large matrices rather than small ones, hence utilizing resources more efficiently. For example AlexNet takes 84% of its inference time for batch size 1 and 33% for batch size 16.

III. FACE FEATURE REPRESENTATION

Deep convolutional networks have recently become the core of face recognition and verification tools even in unconstrained situations. The various networks reported in the literature differ in patch selection and network architecture. The models consist of multiple interleaved layers of convolutions, nonlinear activations, local response normalizations, and max pooling layers. $1 \times 1 \times d$ convolution layers and inception models [4], [7] are two variants of using a large number of wide kernel sized filters for convolution in some deep layers; the latter consists in parallel mixed layers of convolutional and pooling layers concatenated together, and have been reported to provide almost twenty times reduction in time complexity and an improved feature representation.

In general, to use these networks for feature representation the CNN bottleneck layer output is further processed using PCA for dimensionality reduction and an SVM or Bayesian classification tool [19], [20], [21]. The performances of these different networks are improved in various ways:

- The input to the network is an aligned or frontalized face. DeepFace uses 3D frontalization to align the face, whereas OpenFace utilizes a 2D affine transform to align and get a tight crop of the face.
- Different networks on different face patches or alignments are computed and their responses are combined. [21] combines the responses of 25 networks and predicts the distance using PCA and Joint Bayesian Model; [20] uses SVM to combine the predictions of three networks using different face alignments.
- The network is trained with a combination of classification and verification loss [4], [22]. This also avoids the extra dimension reduction and the nonlinear classification tasks.

According to an analysis of popular networks in [23] the following facts are highlighted:

- Large fully connected layers are inefficient for small batches of images as the operations are better optimized over large matrices rather than small ones, hence utilizing resources more efficiently. For example AlexNet takes 84% of its inference time for batch size 1 and 33% for batch size 16.
Accuracy and inference time are in a hyperbolic relationship: in general, model averaging is carried out for a better accuracy thus increasing the inference time. Consequently, the accuracy vs. inference time graph shows a steep slope which eventually flattens when cost complexity outgains accuracy.

Energy constraints are an upper bound on the maximum achievable accuracy and model complexity as it is obvious that in order to achieve a greater accuracy resource usage, power-consumption, and latency increase to a large extent.

The number of operations is a reliable estimate of the inference time.

In real-time situations, it may be meaningless to consider combined networks (for example the concatenation of 25 network outputs which extracts features from 25 different patches of a face) for performance elevation. Although alignment plays a crucial role, also the face detection phase has to be optimized in order to get good performances. Consequently, we need to balance the cost of the overhead (in terms of both time and computational effort) with improvements in accuracy.

The current work utilizes two models as shown in Table I and II. Network 1 is a modified version of FaceNet, which was kindly provided by the e-lab laboratory at Purdue University; Network 2 is the OpenFace network nn4.small2.v1 [11]. In Table I, we provide number of filters and filter sizes for the Spatial Convolution layers, window size and stride for the Maxpool layers, and output feature size for the View and Linear layers. The Inception Layer in Table II is a concatenation (indicated with the symbol ‘:’) of two or four operations: \((f_1, n_1) / (f_2, n_2)\) denotes a layer with \(f_1\) and \(f_2\) filters of size \(n_1\) and \(n_2\). This is further shown in Figure 2. Both networks provide a 128-dimensional feature representation.

We feed the networks with the images of the detected faces; they are not aligned and may not contain a tight face crop (e.g. in case of a miss of the PICO preprocessing), as shown in Figure 3.

### IV. Classification Results

Even if the final goal of our study is face verification, the results we show are for top-1 face recognition in a set of 1700
faces; in this phase we found this approach more informative, since it does not require to set a threshold to determine the reliability of the system. The results are analysed with three different classifiers; the effect of some basic preprocessing on the images fed to the network is also evaluated. It should be noted that an initial preprocessing is first carried out to obtain the best possible crop of the face RoI; this is followed by histogram and other normalizations of the cropped faces.

The ground truth for the various classifiers consists in 11 classes having 32 images each. 11 different sets of scene sequences are used for testing. After face detection, the presence or absence of a particular person is searched for in each scene; then, the detected face images are preprocessed, and finally they feed the network. The network requires a 3-channel input and is tested with (a) a gray image on all the three channels and (b) an RGB color image; it may be observed (Table III) that RGB color images provide a better average performance with a much lower standard deviation between different test sets. Even though grayscale images show some improvement for a few sets, their performances on others (2, 7, 10) are poor, so that the use of RGB images seems to be a better and stable solution.

As already mentioned, three kinds of classifiers are used, namely Bayesian (B), Euclidean Distance (E), Euclidean Distance with the mean face of each class (EM). E and EM are computed as follows:

\[ E = \arg \min_{i=1}^{n} (f_{test} - f_{train}) \]  
\[ EM = \arg \min_{i=1}^{c} (f_{test} - f_{train}) \]

where \( f_{train} \) is the feature vector for each sample in Eqn. 1 and the mean feature vector of each class in Eqn. 2, respectively for \( n \) samples and \( c \) classes.

The results are shown in Table IV. As shown in Equation 2, Euclidean mean provides better results with respect to standard Euclidean distance 1) for most cases. The performances of Bayesian and Euclidean mean are almost the same with the exception of Sets 2 and 7. In Figure 4) it may be seen that Set 2 has little or no variations in terms of pose and illumination but faces are not tightly cropped in most cases, whereas Set 7 has huge variations in terms of scale and illumination. Consequently, we suppose that the Bayesian classifier provides the best verification results on using tight image crops, while the Euclidean mean distance classifier performs better with aligned images.

The different preprocessing variants used in this work include normalized histogram equalization (HN) and normalized average histogram equalization (HAN) (mean of original and equalized image). Two normalizations have been tested, namely global normalization of the face according to neural network training data (NT), and classifier training set mean and standard deviation (CT). As shown in Figure 5-a,b, the global histogram equalization and global average histogram normalization are computed over three different kinds of data referred to as RGB-RGB, RGB-HSV, RGB-YUV, where the first part of the name denotes the color channel data that feeds the network whereas the second part denotes the color channel used to perform the histogram equalization. For example, in case of RGB-HSV the RGB image is converted to the HSV color space and the V channel is normalized before converting the image back to RGB and feeding the network. Using the Bayesian classifier, we verified that HN,NT on RGB-RGB and HAN,NT on RGB-YUV provide better performances with lower deviation between sets. The best performing categories are also evaluated using the two other classifiers as shown in Table V. The results show that histogram normalized images with NT data give the best results with a Bayesian classifier. Normalization (N) results on RGB images using the different classifiers are depicted in Figure 6. It may be seen that all the classifiers give the same average performance; however, the Euclidean mean has a lower standard deviation across the different datasets and can be considered the best one. It may be also observed that the deviation in verification accuracy results among the different test set is larger when using CT normalization instead of NT normalization for E and EM; it is

just the opposite for the Bayesian classifier. Consequently, we decided to use the Bayesian classifier with CT normalization for the comparison of the two networks, shown in Table III.

In Figure 7 it may be seen that the OpenFace network performs poorly when compared to Network 1. This may be due to underlying network differences, the fact that the images are not aligned as expected by the network, and the use of 96 X 96 patches of already very poor quality images, whereas the other network utilizes 240 X 240 patches. We are aware of the fact that the small amount of experiments we have performed does not permit to draw final conclusions about the performances of the system we are building. However, we
think that useful indications are already present (e.g. the larger or smaller standard deviations of the performances) that can guide a reader interested in the design of a system in this field of application.

V. CONCLUSION

The identification of faces in video sequences captured by devices worn by a blind person has been studied in this paper. This includes face detection using PICO filter, preprocessing, and face representation using deep convolution filters. The already challenging task of face recognition/verification from an unconstrained environment is further aggravated here by the fact that the faces may be partially or completely occluded and have to be detected from videos subject to backlighting, low resolution, distortion due to the use of wideangle cameras, and fast movements. Although the overall performance of the face detectors in such scenarios is quite poor, the current task is motivated by the fact that the user mainly has to recognize or verify faces who are approaching, interacting or at least looking directly at him/her; this favors the condition to a certain extent. The current work analyses the performance of two convolution models without face alignment (2D or 3D). The obtained results are satisfactory considering the single unaligned patch approach and promise considerable improvement subject to alignment operations, even if real-time implementation issues have to be taken into account. Indeed, for the same reason the authors do not plan to consider a multi-patch feature extraction for performance enhancement. Work is in progress towards testing the effect of 3D frontalization and 2D affine transformation on the detected faces before feature extraction. As the OpenFace network is supposed to be trained with aligned faces, the former step may significantly enhance the performance on our dataset. Moreover, the effect of finetuning on the networks instead of training a classifier will also be analyzed.

VI. ACKNOWLEDGEMENT

This work has been supported by the University of Trieste - Finanziamento di Ateneo per progetti di ricerca scientifica - FRA 2014, and by a private donation in memory of Angelo Soranzo (1939-2012). The authors also thank Eugenio Culurciello and Alfredo Canziani for kindly providing Network 1.

Abstract - We introduce the image acquisition from X-band Inverse Synthetic Aperture Radar (ISAR) system using measurement instruments for chirp generation and signal modulation in this paper. We design and develop a power amplifier and a signal demodulator, but we use an Arbitrary Waveform Generator (N8241A, Keysight) for chirp generation and a Vector Signal Generator (E8267D, Keysight) for signal modulation. Moreover, ‘Andale’, the Commercial-Off-The-Shelf (COTS) for data recording and Matlab for image post-processing are used. Then, we integrate all together for ISAR image acquisition and acquire vivid ISAR images. The final resolutions of acquired ISAR images are 0.41m range, 0.14m azimuth, the PSLRs are -22.8dB range, -22.3dB azimuth, the ISLRs are -20.2dB range, -17.1dB azimuth, better than the target specification.

I. INTRODUCTION

There are many devices to observe subjects on the earth from a satellite, such as an optical camera, an infrared camera, a Synthetic Aperture Radar (SAR) [1, 2], etc. The optical camera can show targets clearly, but it has limitation when it is rainy, cloudy, snowy, and dark. The Infrared camera can observe targets in the night though, it also cannot distinguish objects when it is rainy, cloudy, and snowy. The SAR, however can observe and monitor the targets regardless of rain, cloud, snow, and dark night. In addition, it can detect underground objects at certain depth, such as ground tunnels. But, the weak point of the SAR image is that the target image is not clear as much as the optical camera image.

The SAR payload of Korea Multi-Purpose Satellite (KOMSAT)-5 made by Thales Alenia Space Italy was launched and is working successfully and then, the development of SAR payload of KOMSAT-6 are driven by Korean industry so that the interest and demands of SAR developments are increasing now in Korea.

The ISAR equipment consists of a chirp generator, a signal modulator, a power amplifier, antenna, a signal demodulator, a signal processor, and post-processing by software for images. In this test, we use measurement instruments for the functions of chirp generation and modulation. Using measurement instruments saves monetary budget and manufacturing time.

This paper organizes as follows. Section II introduces ISAR equipment and test scheme, section III shows the test concept of ISAR and describes test results. Section IV describes resolution measurement of the system. Section V concludes.

II. DESCRIPTION OF TEST SCHEME

The equipment (see Figure 1) of ISAR consists of the chirp generator that produces linear FM chirp pulses, the signal modulator that converts its signal to X-band center frequency, the power amplifier to amplify the magnitude of the signal, the antenna to emit its energy, and the signal demodulator that demodulates and detects the reflected signals, the signal processor that stores in order and processes to be sent to the ground by datalink. In addition, the post-processing software manages the ISAR image with the given raw data.

For chirp generation and modulation, we use measurement instruments, an Arbitrary Waveform Generator (N8241A, Keysight) that has an option of linear FM chirp pulse generation and a Vector Signal Generator (E8267D, Keysight) to convert baseband signal to X-band. We make use of COTS, ‘Andale’ (high speed customized 24TByte) with X6-GSPS FPGA for its signal processing and data recording. Using these measurement instruments and COTS has given us some advantages,
such as stable triggers and changing bandwidth, carrier frequency, PRF, etc. easily. Finally, we employ range compression, range cell migration compensation, and azimuth compression from the range doppler algorithm [1, 2] by Matlab for post-processing to produce ISAR images. Hence, we design and develop a power amplifier and an X-band signal demodulator, subsequently interface them with each equipment. We apply IF sampling and Digital Down Conversion (DDC) scheme here (the sampling rate is over gigahertz). System parameters are summarized in Table 1.

### III. ISAR Test

We carry every equipment inside van like Figure 2. We mount two antenna for transmitting and receiving respectively that means we do not use a circulator, so this scheme reduces RF losses. Because ISAR needs the doppler effect of the target, we position antenna along with the horizontal direction of the moving target. Several ISAR images are obtained.

#### A. Method #1 (10W, 25dBi)

Figure 3 is an ISAR image of a container ship. The 100m-length, 20m-width ship we take pictures on the bridge, approximately 380m away is shown clearly by radar pulses. The velocity that we estimate is 21.5 km/h. The flagpole of the ship is dimly visible, because we believe the size of flagpole is relatively smaller than body size of the ship itself.

#### B. Method #2 (70W, 25dBi)

In this test, we use the 70W power amplifier instead of 10W for a longer distance. At this time, the target is 6.5km away like Figure 5.

The Figure 4 is ISAR images of an airplane. Target images is 380m away, especially about 4m-long engines and 34m-long wigs are shown.
Figure 5: Actual target image (red circle, length 60m, wingspan 60m)

The right picture of Figure 6 is an ISAR image out of focus, because analyzing velocity 342km/h we used is 10km/h off from nominal velocity. The left image, velocity matched one shows clear the figure of aircraft.

Figure 6: ISAR image of an Aircraft (velocity 352km/h, distance 6.5km) (left), Velocity unmatched image (right)

C. Method #3 (70W, 45dBi)

In this test, instead of 25dBi antenna, we use the 2.4m-diameter antenna whose gain is 45dBi in the right picture of Figure 7. At this time, the target is a Cessna 208, smaller than the previous airplane.

Figure 7: 2.4m antenna (left) (45dBi) and actual target image (right) (Cessna 208, length 12.6m, wingspan 15m)

Figure 8 shows an ISAR image of the Cessna. Due to the small sized target and narrow beamwidth of high gain antenna, this ISAR image is not much clearer than the image of Figure 6.

Figure 8: ISAR image of Cessna208 (velocity 240km/h, distance 3.5km)

IV. RESOLUTION MEASUREMENT

We measure the resolution of this system with Impulse Response Function (IRF), the range resolution is 0.41m, the azimuth resolution is 0.14m in Table 2. These results are better than the target resolution specification, we believe signal processing with windowing and filtering gives positive effects to the result.
V. CONCLUSION

We design and develop ISAR system and try to get images from the moving target. We simply compose X-band ISAR system of the measurement instruments (Keysight) for chirp generation and modulation, and COTS. We, furthermore use the range doppler algorithm by Matlab for the post-processing of ISAR images so that those cost effectively and save manufacturing time. After measuring IRF, we finally get 0.41m range resolution, 0.14m azimuth resolution, better than our target resolution (0.5m(range), 0.4m(azimuth)) specification.

Abstract - The purpose of this study was the segmentation of kidneys and abdominal images to assist the diagnosis and to focus on the required area. Kidney segmentation from abdominal images is not an easy task due to the proximity of those organs in the image, the similarity of organ tissues and the occurrence of different properties of the image in each cross-section. In this study, a fully automatic approach was suggested for the kidney segmentation in abdominal computed tomography (CT) images. Both the success of the suggested approach was tested and the performance of the process was evaluated. Area Error Rate (AER) criteria were used to reveal the accuracy of the segmentation operation. Because the vertebral column was used as the reference in the suggested approach, the coordinates of the vertebral column were determined by applying pre-processing to the images. In the second step, the kidney areas were obtained using the Connected Component Labeling (CCL) method. The final step of the study included transferring the operations performed on a PC to a mobile platform. The results obtained reveal that the suggested methodology is a kidney segmentation process that experts can use.

I. INTRODUCTION

Imaging for diagnosis has become a significant subject because detailed information about anatomy is now possible by using various medical imaging methods. Data presented by imaging devices can be easily processed by separating the desired tissues from the rest of the data. Segmentation and imaging are two very close fields that are used in numerous radiological applications. Side effects caused by the treatment are diminished if there is an early diagnosis of the illnesses at the onset, which increases the rate of recovery from the illness. Moreover, early diagnosis decreases the cost of the treatment, and the time and effort spent on treatment.

There are some instances where the data obtained from imaging devices used in radiology are insufficient for medical doctors to make a diagnosis. Therefore, such data must be processed to make it more understandable. The segmentation method of computed tomography (CT) images obtained from different phases is an effective method to find lesions in kidneys and to characterize them.

Segmentation is defined as the separation of any pattern in the image, or any part of the image, from the remaining parts [1]. Segmentation in the medical image-processing field has been widely used in studies of anatomical structures, treatment planning and computer-assisted surgery [2]. Literature shows that the methods developed are currently semi-automated and user-interactive methods. The most significant disadvantage of these is the introduction of a delay in diagnosis. Thus, automatic segmentation is usually preferred by experts.

In this study, unlike others, anatomical characteristics of the abdominal region were utilized. Right and left kidneys were separated by using the coordinates of the vertebral column obtained from its segmentation. The Connected Component Labeling (CCL) method was used for automated kidney segmentation. The performance of this method was evaluated by using an Area Error Rate (AER) method. The following studies were then transferred to mobile media for use on other larger platforms. The materials and the method used in the study are explained in the second section. Next, the performance of the method was evaluated, and experimental results are given. In the third section, the infrastructure of the mobile platform is described and the use of the system on mobile media is explained using schematics. In the last section, the results obtained are discussed.

II. MATERIALS AND METHOD

Thirty patient images were obtained from the image archival storage system of the Department of Medical Faculty Radio-diagnosis, Firat University. CT images were taken in the portal phase, following transusing using an opaque substance. The image matrices have dimensions of 512 x 512 pixel and are in color. They are in the DICOM format. The kidney images obtained were manually segmented by an expert radiologist to obtain references images.

In the pre-processing step of the study, morphological operations were applied to the images. The purpose of these operations was to ensure the success in determining the vertebral column in the kidney segmentation. The segmentation steps are shown in Figure 1.
A. Connected Component Labeling Algorithm

In the second step, the CCL algorithm was used for kidney segmentation. CCL is an algorithm that first labels combined objects in the image, then collects neighboring pixels in a group and finally makes them distinguishable. After grouping, each group on the image is numbered to represent an object. Therefore, the desired result is possible by distinguishing the desired group-numbered object from the others. The CCL algorithm is divided into two groups: 4-neighborhood and 8-neighborhood. Adjoining pixels are included in the operation as neighbors because 8-neighborhood is preferred in many applications [3, 4, 5]. The algorithm gives the pseudo code for the object-numbering for 1 to 8 neighborhoods. The flowchart of the segmentation using the CCL method is shown in Figure 2.

Algorithm 1. Numbering objects by CCL

Step 1: Scan all pixels. If the pixel is not equal to black,
Step 2: Scan all the neighbors of the pixel,
Step 3: If all neighbors are either black or white, that is a new pixel; assign a new label to the pixel
Step 4: If at least one neighbor is labeled (not black or white); assign the least labeled neighbor to that pixel and save the other labels as the same
Step 5: Go back to step 2

AER, G, and B values are obtained for each part after using the CCL algorithm. Segmented kidney images are obtained by assuming that the largest component in certain channels is the kidney. The results obtained are again combined from the split point used in the first step with the original images until dimensions of 512 x 512 pixel are obtained.

B. Area Error Rate

Area error rate (AER) is a method indicating the percentage rate of change of the difference between the segmented areas of the image to be compared [6, 9]. The method uses the area manually selected by a medical doctor and the area automatically found by the suggested method. AER is calculated based on equation 1 [7]. In this equation, M indicates the area manually segmented, while A indicates the area obtained by the suggested method.

\[
AER = \frac{(M \cup A) - (M \cap A)}{M} \times 100
\]  (1)

Table 1 shows the performance evaluations of both right and left kidneys. An error rate for 30 right kidneys was 9.74%, while for 30 left kidneys it was found to be 13.1%.

<table>
<thead>
<tr>
<th></th>
<th>Right Kidney</th>
<th>Left Kidney</th>
</tr>
</thead>
<tbody>
<tr>
<td>AER</td>
<td>9.74</td>
<td>13.1</td>
</tr>
</tbody>
</table>

The discrepancy between the error rate of right and left kidneys is due to the diversity of organs surrounding both kidneys. This value indicates approximately a 15% error rate for both kidneys, but it also reveals an 85% success rate.

III. ANDROID APPLICATION

Transfer of the study to the mobile platform is a bilateral process. Eclipse IDE and Android SDK software was used for the client application, while MATLAB, PHP and MySQL software was used for the server. Figure 3 show the server and client structure that was developed.
The first step in the application is to select patient information and display the corresponding CT data. A medical doctor can send the data to the system over the mobile device or he/she can connect to the system over the mobile device by sending the patient information. Then, the application is run via a command issued by the mobile device. Many image processing steps are used in the application.

In this study, segmentation of the right and left kidneys was conducted on axial abdominal CT images. Next, the segmented image was displayed on the mobile device. Figure 4 shows the original image on the mobile device. After taking the original image, the system performs the segmentation operation without needing a separate starting point for each piece of data. Figure 5 indicates the segmented image on the mobile device.

IV. CONCLUSION

Lesions on kidneys can appear without warning because they do not show any signs for a long time. It is known that 1 one person out of approximately 10,000 people will get kidney cancer, and 1 person out of 30,000 dies due to this illness [8]. Because the onset of the illness is rarely noticed by the patient, early diagnosis on abdominal images is of vital importance. The purpose of the study was to detect any cyst in the kidneys before it reaches an advanced stage by segmenting the abdominal images and perform this operation on mobile media independent of any platform. The CCL algorithm was used for kidney segmentation in CT images whose contrasts were increased. AER success criteria were used to evaluate the performance of the operation. When the segmentation results obtained by the manual and suggested methods are compared, an 85% success rate was achieved. To use the application in a wider environment, a mobile platform was selected that is widely used in daily lives. It was possible to focus on a desired area in the images obtained by segmenting the abdominal images; thus, a successful diagnosis could be made. The present study constitutes the first step in studying kidneys to diagnose the presence of any kidney cysts. Moreover, medical doctors can access data independently from hospital systems and their working areas, which provides a convenient way for doctors to work outside the hospital. The system studied will serve many purposes and provide a basis for further studies.

Abstract - Action recognition in videos is currently in the focus of scientific research due to improvements made in automatic analysis of static images and greater availability of processing power. The paper provides an overview of the key models and methods for action recognition that comprise human models and methods based on estimation of joint trajectories, silhouettes and template matching and spatio-temporal local descriptors. To deal with compound actions and activities, action semantic models are proposed with help of expert knowledge. Since the action recognition task is domain dependent, the methods and models are built and tested on domain specific databases. The paper provides an overview and description of recent video datasets that were created for developing action recognition methods, with an emphasis on datasets with additional modalities such as depth images or accelerometer data.

I. INTRODUCTION

Automatic analysis of videos is nowadays in the focus of research interest. This is due to their ubiquity in ordinary life and usability in many different fields like security surveillance, automation of processes based on visual references, detection of all sorts of abnormalities, and anything that is connected to visual observation.

The key part of automatic analysis of videos is the recognition of individual actions, such as falling down, or jumping. The recognized actions can be used per se, for example for interacting with electronic devices, or can serve as a starting point towards recognizing activities that require further interpretation, such as distinguishing between a normal encounter or a threatening approach.

Over the years, many techniques have been proposed for solving the task of human action recognition in video. Most of them use some kind of supervised machine learning approach, where the models of actions that should be recognized are constructed using the training data consisting of features extracted from videos containing the appropriate actions. Fig. 1. shows the typical workflow of the supervised learning approach, where a prediction model is created in the first workflow and then is used in the second workflow to make a prediction.

In the other, knowledge-based approach, the models of actions used for recognition are constructed mainly by encoding by hand the expert knowledge using a descriptive language and logic operators.

Lately, a newer kind of machine learning approaches for action recognition using deep neural networks have emerged. This approach has been used for automatic extraction of features that will be used for recognition instead of handcrafted features in a classic ML style, as well as an integrated framework of feature extraction and classification where both processes are completely handled in the deep network.

The purpose of this paper is to give an overview of the most used models and methods for activity recognition with their strengths and weaknesses. A list of datasets that are appropriate for this purpose will also be presented.

II. MODELS AND METHODS

Raw video sequences are inappropriate for modeling and classification due to their extremely high dimensionality (proportional to image dimensions and time), where most dimensions do not actually contain any information that is relevant for action recognition. On the other hand, machines perform classification based solely on primary elements like pixels or features. That is why the first step after acquiring videos is typically the extraction of features. Simply put, features are the interesting parts of the image altered in a way that machine can use. Some of the common low-level features are edges (divides between lighter and darker part of the image), corners (points where edges intersect), blobs (regions of image too smooth for an edge to detect), etc.

In action recognition, the features can be roughly divided into those that encode positions or trajectories of different body parts, into those that aim to track the whole figure and into local features that operate on interest points in videos without regard if they belong to a person or not. Both the body part based features and figure based features require additional video processing in order to detect, segment and track the persons in video, which is a non-trivial task. Local features, on the other hand, have an advantage of not requiring any kind of person localization, so they have lately became increasingly interesting to researchers in the field.

A. Body based models

Feature representations for action recognition that are based on human body parts use 2D and 3D features like stick figures (Fig. 3), silhouettes (Fig. 4) or volumes (Fig. 5) to represent information about position and movement of different body parts [1].
Precise full pose reconstruction is a difficult task, and the results can be unreliable due to noise and occlusion, yet it turns out that is not necessary for action recognition. Thus, a different direction of research focused on representation of actions using body silhouettes, without attempting to segment or match individual body parts to a model. This has been used in an early work [6] where a vector quantization scheme was used to turn the silhouette image sequence into a sequence of symbols. The symbol sequences are used to train Hidden Markov Models (HMMs) of actions, which are applied in the recognition phase to find the model that best matches the observed symbol sequence, thus incorporating a flexibility in the duration of actions.

In a more recent work [4], the actions are represented as templates that are volumes formed by stacking the silhouettes of persons performing actions along the time axis (Fig. 4), and the matching is done by template matching. The drawback of silhouette and volume based representations is the fact that silhouette segmentation can be difficult in noisy environments, and view dependence, which can be mitigated by forming different models for different views.

B. Bag of visual words models

Recognition of actions using local features and bag of visual words have an advantage over the approaches that rely on body models, since the extraction of local features doesn’t require any kind of human model or person localization. The local features are extracted by first using an interest point detector and then extracting a local descriptor of that interest point. The descriptors are clustered into visual words. Each image is then represented by a bag of visual words (BOW) which is then used for learning, Fig.6.

The drawback of 2D-time representations is that they are view-dependent, meaning that the features for the same action will be very different depending on the relative orientation of the camera and the person performing the action. On the other hand, the 3D pose estimation from a single view requires models that are more complex. If the single camera requirement is relaxed, solutions using multiple cameras to reconstruct the depth information have been proposed, as in [4]. Lately, affordable depth cameras have emerged that capture 3D depth information using an infrared sensor along with RGB video, which can aid greatly in estimation of joint positions in 3D, but are still limited in use due to modest range of depth sensing. An additional consideration is whether camera view is stationary or mobile [4], whether a single camera is used or there are multiple views available [3] to either reconstruct a 3D representation of the world or to mitigate the effect of occlusions and expand the field of view.
After the points of interest or trajectories information about shape and movement in local surrounding area are successfully detected, they are presented using interest point descriptors. Feature trajectories are typically extracted using the Kanade–Lucas–Tomasi (KLT) [13] tracker or by matching SIFT descriptors [14] between frames.

Majority of descriptors fall under the group of spectra descriptors which are based on computed quantities like color and light intensity, local area gradients, statistical features and moments, surface normals and sorted data like 2D or 3D histograms of any spectral type.

3D, 4D, volumetric and multimodal descriptors are becoming more interesting because of the development of affordable 3D sensors and accelerometers built into mobile devices. Since the field of 3D feature description is early in the development, it is not yet clear which methods will be widely adopted. The most notable at this point are 3D HOG [15], 3D SIFT [16] and HON 4D [17] which are based on familiar 2D methods that are extended into a spatio-temporal 3D space.

The extracted features are then encoded using BOW or Fisher Vector approach [18].

Common classification methods are used in conjunction with the above features for action recognition such as Multi-Layer Perceptron (MLP) in [19], and Support Vector Machine (SVM) [10,9,20,21].

C. Deep learning approaches

Motivated by the success that has been achieved with deep learning methods such as convolutional neural networks (CNNs) [22], used in image and video classification [23], there is an increasing interest to apply that approach in the action recognition field as well. CNNs can learn to extract features automatically from a large number of labeled images and have outperformed the classical ML approach using handcrafted features for image classification task. In [24] the image classification CNN method is extended to handle the temporal dimension of videos. The proposed architecture used several layers of 3D convolution starting from the initial 7-frames deep cube, that generates multiple channels of information that are analogous to handcrafted features, and layers of subsampling that reduces the dimension of the feature vector. The classification itself is also performed by the last layer of the neural network.

An architecture where two parallel networks capture spatial and temporal information were proposed in [25]. One network operates on individual video frames, performing action recognition from still images, and the other operates on the optical flow explicitly describing the motion between frames and forms the temporal recognition stream. The output of the two networks is fused into a final decision score using a SVM classifier. The results obtained with CNNs in action recognition show the similar performance as classical methods [24, 25].

III. ACTIVITY UNDERSTANDING

The previously mentioned methods, due to intensive research that has been done are very accurate in recognition of simple actions but they lack the ability to deal with more complex and hierarchically related actions and activities. Therefore, more descriptive model and logical operators should be used for presenting that kind of activities with help of expert knowledge.

Authors of [26] give an overview of the current research in the field of activity understanding and an overall model of activity understanding task, comprising abstraction and action modeling, Fig.7. Abstraction deals with a problem of translating motion image input into form understandable by action models to determine if an interesting action has occurred. Final output can be a particular activity or summary of actions. Abstraction is performed using either pixel features, objects and their properties or logical facts of knowledge. Action modeling includes traditional classification methods for action recognition, state models for knowledge representation in space-time domain and semantic models for reasoning about sequential actions. State modeling formalisms include: finite state machines (FSMs), Bayesian networks (BN), HMM, etc. Semantic models use an interesting subset of actions defined by the semantic relationships between their sub-actions. Semantic model depends on knowledge of domain expert to classify an activity. It is usually applied in case of more complex actions that vary in their appearance [27, 28, 29]. Semantic models include grammars, Petri nets, constraint satisfaction, etc. The deterministic nature of semantic models makes them sensitive to inaccuracies in lower-level recognition, therefore mechanism of fuzzy reasoning to handle uncertainty in observation and interpretation is generally desired [30]. Authors of [31, 32] used a fuzzy knowledge representation scheme that enables modeling of uncertain knowledge about relations between entities that could be used for indistinct interpretation of borders between actions in motion image sequence.

Figure 7. Activity understanding model after [26]

IV. DATASETS

To start building models for activity recognition it’s essential to acquire good dataset of video samples which reflect desired activities. There are many datasets publicly available for scientific research including recently growing datasets with additional information acquired using RGB-D sensors, accelerometers and position markers that are placed directly on a model that is being observed, multiple sources, etc. In this paper the emphasis will be on these datasets.

Princeton Tracking Benchmark [33] introduced 2013 consists of 100 RGB-D tracking datasets with tracking software and online submission script. Datasets include real world footage of variety of actions performed by humans, pets and object presentations in form of RGB (8 bit PNG format) and
accompanying depth (16 bit PNG format) images (Fig. 8). Annotations are per-frame in a form of bounding box covering target object only. These datasets are more related to tracking than to action recognition but could serve as a starting point in segmentation of scenery.

**Cornell Activity Datasets: CAD-60 & CAD-120** [2]. CAD-60 comes with 60 RGB-D videos of 2 male and 2 female persons in real world closed environment: office, kitchen, bedroom, bathroom, and living room describing 12 activities: rinsing mouth, brushing teeth, wearing contact lens, talking on the phone, drinking water, opening pill container, cooking (chopping), cooking (stirring), talking on couch, relaxing on couch, writing on whiteboard, working on computer, Fig. 9. CAD-120 consists of 120 RGB-D videos with same number of people in similar environment. Activities are divided into 10 high-level activities (making cereal, taking medicine, stacking objects, unstacking objects, microwaving food, picking objects, cleaning objects, taking food, arranging objects, having a meal) and 10 sub-activity labels (reaching, moving, pouring, eating, drinking, opening, placing, closing, scrubbing, null) with object affordance labels like reachable, movable, pourable, closable. Skeleton joint position and orientation is labelled on each frame. RGBD data has resolution of 240 by 320. RGB is saved as three-channel 8-bit PNG file and depth is saved as single-channel 16-bit PNG file.

**Northwestern-UCLA Multiview Action 3D Dataset** [34] contains RGB, depth and human skeleton data captured simultaneously by three Kinect cameras. This dataset include 10 action categories: pick up with one hand, pick up with two hands, drop trash, walk around, sit down, stand up, donning, doffing, throw, carry (Fig. 10). Each action is performed by 10 actors in a library from a variety of viewpoints.

**RGB-D People Dataset** [35] was gathered by a three vertically mounted Kinect sensors on a tower at approximately 1.50 m height. It contains 3000+ RGB-D frames acquired in a university hall and contains mostly upright walking and standing persons seen from different orientations and with different levels of occlusions, Fig. 11. Annotations are made in a form of a square box. Depth images are saved as 16 bits, 1 channel PGM images - 640 by 480. They contain the raw data content from the Kinect sensor. Namely, each pixel has value between [0, 1084]. RGB images are saved as 8 bits, 3 channels PPM images - 640 by 480. Dataset doesn’t provide activity annotations but offers material for an art gallery research.

**UTD Multimodal Human Action Dataset (UTD-MHAD)** [36] was collected using a Kinect sensor and a wearable inertial sensor in an indoor environment. The dataset contains 27 actions performed by 8 subjects (4 females and 4 males). Each subject repeated each action 4 times. The dataset includes 861 data sequences. Four data modalities of RGB videos, depth videos, skeleton joint positions, and the inertial sensor signals were recorded in three channels or threads (Fig. 12). One channel was used for simultaneous capture of depth videos and skeleton positions, one channel for RGB videos, and one channel for the inertial sensor signals (3-axis acceleration and 3-axis rotation signals). For data synchronization, a time stamp for each sample was recorded. The inertial sensor was worn on the subject’s right wrist or the right thigh (see the figure below) depending on whether the action was mostly an arm or a leg type of action.

**Berkeley Multimodal Human Action Database (MHAD)** [37] contains 11 actions performed by 7 male and 5 female subjects in the range 23-30 years of age except for one elderly
subject. All the subjects performed 5 repetitions of each action, yielding about 660 action sequences which correspond to about 82 minutes of total recording time. In addition, a T-pose for each subject was recorded which can be used for the skeleton extraction along with the background data (with and without the chair used in some of the activities). The specified set of actions comprises of the actions with movement in both upper and lower extremities, actions with high dynamics in upper extremities and actions with high dynamics in lower extremities. Each action was simultaneously captured by five different systems: optical motion capture system, four multi-view stereo vision camera arrays, two Microsoft Kinect cameras, six wireless accelerometers and four microphones (Fig. 13).

Dataset of a human performing daily life activities in a scene with occlusions [38] consists of 12 RGB-D video sequences of a person moving in front of a Kinect in a scene with obstacles, Fig.14. In addition to the depth and RGB image, each sequence contains the synchronized ground truth data obtained from a Qualisys motion capture system with 8 infrared cameras. 3D representation of a human model is achieved by using 15 position markers: one for a head, neck and torso and 2 for shoulders, elbows, wrists, hips and knees.

Recording video is another way of acquiring dataset. Using private dataset allows customization to adopt to a desired method, however, it is time consuming and it requires significant resources to collect desired footages.

When building private dataset one of the things that needs consideration is what approach regarding camera number would be most suitable. When one camera is used depth perception is lost and observed object can be completely or partly hidden. Multiple cameras concentrated on an object of observation from different positions give much more information. The position of cameras can be calculated like in [39] for an optimal solution. Multiple cameras can be set up two ways. Camera fields can overlap, which is more suitable for detail action examination, or they can be put side by side, the so-called “art gallery”. This way is used more in surveillance [40]. Art gallery, also, allows greater filed coverage with a same resources but shares the problem as one camera approach, only partial image is visible.

Overlapping cameras provide info about the object from different perspectives but there is an occlusion problem. This can be avoided by using algorithms like in [41] where input from different cameras are used sequentially which require less samples and computational power.

Art gallery and one camera approach generally suffer from absence of depth perception. Fortunately, latest development in game industry brought affordable RGB-D sensors like Microsoft Kinect and Asus Xtion which give depth based on two cameras and widespread use by using infrared spectrum. Still, even though these sensors perform well they are still inferior compared to marker based systems [39].

V. CONCLUSION

In this paper, an overview of models, methods for action recognition is presented. Human models and methods that are based on trajectories, silhouettes and template matching, spatio-temporal local descriptors and descriptor-based methods are presented along with their advantages and disadvantages. Recognition of actions using local features have an advantage over the classical approaches, since the extraction of local features doesn’t require any kind of human model or person localization. There is in an increased interest in using convolutional neural networks that can automatically learn to extract features, and show state-of-the art performance.

In case of recognition of actions and activities that are more complex, semantic models that use expert knowledge are commonly proposed.

In addition, paper presents, in detail, available image databases appropriate for the tasks of action recognition with additional information acquired using RGB-D sensors, accelerometers and position markers.

ACKNOWLEDGMENT

This research was fully supported by Croatian Science Foundation under the project Automatic recognition of actions and activities in multimedia content from the sports domain (RAASS).

Abstract—The proper planning of repairs and rehabilitation of the asphalt pavement is one of the important tasks for safe driving. The most common form of distress on asphalt pavements are potholes, which can compromise safety, and result in vehicle damage. Timely repairing potholes is crucial in ensuring the safety, quality of driving, and reducing the cost of vehicle maintenance. Many of the existing methods for pothole detection often use sophisticated equipment and algorithms, which require substantial amount of data for filtering and training. Consequently, as a result of intensive computational processing, this can lead to long execution time and increased power consumption. In this paper, we propose an efficient unsupervised vision-based method for pothole detection without the process of training and filtering. Our method first extracts asphalt pavements by analysing RGB color space and performing image segmentation. When the asphalt pavement is detected, the search continues in the detected region only. The method is tested on online image data set captured from different cameras and angles, with different irregular shapes and number of potholes. The results indicate that the method is suitable as a pre-processing step for other supervised methods.

I. INTRODUCTION

The continuous inspection and assessment of physical and functional condition of civil infrastructure is crucial for safety, serviceability and rideability. Currently, the manual visual inspection at regular intervals is the main form of conditions assessment in most countries. Unfortunately, due to insufficient inspection and condition assessment this method had some tragic consequences in countries such as Japan and USA. The other form of inspection is automatic visual inspection which accounts for only 0.4% of all inspections. Automatic inspection uses specialized vehicles that are mounted with laser scanners, pavement profilers, accelerometers, image and video cameras, and positioning systems. Current automatic inspection methods have several restrictions, such as the number of defects they can detect, the price of sensor equipment and the level of detail they can attain.

The most common form of distresses on asphalt pavements are potholes - small, bowl-shaped depressions in the pavement surface. The repair of potholes is necessary in situations where potholes compromise safety and pavement rideability. The automatic pothole detection systems are based on 3D reconstruction, vibration and vision methods. The 3D reconstruction requires high cost laser scanners, while vibration based approach is unreliable on a surface such as bridge expansion joints due to surface vibrations. The vision-based methods use various image processing techniques to detect potholes on 2D images or video data. Among existing methods many use supervision, which requires a training data set and some form of filtering. Unfortunately, supervision methods suffer from the problem of overfitting, where characteristics of a training set are memorized, instead of capturing the desired pattern.

In this paper, we address the problem of automatic pothole detection by automatic analysis of selected 2D images of asphalt pavement. We propose a new unsupervised vision-based method to detect potholes. First, we extract the asphalt pavement (region of interest) and we limit the search for potholes in that region only. The region of interest is detected through manipulation of B component in RGB color space, and two-level dynamic selection of asphalt pixels (seed points) based on a standard deviation of an image. Once the asphalt pavement is found, we proceed to detect potholes by comparing two cropped images, the idea based on the method from our previous research.

The effectiveness of our method is verified on a newly formed image data set from selected images from Google search engine. The data set contains highly unstructured images taken from different cameras and shooting angles, with different irregular shapes and number of potholes. Our method is designed for use under daytime fair weather conditions, which is consistent with the current practice. The method is low-cost and efficient since it does not require expensive equipment, filtering nor training data. Also, the image quality does not significantly affect the accuracy. The results show that the method detected potholes with reasonable accuracy. Since the method uses manipulation of B component in RGB space and image segmentation it can be easily and widely adopted for hardware implementation.

This paper is organized as follows: related work is briefly...
reviewed in section II. In section III, we proposed a new method for pothole detection. The implementation details, data set and experimental results are presented in section IV. We concluded the paper with some remarks in section V.

II. RELATED WORK

The existing approaches for pothole detection can be classified into three groups [7]: 3D reconstruction-based, vibration-based and vision-based. A 3D reconstruction of the pavement surface can be acquired by laser scanners [8] [9], stereo-vision algorithms by using a pair of video cameras [10], [11], [12], and visualization using Microsoft Kinect sensor [13], [14], [15]. These methods visualize 3D pavement surface data by using sophisticated, high cost equipment, and exhibit high computational cost. A vibration-based approaches [16], [17], [18], [19] use accelerometers to assess pavement condition based on the mechanical responses of the vehicle which carries equipment. The main problem of this approach is that it cannot be used at bridge expansion joints and cannot detect pothole in the center of a lane.

A vision-based approach uses various image processing techniques to detect potholes on 2D images or video input. In [20], Karuppuswamy et al. proposed a new method based on integrating vision and motion system for detection of simulated potholes. The application of the method is limited due to the simulation limitations (potholes smaller than 2 feet in diameter, and the color of pothole). In [21], Koch et al. proposed a novel supervised approach for automated pothole detection based on asphalt pavement images. This approach is based on pothole texture extraction and comparison, where the surface texture inside a pothole candidate has to be described and compared with the texture of the surrounding region. This implies existence of a number of pothole texture samples from which the system is trained. System can detect a pothole based on this training results. Additionally, four spot filters are required to be applied to original gray-level image in order to emphasize structural texture characteristics.

In our previous work [6], we proposed new unsupervised vision-based method which does not require expensive equipment, additional filtering nor training phase. Our method deployed image processing and spectral clustering for identification and rough estimation of potholes. The effectiveness has been verified on image data selected from Google image collection. The accuracy of a pothole surface area was about 81%, thus we concluded that the method can be used for rough estimation for repairs and rehabilitation of pavements.

In regards to detection of potholes over a sequence of frames, Koch et al. [22] extended their original method with video processing [23]. Radopoulou et al. [24] proposed the use of Semantic Texton Forests (supervised learning algorithm) for detection of several defects occurring in video frames.

III. METHODOLOGY

The overall design of our method is depicted in Figure 1. The method consists of three major steps:

(A) Image Pre-processing

(B) Region of Interest Extraction

(C) Pothole detection

A. Image Pre-processing

The first step consists of two phases: image resizing and image segmentation. The size of an image does not effect the quality of pothole detection. Thus, in order to decrease the number of computations, we first decrease the size of an image by $\alpha$ times [1].

$$\alpha = \begin{cases} 400/\text{Columns}, & \text{for Rows} \geq 301 \quad || \quad \text{Columns} \geq 401 \\ 400/\text{Columns}, & \text{for Columns} < 181 \\ 1, & \text{otherwise} \end{cases}$$  

![Fig. 1: Block diagram of proposed method for pothole detection.](image-url)
In the image segmentation phase, the arithmetic mean $\mu$ and the standard deviation $\sigma$ are calculated by equations (2) and (3).

$$\mu = \frac{1}{N \times M \times 3} \sum_x \sum_y \sum_{[R,G,B]} p(x,y)_{[R,G,B]}$$

$$\sigma = \sqrt{\frac{1}{3NM-1} \sum_x \sum_y \sum_{[R,G,B]} [p(x,y)_{[R,G,B]} - \mu]^2}$$

The parameters $x, y, N, M$ and $[R,G,B]$ are row and column indices, image height and weight, and RGB color components of an image $I$, respectively. The $p(x,y)_{[R,G,B]}$ represents pixel values on the point $(x,y)$ for the color components: red, green and blue.

We replace the original image pixels of $R$, $G$ and $B$ components as shown by criterias in the equations (a,b,c), respectively, and the final $\hat{I}$ image (d), which is passed to the next step together with parameters $\mu$ and $\sigma$.

$$I'_{[R,G,B]}(x,y) = \begin{cases} (0,0,0), & I_{G(x,y)} - I_{R(x,y)} + I_{B(x,y)} \geq 15 > 0 \\ (0,0,0), & I_{B(x,y)} - I_{R(x,y)} > 20 \\ (0,0,0), & I_{G(x,y)} - I_{R(x,y)} > 15 \end{cases}$$

$$(0,0,0), \quad I''_{[R,G,B]}(x,y) < \sigma$$

$$(255,255,255), \quad I''_{[R,G,B]}(x,y) > 0$$

$$(0,0,0), \quad I''_{[R,G,B]}(x,y) = 0$$

**B. Region of Interest Extraction**

The region of interest is the area on which potholes can be found, i.e. asphalt pavement. The input for this step is the $B$ component from RGB color space ($\hat{I}_{[B]}$) from the previous step, which is a black-white image (0,255). First, we form new matrix which contains pixel positions of all white pixels in an image. Second, we select a dynamic number of pixels, based on the standard deviation of an image ($\sigma/2$), to form the first level seed points. The algorithm for finding the first level seed points is shown in Algorithm [1]. The result of Algorithm [1] is presented in the figure Fig. [2b]. The red circles represent the first level seed points.

**Algorithm 1** The finding of first level seed points

Require: $\hat{I}_{[B]}$; $\sigma$ - standard deviation of the original image $I$

$(N,M) \leftarrow$ size of $\hat{I}_{[B]}$

return (seedPoints) $\triangleright$ Selection of seed points at the first level

$$C = \begin{cases} \frac{\sigma}{2}, & \sigma > 60 \\ \frac{\sigma}{3}, & \text{otherwise} \end{cases}$$

Third, we introduce the second level seed points in order to detect asphalt pavement more accurately. The second level is formed based on the values of neighboring pixels from the first level. For each first level seed point (red circle), we inspect four neighboring windows of size $C \times C$, where $C$ is formed by $7$. The windows are illustrated in Fig. [3b]. Then,
for each selected window (TopLeftWindow, TopRightWindow, BottomLeftWindow, BottomRightWindow), we calculate average pixel value. The second level seed points are selected by comparing average pixel value to 250. If the value is larger or equal to 250, the selected second level seed point is diagonally opposite pixel from the first level seed point (for example $nP_1$, $nP_2$, $nP_3$, and/or $nP_4$). This step is repeated $n$ times in order to cover as much of the region of interest. The number of iterations $n = 5$ is empirically selected. The second level seed points are illustrated in Fig. 3(c) as blue points. The region of interest is extracted based on the position of these points, while the values of pixels from the rest of the region is changed to 0. The final result is presented in the figure Fig. 3(d).

C. Pothole detection

The third and final step consists of three phases: the method of cropped images and Otsu thresholding, linear and image boundary shapes elimination and detection of pothole regions.

The first phase is based on our previous work [6], where we proposed a new unsupervised method based on image processing and spectral clustering for identification and estimation of potholes on asphalt pavements. In this paper, we use only the first and a small portion of the second step from our previous work for the purpose of pothole detection. The majority of second and third steps were based on spectral clustering, and they are now not necessary due to a newly proposed preprocessing and region of interest extraction steps. There are additional differences when compared to the previous method. The first difference is the input image into the first step, which is now the result of Region of Interest Extraction step ($I_{ROI}$). The second difference is that we use only the step for elimination of all linear and image boundary shapes from the second step of the previous method, and disregard the rest.

The measure for removing all linear regions is the same and it is defined by eccentricity $\epsilon$ of shapes [25].

The resulting image after the first and second steps is shown in Fig. 4(a) and b), respectively. Based on the shapes detected, we draw rectangles over detected potholes in the final step, as shown in Fig. 5.

IV. IMPLEMENTATION AND RESULTS

A. Implementation

Our method has been implemented in MATLAB version 7.11.0 (R2010b) with Image Processing Toolbox. The image processing was performed on Intel Core2 2.80 GHz CPU with 8GB of RAM.

B. Dataset

The common practice for testing an pothole detection method is to generate a a data set with in-expensive and omnipresent equipment mounted on a passenger vehicle, i.e. off the shelf digital cameras for video and photo acquisition. Such a data set usually captures images taken from only one angle (front or back camera), which enables extraction of parameters (such as vanishing point, pavement lane and its surroundings, etc) for narrowing the scope of search. Unfortunately, no publically available data set exists for detection and classification of any defect type [26]. This prevents true verification of results and makes comparison between different methods very difficult.
The effectiveness of our method is verified on an image data set formed from selected images from Google search engine (keyword “pothole”). The selected images are collected with different types of cameras. Images are taken from various angles with different irregular shapes and number of potholes. We believe that this unstructured data set can be used to examine the true potential of any pothole detection method.

### C. Results

The method was tested on more than 80 different pothole images captured from various cameras, shooting angles, different irregular shapes and number of potholes, different sizes and backgrounds. The capabilities of our method on selected images are shown in Fig. 5. The execution time varies significantly on the complexity of an image. The average execution time on a given data set is 465.71 ms with average mean error of 7%.

The detection accuracy is calculated by comparing the detected number of potholes and an actual number of potholes visible on an image (calculated manually). We considered detection successful if the method detected more than half of potholes on an image. On a given data set the accuracy was 82%. The method shows promising results on pothole images from simple to complicated background, and high illumination. Since our method does not require any training stage, it has low computational cost when compared with supervised methods. The results indicate that the method is suitable as a pre-processing step for other supervised methods.

### V. Conclusion

In this paper we proposed a new unsupervised method for automatic detection of potholes based on RGB color space image segmentation. Potholes are bowl-shaped depressions in the asphalt pavement, thus the region of interest was defined as asphalt pavement. Hence, we narrowed the search for potholes in this region only. The effectiveness of the method depends on the extraction of ROI accuracy. Once ROI is extracted, the potholes are detected by comparing two cropped images and performing Otsu thresholding method. Once all linear and image boundary shapes are eliminated, the remaining regions are potential potholes.

The method was tested on 80 different pothole images, and the detection accuracy is calculated manually. On a given data set, our method detected all potholes and the surface estimation was 82% accurate. Thus, the method is suitable for rough estimation of potholes. The results show that the method detected potholes with reasonable accuracy.

Abstract - The angular Glagolitic documents dated from the XIII to XV century in the hand-printed form and from the XV up to XIX century in the printed form. During such a wide period of time, the way of writing documents was changed. It is particularly true for so-called old and new Glagolitic orthography. The old Glagolitic orthography was used in all documents whose origin is Croatia as well as when the editors were Croats. This was spread in the period from the XIII to the first half of XIV century. After that period, under the influence of the Latin script, the Glagolitic orthography changed to so-called new one. The paper proposes a new automatic methodology for the classification and differentiation of the Glagolitic documents written by old and new orthography style. It consists of initial document transformation to coded text according to the horizontal energy levels in the text line. This coded text is then seen as an image. The image is subjected to the texture analysis in order to extract a feature vector. The extracted feature vector is used as an input to the classification tool. As a final result, the classification tool differentiates Glagolitic documents written in different orthography styles. The experiment is based on an excerpt of the original Glagolitic documents dated from the XIV to XIX century. The obtained results regarding differentiation of Glagolitic documents are very promising.

I. INTRODUCTION

Documents in a given language can be characterized by different orthography rules. Orthography is an important aspect of the natural language processing which is mainly connected to the written language. In particular, it defines the set of rules of "correct writing", realizing a certain capitalization, emphasis, hyphenation, punctuation and word breaks style [1].

A language in a given historical period is subjected to evolution due to multiple influences. Consequently, its orthography is subjected to variation, too. Sometimes, these variations in orthography are so visible that they are connected to a new development of the language. In this case, specific orthography rules may characterize the origin of the historical document. For some languages, dating and printing origin of the documents may be easily identified by the differences in orthography style.

Some work has been introduced in the literature for orthography recognition. In particular, it analyzed the connection between the distinction of some tokens during the evolution of the language [2] and in multiple languages [3]. This was accomplished by employing traditional linguistic methods, such as bi-grams, tri-grams, probabilistic mapping and changes in tokens and vocabulary [4]. The main limitation of the proposed approaches is their lack of generality. In particular, they have been introduced for orthography differentiation in the same language or among different languages, but they have not been or cannot be applied in both the contexts.

To overcome the limitations of the previous works, we propose a new more general method for orthography differentiation and recognition. It may capture the changes in orthography style determining the evolution of the script in the same language or identify the orthography changes tracing the evolution in a different language. In this paper, the method is specifically employed for recognition of documents in angular Glagolitic script of the Croatian language as written in old or new orthography style. To the best of our knowledge, it is the first time that a similar approach has been introduced in the literature. The angular Glagolitic documents dated from the XIII to XV century mainly in their hand-printed form, and from XV up to XIX century in their printed form. The old Glagolitic orthography, whose spreading advanced in the period from the XIII to the first half of XIV century, was used in hand-printed and printed documents from the Croatian region or where editors were Croats [5]. After that period, under the influence of the Latin language, the orthography was changed into the new one. It followed the change between hand-printed and printed documents [6]. Because the old and new orthography styles are mainly related to two different historical periods, the method is implicitly able to identify the origin of the Medieval Croatian documents. In particular, old and new orthography styles of Glagolitic documents represent the same combination of letters in spite of different ways of writing capitals. Although a local approach has a clear advantage over a global one, the orthography differentiation by extracting certain letters is superfluous. The only solution to solve such a problem is a transformation of a given information into another space, which can differentiate given orthography styles. This has
been established by coding each letter according to its energy projection profile. After a coding phase, transforming the document into a codified image, texture analysis is applied to the image for feature extraction. Finally, features of the document are classified for orthography recognition.

The paper is organized as follows. Section II describes the main concepts underlying the method, including script coding, texture analysis and classification. Section III presents the experiment. Section IV makes a discussion about the experiment. Finally, V makes the conclusions and outlines future work directions.

II. THE METHOD

The proposed method has the aim to differentiate and recognize the angular Glagolitic documents as written in old or new orthography style.

It is composed of the following steps: (i) script coding, (ii) texture analysis, and (iii) classification. First, the horizontal projection profile is applied to segment text lines in text establishing a central line in each text line. Then, each blob is framed by the bounding box. Furthermore, the distribution of the blob heights and its center point can be extracted. These features are used in a classification according to typographical features [7]. It is illustrated in Fig. 1. Then, script coding classifies the letters of the document into four types according to their horizontal energy profile in the text line. It provides a mapping of each letter to a certain code representing the class of the letter. In this way, the document is transformed into a sequence of codes. This determines linear patterns of codes inside the document which are able to characterize the script of the document. Then, coded text is subjected to transformation into an image. Disposition, location and length of the linear patterns are quite dissimilar in documents written by different scripts. For this reason, application of texture analysis on the image corresponding to the coded text determines features which can differentiate documents as given in the different scripts [8]. Because orthography style of the document is related to script characteristics, this procedure directly realizes the differentiation of the orthography styles. Finally, classification employed on the obtained document features is able to recognize the orthography style of the document (old or new one). Fig. 2 shows the main steps of the proposed method.

A. Script Coding

Script coding is the first and essential step of the proposed method for orthography recognition. Its aim is to classify each letter in the text into a certain script type, based on the horizontal energy profile of the letter determining its position in the text line area. Fig. 3 shows such a classification of the letters based on their location in the text line area. According to that, letters are classified as: (i) base letters, (ii) ascender letters, (iii) descendent letters, and (iv) full letters [9]. Each class is associated to a numerical code in the set of 4 codes \{0, 1, 2, 3\}. In particular, we have that: (i) base letter corresponds to 0, (ii) ascender letter corresponds to 1, (iii)
feature extraction process.

Next, we show that script coding is a very useful task for orthography differentiation in Glagolitic documents. In particular, old orthography style represents the capital letters as descendent ones, while new orthography style writes the capital letters as ascender ones, like in the Latin alphabet. This characteristic allows to make some differentiation based on script types. As an example, we report the coding of a printed text excerpt in Glagolitic script and of a hand-printed text excerpt in Glagolitic script in the old orthography style, and of a printed text excerpt in Glagolitic script in the new orthography style. Fig. 5 depicts the printed text excerpt in the old orthography style and its corresponding coding. Fig. 6 shows the hand-printed text excerpt in the old orthography style. The printed text excerpt in the new orthography style is depicted in Fig. 7. We may intuitively observe that some differences occur at the level of linear patterns between old and new orthography (see Figs. 5-6 (b) and Fig. 7 (b)). Table I quantifies the distribution of the script types for the three text excerpts in Figs. 5, 6 and 7. We can observe that some distinction between old and new orthography is clearly visible in terms of descendent and full letters. In fact, we have around 3.5% more of descendent letters and around 5% more of full letters in the new orthography style. Differently, hand-printed and printed texts in old orthography style exhibit a similar percentage of descendent and full letters. This confirms the efficacy of the proposed script coding.

B. Texture Analysis

Image I is subjected to texture analysis for the features extraction. Texture brings information about the disposition of the intensities in the image, in order to generate the features. Run-length statistics method for texture extraction is in the focus.

Run-length statistics are characterized by the concept of run. It is a sequence of consecutive pixels of the same intensity along a given direction of the texture. If image I has M intensity levels and maximum length of a run N, the run-length matrix P can be computed by considering the runs in I along a given direction. An element at position (i,j) of P contains the number of runs of intensity level i and length j. Fig. 8 shows an example of run-length matrix generated from an image pattern where each gray level is represented by the numerical code.

Starting from p, eleven features can be generated: (i) Short run emphasis (SRE), (ii) Long run emphasis (LRE), (iii) Gray-level non-uniformity (GLN), (iv) Run length non-uniformity (RLN), and (v) Run percentage (RP) [13]; (vi) Low gray-level run emphasis (LGRE), and (vii) High gray-level run emphasis (HGRE) [14]; (viii) Short run low gray-level emphasis (SRLGE), (ix) Short run high gray-level emphasis (SRHGE), (x) Long run low gray-level emphasis (LRLGE), and (xi) Long run high gray-level emphasis (LRHGE) [15].

Table II reports the 11 run-length features. N represents the total number of runs, while np is the number of pixels of image I.

In particular, SRE quantifies the distribution of short runs and it is sensitive to their occurrence. Accordingly, it will take higher values for finer textures. LRE evaluates the distribution of long runs. Hence, it will have higher values for coarser textures. GLN quantifies the similarity of gray levels over the image. If image presents some differences in gray levels, GLN will take low values. RLN measures the similarity of the length of the runs over the image. Hence, it will have low values if runs exhibit different length. RP quantifies the homogeneity and distribution of runs along a given direction. If the length of the runs is 1 for all gray levels along a given direction, RP will take the highest value.

Furthermore, SRLGE, SRHGE, LRLGE and LRHGE are based on the concept of joint statistical measure of gray level and run-length.

C. Classification

Feature vector representing the document composed of 11 run-length features is classified by Naive Bayes (NB) method [16] for recognition of its orthography style. We adopted NB method because it is quite robust to noise and extensively used for text document classification [17], for which it obtained good accuracy results [18]. After a training phase, the test feature vector is the input of the classification process, recognizing the script of the corresponding document as given in the old or new orthography style.

NB method is based on the assumption of conditional independence between the features, which means that all features are mutually independent, considering the class label value. In particular, given a binary classification problem with the class label given as 1 or 0, let $n$ be the number of features (in our case we have $n=11$ features) and $x_i = \{x_1, ..., x_n\}$ be a feature vector with the associated class label $y_i$. Considering the assumption of conditional independence, the NB classifier is defined as follows:

$$f_{nb}(x_i) = \frac{p(y_i=1)}{p(y_i=0)} \prod_{i=1}^{n} \frac{p(x_i^h \mid y_i=1)}{p(x_i^h \mid y_i=0)}.$$  

where $p(y_i=1)$ is the probability of occurrence of class label $y_i=1$, and $p(x_i^h \mid y_i=1)$ is the probability of occurrence of the feature value $x_i^h$ given the class label $y_i=1$. In order to classify a test feature vector $x_i$, the probability terms in (1) will be computed for its feature values according to the training set. In the end, $x_i$ will take the class label 1 if and only if $f_{nb}(x_i) > 1$, otherwise it will take the class label 0. When the features take numerical values, which is specifically our case, the probability term is computed by the normal function as follows:

$$p(x_i^h \mid y_i) = f(x_i^h, \mu_{i,h}, \sigma_{i,h}) = \frac{1}{\sqrt{2\pi}\sigma_{i,h}} \exp\left[\frac{-(x_i^h - \mu_{i,h})^2}{2\sigma_{i,h}^2}\right],$$

where $\mu_{i,h}$ and $\sigma_{i,h}$ are respectively the mean and the standard deviation of the values of $h$-th feature when class label is $y_i$.

III. EXPERIMENT

An experiment is conducted for evaluating the accuracy of the proposed method in old and new orthography recognition of the angular Glagolitic documents. Accordingly, the method is tested on a custom-oriented database of thirteen printed text excerpts in Glagolitic script. Five out of thirteen texts are written in the old Glagolitic orthography style, while eight out of thirteen texts are given in the new Glagolitic orthography style. Texts in the old orthography style have been extracted from the well-known book entitled Missale Romanum Glagoliticum dated from 1483 [7], [19]. It is the first printed book in Glagolitic script and represents a wonderful and important contribution to Croatian history.

About the texts in the new orthography style, six out of eight texts have been extracted from the book The Confession and Knowledge of the True Christian Faith dated from 1564 [6]. Finally, two out of eight texts have

been extracted from the book *Foundations of the Old Slavic language* dated from 1862 [12]. All historical Glagolitic books have been found at the National Library of Zagreb in their digitalized format. Text excerpts have been randomly selected from the books, extracted from them and processed in their digital format. Fig. 9 shows an example of two text excerpts from selected books in the old and new Glagolitic orthography style.

IV. RESULTS AND DISCUSSION

The proposed method has been implemented in MATLAB R2015a on a laptop computer Quad-Core 2.2 GHz with 8 GB RAM and UNIX operating system.

A test involving different feature representations, such as co-occurrence-based and ALBP-based features [20], has been performed. In particular, image patterns have been processed by run-length, co-occurrence and ALBP methods in order to obtain three different representations. In the end, we observed that run-length statistics received the best accuracy results in this context. For this reason, they have been definitively employed for this analysis.

Because run-length statistics determine numerical feature values, NB method uses (2) to compute the probability terms by the normal function. Furthermore, classification of the texts for orthography recognition has been performed by other two different methods: Support Vector Machine (SVM) [21], and K-Nearest Neighbors (K-NN) [22]. Specifically, a linear kernel function for SVM demonstrated to be enough for our purposes. For K-NN, the cosine similarity was used, which performed considerably better than the other measures. The number of neighbors has been fixed to 5, because different values did not obtain considerable improvements in classification accuracy. Obtained results demonstrated that NB is the most accurate method for orthography recognition. According to that, it has been employed as the classifier inside the system.

Because SVM and K-NN methods are based on the concept of distance which is sensitive to large differences in the values, the feature vectors have been normalized before the application of the classification task. In particular, we adopted the following normalization formula for every value inside each feature vector of the database:

\[ x'_i = \frac{x_i - \min_i}{\max_i - \min_i}. \]  

(3)

where \( x_i \) is the value of \( h \)-th feature inside the \( x_i \) feature vector, \( \min_i \) is the minimum value of \( h \)-th feature in the database, and \( \max_i \) is the maximum value of \( h \)-th feature in the database.

Our task is a binary classification problem, where the orthography of the text excerpt is identified as the new or old one, according to the script characteristics. In order to evaluate the classification accuracy, the confusion matrix is generated between the classification result of the method and the ground truth labeling of the texts in old and new orthography [23]. From the confusion matrix, precision, recall, and \( f \)-measure are computed. *Precision* is the ratio between retrieved and relevant documents and all retrieved documents. *Recall* is the ratio between relevant retrieved documents and all relevant documents. *F-Measure* is the harmonic mean of precision and recall.

In order to make the evaluation independent from the adopted training and test sets, the K-fold cross validation is employed on the database [24]. In particular, the database is randomly divided into K folds. Then, each fold is alternately used as the test set, while the remaining K-1 folds are employed as the training set. Every time, the performance measures are computed on the found classification solution. In the end, the average precision, recall and \( f \)-measure, together with the standard deviation values, are reported as the final result. In this case, we fixed \( K \)=10 for cross validation, which is a typical value.

Fig. 10 shows the glyphplot of the feature vectors in the database. It realizes a representation and analysis of the multivariate data in the database. Each feature vector is represented as a "star", called glyph, where \( i \)-th spoke has a length which is proportional to \( i \)-th feature value. Each feature (column of the database) is shifted and scaled separately in the interval \([0,1]\), and glyphs are centered inside a rectangular grid for visualization. Finally, glyphs are labeled as 'O' (old orthography style) or 'N' (new orthography style), according to the class label of the corresponding feature vector in the database. We can clearly observe that proposed feature representation has a good discriminatory capability. In fact, most of the glyphs in the old orthography style are easily separable inside the grid from glyphs in the new orthography style.

![Figure 10. Glyphplot of the feature vectors in the database](image)
Table III reports the average precision, recall and f-measure, together with the corresponding standard deviation (in parenthesis), when NB method is employed inside the system. Results are computed for each class of old and new orthography. Furthermore, the results of NB method are compared with those obtained by SVM and K-NN methods. They confirm that NB method receives the best classification results, with the lowest values of standard deviation. In fact, it obtains an f-measure value of 0.97 for new orthography and of 0.90 for old orthography, which are high values of the performance measure. Differently, SVM does not overcome 0.87 for old orthography and 0.80 for new orthography. Finally, K-NN obtains 0.93 for new orthography and 0.80 for old orthography, which are lower than values obtained by NB method. Similar results are clearly visible also in terms of precision and recall. We may observe that results obtained by SVM and K-NN never overcome the results obtained by NB for each orthography class. In conclusion, it demonstrates the efficacy of our system in solving the orthography recognition problem.

V. CONCLUSION

This paper proposed a new method for recognition of the old and new orthography style in hand-printed and printed angular Glagolitic documents. Because differentiation in orthography style is related to different historical periods of the Glagolitic script, this method is implicitly able to identify the historical period of the document. It consists of coding the document into a long sequence of numerical codes, transforming it into an image and extracting textural features from image by run-length statistics. Finally, classification by NB method is employed on the feature vector of the document for orthography recognition. Results obtained on a custom-oriented database of Glagolitic text excerpts in the old and new orthography style show positive and encouraging results. Future work will provide an experiment on a larger database of text excerpts extracted from a huge variety of Glagolitic books.

An evolutionary approach to route the heterogeneous groups of underwater robots

M.Yu. Kenzin, I.V. Bychkov and N.N. Maksimkin
Matrosov Institute for System Dynamics and Control Theory SB RAS, Irkutsk, Russia
gorthauers@gmail.com

Abstract - An evolutionary approach to solve the dynamic routing problem for the heterogeneous group of robots is presented. Since robots in the group may differ by their speed and, more importantly, by their functionality, each robot is able of performing only a specific subset of tasks among all tasks of the mission. The routing problem is to find a feasible group route ensuring well-timed accomplishment of all tasks. We propose a variation of the evolutionary algorithm to effectively solve the problem described. The heterogeneity factor implies some specific constraints on the genetic operators, thus we have developed both a new multi-mode mutation and crossover operators as well as the adapted algorithm structure to answer these changes. A software modeling system implementing all the necessary computational procedures has been developed; the results of computations are given.

I. INTRODUCTION

The rapid evolution of the subsea technologies in recent years has significantly expanded the scope of the autonomous underwater vehicles (AUV) implementation, which includes the usage of distributed groups of underwater robots to perform stand-alone multi-objective missions of long duration. Such large-scale missions demand handling of a range of different underwater works and operations in different areas of the underwater space. The effective coordination of AUVs is required not only during group movement while following preplanned trajectories [1], but, in the first place, on the upper level of the control system that is responsible for both task allocation and path planning. In this regard, it is a problem of considerable practical interest to effectively route the group of functionally heterogeneous vehicles.

A significant number of papers examining different approaches to solving the vehicle routing problems (VRPs) address classical statements of the problem such as capacitated routing, routing with time windows, etc. In recent years, the research community has turned to more advanced variants of the VRPs, which are aimed at a more accurate simulation of real-world problems and were considered too difficult to handle [2] before. These variants include new complex requirements and restrictions, such as the heterogeneity of the vehicles in the group, new types of restrictions on length and duration of the routes, multiple visits requirement, etc.

In this paper, we propose an approach to solving the problem of heterogeneous robots group control as a new variation of a vehicle routing problem, which is to find a feasible and efficient route for the group under specific spatio-temporal constraints. To do this, we combine the genetic algorithms with new specialized constructed and improvement heuristics.

II. GENERAL MODEL

In general, the multi-objective mission of the AUVs group is to visit and inspect (perform some underwater works) the set of waypoints (objectives) under certain requirements [3]. The vehicles in the group have different sets of on-board equipment, enabling each AUV to inspect only a certain subset of mission objectives. Thus, the routing problem here is to find a feasible group route ensuring, as far as possible, the most effective inspection of the objectives. It is formally defined as follows.

Assume there is a set of waypoints (objectives) \( N = \{1, \ldots, n\} \) within the given water area. These objectives are defined not only by their location in space, but also by the time interval \( s_i \) and the type of equipment \( w_i \in \{1, \ldots, w\} \) required for its inspection. In addition, each objective \( i \in N \) receives its periodicity value \( p_i \). It means that the duration of the time interval between its two successive inspections by robots of the group should preferably be equal to \( p_i \). In that way, in case of arriving to the objective ahead of time, an AUV should loiter before starting the inspection. The inspection of waypoints in equal time periods provides an efficient way to study the dynamics of various underwater processes with AUVs taking samples and measurement, photo and video shoots.

The group of robots performing the mission consists of \( M \) vehicles with cruising speed \( v^k, k = 1, \ldots, M \) and a set of on-board equipment \( u^k = \{u^k_1, u^k_2, \ldots, u^k_w\}, \ u^k_i \in \{0,1\}, \ i = 1, \ldots, w \). Thus, the AUV \( k \in M \) is able to inspect \( i \)-th objective if and only if \( u^k_i = 1 \) (Fig. 1).

We define the dummy nodes \( n^c \) for the AUVs initial positions. Let \( V = N \cup \{n^c\} \) denote the set of all waypoints and AUVs locations. Let the \( \varepsilon = \{(i,j) : i, j \in V, i \neq j\} \) define the set of edges. The connected graph \( G = (V, \varepsilon) \) represents the “roadmap” for the current mission of the group.
III. OBJECTIVE FUNCTION

The effectiveness of the group work is defined by regularity of well-timed inspections of all objectives. Situations, when AUV arrives too late and delays the inspection of the objective, are undesirable and should be penalized via efficiency criteria (objective function).

In order to construct reasonable efficiency criterion for the group route, we define an additional function $a_i(t)$ corresponding to each objective $i$ of the mission that defines the “hotness” of corresponding objective at specified moments of time:

$$a_i(t) = \begin{cases} \bar{a}(t-(t_k+s_i))/p_i, & t \in [t_k+s_i, t_k+s_{i+1}] \\ 0, & t \in [t_k, t_k+s_i] \end{cases},$$

where $t_{i1}, t_{i2}, ..., t_{iK}$ is a sequence of moments when the objective $i$ is expected to be visited by AUVs according to the current route, and $\bar{a}$ is a constant threshold value that is equal for all objectives. This way, the inspection of the objective $i$ resets its “hotness” to a zero value, following that the function (1) begins to increase until next inspection, while reaching the threshold value $\bar{a}$ in the period of $p_i$ (Fig. 2).

Now we define a function to calculate a penalty for delaying the inspection of the objective:

$$\varphi(a, t) = \begin{cases} a_i(t) - \bar{a}, & a_i(t) > \bar{a} \\ 0, & a_i(t) \leq \bar{a} \end{cases}$$

(2)

Hence, the total penalty for the group route $R$ is a sum of penalties (2) for each inspection made by all AUVs within the route:

$$\Phi(R) = \sum_{i=1}^{M} \sum_{j=1}^{N} \varphi(a_i, t_i),$$

(3)

where $m$ stands for $V_j(r_i)$ and $t_i$ values represent the time moments of expected inspections of corresponding objectives.

However, function (3) considers only those waypoints that are being included in the group route $R$ and only in the moments of their inspections. For this reason, it is needed to consider an additional function, which would neglect the well-timed inspection, but would estimate the level of “completeness” of all objectives at the end of group movement:

$$\Psi(R) = \sum_{i=1}^{M} a_i(t_0 + t_k),$$

(4)

where $t_k$ is the moment of the mission end. The function (4) also allows us to instantly provide the group routes with two positive features: it encourages the group to inspect each waypoint of the mission and it indirectly normalizes durations of routes of all vehicles in the group.

Hence, the final efficiency criterion for the group route is as follows:

$$f(R) = M \cdot \Phi(R) + \Psi(R), R \in Z,$$

(5)

where $Z$ is the set of all possible routes. It is also should be noted that function (1) is constructed in such a way that “hotness” of objectives with lesser periodicity grows faster. In that way, delaying of inspections would happen preferably with waypoints of the biggest periodicity.

Since we have the final criterion in the explicit form, we can use it as the objective function to compare different group routes on the graph $G$.

Figure 2. Graphical representation of the “hotness” function
IV. EVOLUTIONARY APPROACH

For a broad combinatorial class of vehicle routing problems there are no algorithms solving it in polynomial time, which leads us to the class of approximation algorithms that allow obtaining rational sub-optimal solutions in low computational time. Another layer of complexity is implied by a "bad" neighborhood structure of the described patrol routing problem, making it difficult to allocate and find qualitative and feasible solutions, as they may not be in the neighborhood of other feasible high-quality solutions in the search space.

A comprehensive survey of various approaches to solving the VRP concludes that evolutionary algorithms (EA) generally outperform any other heuristics or metaheuristics [5]. Their main advantage is the ability to find solutions to poorly structured problems and problems with complex constraints, because EAs require a relatively small amount of information about the nature of the problem. The main drawback here is that algorithm’s speed and efficiency strongly depend on the construction heuristics and improvement heuristics.

We propose a hybrid evolutionary approach featuring specialized genetic operators and solutions improvement heuristics addressing both the expected large-dimension of the problem and spatio-temporal constraints that primarily arise from the AUV's heterogeneity.

The construction of the initial population of solutions is the first and crucial step to achieve good rational solutions rapidly. The aim of this step is to construct a set of only feasible chromosomes that ensures coverage of a significant portion of the search space and contains a variety of good solutions. We propose to achieve this requirement by means of three different construction heuristics: sequential insertion and two parallel insertions.

The first heuristic is a "random insertion with no duplicates". It builds AUVs routes sequentially: at first, the route for the one single vehicle is fully generated, then for the next vehicle, etc. The starting objective for each vehicle is randomly selected from the entire set of permissible objectives for the current AUV. All subsequent objectives are selected in the same manner but with the additional requirement to be different, if possible, from the previous objective of this vehicle.

The next two constructive heuristics are based on the time-oriented nearest-neighbor insertion heuristic by Solomon [6] and are parallel, i.e. they build routes for all vehicles in the group simultaneously. Both heuristics require the construction of an auxiliary vector $Q=\{q_1, q_2, \ldots, q_{M\times h}\}$ of the mission objectives, ordered by the time of their required visits. Each element $q_i$ of this vector is a pair $\{e_i, t_i\}$, where $e_i$ stands for the index (number) of the objective and $t_i$ corresponds to the time moment of its scheduled inspection. The vector $Q$ is formed as follows:

1. Construct $Q$ from the pairs $\{e_i, t_i\}$ corresponding only to the first objective. Thus, we obtain a sequence of time moments when this objective should be inspected by the vehicles of the group.
2. Perform the same procedure for the next objective with the only difference being that the temporary vector $\tilde{Q}$ of the same structure is used instead of $Q$.
3. Merge two created vectors together by "attaching" vector $\tilde{Q}$ to the vector $Q$ and then reorder the elements $q$ of the new extended vector $Q$ in the ascending order of values $t_i$ in pairs $\{e_i, t_i\}$.
4. Reduce vector $Q$ to the first $M \times h$ elements, which returns $Q$ to its initial length.
5. Repeat 2-4 for the rest of objectives of the mission. The resulting sequence of indexes $e$ in the pairs $\{e_i, t_i\}$ will match the order in which the objectives of the mission should be visited and inspected according to their periodicity.

Both parallel heuristics use the vector $Q$ as a source of objectives to pick and insert into routes of different vehicles. For the first heuristic of "time-greedy insertion", the probability to select each AUV for the current objective is inversely proportional to the number of objectives already assigned to this vehicle, while for the second "quality-greedy insertion" this probability depends also on the distance between the current objective and the last objective in the route of each AUV. The use of two parallel heuristics here provides the population diversity not only among the solutions built with the random insertion, but also within the set of more qualitative solutions.

It should be noted that at each iteration only those AUVs are considered, which have all the required on-board equipment. This restriction guarantees us the feasibility of each solution obtained by the heuristics proposed. The population constructed is then evaluated with the objective function (5). According to the results of ranking, the tournament selection chooses a set of solutions for procreation and mutations.

We suggest using a number of specialized genetic operators that guarantee the feasibility of the offspring solution: two different variants of crossover and the multimode mutation.

The multimode mutations proposed consists of four operators: add new objective into the route, remove the objective from the route, change the objective within the route to another objective, swap two objectives within the route of the same AUV. When mutation operators are implied, all changes are also verified on admissibility.

The first crossover is called "one-plus-one-point" and it is a modification of the standard two-point crossover with the additional rule to choose randomly only the first point. The second one is then defined automatically within the route of the same vehicle as the first point.
The second crossover is "focused on inheritance" and it is based on the "adaptive memory" crossover proposed in [7]. The proposed crossover identifies the common characteristics of the parental individuals and copies them to the offspring-solution, which is a kind of adaptive memory procedure. Initially, the two solutions are selected. If there are common parts between the solutions, then these parts are inherited to the offspring: all parts left empty inherit the values from the best solutions in the adaptive memory or from some random solutions in the population. At each iteration, the adaptive memory is updated based on the best solutions found. The structure of such crossover also ensures the feasibility of resulting chromosomes.

The mechanisms of parallel populations with migration (island model) and elitism provide faster algorithm convergence rate while preventing premature convergence to a local optima. The procedure of clone removal preserves diversity of new populations on each iteration of evolutionary algorithm.

To improve the efficiency of the population creation procedure, all probabilistic genetic parameters are constantly changed at the end of each iteration of the algorithm. Being determined by the current efficiency of the genetic operators these changes allow algorithm to adapt to the different situations on the different steps of processing. The implementation of the adaptation mechanism may significantly increase the speed of computing in those cases when some genetic operators begin to work significantly better than others [3].

V. CONCLUSION

The approach proposed has been implemented in our modeling framework «AUV Mission Planner» and has demonstrated the high efficiency and reliability even under the strongest requirements and restrictions during a series of simulation studies. The suggested modification of the evolutionary algorithms has the ability to rapidly generate a set of rational and feasible solutions of high quality and to effectively improve the populations of solutions to meet the required conditions.

We have evaluated the impact of each embedded heuristic on the rate and quality of the algorithm convergence (Fig. 3). The average deviation of the resulting solutions from the optimal ones is 2.8%.

The proposed algorithm structure and new heuristics can be used not only to efficiently route the heterogeneous robot groups during multi-objective missions, but also to address other statements of VRPs and its modern variations.

The routing problem statement described by itself can be singled out as a separate subclass of VRP that combines the features of a periodic VRP and VRP with time windows and requires the original approach to address it effectively.

Abstract – Low cost robotic solutions are of great importance for improvement and development of robotics. In this paper, two visually guided low cost robot arms are proposed. The proposed system performs automatic hand-eye calibration and, after the calibration, positions its end effector above the object of interest using visual servoing based on off the shelf marker tracker. The presented experiments demonstrate positioning accuracy of the proposed setup.

I. INTRODUCTION

Robot arms are today widely used in industrial automation. Their accuracy, reliability and flexibility make them unavoidable components of many production processes. However, high cost of industrial robot arms hinders their wide application in households and education. The prices of the smallest industrial robot arms with sub-millimeter repeatability are incomparably higher than prices of average household machines. Therefore, low cost robotic solutions are of the great importance for the further development of robotics, since they broaden the population of robot users and also expand the base of researchers in this field.

In this paper, development of low cost robot arms is considered. The proposed solution consists of only basic components, which allow implementation of a vision-based robot manipulation system. The presented research is biologically inspired in the sense that hand-eye coordination, typical for living beings, is used to achieve positioning accuracy instead of relying on proprioceptive sensors in the robot joints, common in a vast majority of industrial robots. The goal of this investigation is to find out what accuracy can be achieved with such a simple configuration.

The paper is structured as follows. Section 2 provides a short overview of related research. Section 3 explains components of the proposed vision-based robot manipulation system and implementation of the calibration and visual servoing algorithms, while Section 4 presents the performed experiments and their results. Finally, Conclusion comments on the results and offers ideas for future work.

II. RELATED RESEARCH

There exist many researches where visual servoing is applied for control of a robotic arm. In some of them, industrial robots [1] are being used and eye-in-hand [2], or hybrid eye-to-hand/eye-in-hand [3] configuration is applied. Also, variety of hand-eye calibration methods are applied, such as convex linear matrix inequality [4]. Our setup consists of a low-cost robotic arm and an off-the-shelf camera in eye-to-hand configuration. This setup, which consists of significantly less expensive components in comparison to the hardware used in the aforementioned related research, together with an evaluation of the absolute positioning accuracy achieved by the proposed system represents the contribution of this paper.

III. VISION BASED ROBOT MANIPULATION SYSTEM

A. Components

Since the main goal of this paper is to provide an insight in the positioning accuracy which can be achieved by low cost vision guided robot manipulators, all

Figure 1. Dobot Arm mounted on the stand
components are acquired from the lower price specter. The robot manipulation system shown in Figure 1 consists of a robot arm, a camera mounted on a stand, a marker used for visual servoing installed on the robot’s end effector and a vision-based robot control software.

Two robots are considered: Dobot Arm V1.0 and a custom made robot arm in SCARA configuration, named VICRA (Vision Controlled Robot Arm). The price of the Dobot Arm was 900$ and the manufacturing of the mechanical construction which connects the robot arm with a camera on a pan-tilt head costed 320 EUR. The development and manufacturing of VICRA prototype costed approximately 3000 EUR.

The Dobot package includes Dobot Arm, Dobot controller, 5 pieces of effectors, power adaptor, USB cable, toolkit, extension cable and base. Dobot Arm has 4 axes and 0.5 kg payload with maximum reach of 320 mm and +/- 0.2 mm position repeatability. Dobot Arm has three joints with stepper motors: base, rear arm and forearm, and the fourth joint with rotation servo. It weights 3 kg and it is made of aluminum alloy. Dobot Arm is controlled by Dobot Controller which is based on Arduino Mega 2560 and FPGA board placed inside a control box. It can communicate with a PC via USB-UART. A Dobot Arm is shown in Figure 2. The Dobot arm and the RGB-D camera are mounted on a stand thereby forming a compact vision-based robot manipulation unit. The stand was designed in SketchUp [13] and built in a local workshop. The stand shown in Figure 1 was designed to provide secure camera holding in adequate position w.r.t. the robotic arm. The camera is positioned in such a way that the robot arm workspace is completely contained inside the camera’s field of view. It is located sufficiently close to the robot’s workspace in order to achieve precise measurement of objects which the robot should manipulate with. In the same time, the distance to the closest object must be greater than the lower bound of the camera range. Furthermore, the marker used for visual servoing must always be clearly visible.

VICRA, shown in Figure 3, is a custom made robot arm in SCARA configuration. It has one translational and three rotational joints. The first three joints, which position the tool, are driven by stepper motors, while the fourth joint, which defines the tool orientation, is driven by a DC servo motor. The currently used tool is a gripper driven by a servo motor, but it can easily be replaced by alternative tools. The first translational joint enables vertical reach of approximately 0.6 m and the two rotational joints enable horizontal reach of approximately 0.6 m. The weight of the robot is approximately 8 kg, which makes it suitable for mounting on a mobile platform. The robot is controlled by Arduino Mega 2560 with RAMPS 1.4 shield which communicates with a PC via USB. The robot is designed for a pan-tilt head with a camera to be mounted on the top of the first axis, in order to support computer vision-based control. Also, inexpensive micro-switches are used as end-stop for all three axes.

Each of the two considered robot arms has its advantages and drawbacks. VICRA is more expensive than Dobot, but it has greater payload and wider operative range. Also, because of its configuration, in specific positions, Dobot’s joints interfere with camera’s view of the marker used for visual feedback. On the other hand, VICRA provides undisturbed view of the marker in each position.

Both considered robot configurations are four axes robot arms, whose absolute positioning is achieved by a 3D perception sensor being the only sensor applied. The first three axes of the robot are driven by stepper motors without encoders and the fourth axis is driven by a DC servo motor. The robots are controlled by an Arduino-based controller and the applied 3D perception sensor is
an affordable off-the-shelf RGB-D camera, Orbec Astra S, costing 150 US$.

Although a common RGB-camera can be used for implementation of visual feedback, a RGB-D camera Orbec Astra S is used in the considered system because we wanted to build a system with 3D vision capability, since results of recent computer vision research clearly demonstrate advantages of 3D vision systems [6]–[10]. Orbec Astra S is a camera optimized for short-range use cases, from 0.35 m to 2.5 m. It is compatible with existing OpenNI [14] applications and provided with Astra SDK software. Astra SDK is used for acquiring image from the camera which is then processed by algorithms presented in Sections III.B and III.C. Even though presented manipulation module currently doesn’t use depth obtained from the RGB-D camera, it is planned to use this information in future versions.

Both robot manipulators are based on stepper motors and no absolute encoders or any other proprioceptive sensor are used in this research for measuring absolute position. Stepper motors are controlled by series of impulses defining relative changes in joint angles. Hence, in order to achieve absolute positioning, the initial position must be known. Furthermore, stepper motors could lose impulses, which could lead to wrong positioning. In order to achieve precise absolute positioning, visual servoing using RGB-D camera is applied.

Visual servoing is implemented by detection and localization of a marker mounted on the robot arm close to the end-effector. Marker detection and pose estimation is implemented using ArUco library for augmented reality [11] based on Open CV [12]. Since an object of interest is not always captured in the current camera field of view, the camera is mounted on a pan-tilt head. This way, the camera is able to rotate up and down, left and right and find the right angle to successfully capture objects of interest. The pan-tilt head also allows navigation of mobile robot manipulator, which can be created by mounting of the presented vision guided robot arm on a mobile platform. In the experiments reported in this paper, the capabilities of the pan-tilt head are not used, i.e. the camera orientation remains fixed during the experiment.

The control software consists of functions for controlling robot’s joints [15], built in Python, and functions for visual servoing written in C++.

B. Hand-Eye Calibration

Systems where a robotic “hand” is guided by a camera, which represents “eyes”, are called Hand-eye systems. There are two main types of these systems: (i) the eye-in-hand configuration, where the camera is mounted on the arm, close to its end effector, and moves along with the end-effector, and (ii) the eye-to-hand configuration, where the camera is stationary and overlooks the robot’s movements. In this paper, the second configuration is used, primarily because the camera was too big to be mounted on the applied robot arms. In order to be able to coordinate the robot movement with the information obtained from the camera images, the pose of the robot reference frame $S_B$ w.r.t. the camera reference frame $S_C$ must be determined. A calibration procedure used to compute this pose is known as hand-eye calibration.

To perform a hand-eye calibration, a set of images of a calibration object is acquired. The calibration object used in the research presented in this paper is a marker mounted close to the end effector of the robot arm, which is also used for visual servoing.

First, let’s introduce the notation used in the rest of this paper. In this paper, $^aT_b$ denotes the homogeneous transformation matrix representing the pose of a reference frame $S_a$ w.r.t. a reference frame $S_b$. Analogously, $^aR_b$ and $^a_t_b$ denote rotation matrix and translation vector defining the orientation and position of $S_a$ w.r.t. $S_b$ respectively. A rotation matrix and a translation vector are included in a homogeneous transformation matrix as follows

$$^aT_b = \begin{pmatrix} ^aR_b & ^a_t_b \\ 0 & 0 & 0 & 1 \end{pmatrix}.$$

Furthermore, the following notation is used for reference frames: $R$ represents robot, $C$ camera, $G$ tool, and $M$ marker reference frame.

The pose of $S_B$ w.r.t. $S_C$ can be computed from three marker positions, referred to in this section as position 0, 1 and 2. Assuming that the marker is clearly visible, the applied vision software provides us with 3D position of the marker denoted by $^c_t_M(k)$, for each robot position $k = 0, 1, 2$.

If the robot moves from position 0 to position 1 along the $x$-axis of its reference frame, then the marker positions $^c_t_M(0)$ and $^c_t_M(1)$ define the $x$-axis of the robot reference frame viewed from the camera reference frame, i.e. unit vector

$$^c_{x_R} = \frac{^c_t_M(1) - ^c_t_M(0)}{\left\| ^c_t_M(1) - ^c_t_M(0) \right\|},$$

represents the $x$-axis of $S_B$ w.r.t. $S_C$.

Furthermore, if the robot moves from position 1 to position 2, where the both positions have the same $z$-coordinate in the robot reference frame, then the marker positions $^c_t_M(1)$ and $^c_t_M(2)$ define a vector perpendicular to the $z$-axis of the robot reference frame. Consequently, unit vector

$$^c_{z_R} = \frac{^c_{x_R} \times \hat{b}}{\left\| ^c_{x_R} \times \hat{b} \right\|},$$

represents the $z$-axis of $S_B$ w.r.t. $S_C$.

1334 MIPRO 2017/CIS
where
\[ \mathbf{b} = c\mathbf{t}_M(2) - c\mathbf{t}_D(1), \]
(3)
represents the z-axis of \( S_R \) w.r.t. \( S_C \). Vectors \( c\mathbf{x}_R \) and \( c\mathbf{z}_R \) completely define the orientation of \( S_R \) w.r.t. \( S_C \), which can be represented by rotation matrix
\[ c\mathbf{R}_R = \begin{bmatrix} c\mathbf{x}_R & c\mathbf{y}_R & c\mathbf{z}_R \end{bmatrix} \]
(4)
where
\[ c\mathbf{y}_R = c\mathbf{z}_R \times c\mathbf{x}_R. \]
(5)
The position of the origin of \( S_R \) w.r.t. \( S_C \) can be computed from \( c\mathbf{t}_M(0) \), the previously determined rotation matrix \( c\mathbf{R}_R \) and the position of the marker w.r.t. the robot end effector \( c\mathbf{t}_E \), which is expected to be known in advance. The relation between \( c\mathbf{t}_M(0) \) and the corresponding position of the end effector w.r.t. robot reference frame can be described by the following equation
\[ \begin{bmatrix} c\mathbf{t}_M(0) \\ 1 \end{bmatrix} = c\mathbf{R}_R c\mathbf{T}_C - c\mathbf{t}_M \begin{bmatrix} 0 \\ 1 \end{bmatrix} c\mathbf{T}_C. \]
(6)
The both considered robots are constructed in such a way that the z-axis of the tool reference frame \( S_G \) is always parallel to the z-axis of \( S_R \). Hence, if position 0 is selected so that the x-axis of \( S_G \) is parallel to the x-axis of \( S_R \), then \( c\mathbf{R}_G \) is the identity matrix and (6) can be written as
\[ c\mathbf{t}_M(0) = c\mathbf{R}_R \cdot \left( c\mathbf{t}_M + c\mathbf{T}_G(0) \right) + c\mathbf{t}_E. \]
Consequently, vector \( c\mathbf{t}_R \) can be computed by
\[ c\mathbf{t}_R = c\mathbf{t}_M(0) - c\mathbf{R}_R \cdot \left( c\mathbf{t}_M + c\mathbf{T}_G(0) \right). \]
(7)
The eye-to-hand calibration is performed in the following steps.

**Step 1.** Position the robot tool at an arbitrary position \( c\mathbf{t}_d(0) \) on the x-axis of the robot RF.

**Step 2.** Capture an image and measure \( c\mathbf{t}_d(0) \).

**Step 3.** Move the robot tool in the x-direction for distance a. The resulting position is \( c\mathbf{t}_d(1) \).

**Step 4.** Capture an image and measure \( c\mathbf{t}_d(1) \) using the tracking tool.

**Step 5.** Move the robot tool in the y-direction for distance b. The resulting position is \( c\mathbf{t}_d(2) \).

**Step 6.** Capture an image and measure \( c\mathbf{t}_d(2) \) using the tracking tool.

**Step 7.** Compute \( c\mathbf{R}_R \) using equations (1) – (5) and \( c\mathbf{t}_E \) by (7).

### C. Visual Servoing

The visual servoing algorithm presented in this section computes changes of joints variables required to move the marker in a wanted position based on the image acquired by the camera, a desired marker position \( c\mathbf{t}_M \) w.r.t. the camera reference frame and the pose of the robot reference frame w.r.t. the camera reference frame \( c\mathbf{T}_E \) obtained by calibration. In a practical application, the desired marker position \( c\mathbf{t}_M \) is computed from a pose of an object of interest obtained by an appropriate computer vision software, which is not a subject of this paper. The task of the presented visual servoing algorithm is to position the marker at \( c\mathbf{t}_M \) within a given tolerance. The visual servoing algorithm consists of the following steps.

**Step 1.** Based on a given image, the current marker position \( ^c\mathbf{t}_M \) w.r.t. the camera is computed using a tracking tool (in the current implementation, this is ArUco software).

**Step 2.** Compute the current marker position it the robot reference frame by \( ^a\mathbf{t}_M = ^a\mathbf{T}_C \cdot ^c\mathbf{t}_M \).

**Step 3.** Compute joint angles \( \mathbf{q} \) from \( ^a\mathbf{t}_M \) by inverse kinematics.

**Step 4.** Compute the reference marker position in the robot reference frame by \( ^a\mathbf{t}_M = ^a\mathbf{T}_C \cdot ^c\mathbf{t}_M \).

**Step 5.** Compute new joint angles \( \mathbf{q}_n \) from \( ^a\mathbf{t}_M \) by inverse kinematics.

**Step 6.** Compute the required changes in joint angles by \( \Delta \mathbf{q} = \mathbf{q}_n - \mathbf{q} \).

**Step 7.** Send \( \Delta \mathbf{q} \) to the robot controller.

These steps are repeated iteratively until the marker reaches the desired position within a given tolerance.

### IV. EXPERIMENTAL EVALUATION

In order to test the developed system, two test case scenarios were performed. In the first experiment, the accuracy of the camera calibration was evaluated by comparing the estimation of the tool position measured by vision, the tool position given to the robot and the actual tool position measured manually. In the second experiment, the goal was to test the accuracy of the implemented visual servoing algorithm. The experiments were performed using Dobot Arm. Since the positioning accuracy depends on visual feedback and not on the mechanical construction of the robot, similar results are expected to be obtained by VICRA. Nevertheless, experiments with VICRA are not included in this paper, since its development is still in progress.

In order to facilitate manual measurements, in the first experiment, a laser pointer is mounted instead of a gripping tool. The manually measured positions are considered in this analysis as the ground truth positions. The tool positions given to the robot are referred to in this section as robot positions and the positions measured by
vision are referred to as vision measurements. After camera calibration, a square matrix of 10 × 10 points is given to the robot as reference positions. The robot’s task was to move to these points, one by one, wait for the vision system to calculate the tool pose and a human operator to measure the tool position. In order to allow comparison of the measurement obtained by vision to the open-loop robot positioning and the manual measurements, the pose estimated by the vision system is transformed in the robot reference frame. Since the robot has a laser as the end effector, the point projected by the laser on a millimeter paper allowed an easy measurement in the robot reference frame. After all 100 points were processed, a statistical analysis is performed. The results of this analysis are shown in the middle column of Table I and Table II. In Table I, the statistics of the difference between the ground truth positions and the vision measurements is shown, where Δx_{max} and Δy_{max} represent the maximal absolute difference in the x- and y-coordinates, Δd_{max} represents the maximal distance, while σ_{x}, σ_{y}, and σ_{d} represent the standard deviations of the x-coordinates, y-coordinates and distances. The analogous statistical analysis of the difference between the ground truth positions and the tool positions given to the robot is shown in Table II.

The presented analysis shows that the calibration procedure proposed in Section III.B, although fast and simple, provides the transformation \( ^{c} T_r \) with significant inaccuracy. We noticed that both the measurements obtained by vision and the robot open-loop positioning have significant bias, which could possibly be reduced by an additional calibration step. In order to estimate to which extent the considered positioning errors represent random noise and to which extent these errors contain a bias, which could be reduced by an additional correction step or a more thorough calibration procedure, we performed the following analysis. We computed values \( a_x, b_x, a_y \), and \( b_y \) which minimize the following error functions

\[
\mathcal{E}_s(a_x, b_y) = \sum_i (x_i - x'_i)^2,
\]

where \( x_i \) and \( y_i \) are reference values obtained by manual measurement, while \( x'_i \) and \( y'_i \) are values obtained by linear mapping of the measured values \( x_i \) and \( y_i \), defined by

\[
x'_i = a_x x_i + b_x, \quad y'_i = a_y y_i + b_y.
\]

The statistics of the vision error and robot error for the values obtained by mapping (8) is shown in the last column of Table I and Table II. This analysis indicates that the positioning error can be significantly reduced by an additional correction step, such as the linear mapping proposed in this section. If the robot is required to have a good positioning accuracy within an approximately planar workspace, then the presented linear mapping can be used as the final calibration step, resulting in a more accurate positioning. If the robot is required to have accurate positioning in a wider workspace including significant changes in z-direction, then a more thorough calibration procedure should be applied.

In the second experiment, visual servoing accuracy was evaluated. A marker which represented an object on the scene, was put in 30 different positions, one by one, in the robot’s working region. This marker is referred to in this paper as target marker. After capturing an image, the center of the target marker representing the desired position was determined.

The robot initially moved to this position by setting its joints to the values computed by inverse kinematics. If the difference between the robot’s position and the target marker after this movement was greater than a given threshold, which was 3 mm in this case, the visual servoing algorithm described in Section III.C was applied. This process is repeated until the positioning error falls below the given threshold. After the robot stopped moving, the distance between the laser point on the millimeter paper, which represents the position of the end effector, and the center of the target marker was measured by the human operator. The results of the
described experiment are given in Table III, where $\Delta d_{\text{max}}$ represents the maximum distance between the center of the target marker and the laser position and $\sigma_d$ represents the standard deviation of this distance.

V. CONCLUSION AND FUTURE WORK

In this paper, a simple vision guided robot manipulation system consisting of a low cost robot arm and an off-the-shelf RGB-D camera is presented. As the main contribution, we emphasize the development of a low-cost solution which can be used by a wide population of developers. Furthermore, an analysis of the positioning accuracy of the developed system achieved by visual servoing without proprioceptive sensors is presented. From the results of this analysis it can be concluded that the positioning error is within 6 mm with standard deviation of 1.42 mm.

The main error source in the proposed positioning system comes from inaccurate determination of the marker distance w.r.t. the camera reference frame. We expect that a significant improvement to the given system can be achieved by fusing the measurement obtained by ArUco software with depth information provided by a RGB-D camera. This will be the topic of our future research.

Abstract—Automated methods for computing derivatives of cost functions are essential to many modern applications of machine learning. Reverse-mode automatic differentiation provides relatively cheap means for it but generated code often requires a lot of memory and is hardly amenable to later optimizations. Symbolic differentiation, on the other hand, generates much more flexible code, yet applying it to multidimensional tensors is a poorly studied topic. In this paper, we present a method for symbolic tensor differentiation based on extended Einstein indexing notation, which allows to overcome many limitations of both - automatic and classic symbolic differentiation, and generate efficient code for CPU and GPU.

Keywords: symbolic differentiation, Einstein notation, machine learning.

I. INTRODUCTION

A significant portion of machine learning (ML) algorithms directly relies on gradient-based optimization methods. As their name states, these methods require computing a gradient of a loss function on each step of optimization. Simple models like logistic regression have well-known formulas for computing partial derivatives. However, recent progress in machine learning and especially deep neural networks has given a rise to much more complicated models and loss functions.

Manually computing gradients of such functions is time-consuming and error-prone, so often computer-based methods are used instead. Such methods fall into several categories, and each category has its advantages and disadvantages. In this paper, we present a method that combines parts of 2 of these categories and is specifically designed with a focus on machine learning applications. One important difference from other approaches is that our method also supports efficient calculation of derivatives of functions from $R^m$ to $R^n$ where both $m$ and $n$ are large, whereas other methods either require one of them to be small (e.g. [1], [2]), or can’t handle vector functions at all (e.g. [3], [4]).

The rest of this paper is structured as follow. In the next section, we revisit major families of computer-based differentiation algorithms and explain where our method falls in. In section 3 we describe actual method as applied to scalars (numbers), while in section 4 we extend it to higher-order tensors using Einstein notation.

II. OVERVIEW OF COMPUTER-BASED DIFFERENTIATION METHODS

To the best of our knowledge, most computer-based differentiation methods are divided into 3 main categories:

1) Numeric (also known as finite difference methods)
2) Symbolic
3) Automatic

Numeric differentiation (ND) methods are the simplest ones and directly rely on the definition of derivative. We say that $\frac{df}{dx}$ is a derivative of a function $f(x)$ with respect to $x$ if:

$$\frac{df}{dx} = \lim_{\Delta x \to 0} \frac{f(x + \Delta x) - f(x)}{\Delta x}$$

Given this definition, we can calculate derivative of any function by computing it at $x$ and $x + \Delta x$ where $\Delta x$ is some little constant, and then dividing the result by that constant.

The major advantage of this method is that it’s able to compute derivatives of any function differentiable at both - $x$ and $\Delta x$. The main disadvantage comes from complexity of choosing good $\Delta x$: too small values may lead to round-off errors during floating point operations, while too large values lead to weak approximation of the real value of a derivative. Attempts have been done to improve precision using multiple differences (e.g. [5]), but in general case accuracy of numeric differentiation stays unstable.

Symbolic differentiation (SD) takes a different approach - instead of evaluating a function, it constructs a symbolic expression representing its derivative. Technically, symbolic differentiation relies on a fact that algebraic expressions are either primitive (e.g. summation, product, exponent, etc.) or a combination of the above. For primitive expressions there’s already a well-known set of rules, i.e. $\frac{d}{dx} \cos(x) = \sin(x)$. Combined expressions are handled using the chain rule, i.e. if $z = z(y)$ is a function of $y$ which in turn is a function $y = y(x)$ of $x$, then the derivative $\frac{dz}{dx}$ may be expressed as:

$$\frac{dz}{dx} = \frac{dz}{dy} \frac{dy}{dx}$$

Or, in case of several intermediate functions $y_i$:

$$\frac{dz}{dx} = \sum \frac{dz}{dy_i} \frac{dy_i}{dx}$$
The chain rule and differentiation rules for primitive expressions make it possible to divide any algebraic expression into primitive parts, differentiate each part and then combine the results. Here we demonstrate this method by example.

Let’s say we want to differentiate expression \( f(x) = \sin(x^2) \). Since there are only 2 calls, we can introduce one intermediate function \( g(x) \) so that \( f(x) = \sin(g(x)) \). Using the chain rule from above we get:

\[
\frac{df}{dx} = \frac{df}{dg} \frac{dg}{dx} = \frac{d\sin(g)}{dg} \frac{d(g^2)}{dx}
\]

From primitive rules we know that \( \frac{d}{dg}\sin(g) = \cos(g) \) and \( \frac{d}{dx} x^2 = 2x \). Replacing \( g \) with its original value and multiplying two derivatives we get:

\[
\frac{df}{dx} = \cos(x^2) \times 2x
\]

Which is the correct derivative of the specified function.

Unlike numeric approach, symbolic differentiation produces code for exact calculation of derivatives. Also, in many cases this code is as efficient as possible and close to what a human expert would derive. Moreover, produced symbolic expression may then be further optimized (e.g. to fit memory requirements or improve numeric stability) or even translated to GPU or any other computation engine, which is extremely valuable property in the context of neural networks and related models.

On the other hand, symbolic differentiation has much more limited applicability. First of all, since the goal of this family of methods is to produce symbolic expression of a derivative, it is limited to functions continuously differentiable in all points. In computer program, however, most conditions and loops introduce discontinuity, so they are normally not allowed. Another restriction of symbolic differentiation is that most practical implementations (including highly adopted [3] and [4]), are essentially univariate, i.e. they don’t support vector inputs and are thus inapplicable to most machine learning functions.

**Automatic differentiation (AD)** is a set of techniques to numerically evaluate the derivative of a function. Similarly to symbolic differentiation, it decomposes algebraic expressions into a set of primitive subexpressions and then uses the chain rule to combine the results. Unlike symbolic approach, however, AD doesn’t produce a new expression, but only computes a derivative at a point, so it can easily handle conditions and loops. AD has 2 main modes: forward and reverse.

**Forward-mode AD** consists of a single pass from input arguments to the value of a function, during which both - value of the function and its derivative - are calculated. Typically, this mode is implemented using dual numbers - a special extension of real numbers with additional part that holds the derivative of a variable in question. However, this method has pretty bad complexity for function \( R^m \rightarrow R^n \) where \( m \gg n \) such as most loss functions in machine learning. Thus we don’t dive deeper in the description of this method and guide interested reader to [2].

**Reverse-mode AD** consists of 2 passes. On the **forward** pass it computes values of all primitive expressions and records them into intermediate variables on a so-called ”tape”. On the **reverse** pass, the method starts with the derivative of output variable by itself (i.e. always 1) and traverses expression tree backward to calculate derivatives of the output w.r.t. each of intermediate variables. Here’s an example of such computation.

Let’s say we want to differentiate function \( z = \sin(x^2) \) at point \( x = 2 \). This complex expression contains 2 primitive expressions, which we compute and immediately write the results onto the tape:

1) \( y = x^2 = 4 \)
2) \( z = \sin(y) \approx -0.756 \)

By convention, we also replace input and output variables by new indexed names to make all variables look similar. This way we get:

1) \( w_1 = x = 2 \)
2) \( w_2 = w_1^2 = 4 \)
3) \( w_3 = \sin(w_2) \approx -0.756 \)

We seek to find derivative \( \frac{dz}{dx} = \frac{d\sin(w_2)}{dw_2} \). We start with the fact that the derivative of the output variable w.r.t. itself is \( \frac{dw_2}{dw_2} = 1 \) (the proof is trivially inferred from the definition of derivative).

From the chain rule we know that \( \frac{dw_3}{dx} = \frac{d\sin(w_2)}{dw_2} \times \frac{d\sin(w_2)}{dw_2} \). We already know that \( \frac{dw_3}{dw_2} = 1 \) and from primitive rules we also know that \( \frac{d\sin(w_2)}{dw_2} = \cos(w_2) = \cos(4) \approx -0.654 \), so multiplying these parts we get \( \frac{dw_3}{dx} = 1 \times 0.654 = 0.654 \). Note, that AD doesn’t ever create or transform symbolic expressions, but just calculates actual values of intermediate variables and their derivatives.

Reverse-mode AD has gained particular popularity in the field of machine learning and is implemented in such frameworks as Theano [6] and TensorFlow [7], as well as in dedicated libraries such as AutoGrad [8]. Strengths of this method include efficient (in terms of processing time) calculation of derivative of functions \( R^m \rightarrow R^n \) where \( m \gg n \) and transparent handling of multivariate vectors. Downsides of AD include high memory usage (because of the need to keep all variables on a tape during both - forward and reverse pass) and lack of symbolic representation that could be used for further optimizations and code generation.

There’s also a few methods that try to combine strengths of symbolic and automatic differentiation. One notable example is the **D* algorithm** from [9]. In their paper, Guenter et al. describe a library in C++ that overloads common algebraic operations for their V(ariable) class to produce expression graph, and then aggressively optimize this graph to eliminate repeating blocks. The D* allows for vector-valued functions where each output component may represent an independent function of input arguments. This gives flexibility in defining vector-valued functions, but in the worst case (i.e. when there are no repeating blocks to be eliminated) may result in a run time proportional to the number of output values.
Our method is similar in spirit to D*, but instead of supporting independent functions, we limit output components to functions of the same basic structure and only different indices (e.g. $z_i = f(x_i, y_k)$). This is much more common in machine learning and enables generating more compact code with much smaller run time. Moreover, our method works with functions that output not only vectors, but also matrices and, in general, tensors of any rank.

In the next section we describe our method in a way that works for scalars, and in section 4 we extend this framework to support higher-order tensors.

III. SYMBOLIC METHOD FOR SCALARS

The ultimate goal of our method is to be able to produce symbolic derivatives for algebraic functions commonly used in machine learning. Since we seek for a symbolic representation, we limit our framework to continuously differentiable functions, i.e. we don’t support conditional operators and loops as they may, in general case, introduce points of discontinuity. To our mind, this is not a hard limitation in the context of ML since most loss functions that use loops can be formulated as a combination of higher-order derivatives such as vectors and matrices. For example, matrix-by-vector product above can be transformed into a form with summation. We do, however, support operators like $min, max, sign$ and similar that may be thought of as conditional, but don’t create discontinuity points.

In general, our method is based on approach used in reverse-mode AD, but instead of computing values of variables and derivatives, we compose their symbolic expressions to build a computational graph suitable for further optimization. For demonstration purposes, let’s consider expression $z = x_1x_2 + sin(x_1)$ and find derivatives $\frac{dz}{dx_1}$ and $\frac{dz}{dx_2}$.

Forward pass in our case consists of 2 stages: recording all primitive operations onto a tape and evaluating “example values” (which we explain later in this section). Recording operations includes parsing subexpressions into intermediate values and constructing a list of primitive expressions, e.g. for expression above such a list would look like this:

1) $w_1 = x_1$
2) $w_2 = x_2$
3) $w_3 = w_1 \times w_2$
4) $w_4 = sin(w_1)$
5) $z = w_5 = w_3 + w_4$

This expression list, however, lacks type information needed to distinguish between scalars and higher-rank tensors. To obtain this information, we introduce a notion of “example values” - values attached to each variable and having the same type as real values could have. E.g. we can use value 1 for $x_1$ and $x_2$ to indicate that input parameters are scalars, or random 2x2 matrices to indicate that they are instances of tensor-2. Note, that real values passed to generated expression later don’t need to have the same value or size (for tensors), but only the same type and number of dimensions.

After we have obtained example values of input parameters we can evaluate each primitive expression and infer example values for all intermediate and final variables.

Reverse pass, just as in the case of AD, starts with the derivative of an output variable w.r.t. to itself and propagates derivatives back to input variables. However, instead of propagating concrete values we aggregate symbolic expressions, i.e. build a formula describing how to calculate it from input and intermediate variables. We demonstrate it by example:

1) $\frac{dz}{dx_1} = \frac{dz}{dw_5} = 1$
2) $\frac{dz}{dx_2} = 1 \times 1 = 1$
3) $\frac{dz}{dw_3} = 1 \times 1 = 1$
4) $\frac{dz}{dw_1} = 1 \times \cos(w_1) = \cos(w_1)$
5) $\frac{dz}{dw_2} = 1 \times w_1$
6) $\frac{dz}{dw_4} = \cos(w_1) + 1 \times w_2 = \cos(w_1) + w_2$

Note that in our calculations we encounter $\frac{dz}{dw_1}$ twice - at lines 4 and 6. First time we calculate derivative of $\frac{dz}{dw_1}$ via $w_4$ only, while second time we also include the derivative via $w_3$. Also note, that we simplify expressions where possible, e.g. use 1 instead of $1 \times 1$ - although it’s not strictly necessary, it simplifies reading and reduces run time of implementation.

So we finish with 2 formulas:

$$\frac{dz}{dx_1} = \frac{dz}{dw_5} = \cos(w_1) + w_2$$
$$\frac{dz}{dx_2} = \frac{dz}{dw_2} = w_1$$

These formulas may then be applied to any (scalar) input values $x_1$ and $x_2$ to immediately obtain the result.

IV. SYMBOLIC METHOD FOR HIGHER-ORDER TENSORS

It’s tempting to apply the same approach to differentiation of higher-order derivatives such as vectors and matrices. For example, for dot product of two vectors $z = \mathbf{x} \cdot \mathbf{y}$ we can easily show that $\frac{dz}{dx} = \mathbf{y}$. However, this approach doesn’t work for more complex operations because not all such derivatives have symbolic representation. One such example is the matrix-by-vector product:

$$W\mathbf{x}$$

In this case derivative $\frac{\partial W}{\partial \mathbf{x}}$ is a tensor with 3 dimensions that cannot be straightforwardly expressed as a combination of input vectors and matrices.

Although we cannot infer symbolic rules for tensors themselves, we still can do it for tensor components. We note here that for any function on tensors each component of an output tensor is a function of zero or more components of input tensors. For example, matrix-by-vector product above can be rewritten as:

$$\sum_k W_{ik}x_k, \forall i$$

Now instead of a tensor expression, we have a set of scalar expressions over indexed variables $W_{ik}$ and $x_k$, which is much easier target. However, before we move to differentiation of these indexed expression, we need to make one more change to our notation.
Since we want to use symbolic differentiation from a programming language, we need a way to represent such expressions in programming notation, and symbols like \( \sum \) and \( \forall \) don’t have straightforward counterpart in programming. Even if we find appropriate representation, tensor expressions in index notation very quickly become bulky. Fortunately, these issues have already been addressed previously and have a solution in so-called Einstein indexing notation or just Einstein notation.

According to classic Einstein notation [10], unless otherwise stated:

1) a summation is assumed over all indices that appear twice in a product
2) no summation is assumed over indices that appear only once

Given these rules, we can rewrite matrix-by-vector product in a shorter form:

\[ W_{ik} x_k \]

which also plays well with array indexing notation in many programming languages, e.g. in Python or Julia:

\[ W[i, k] \times x[k] \]

Note, that for an index to be a "sum" index it should appear exactly in the same product term. For example, in the following expression index \( i \), although appearing twice, is still "for all" index:

\[ x_i + y_i \]

The "unless otherwise stated" part is also important. In particular, when an expression is an equation, the common approach is to consider all indices appearing on the left-hand side (LHS) to be "for all" and all the others - "sum" indices. E.g. we may write:

\[ y = x_i \]

to indicate summation over components of vector \( x \).

Although Einstein notation is quite powerful by itself, it was designed for humans and doesn’t cover a few important cases that may arise during automatic expression processing. Below we describe these cases and introduce several extensions to classic Einstein notation that help to overcome them.

First of all, since summation is a special operation that requires either product term or an equation with LHS, how do we represent it when none of these conditions is available? For example, how do we express:

\[ \sum_i x_i \]

To deal with such cases we introduce a notion of **pseudo-one** - a special object similar to a tensor of all ones, but with undefined size. For example, we write one-dimensional pseudo-one as:

\[ 1_i \]

This object is only valid when it’s being multiplied by other variables, and in this case it simply results in summation over pseudo-one indices. Now, having a notion of pseudo-one, we can represent a sum of vector components as:

\[ \sum_i x_i \rightarrow x_i 1_i \]

Another corner case is conditional expressions. For example, as we will show later, in expression \( y_i = W_{ik} x_k \) derivative \( \frac{\partial y_i}{\partial W_{mn}} \) is a 3 dimensional tensor with components defined as:

\[
\frac{\partial y_i}{\partial W_{mn}} = \begin{cases} 
  x_n, & \text{if } i = m, \\
  0, & \text{otherwise}.
\end{cases}
\]

Again, this expression is pretty inconvenient to work with, especially when we have to multiply it by other expressions of the same kind. To tackle with it, we introduce **guards** - conditional subexpressions on indices that either pass the main expression as is (if the condition is true) or turn it into zero (otherwise). For example, derivative \( \frac{\partial y_i}{\partial W_{mn}} \) can now be written as:

\[
\frac{\partial y_i}{\partial W_{mn}} = x_n | i = m
\]

where everything after a bar is a guard.

One may argue that this notation is limited because it assumes one of conditional branches to be zero and it’s not possible to represent, for example, such expression:

\[ Z_{imn} = \begin{cases} 
  x_n, & \text{if } i = m, \\
  y_n, & \text{otherwise}.
\end{cases}
\]

Indeed, notation with guards is optimized for conditions with zero branch, but one can still represent other conditions as a sum of separate branches multiplied by positive or negative condition. E.g.:

\[ Z_{imn} = (x_n|i = m) + (y_n|i \neq m) \]

Now, having this extended Einstein notation in mind, we can eventually describe our method for symbolic tensor differentiation.

Our method consists of 5 principal steps:

1) parse expression into a list of primitive expressions
2) convert each primitive expression to Einstein notation
3) apply known differentiation rules to primitive expressions
4) combine resulting derivatives using the chain rule
5) convert derivative expression from Einstein notation to vectorized one

We do **expression parsing** exactly the same way as we did previously: each function call is transformed into a separate primitive expression. For example, linear transformation:
\[ y = Wx + b \]
is parsed into two simpler expressions:
\[ t = Wx \]
\[ y = t + b \]

We convert from vectorized into Einstein notation using a set of predefined rules. Each rule simply describes how components of output tensor depend on components of input tensors. Since at this step we deal only with primitive expressions, we only need to define one rule for each operation and operand types plus one special rule for elementwise operations (e.g. Hadamard product, which we denote here with \( \circ \)). The rules are easy to infer, so we provide here only a few examples for demonstration purposes:

\[
\begin{align*}
y &= Wx & \rightarrow & \quad y_i = W_{ik}x_k \\
Z &= X \circ Y & \rightarrow & \quad Z_{ij} = X_{ij} \times Y_{ij} \\
y &= \text{sum}(x) & \rightarrow & \quad y = x_i \times 1_i
\end{align*}
\]

Rules for finding derivatives of primitive expressions in Einstein notation are similar to those of scalar expressions, but with two exceptions:
1) all variables are indexed, and
2) where derivative turns zero, guards are used

We designate tensor derivatives in Einstein notation as:
\[
\frac{\partial Y_{ij}}{\partial X_{st}}
\]

where \( Y \) is the dependent variable, \( X \) is the variable we differentiate with respect to, and \( I \) and \( J \) are sets of unique indices of appropriate length. For example, given an expression:
\[
y_i = W_{ik}x_k
\]

derivative \( \frac{\partial y_i}{\partial W_{mn}} \) describes how \( i \)th component of output vector \( y \) depends on \((m, n)\)th component of input matrix \( W \).

It’s easy to show that \( y_i \) depends only on \( i \)th row of matrix \( W \), i.e. derivative is non-zero only when \( i = m \), and when this condition holds, changing \( W_{mn} \) by 1 leads to corresponding change in \( y_i \) by \( x_n \). We write both these statements as:
\[
\frac{\partial y_i}{\partial W_{mn}} = x_n \quad |i = m
\]

Other rules are inferred in a similar way, so we show only a couple of them for reference:
\[
\begin{align*}
y_i &= W_{ik}x_k & \rightarrow & \quad \frac{\partial y_i}{\partial x_m} = W_{im} \\
Z_{ij} &= X_{ij} \times Y_{ij} & \rightarrow & \quad \frac{\partial Z_{ij}}{\partial X_{mn}} = 1 \quad |i = m, j = n \\
y &= x_i \times 1_i & \rightarrow & \quad \frac{\partial y}{\partial x_m} = 1
\end{align*}
\]

We combine derivatives of primitive expressions using the standard chain rule. If guards are present in one or both expressions, they are combined together. For example, if we have derivatives of 2 primitive expressions in the same operator chain:
\[
\begin{align*}
\frac{\partial Z_{ij}}{\partial Y_{mn}} &= U_{nj} \quad |i = m \\
\frac{\partial Y_{mn}}{\partial X_{st}} &= W_{tn} \quad |m = s
\end{align*}
\]
then after applying the chain rule we get:
\[
\frac{\partial Z_{ij}}{\partial X_{st}} = U_{nj}W_{tn} \quad |i = m, m = s
\]
which is naturally simplified to:
\[
\frac{\partial Z_{ij}}{\partial X_{st}} = U_{nj}W_{tn} \quad |i = s
\]

It’s also worth to note that despite automatic construction the resulting expression is still valid in Einstein notation: we indeed sum out \( n \) index and leave all the others.

Finally, we convert expressions in Einstein notation back to vectorized one using predefined rules. Note, that conversion between vectorized and Einstein notation doesn’t make one-to-one relation, but rather many-to-one (in both directions). For example, both of the following rules are used if different contexts:
\[
\begin{align*}
y &= x,1_i & \rightarrow & \quad y = \text{sum}(x) \\
y &= x_i & \rightarrow & \quad y = \text{sum}(x)
\end{align*}
\]

Both expressions are valid and both designate sum over components of vector \( x \).

V. CODE GENERATION FOR GPU

Conversion to vectorized notation may be seen as code generation for executing on CPU (central processing unit). But it’s not the only possible backend - we can equally generate code for alternative runtime systems. One popular choice of such systems is GPU (graphics processing unit) which provides means for executing code with very high level of parallelism.

In a typical GPGPU (general-purpose GPU) program, data is copied into device’s memory, and then a number of so-called kernels is run over them. Each kernel consists of a set of relatively simple instructions executed on each datum in parallel (up to the number of available GPU threads). This plays especially well with our Einstein notation which essentially is a way to describe how to calculate each output variable.

Below we describe several techniques for code generation for GPU that we used in our work.

One of the major bottlenecks in GPU computing is data transfer between main and device’s memory, so we try to avoid it as much as possible. Fortunately, in our expressions,
we always know input and output variables, so we load them to and from a device exactly once for each function we analyze.

Another advantage of upfront expression analysis is that we can reuse data buffers. To do this, we keep track of:

1) type and size of each variable’s buffer
2) variable’s lifetime

Each time we need to create a new temporary variable we first look for a suitable buffer in a cache of existing variables. If there’s one and the corresponding variable isn’t used later than current expression, this buffer is reused. One very frequent example is elementwise operations. E.g. the following expression (in mathematical notation):

\[ c_i := a_i + b_i \]

is actually translated into

\[ b_i := a_i + b_i \]

(Here we use := to denote assignment in order not to abuse equality sign =)

Another useful property of elementwise operations is that they may be grouped into a single kernel. Enqueuing a kernel has its own overhead, running several instructions in a single kernel helps to fix it. For example, in our tests running a logistic function \( 1/(1 + e^{x_i}) \) in single kernel turned to be 1.4 times faster than running 3 separate kernels for exponent, summation and division (0.057 ms vs 0.08 ms for 50000-element 32-bit vectors using OpenCL).

Finally, for matrix multiplication and other aggregation functions we use a library implementing BLAS specification [11].

VI. IMPLEMENTATION IN JULIA

We provide a reference implementation in XDiff.jl [12] package in the Julia programming language. Below we provide the rationale for choosing the language and some other design decisions.

We chose Julia for several main reasons:

1) Julia supports literals for vectors and matrices and a large number of built-in mathematical functions
2) it also supports symbolic programming, i.e. variables and expressions may be represented as first-class citizens in Julia
3) operator overloading allows extending semantics of expressions to support, for example, symbolic product and summation

For comparison, in Python/C++ TensorFlow the whole new language with its own abstract syntax tree and a set of standard functions had to be designed for the same purposes.

Below we describe how we transfer some concepts from mathematical to programming notation.

As we’ve already described in the text, we represent variable indices using standard array indexing, e.g.:

\[ y[i] = W[i,k] * x[k] \]

Since Julia doesn’t support indexing of number literals, we replace pseudo-one notation \( i \) with symbol \([n] \).

Finally, to represent guards we use index comparison (e.g. \((i == m)\)) and add it as an additional product term to the main expression. E.g.:

\[ \frac{\partial y}{\partial W_{mn}} = x_n \quad | \quad i = m \]

is translated into

\[ dy_{\cdot \cdot}[i, m, n] = x[n] * (i == m) \]

When being multiplied by a number, boolean expression \((i == m)\) is converted into either 1 (true) or 0 (false). Thus when the condition holds, guard simply disappears, otherwise the whole expression turns into zero.

We generate code for GPU in OpenCL’s format. This choice is due to OpenCL’s widespread and portability, however, described techniques can be equally applied to other GPGPU systems (notably, CUDA).

VII. CONCLUSION

We have introduced a method for symbolic tensor differentiation using extended Einstein notation. The proposed method can be efficiently applied to functions where both - input and output - are tensors. We have also described techniques for code generation for CPU and GPU. The correctness of approach is proved by our reference implementation.

REFERENCES

Abstract - Artificial intelligence software tools could help scientists in reasoning on huge amount of data. This paper shows how Prolog can be used for analyzing air pollution data. Ecological data about air pollutant concentrations, previously measured with automatic stations, were transformed in a form suitable for processing and reasoning in Prolog system. A set of reasoning rules for analyzing air pollutants concentrations were defined and used for comparing level of concentration according to standards. Results of making goals and executing queries in Prolog are presented, visualized and analyzed.

I. INTRODUCTION

Experts, scientists and researchers in the field of environmental protection and ecology have a variety of tools for collecting and analyzing data, but relatively small number of tools that enable reasoning [1]. The ecological and eco informatics data, as well as knowledge bases are already extremely large and growing continually. This growing knowledge and huge amount of data challenges researchers to develop new and more efficient ways of organizing, processing and analyzing knowledge. Research results, methods and tools from artificial intelligence (AI) area may provide computerized tools, methods and techniques that aid ecologists in thinking and reasoning and provide mechanisms for applying ecological knowledge to real, complex problems [2]. According to [3], further development of the high performance computing and knowledge management tools, associated with AI techniques, is desired to promote long-term viability of the environmental informatics.

Aim of this paper is to present how Prolog could be used in analysis of air pollution data. Previously collected data from measurement stations are transformed in a suitable form for processing in Prolog. Reasoning rules are formulated to enable comparison of obtained data with values that are defined in standards.

II. RELATED WORK

Artificial intelligence area of expert systems development has significant appliance in environmental protection in recent years. Expert systems, databases and geographical information systems were combined for air quality modeling [4]. The use of mentioned tools and methods was focused on emission reduction scenario formation and evaluation. An expert system for evaluating the ecological quality of streams and rivers is presented in [5]. Oprea et al. [6] present an expert system developed for environmental diagnosis within three modules: for air pollution analysis and dispersion assessments, for surface water pollution analysis, and for soil erosion risk assessments.

Fuzzy expert systems approach is used because decision-making often involves gray areas, not only “black and white” reasoning [7]. Fuzzy expert systems and their applications can be found in ecological planning [2] or for power system diagnosis [8]. The aim of the expert system presented in [9] is to help in the decision-making process in the battle against pollution of the aquatic environment, which is vital for public health and the economy. This fuzzy expert system monitors seawater quality and pollution through a sensor network. Paper [10] proposes a new evaluation model using fuzzy inferences providing a new air quality index.

Neural networks, as a part of AI, also were used in ecology area for air pollution analyses. Ibarra-Berastegi et al. [11] focus on the prediction for five air pollutants on six locations in the area of Bilbao, in Spain.

Knowledge representation and reasoning is the area of AI concerned with how knowledge can be represented symbolically and manipulated in an automated way by reasoning programs [12]. Knowledge-based systems and their applications as another part of artificial intelligence were used in ecology for climate forecasting [13], for environmental protection [14] and for wastewater treatment [15]. Neagu et al. [16] propose a neuro-fuzzy knowledge-based system, an efficient decision support system that could function as a predictive tool in an air quality operational center.

Ecological informatics research is based on large quantities of collected data, which must be cleaned, shared, visualized and analyzed by research collaborators. To resolve this difficulty, Jaroenutsasin et al. [17] have presented online system for weather data analysis and visualization - consisting of online weather data portal combined with data analysis and visualization software tools. The Gutierrez-Corea et al. [18] present how climate and weather data, obtained from various automatic stations, could be qualitatively and quantitatively analyzed. A rule-based decision support system has been developed to assist decision makers in preparing the EU program of measures in the field of hydro morphological modelling [19]. Decision support system is created [19] to enable decision-making process in a qualitative manner based on the knowledge of experts. The construction of reusable knowledge libraries enables a wider range of applications to ecological modeling and better ways of
dealing with the complexity of ecological and environmental systems.

III. RESEARCH METHODOLOGY

Methodology and procedures used in this research include gathering air pollution data collected from three automatic measurement stations, installed in the province of Vojvodina, Republic of Serbia. These stations were located in year 2008 at three different locations, where air pollution is measured automatically every day: at urban city street, in industrial zone and in protected nature region. Raw measured data are downloaded from the website of Provincial Secretariat for Protection of Environment and Sustainable Development.

Data representation and automated reasoning are done with SWI-Prolog, a free version of Prolog that was developed at University of Amsterdam. Reasoning rules for data processing were created on the basis of regulations for air quality standards for European Union and regulations for air quality standards for Serbia.

Finally, visualization of analyses was performed using Microsoft Excel spreadsheet software for creating tables, using mathematical functions and presenting results in charts at worksheets.

IV. REASONING WITH AIR POLLUTION DATA

A. Collecting air pollution data

Air pollution data were collected from three automatic stations installed in the province of Vojvodina, Republic of Serbia. Monitoring data are stored and published at Internet portal of Provincial Secretariat for Protection of Environment and Sustainable Development of Vojvodina region (http://www.ekourb.vojvodina.gov.rs). These air stations were configured to take a reading every hour. It provides raw measurements of air pollutant concentrations and, with appropriate analysis and interpretation, these measurements can be transformed into useful information about air quality. In this paper, sample raw data from the year 2014 was used.

The data measurement used in this research was carried out with automatic measuring stations designed to monitor pollution levels with referent method (shown on Fig. 1) in:

- City of Zrenjanin - at location: 45°16’N and 19°52’E, in urban residential and commercial zone, on 75m of altitude, code station is RS10005, city with poorly developed industry around 80,000 inhabitants;
- City of Novi Sad - at location 45°23’N and 20°23’E, in urban industrial zone, on 80m of altitude, code station is RS10003, city with developed industry with around 300,000 inhabitants;
- Obedskas Bara - protected nature region near Sava river, at location 44°44’N and 19°59’E, on 75m of altitude, code station is RS10001, established in 1951 on 100km2 area with more than 200 birds species;

B. Preparing data for reasoning

Knowledge representation and reasoning considers how knowledge is represented symbolically and manipulated by automated reasoning systems [12]. In this study, reasoning was done with Prolog language for executing logical programs.

In Prolog language there are three types of sentences that form a single program: facts, rules and goals. Rules for reasoning are symbolically presented formulas that contain implication, facts are clause with empty body and goals are conclusions that have to be proved. All these sentences were defined in order to present ecoinformatics data and analyze results, queried out with reasoning rules.

C. Facts

The facts include measured eco data from the real world, collected with monitoring stations. Creating facts, as an internal base of available air monitoring data that are required for processing in PROLOG system, requires a user defined predicate that is called “airdata”. This predicate has thirteen arguments, in a following form:

airdata (S, D, H, X1, X2, X3, X4, X5, X6, X7, X8, X9, X10).

where:
S is a station code number,
D is date of the measurement,
H is time of the measurement,
X1 is sulfur-dioxide concentration (SO2),
X2 is hydrogen sulfide concentration (H2S),
X3 is ozone concentration (O3),
X4 is benzene concentration (B),
X5 is toluene concentration (T),
X6 is ethyl benzene concentration (E),
X7 is particulate matter concentration (PM2.5),
X8 is o-xylene concentration (OX),
X9 is particulate matter concentration (PM10),
X10 is a concentration of carbon monoxide (CO).

Total number of facts created from data collected from automatic stations is 1160.

D. Reasoning rules

Reasoning rules that were introduced in [20] are extended in this paper. Aim of reasoning rules is to enable processing related to determination of pollution level compared to standard values. The rules are created to include regulations on limit values and emissions measuring methods. Air quality standards for European Union (European air quality database; Directive 2008/50/EC) define air pollutants as components to be measured and the required levels of these air pollutants related to certain time period of measurement [21]. This regulation allows the following maximum concentrations of air pollutants in urban region:

- PM10 - for one hour 50 \( \mu \text{g/m}^3 \) and for three hours 150 \( \mu \text{g/m}^3 \),
- NO2 - for one hour 150 \( \mu \text{g/m}^3 \) and for one day 50 \( \mu \text{g/m}^3 \),
- O3 - for one hour 150 \( \mu \text{g/m}^3 \) and for one day 85 \( \mu \text{g/m}^3 \),
- CO - for one hour 10 mg/m3 and for one day 5 mg/m3,
- SO2 - for one hour 350 \( \mu \text{g/m}^3 \) and for one day 150 \( \mu \text{g/m}^3 \),
- T - for one hour 7.5 g/m3,
- E - for one hour 5 g/m3.

Four groups of reasoning rules were created – one group of rules is oriented towards finding air pollutant concentrations greater than is allowed with mentioned regulations in European Union, while three groups of rules support calculating average concentrations of air pollutants. Total number of defined reasoning rules is 32, eight in each group. In this paper only a few rules from each group were presented.

Examples of reasoning rules from the first group (determine if the concentration of air pollutant is greater than it is allowed as per appropriate regulations):

\[
\text{pollutionSO2}(\text{STATION}, \text{DAY}, \text{HOUR}, \text{SO2})\text{:- airdata(}\text{STATION}, \text{DAY}, \text{HOUR}, \text{SO2}_, _, _, _, _, _, _, _, _, _\text{), SO2}>350.} \tag{1}
\]

\[
\text{pollutionT}(\text{STATION}, \text{DAY}, \text{HOUR}, \text{T})\text{:- airdata(}\text{STATION}, \text{DAY}, \text{HOUR}_, _, _, T_, _, _, _, _, _, _\text{), T}>7.5.} \tag{2}
\]

\[
\text{pollutionB}(\text{STATION}, \text{DAY}, \text{HOUR}, \text{B})\text{:- airdata(}\text{STATION}, \text{DAY}, \text{HOUR}_, _, _, B_, _, _, _, _, _, _, _\text{), B}>5.} \tag{3}
\]

Examples of reasoning rules from the second group (for calculating the average concentration of air pollutant in whole observed period):

\[
\text{avgT}(\text{STATION}, \text{AV})\text{:- findall(T, airdata(}\text{STATION}_, _, _, _, _, _, T_, _, _, _, _, _, _, _\text{),LP), sumlist(LP,SP), length(LP,LP),AV is SP/L.} \tag{4}
\]

\[
\text{avgB}(\text{STATION}, \text{AV})\text{:- findall(B, airdata(}\text{STATION}_, _, _, _, B_, _, _, _, _, _, _, _, _\text{),LP), sumlist(LP,SP), length(LP,LP),AV is SP/L.} \tag{5}
\]

\[
\text{avgE}(\text{STATION}, \text{AV})\text{:- findall(T, airdata(}\text{STATION}_, _, _, _, _, _, T_, _, _, _, _, _, _, _\text{),LP), sumlist(LP,SP), length(LP,LP),AV is SP/L.} \tag{6}
\]

Examples of reasoning rules from the third group (for calculating the average concentrations of air pollutants in one day):

\[
\text{avgdayH2S}(\text{STATION}, \text{AV}, \text{DAY})\text{:- findall(H2S, airdata(}\text{STATION}, \text{DAY}_, _, _, H2S_, _, _, _, _, _, _, _\text{),LP), sumlist(LP,SP),length(LP,LP),AV is SP/L.} \tag{7}
\]

\[
\text{avgdaySO2}(\text{STATION}, \text{AV}, \text{DAY})\text{:- findall(SO2, airdata(}\text{STATION}, \text{DAY}_, _, _, SO2_, _, _, _, _, _, _, _\text{),LP), sumlist(LP,SP),length(LP,LP),AV is SP/L.} \tag{8}
\]

Examples of reasoning rules from the fourth group (for calculating the average concentrations of air pollutants in one hour):

\[
\text{avghourH2S}(\text{STATION}, \text{AV}, \text{HOUR})\text{:- findall(H2S, airdata(}\text{STATION}_, \text{HOUR}_, _, H2S_, _, _, _, _, _, _, _\text{),LP), sumlist(LP,SP),length(LP,LP),AV is SP/L.} \tag{9}
\]

\[
\text{avghourSO2}(\text{STATION}, \text{AV}, \text{HOUR})\text{:- findall(SO2, airdata(}\text{STATION}_, \text{HOUR}, SO2_, _, _, _, _, _, _, _, _\text{),LP), sumlist(LP,SP),length(LP,LP),AV is SP/L.} \tag{10}
\]

In previously presented examples:

- AV, HOUR, DAY, H2S, SO2, B, T, E, LP, SP, and L are variables;
- findall, sumlist, length are built-in predicates;
- airdata, pollutionSO2, pollutionT, pollutionB, avgT, avgB, avgE, avghourH2S, avghourSO2 are user-defined predicates.

Reasoning rules for calculating the average concentrations of air pollutants are created with “findall” predicate in SWI-Prolog that forms a list of values for calculation. These built-in predicates avoid usage of recursion principle. This results in significant reduction of the Prolog program length. Another used built-in predicate was the “sumlist” for summarizing all the values in previous formed list and the “length” predicate for counting the number of list elements. Finally, the average value of air pollutant concentration (AV) was calculated as derivation of this sum (SP) and the number of elements in list (L). Unused variables in each rule are marked with “_” symbol for every argument that has not been used.
E. Goals

Goals with only one literal are called queries. Four types of queries are defined within SWI-PROLOG, based on previously presented reasoning rules. These goals are different in arguments used, as well as in variables that contain values of measured air pollutants.

First example of query for the rule from the first group (1) – “When were the concentrations of sulfur-dioxide higher than it is allowed with standards?”

?- pollutionSO2(STATION,DAY,HOUR,SO2).
false.

Answer for this query is “false”. It could be concluded that the concentration of this air pollutant was not high in searched period, because all measured values for this pollutant were smaller than the given value in the rule.

Second example of query for the rule from the first group (3) – “When were the concentrations of benzene higher than it is allowed with standards?”

?- pollutionB(STATION,DAY,HOUR,B).
STATION = 'RS10005',
DAY = '2014-05-06',
HOUR = '06:00:00',
B = 5.45;
STATION = 'RS10005',
DAY = '2014-05-09',
HOUR = '22:00:00',
B = 5.38;
STATION = 'RS10005',
DAY = '2014-05-10',
HOUR = '22:00:00',
B = 10.41;
STATION = 'RS10005',
DAY = '2014-05-10',
HOUR = '23:00:00',
B = 12.09;
STATION = 'RS10005',
DAY = '2014-05-11',
HOUR = '00:00:00',
B = 5.62;
STATION = 'RS10005',
DAY = '2014-05-13',
HOUR = '22:00:00',
B = 5.69;
STATION = 'RS10005',
DAY = '2014-05-18',
HOUR = '21:00:00',
B = 6.97;
STATION = 'RS10005',
DAY = '2014-05-18',
HOUR = '22:00:00',
B = 6.49;
false.

Answer for the second query was created with multiple use of the unification process. Prolog listed all values for variables defined in query that displays station code, day, hour and concentration for this pollutant when it was greater from the given value in the rule. “False” at the end of reached goals list means that there is no other results that can be concluded with this reasoning.

Third example of a query for the rule from the second group (4) – “What was the calculated average concentration of toluene in whole observed period in city of Zrenjanin, at urban street location?”

?- avgT('RS10005',AV).
AV = 1.9379999999999993.

Fourth example of a query related to a rule from the second group (4) – “What was the calculated average concentration of toluene in whole observed period in city of Novi Sad, in industrial zone?”

?- avgT('RS10003',AV).
AV = 0.81648611111111109.

Fifth example of a query - for a rule in the second group (4) – “What was the calculated average concentration of toluene in whole observed period at Obeda Bara, which is a protected nature region?”

?- avgT('RS10001',AV).
AV = 0.04232526881720394.

Sixth example of a query - a rule from the third group (7) - “What was the average concentration of hydrogen sulfide for May 1st, 2014, in city of Zrenjanin, in urban street?”

?- avgdayH2S('RS10005',AV,'2014-05-01').
AV = 1.0970833333333333332.

Seventh example of query is for rule in the fourth group (9) – “What is average concentration of hydrogen sulfide in midnight for all days in observed period in city of Novi Sad, in industrial zone?”

?- avghourH2S('RS10003',AV,'00:00:00').
AV = 5.461333333333333.

V. RESULTS AND DISCUSSION

Prolog program, with air pollution data and reasoning rules, consists of 2192 Prolog sentences that were executed and processed. Goals were made in order to get answers for discovering when were the concentrations of air pollutants higher than it is allowed with EU standards and what was the average values of the pollutants.

One of the goals of research, presented in this paper, was to compare concentrations of air pollutants at three different environmental locations.

Results of executing queries based on reasoning rules in first group shows that the average concentrations of air
pollutants were greater than it is recommended by regulative: for ozone, in city of Zrenjanin it were detected 47 hours when concentrations were greater than 150 μg/m3, for toluene 20 hours when concentrations were greater than 7.5 g/m3 (14 in Zrenjanin and 6 in Novi Sad), for benzene nine times concentrations were greater than 5 g/m3, for PM10 75 hours, all in Zrenjanin. For carbon monoxide, ethyl benzene, o-xylene and sulfur dioxide it has not been found greater concentrations of pollutants in all 2160 measurements.

### TABLE I. AVERAGE CONCENTRATIONS FOR H2S

<table>
<thead>
<tr>
<th>H2S</th>
<th>RS10005 Zrenjanin</th>
<th>RS10003 Novi Sad</th>
<th>RS10001 Obedska Bara</th>
</tr>
</thead>
<tbody>

<td>4.78</td>
<td>10.32</td>
<td>3.24</td>
</tr>
</tbody>
</table>

Values for other pollutants like ozone, particulate matter, o-xylene and carbon monoxide are not presented in this table because the automatic station RS10005 in Zrenjanin measures theses concentrations while RS10003 in Novi Sad and RS10001 in Obedska bara do not have measured data for these four air pollutants.

Average concentrations for air pollutants, in May 2014, calculated with reasoning rules from the second group are:

- for SO2 6.29 μg/m3,
- for H2S 2.19 μg/m3,
- for toluene 0.93 g/m3,
- for benzene 0.58 g/m3,
- for ethyl benzene 0.2 g/m3.

For station in urban street in Zrenjanin, average concentrations for other four air pollutants, in May 2014, are:

- for PM10 21.76 μg/m3,
- for CO 0.48 mg/m3,
- for O3 89.96 μg/m3,
- for o-xylene 0.6 μg/m3.
VI. CONCLUSION

This paper shows research with empirical results of applying SWI-Prolog in reasoning with specific type of data – air pollution data.

This paper demonstrates using SWI-Prolog in reasoning on air-pollution data regarding comparison with EU standard levels of pollution. The raw data were collected from three measurement stations and adaptation of the data was made to enable processing within SWI-Prolog. The results of air pollution data processing within SWI-Prolog show how special types of predicates could be used from standard list of predicates, as well as the creation and usage of user-defined predicates.

The proposed method of reasoning with huge amounts of data and creating a program that includes specific domain knowledge could be applied in many other areas and scientific disciplines. Moreover, tools like SWI-Prolog could be used for educating students in the science of ecology, environmental protection, information technologies or ecoinformatics. It can be used for solving complex problems and for finding more efficient ways of processing and analyzing human work and knowledge.

Future work could include using fuzzy logic or building fuzzy expert systems with possibility to predict air pollutant concentrations.

Abstract - The effective management of scalable applications for solving large problems in a heterogeneous distributed computing environment is the non-trivial problem. Scalable applications generate competitive job flows that have be executed with the help of shared resources of the environment. The promising approach to solve this problem is to use multi-agent technologies. To this end, we develop a multi-agent system for the management of scalable applications. In contrast to known multi-agent systems, our system is based on applying a special conceptual model of the environment. It includes several components of a comprehensive knowledge about both the environment and subject domains of solved problems. We propose a new approach to an elicitation of these knowledge components through an integrated use of the conceptual modelling of distributed computing, classification of jobs and resources, and parameters adjustment for agent algorithms. With this approach, specialists in various fields of distributed computing considered as users of the environment, can apply their own knowledge at different levels of the problem solving process. This flexibility and algorithm adaptation are benefits of our approach. Extensive modeling and practical experiments, with variation of important parameters of applications execution, show the efficiency of our management under developed multi-agent system for scalable applications.

I. INTRODUCTION

High-performance computing (HPC) is an important component for effective solving large problems and mathematical modeling in various subject domains. HPC is based on the parallel execution of computational processes that are characterized different degrees of an interrelationship between them.

A rapid increase of the computational elements in systems for HPC leads to need for scalable applications. A computations scalability means that a problem solving time decreases with increasing a number of the nodes used by an application. Thus, the solved problem has to have an ability to be decomposed into sub problems, which can be solved as much independently as possible.

HPC supercomputers and clusters provide solutions within various distributed computing environments that include heterogeneous, autonomous and geographically distributed nodes that can have complex hybrid structures, special computational characteristics and administrative policies [1]. The nodes can have different owners with own criteria of the usage (efficiency, profit, load balancing, power consumption, etc.).

Resources management system (RMS) is used for computations management at the node level. The known traditional RMSs are Grid Engine [4], PBS Torque [5], HTCondor [6], and SLURM [7].

The specialized middleware is used for computations management of distributed nodes through an interaction with RMSs and their substitution. For example, the Globus Toolkit [8] supports various the standards and compatibility with various DRMSs, and GridWay [9].

Usually, the environment supports the collective usage of its resources by users for the large range of problem classes. Problem specification includes information about the required computational resources, executable programs, input and output data, quality criteria (time, cost, reliability, etc.), and other required issues. The specification describes a computational job for the traditional RMSs and meta-schedulers used in environment nodes.

In general, we assume that the job includes the set of interconnected programs. The job specifications are generated by applications in the form a workflow [10, 11, 12]. It can be represented by Directed Acyclic Graph (DAG) according to logical and information relations between the programs.

Workflow management systems (WMSs) largely used for solving scientific problems are known. There are the following systems: Condor DAGMan, Pegasus, Taverna, UNICORE, etc. [13]. Nevertheless, the workflow management problems in heterogeneous distributed computing environment is not completely solved [14].

One of problem is a concordance of all solving processes. WMS operates at the application level. Its objective is to obtain best resources for workflows.

Unlike WMSs, RMSs and meta-schedulers operate at the environment level. Node administrators can configure RMSs and meta-schedulers to determine common rules of a resources usage and policies for the allocation of quotas and rights for users and their jobs. However, the effective coordination of users and owners of the resources in processes of their allocation for solved problems, taking
into account the specificity of subject domains, often remains beyond their capabilities.

A promising approach for solving this non-trivial problem is applying a multi-agent technologies based on the self-organization of agent communities [15]. Within such an approach, a Multi-Agent System (MAS) implements the computations management. Agents can represent users and owners of the resources, and interact themselves with aim to meet their interests.

We know the range of MASs, successfully used for distributed computing management in practice [16,17]. Nevertheless, there are additional components of knowledge that do not used by these systems. They do not include the knowledge about the specific subject domain, job properties, agent algorithm parameters, etc.

To this end, we develop a multi-agent system for the management of scalable applications that allows specialists in various fields of distributed computing can apply their own knowledge at different levels of the problem solving process. The special attention is on a job classification system.

II. MULTI-AGENT SYSTEM

The developed MAS has a hierarchical structure, which includes two or more functional levels, and operates on the base of self-organization. At each level, agents play a variety of roles, and perform different functions. The roles may be permanent or temporal. Their changes occur at discrete times when agents need to solve new problems. Each level is related with the conceptual model knowledge layers.

Agents are autonomous, and computing management is based on their interaction. They can be organized in virtual communities. In these communities, agents interact using a cooperation or competition. The formation of virtual communities allows the MAS to adapt the management process to the new challenges.

The MAS applies the algorithm for the static resource allocation based on economic mechanisms for regulation of resources demand and supply. It uses a model of the Vickrey auction with one-round bidding [18].

The users formulate problems and define criteria of their solving. User agents create and classify jobs based on the problem formulations. Then, these agents submit the jobs to agents responsible for resource allocation.

A virtual community of agents that most suitable for the problem solving is created. Agents use the classification system of resources and jobs for self-organization into the virtual community.

Each agent of the virtual community sets bids for all jobs that reflect the genuine value of these jobs and maximal utility of the bids for this agent. The steady state of the virtual community is achieved at the end of the auction. This state is similar to the equilibrium that has been defined by Nash [19] in the game theory. Rules of the Vickrey auction provides simplicity and satisfactory rate of the decision-making by agents.

According to results of bidding, the virtual community manage the job execution. In the process of computing, agents may reallocate its own computational load among other agents through interaction with their neighbors.

Agents can also provide dynamic decomposition of a problem into sub-problems, when additional free resources are available. The decomposition is carried out in order to accelerate the problem solving and make it scalable.

There are large variety of knowledge elicitation methods [20]. Conceptual and simulation modeling are major methods used by agents. Our implementation of these methods is based on conceptual programming [21, 22].

III. CONCEPTUAL MODEL

With high-level languages and methods, conceptual modeling becomes a powerful tool for complex systems design. A conceptual model has to allow the system designers and developers to represent and structure the results of their expert analysis of a subject domain.

In this regard, the conceptual model of a subject-oriented distributed computing environment includes the following components of comprehensive knowledge:

- Computational knowledge about software modules (programs) for solving problems in subject domains and working with the environment objects, including planning of their actions;
- Schematic knowledge about the modular structure of models and algorithms, problem formulations and workflows;
- Production knowledge to support decision-making for selecting optimal algorithms, depending on the workflow and environment states;
- Knowledge about the software and hardware infrastructure of the environment and administrative policies in its nodes, including an information about users, their problems and jobs.

We develop the specialized high-level toolkit named SIRIUS II for designing the conceptual models. This toolkit provides elicitation the subject-oriented knowledge of application developers. Detailed information about the conceptual model can be found in [23, 24].

IV. JOB CLASSIFICATION SYSTEM

We developed the job classification system to improve the resource allocation. This system allows to elicit knowledge of the administrators about a conformity of jobs and resources. Such a knowledge provides a possibility to determine a job class and select conformable resources.

Requirements to a computer system for a problem solving included in jobs represent explicit characteristics such as the problem solving time, RAM, disk memory, number of nodes, processors and cores, program libraries, compilers, their keys, etc.
Our job classification system allows the administrators to use these characteristics without changes, and develop new characteristics based on the value ranges for original characteristics. For example, they can create the new special characteristics with different ranges for the requested core number, problem solving time, and define job classes based on these characteristics.

Additionally, the administrators can develop implicit job characteristics using the conceptual model knowledge. These characteristics are based on the knowledge about methods, algorithms, programs execution conditions, computational history, etc.

A. Classification Model

A classification model has a set of explicit and implicit job characteristics \( h_1, h_2, \ldots, h_k \). Each characteristic \( h_i \) for \( i \in [1,K] \) is defined by its rank \( r_i \geq 1 \), weight \( w_i \geq 0 \), and range \( R_i \) of values including the symbol \( \theta \) of an uncertainty [25, 26]. Characteristics are partially descending ordered in accordance with their ranks.

We can define \( m \) job classes based on the set of characteristics. Each new class \( c_j \) is defined using the two disjoint sets of characteristics: mandatory and optional subsets. The characteristic \( h_i \) included in one of these subsets for the class \( c_j \) has the specialized range \( R_{j \text{spec}} \subseteq R_i \setminus \{ \theta \} \) of values.

Let us denote by \( x \) and \( y \) the Boolean vectors of dimensions \( k \) and \( m \), respectively.

Value of the element \( x_i \) is defined as follows:

\[
x_i = \begin{cases} 0, & \text{if } R_{j \text{job}} \subseteq \{ \theta \}, \\ 1, & \text{if } R_{j \text{job}} \subseteq R_i \setminus \{ \theta \}, 
\end{cases}
\]

where \( R_{j \text{job}} \) is the range of values, requested for the characteristic \( h_i \). The value \( x_i = 1 \) (\( x_i = 0 \)) shows that the characteristic \( h_i \) is used (not used) in the job specification.

The vector \( x \) satisfies \( \bigwedge_{i=1}^k x_i = 0 \).

Definition the following characteristic function:

\[
\chi_j(x) = \begin{cases} 0, & \text{if } \exists i : (x_i = 1) \wedge (R_{i \text{job}} \subseteq R_{j \text{spec}}), \\ 1, & \text{otherwise}, 
\end{cases}
\]

where \( i \in [1,k], j \in [1,m] \). The value \( \chi_j(x) = 1 \) (\( \chi_j(x) = 0 \)) means that the job is matched (mismatched) to the class \( c_j \).

We implement a primary job classification applying the function \( \chi_j(x) \) for \( m \) classes: \( y_j = \chi_j(x) \), where \( y_j = 1 \) (\( y_j = 0 \)), means that the job match (mismatch) to the class \( c_j \), \( j \in [1,m] \). It is obvious that the job can match to several classes.

To this end, we use the additional characteristic function \( \varphi_{y_j}(x,y) \) to determine when the job match (\( \varphi_{y_j}(x,y) = 1 \)) or mismatch (\( \varphi_{y_j}(x,y) = 0 \)) to the class \( c_j \) taking into account the four properties of job characteristics:

1. Probabilistic measure based on the number of optional characteristics matching to the class \( \{ l = 1 \} \);
2. Aggregated rank \( \{ l = 2 \} \);
3. Summary weight \( \{ l = 3 \} \);
4. Probabilistic measure based on the computational history of jobs \( \{ l = 4 \} \).

These functions allow implementing various variants of the additional job classification based on the primary job classification. The job classification intended for the primary filtration of the resources set. In general, it provides forming the residual set \( V \) of resources for the job execution.

B. Job Classification Algorithm

In the job classification system, the administrator creates the sets of characteristics and classes, and defines conformity of jobs and resources using own expert knowledge. The MAS uses the sorting method for the knowledge elicitation.

During the system operation, the administrator can modify and add resources and job classes including inheritance mechanisms usage.

When the job submitted in the MAS, agents apply the job classification algorithm described below.

Majority stages of the algorithm:

1. Initialization of the vector \( y : y_j = 0, j = 1, m \).
2. Primary job classification: \( y_j = \chi_j(x), j = 1, m \).
3. If the vector \( y \) satisfies \( \forall y_j = 0 \), then the job classification is not possible. Go to the stage 6.
4. Otherwise, if the vector \( y \) satisfies \( \forall y_j \neq 0 \), then the single element \( y_j = 1 \) exists and the job matches to the single class \( c_j \). Go to the stage 6.
5. Otherwise, \( y_j = \varphi_{y_j}(x,y), \forall j : y_j = 1, l = 1, 4 \).
6. Completion of the algorithm.

After the job classification, the MAS specializes this job by adding the directive how to use the selected resources. The MAS creates the virtual community of agents corresponding to selected resources. Then, it submits the specialized job to these agents. They perform the final selection and allocation of resources.
V. AGENT ALGORITHM ADJUSTMENT

Algorithms for the resource allocation have the following control parameters:

- Limits of the node components load;
- Bonuses for limits satisfying;
- Penalties for limits exceeding;
- Priorities of job classes;
- Degree of desire to carry out the jobs of defined classes.

Administrators as experts set the initial values of these parameters in configuring the MAS. These parameters are automatically adjusted based on simulation modeling and meta-monitoring in a process of the MAS operation.

Figure 1 shows the block diagram of the parameter adjustment of agent algorithms.

Table I describes the parameters used on the block diagram.

TABLE I. PARAMETERS DESCRIPTION

<table>
<thead>
<tr>
<th>Notation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>f</td>
<td>Job flow</td>
</tr>
<tr>
<td>f_{opt}</td>
<td>Optimized job flow</td>
</tr>
<tr>
<td>d</td>
<td>Job distribution</td>
</tr>
<tr>
<td>inf</td>
<td>Information about the environment state</td>
</tr>
<tr>
<td>e</td>
<td>Evaluation of the environment state</td>
</tr>

</tr>
</tbody>
</table>

Agents for parameter adjustment use the simulation modeling to solve the following problem:

\[ v_i(z) \rightarrow \min(\max), \]  

\[ v_i^{\text{min}} \leq v_i \leq v_i^{\text{max}}, \quad i = 1, \ldots, n. \]  

We create the simulation model as the parameter sweep application that generates the large number of model copies [27]. Each independent copy runs with the single values variant of its input variables. A meta-monitoring system provides the actual evaluation of the environment state. After execution of all copies, the environment services provide the collection of simulation results represented by variants of the vector \( v \). We apply multi-criteria selection of the results to form the vector \( u \) with evaluation of components of the vector \( v \) using the conditions represented in (1) and (2) [28, 29]. Administrators assign an extremum for each component of the vector \( v \) before the simulation modeling.

The parameter adjustment provides for agents the efficiency of their bids for jobs at the Vickrey auction.

We consider the parameter adjustment as the element of agent learning. A feedback for learning process is implemented using the bonuses and penalties. Agents correct own decision-making taking into account this feedback.

VI. EXPERIMENTAL ANALYSIS

In this section, we provides results of extensive modelling and practical experiments with the developed MAS.

We obtained and analyzed the computational history about 80000 real jobs executed in one day on three computer clusters with different computational resources (Table II).

<table>
<thead>
<tr>
<th>Cluster</th>
<th>Peak performance</th>
<th>Processor</th>
<th>Nodes/processors/cores numbers</th>
<th>RMS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cluster 1</td>
<td>1.50 TFlops</td>
<td>Intel Xeon E5345</td>
<td>20/40/160</td>

</tr>
<tr>
<td>Cluster 3</td>
<td>0.17 TFlops</td>
<td>Intel Xeon</td>
<td>16/32/32</td>
<td>SUPPZ [31]</td>
</tr>
</tbody>
</table>

Clusters 1 and Cluster 3 include dedicated nodes that are used within cluster only. Non-dedicated nodes of the Cluster 2 are used by owners and cluster users. In the Cleo, all cores of a node are allocated for a job request, regardless of the number of requested cores. Often, it leads to inefficient resource loading. We solve this problem using classification system.

In the classification system, we define six parental classes of jobs based on the analysis of computational history (Table III). These classes differ by the number of requested cores and execution time. Then, we created additional classes of jobs based on the parental classes taking into account the required RAM, disk space, system, applied software, etc. Each additional class is related to one of the clusters.
We generated the job flow in accordance to the obtained computational history. Each job is classified and submitted by the MAS to the matched cluster.

Table III presents the experimental results for 6 classes showing the following parameters:

- Number \( n_1 \) of requested cores,
- Requested execution time \( r \) in minutes,
- Number \( n_2 \) of jobs for the given class,
- Number \( n_3 \) of reallocation jobs.

<table>
<thead>
<tr>

<td>( \geq 60 )</td>
<td>3312</td>
<td>95</td>
</tr>
</tbody>
</table>

The average processor load for three clusters during the job flow processing is improved by 18 %, 25 % and 30 % respectively (Figure 4).

![Figure 4. Jobs distribution with their classification](image1)

In the following experiment, the synthetic job flow is processed in the distributed computing environment including three clusters. The jobs represent a copy of the same workflow.

We compare the efficiency of processor load with management under the meta-scheduler of HTCondor version 6.6.8, GridWay version 5.12 and developed MAS, which as middleware interact with clusters RMSs.

We execute an application for warehouse logistics problem solving. Figure 5 illustrates the advantages of the MAS in comparison with target systems for this example. These advantages are achieved due to the control parameters adjustment represented in the Section V.

![Figure 5. Cluster load with three management systems](image2)

Experiments is carried out in the distributed computing environment based on resources of the Irkutsk state university and Center of collective usage “Irkutsk Supercomputer Center of SB RAS” [32].

**VII. Conclusion**

In this paper, we address a problem of the multi-agent management in distributed computing. We showed that its efficiency significantly depends on ability to use the subject-oriented knowledge.

We propose the approach to elicit, represent and use the comprehensive knowledge about both the distributed computing environment and subject domains of solved problems. Specialists in various fields of distributed
computing can generate this knowledge at different levels of the problem solving process based on own skills and experience. We also developed the MAS for the management of scalable applications that generate job flows. The MAS operates based on the self-organization.

Comprehensive modelling and practical experiments, with variation of important parameters, show the efficiency of our management under the developed MAS due to elicitation and using the conceptual knowledge.

As future work, we will continue the MAS evolution, expanding the subject-oriented knowledge usage.

Abstract - Optimization of a large-scale Traveling Salesman Problem, which is a well-known NP-hard problem in combinatorial optimization, is a time-consuming problem. A modern approach to dealing with such time-consuming problems is with the use of distributed computing, which can significantly improve the speed of the problem-solving algorithm. In this paper, we discuss the design approaches for an agent-based distributed algorithm and their benefits. Based on further analysis and experiments, we have improved our previous agent-based Ant Colony Optimization algorithm for Solving Traveling Salesman Problem using Siebog multiagent middleware.

I. INTRODUCTION

Distributed system can be defined as a network of independent components that communicate and coordinate their actions only by passing messages [1]. The motivation behind the use of distributed systems is the fact that distributed data computing can lower the cost of data processing and increase the system’s robustness with data replication. When used properly, distributed computing can achieve a computational result much more quickly than a single computer can.

One area inherently amenable to parallelization and distributed computing is swarm intelligence. [5]

Ant colony optimization (ACO) [2] is one of the swarm based optimization algorithms used for solving wide range combinatorial optimization problems. It is inspired by the behavior exhibited by ant colonies while searching for a food source. One of the characteristics of ant colonies is that they have the ability to find the shortest path to a food source, by using a large number of independent ants that use only pheromones as a means of communication. In ACO each ant can be seen as an independent processing agent searching through an environment.

In this paper, we describe our intention to improve the execution speed of our previous agent-based distributed ACO algorithm for Traveling Salesman Problem (TSP). The algorithm was initially developed to showcase Siebog’s distributive capabilities [6, 7]. Although successful, the algorithm didn’t fully utilize all the capabilities offered by the Siebog design.

Siebog is our FIPA compliant multiagent middleware built using the Java Platform, Enterprise Edition (Java EE) [8, 9, 10]. Siebog supports both client-side and server-side agents. Client-side agents execute their code on browsers, as JavaScript code, while server-side agents are being executed as EJB (Enterprise Java Beans) components. Siebog utilizes the standards and technologies readily available in Java EE, in order to provide automatic agent load balancing and fault tolerance on the server side [7]. It also uses Java EE built-in features to implement core agent functionalities:

- it uses JMS (Java Message Service) to exchange messages between agents,
- it uses JNDI (Java Naming and Directory Service) as agent discovery service (agent "yellow pages"),
- it uses JAAS (Java Authentication and Authorization Service) to implement security concepts.

This paper is organized as follows. Section 2 provides an overview of relevant literature. The formulas of ACO for TSP are presented in Section 3. Section 4 presents our proposed model. The results of the model are presented in Section 4. Finally, Section 5 outlines general conclusion and further work.

II. RELATED WORK

Over the years there have been many attempts at developing optimal parallel and distributed algorithms for ACO. A survey on parallel ant colony optimization was reported by [11]. Authors of that work proposed a new taxonomy for classifying parallel ACO. Their classification includes: master-slave model, cellular model, parallel independent runs model, multi-colony model, and hybrid model. Classification best suited for this work is the multi-colony model.

In a standard multi-colony model configuration, introduced by [12, 13], different colonies of ants work on the same problem independently. Pheromones aren’t shared between the colonies, but after a number of iterations colonies exchange their best solution in order to influence each other via elitist strategy.

The standard multi-colony configuration was successfully applied to various optimization problems,
with improvements over the sequential ACO. Notably, authors of [14], developed a parallel ant colony systems (PACS). Their preliminary test on three datasets showed that PACS outperforms sequential algorithms, especially with larger datasets.

Another notable distributed agent-based algorithm for solving TSP, named ACODA, was developed by [3]. Their experimental results show execution time improvement, and that the system, by partitioning the map between agents, supports scalability.

III. ACO FOR TSP

ACO algorithm is inspired by the behavior exhibited by ants while searching for a food source. Ants, while searching for a food source, secrete pheromones on their way back to the anhill. Other ants can detect paths with secreted pheromones and they may become attracted to them. The paths become more attractive when more pheromone is deposited on them. Another property of the pheromones is that they evaporate over time. Evaporation makes the longer paths less interesting, which decreases the probability that an ant will choose it. However, evaporation will have less influence on shorter paths, due to the fact that they are refreshed more frequently. In time, ants will converge towards the shortest path due to largest concentration of pheromones [2][3].

Mathematical model of ACO for TSP we used in our work is fully described in [2][3], briefly summarized the formulas are the following:

An ant located at a city (node) \( i \) chooses to go to city \( j \) with the probability:

\[
P_{i,j} = \left( \frac{\tau_{i,j}}{\sum \tau_{i,j}} \right)^\alpha \left( \frac{\eta_{i,j}}{\sum \eta_{i,j}} \right)^\beta,
\]

where \( \tau_{i,j} \) - is the amount of the pheromone deposited on edge \((i,j)\), \( \eta_{i,j} \) - is the inverse of the weight of edge \((i,j)\), \( \alpha \) - is a parameter to control the influence of parameter \( \tau_{i,j} \), \( \beta \) - is a parameter to control the influence of \( \eta_{i,j} \), \( j \) - represents a city reachable from city \( i \) that was not yet visited by that ant. When an ant determines a new tour of a cost \( L \) it will increase every edge of the tour with the value \( \Delta \tau_{i,j} \) which is inversely proportional to the cost of tour. Pheromone update and evaporation, are done while ant traces back its steps, with the formula:

\[
\tau_{i,j} = (1 - \rho)\tau_{i,j} + \rho \Delta \tau_{i,j},
\]

where \( \rho \) is the evaporation rate in the range \( 0 \leq \rho < 1 \). In order to increase the exploration rate an ant can apply local evaporation of to a node with the formula:

\[
\tau_{i,j} = (1 - \xi)\tau_{i,j} + \xi \tau_0,
\]

where \( \xi \) is the local evaporation rate in the range \( 0 \leq \xi < 1 \) and \( \tau_0 = 1/nC \) in which \( n \) represents the number of nodes and \( C \) represents the tour cost approximation (\( C \) usually equals to product of number of nodes and average edge cost between them).

IV. PROPOSED MODEL

When designing an agent based ACO algorithm, we considered two distinct approaches. Approaches are characterized by the representation of the ants. That is, ants can be represented as either an agent in the system or as a message exchanged in the system.

Initially, to display Siebgs capabilities, an ACO algorithm was developed in which ants were represented as agents, and the problem space was represented by a single map agent. Although not optimized, that algorithm showed that our multi-agent middleware had all the necessary capabilities required for distributed computing, but it had a major flaw brought on by the nature of distributed systems. As mentioned before, distributed systems communicate over a physical network which introduces a delay to the system. That delay combined with a bottleneck which is a single map agent and synchronous access to it resulted in a significant increase in time required for algorithm execution (for a simple map of 16 nodes, the time required was about 1h55m on commodity hardware and about 10m on high-end hardware). In order to improve the execution time we have redesigned the ant itself. In fact, we have implemented it as a message instead of an agent.

In the first approach, ants are agents that search through the problem space. The problem space is represented and maintained by one or more map agents. Ant agents are the algorithm executors, they start the search, use the problem space data to perform calculations, and notify map agents about necessary updates to the problem space. The behavior of map agents can be described as purely responsive because all of their actions are responses to queries generated by ant agents. There are three distinct messaging types, illustrated in Figure 1A, in this approach:

1. Initialization messaging – with which an ant agent request a list of nodes in the problem space,
2. Local move messaging – when choosing the next node to visit an ant queries the map agent for pheromone levels in path from current node to next nodes,
3. Update tour – after finding a possible solution, an ant notifies all map agents about it.

To decrease the number of messages in our distributed system, for the second approach, we represented ants as messages exchanged by map agents. To accommodate such changes, we extended map agents by adding them algorithm execution functionality. Algorithm execution functionality is represented as an infinite loop which takes and processes an ant from the ant queue. After processing (choosing the next node that ants will visit, and updating the problem space), the ant is either sent to another map agent or added to the end of the ant queue, depending on the node to which the ant will go to next. In this approach, there are two distinct messaging types (illustrated in Figure 1B):

1. Send ant – this message happens when an ant needs to visit a node managed by another map agent,
2. Update tour – when the ant returns to its initial map agent with a possible solution, that map agent notifies other map agents about it.

To fully optimize the algorithm execution in this approach, we have used Siebog’s flexibility to separate the agents’ message processing from the algorithm execution. The separation is achieved by using a separate thread for the algorithm execution. With that, each map agent is able to process messages, update the problem space, and execute the algorithm steps in parallel.

Inspired by [2], our agent-based algorithm, given in table 1., consists of several steps regardless of the chosen approach.

**TABLE 1. STEPS OF AN ACO ALGORITHM**

```python
SEARCH_STEP(ant):
    GET_MAP_DATA()
    if COMPLETED_TOUR(ant):
        NOTIFY_TOUR(ant)
    REINITIALIZE(ant)
    else:
        ANT_MOVE(map_data, ant)

ANT_MOVE(map_data, ant):
    node = perform random choice per equation 1
    UPDATE_ANT_PATH(ant, node)
    apply local evaporation using equation 4
    SEND_ANT(ant, node)

SEND_ANT(ant, node):
    if node.agent != current_map_agent:
        SEARCH_STEP(ant)
    else:
        SEND(ant, node.agent)

NOTIFY_TOUR(ant):
    for edge in ant.tour:
        update pheromone levels using equation 3
    if STOP_CRITERIA_MET():
        STOP_SEARCH()
```

When the client initiates the search, the problem space is loaded and distributed among a number of map agents. In order to decrease the initial workload of each map agent, ants are evenly assigned to the client. The client defines the number of ants used in the search. Each ant begins its search of the problem space from a randomly chosen node managed by their assigned map agent. After the initial pick of a start node, ants repeatedly execute the SEARCH_STEP functionality until they return to their start node. In the ant as an agent approach, to complete each step, ant first requests the pheromone levels of each possible path it can take from the current node. When the ant gets a response from a map agent, it executes appropriate calculations to choose the next node it will visit. After choosing the node, it notifies the map agent to apply the calculated local pheromone evaporation and repeats this process again with the next node. On the other hand, in ant as a message approach all calculation are done by map agents. The step of the search process is represented by taking the ant from the ant queue, calculating the next node, and putting the ant at the back of the ant queue (or sending it to another map agent).

During a single ANT_MOVE the ant uses pheromone data, of all the paths it can take, to choose a path that is a city, it will visit next. When the ant chooses the next city, it updates its tour cost by adding the cost of the taken path. With the new data generated by ant, appropriate map agents apply local evaporation to the taken path. In the ant as a message approach, the last step of the ant move is to send it to next map agent (if the next city belongs to another agent), or to add him to the end of the ant queue (if the next city belongs to the map agent). On the other hand, in the ant as an agent approach, the ant agents receive the agent id of the appropriate map agent it needs to query for the map data.

When the ant finishes its tour, it returns to the ant hill (starting city) while depositing the pheromone on the
V. EVALUATION AND RESULTS

In order to properly represent the results and compare them with the execution speed of initial implementation, we used a single Siebog node for testing. The machine used for Siebog node had a 4 virtual CPUs and 8 GB of RAM, running a 64-bit version of Windows 7.

Execution speed was tested by measuring the time required for each ant to complete 200 tours of the search space. It happens under requirement that the number of ants is equal to the number of cities on the map. We ran the test on benchmark TSP maps selected from TSPLIB [3], the results are presented in table 2.

The results show that ant as a message approach is significantly faster than ant as an agent approach. When compared to the initial implementation which required 1h55m for ulysses16, both approaches show considerable improvement in the execution speed.

The speed discrepancy between two approaches can be attributed to several factors. For the smallest map of 16 nodes, the major factor is the delay introduced by messages subsystem, which can introduce the delay from 5ms up to 25ms per message. On the other hand, with larger maps in which more ants are required to properly conduct the search, another major contributing factor to execution time is the number of available threads. Ant represented as an agent requires a separate thread for each agent to fully parallelize the execution of the algorithm. When working with large maps, that number can exceed the number of threads available in the appropriate thread pool (in the conducted test, Siebog had 50 threads available in the thread pool).

From the given results we can conclude that the better approach for this type of problem is the ant as a message approach. Advantage of the ant as a message is twofold. Firstly, it separates message processing from the algorithm execution, which parallelizes the task done by single map agent. Secondly, the number of messages exchanged in this approach is greatly reduced, which in turn improves the execution speed. On the other hand, ant as an agent approach can be considered as an underutilization of processing power. The processing requirements done by ant agents are not complex and require less time than it’s required by message exchange. Benefits of ant as an agent approach could only be achieved with the problems where the performed tasks, done by agents, are computationally intensive.

VI. CONCLUSION

In this paper, we have presented our attempts at improving the execution speed of a distributed agent-based ACO algorithm for TSP, designed for the Siebog multiagent middleware. During the design phase, we considered two distinct approaches in the design of our agent-based algorithm: ant as an agent and ant as a message.

Evaluation of those approaches has shown that optimizing and reducing the number of messages exchanged greatly improves the execution speed of the algorithm. Achieved results show that, with the utilization of the Siebog flexibility, the better solution for this type of problem is the realization of ant as a message.

For the future work, we intend to test and optimize the fully distributed algorithm on a Siebog cluster and compare results with other similar approaches. We believe that with further optimizations of the algorithm, combined with Siebog capabilities, we can produce competitive results.

Abstract— Automated testing in massively multi-player on-line role playing games (MMORPG) is a challenging task due to the complexity of such games and their large numbers of mutually distributed but interacting components. Large-scale multi-agent systems (LSMAS) provide us with a suitable formalism to address such complex problems. Herein a first step towards an automated game testing environment, built for the open source Mana World MMORPG, will be presented that allows the implementation of software agents and agent organizations and provide the developers with valuable game-play and testing data.

I. INTRODUCTION

Automated game testing in general, presents a challenging problem most game developers have to face eventually due to the emerging complexity of contemporary video games. Especially massively multi-player on-line games (MMO) which allow for thousands and sometimes even hundreds of thousands players playing simultaneously, are an additional challenge due to the possible mutual interactions between players, especially in the form of organizing their behaviour to perform certain game-related tasks. Additionally MMO role-playing games (MMORPG) which, beside massiveness of simultaneous players, feature also complex logical tasks or quests for the players, are even more complex for automated testing, since implemented player bots, have to perform complex reasoning and plan their actions to solve certain tasks.

While most of the literature deals with techniques of preventing automated players from playing MMO games (like [1], [2], [3]) there were only few attempts to create automated testing environments for large-scale settings. For example in [4] Jung et al. developed the VENUS simulator and present an efficient method for simulating large numbers of virtual clients in on-line games in order to ensure game stability. In [5], [6] the VENUS II system is proposed, which allows for blackbox and scenario-based testing by generating user packages based on game grammar. In this way various game scenarios can be generated and tested in the simulation environment. In [7] Mellon provides us with lessons learned from automated testing of The Sims On-line MMO game. Therein the development team used a constrained test client, based on the actual game client application, that was controlled using various scripting approaches.

Herein we will use a game logic oriented approach that, besides load and stability testing, should also allow for the testing of actual quests in a given MMORPG. All the previously outlined approaches are not developed for role-playing games (RPGs) which include complex logical quests that often foster various forms of organizing between players. Large-scale multi-agent systems (LSMAS) provide us with the necessary foundations to address such complex scenarios [8], [9], [10], [11]. For our purpose we have used the open source MMORPG called the Mana World1 in order to develop an agent based testing framework. The testing framework is part of a larger context of building a graphical modelling tool for the semi-automated development of LSMASs [12], [13], as part of the ModelMMORPG2 project. This work in progress paper shows the initial efforts in building the various components of the to be established framework.

The rest of this paper is organized as follows: firstly in section II we provide a short overview of the Mana World MMORPG game. In section III a motivation for using an agent based approach to automated testing is given. In section IV an overview of the implementation of the framework is provided. In the end in section V we draw our conclusions and give guidelines for future work in this area.

II. THE MANA WORLD

The Mana World is a free open source MMORPG which is implemented with a 2D graphics interface (see figure 1), similar to classic RPG games like Zelda or Final Fantasy.
There are several official game servers available for players to connect to, but being an open source game developed under the GPL license, it allows players to implement their own local servers by using the server source code freely available at the GitHub service.

The game itself facilitates character personalization and development, mutual interaction by using several in-game mechanisms such as chat, trade, fights, social network creation, tagging (friends/enemies), party creation, story development, quest solving, etc.

The important aspect of solving quests is to encourage players to form parties as in-game organizations within which there are internal rules, task delegations, responsibilities, interrelations and other aspects of such goal-oriented communities which all are scientifically engaging for analytical observations and represent a critical input for modeling and simulations of artificial players.

The game server used in this work is called TMW Athena, and is composed of three distinct servers:

- **Character server** – dedicated to managing characters and connecting them to the map server.
- **Login server** – dedicated to managing accounts and connecting to the character server.
- **Map server** – dedicated to managing the game content (such as monsters, items, maps, etc.) and the interaction of such game contents with the players.

Understanding the structure and the communication protocols of the client/server interaction formed the basic prerequisite for further game development and manipulation.

III. AGENT-BASED APPROACH TO AUTOMATED MMORPG TESTING

Herein we have chosen to approach the problem of automated testing of MMORPGs using LSMAS. There are several reasons for that: (1) MMORPG players are by definition distributed entities that interact, compete, collaborate and organize – a definition that closely matches the one of (artificial) agents, (2) MMORPG players have to solve complex tasks in forms of puzzles and quests indicating reasoning capabilities as of intelligent agents, (3) MMORPG avatars are situated in a predefined but complex environment in which they have to act both reactively and proactively in order to achieve game objectives, as do agents in (more or less) realistic environments.

In the mentioned ModelMMORPG project we have partially developed an organizational ontology and metamodel for graphical modelling of LSMAS (see for example [14], [15], [8]) that allows for modelling a wide range of various LSMAS scenarios. Automated testing of MMORPGs is one such scenario, as we will show further.

IV. IMPLEMENTATION

The testing framework consists of three logical layers: (1) a lower-level interface (dealing with the technical implementation of the Mana World client network protocol), (2) a higher-level interface (implementing actual agent classes, agent behaviours, roles, agent communication, agent reasoning, knowledge bases etc.), and (3) a modelling tool (allowing for graphical modelling of tests and generating agent implementation stubs to be developed further for individual test).
These three layers are described in more detail in the following subsections.

Our approach in developing tests is loosely a top down approach. Firstly, agent organizations, which represent the various players' forms of organizing (e.g. guilds, parties, etc.) are modelled using a graphical modelling language that we have developed. Then the model is translated into a concrete implementation of agent classes facilitated through and agent-based platform called SPADE (Smart Python Agent Development Environment) [16]. These agent classes, are then extended with low-level game client methods that allow various game related tasks like walking around, picking up items, fighting etc., to be performed by agents.

A. Lower-level Interface

The lower-level interface was loosely based on an old Python script used to implement bots for the Mana World. The script has been rewritten in full and extended with multiple details of client implementation in order to allow agents to connect to the game server, create avatars, and perform all relevant tasks to be able to solve quests.

figure 2 shows a sample session of the lower-level interface. The provided screenshots illustrate changing Python player coordinates by using the "setDestination" function of the "Connection" class.

The following listing shows the actual implementation of the Python function which enables the basic navigation of the character on the loaded map by using two-dimensional coordinate values.

```python

```def` setDestination(self, x, y, direction):
    """Set destination (walk to given x, y coordinates with orientation direction like in setDirection)""
    debug("SET_DESTINATION")
    debug("X: %d" %x)
    debug("Y: %d" %y)

    data = bin(x)[−10:].replace('b', '0').rjust(10).replace('0', 'b') + bin(y)[−10:].replace('b', '0').rjust(10).replace('0', 'b') + bin(direction)[−4:].replace('b', '0').rjust(4).replace('0', 'b')

    data = data[:8], data[8:16],
    data = [int('0b' + i, 2) for i in data]

    b1, b2, b3 = data
```

B. Higher-level Interface

The higher-level interface is being developed using the mentioned SPADE platform in Python. It currently features basic agent classes, agent behaviours and communication facilities to allow agents to organize mutually. The agent classes closely resemble a BDI (belief-desire-intention) architecture in which agents act based on their beliefs (knowledge about the world they live in), desires (objectives they want to pursue) and intentions (plans and commitments on achieving objectives through acting upon the environment).

The knowledge about the Mana World is stored in a specially developed [10] SWI Prolog knowledge base that can be directly accessed by the agent through its knowledge base interface.3

The knowledge base also featured an automated planner based on the STRIPS algorithm [17]. In the planner all quests are coded in form of STRIPS rules comprising three parts: (1) preconditions – statements that have to be true about the world in order for the rule to be applicable, (2) deletions – statements that won’t be true about the world when the rule is executed, and (3) insertions – statements that will become true about the world only after the rule has been executed. In this way game related quests can be modelled quite easily, for example to solve a quest in which the player has to buy a certain item from some NPC (non-playing character) for a certain amount of money a rule would include the following statements:

- **Preconditions**: player has enough money, player is within reach of the NPC
- **Deletions**: player hasn’t the payed money any more
- **Insertions**: player has acquired the wanted item.

The planner also features a list of quests to be solved, which is queried by the player agent every time the environment is updated in order to test if the preconditions of a certain quest to be solved are met. If this is the case, the agent tries to solve the quest, else the quest is put back into the list for a later time. In case the agent doesn’t have any quests to be solved it does a random walk in the environment to find an NPC and get an actual quest.

C. Graphical Modeling Tool

The basis of the system of agents using the mentioned interfaces, allowing them to communicate with the game engine, is, in the context of this paper and the accompanying research, constructed using a customized graphical modelling tool.4

The modeling tool, in its present work-in-progress version, provides the user with functionalities that allow them to model

3SPADE allows for using SWI, XSB, eCLiPSe, Flora-2, SPARQL and integrated first-order logic knowledge-bases.

4The model is available at https://github.com/Balannen/LSMASOMM
Fig. 2: Manipulating player coordinates with the Python client

a system comprising agents, groups of agents, roles as special types of grouped constraints, actions granted to individual agents upon playing a specific role, sets of actions designated as processes that are poised to fulfill specific goals, and quests (in-game goals) that consist of a series of subgoals or tasks that are reachable by a specific combination of processes, i.e. action sets.

The elementary concept of such a model, applicable to the example shown in this paper, is an organisational unit representing an individual agent. Since the idea of roles is integral to the organizational approach which, in turn, is in the basis of the models developed for the mentioned modelling tool, roles are a de facto central elements of a model. Figure 3 shows a situation that is possible within The Mana World game, detailed as follows. Individual agents, shown yellow in Fig. 3, are modeled following the tabula rasa idea, i.e. the only behavior they possess at this stage of the metamodel is intended for changing roles, thus gaining new actions. It is useful to note here that the element named Player in Fig. 3 represents a class of individual players, i.e. individual agent-players will be instantiated at runtime. Those individual players can form groups (most commonly called parties in an MMORPG) that utilize cooperative power of players. Each player can play a number of roles (e.g. Herbalist, Scout, Warrior), shown in blue in Fig. 3, at the moment constrained to one at any given point in time. The roles shown in Fig. 3 provide players with actions needed to successfully complete tasks (shown in red in Fig. 3) that form the quest called The Quest for the Dragon Egg (the topmost red element in Fig. 3).

One of the novel features in the context of LSMAS models and modeling tools, that this particular tool provides, even though only in initial stages at the moment, is SPADE code generating functionality. This functionality, still in a work-in-progress state, generates basic code, i.e. a code skeleton, for the modeled system, thus giving the model users basic overview of their system, and advanced system functionalities not explicitly visible in the model, e.g. system and services for agents’ role changing actions and utilization of available knowledge on ways of solving quests based on their respective wanted tasks.

V. CONCLUSION & FUTURE WORK

In this work-in-progress paper we have presented the current state of implementation of an agent-based automated MMORPG testing system using a game-oriented approach. As opposed to most other approaches, the proposed system will allow for testing game-logic by implementing agents that use a specially created knowledge-base to be able to solve quests in the selected MMORPG called the Mana World. We believe that this approach can be extended to any MMORPG, given that the various quests or rules of the game can be coded into a new knowledge base.

Currently the proposed system comprises three components: (1) a lower-level interface, (2) a higher-level interface, and (3) a graphical modelling tool. Whilst the lower-level interface is fully developed at the time of writing this paper, the other two components are still being tested and developed further. Especially, in the higher-level interface, the connection between an agent’s perception of the environment and the knowledge base has to be improved, so that agents can rely on up-to-date information from the environment. The modelling tool features necessary concepts for successful description of a system, but even slightly complex systems cause a cluttered and unfriendly interface. Therefore a multi-perspective modeling approach has to be enabled, allowing users to develop a model on various levels presented by different models. The code generating feature has to be upgraded appropriately to conform to the idea of multi-model modeling. Lastly, one of the foreseen improvements of the modelling tool is introduction of concepts for modelling additional selected organizational features of the system. These and similar tasks are part of our future work.
ACKNOWLEDGMENT

This work has been supported in full by the Croatian Science Foundation under the project number 8537. We would also like to acknowledge the Mana World development team which often helped us with various implementation specific details.

On the Properties of Discrete-Event Systems with Observable States

Nadezhda Nagul
Matrosov Institute for System Dynamics and Control Theory, Siberian Branch of the Russian Academy of Science, Lermontov str., 134, 664033 Irkutsk, Russia
Email: sapling@icc.ru

Abstract—We address the issue of study the properties of discrete-event systems (DES) with partially observed events and observable states. Two ways of introducing state observations in the system are considered. To show that properties of languages generated by DES, which are essential for constructing supervisors to control DES behavior, such as controllability and observability, are preserved after this transformation, the method of logical-algebraic equations (LAE-method) is exploited. The LAE-method allows one to examine preservation of property of system under morphism-like mapping to another system that is usually more complex than the original system. Thus, once the property is proved to be valid in the original system, it is immediately valid in another.

I. INTRODUCTION

This paper is a continuation of the previous work [1] presented an application of the method of logical-algebraic equations (LAE-method) to the field of discrete-event systems (DES), in particular, for studying properties of supervisors for controlled partially observed DES. Widely used, DES describe system evolution by considering the occurrence of some event sequences. The development of DES theory is driven by the rapid progress of manufacturing systems and communication networks, technological processes, transportation networks, automated and robotic systems, and others, primarily man-made systems. To regulate DES behavior, the Ramadge-Wonham framework of supervisory control is commonly used, adopting ideas from logic, language and automaton theory.

Since in practice only a part of system behavior may usually be observed and used to generate proper control action, the concept of observability plays an important role in supervisory control theory. Initially RW-supervisory control was language based, so the concept of observability was applied to events only and information on states was not used to form control patterns. However, it is often the case that sensors monitor system states as well as changes of those states, usually interpreted as events. In robotics applications observations made by sensory measurements monitoring environment or observations of effects of control actions on system state are presented as observable uncontrollable events [2]. So taking state observations into account seems useful. Even so, there are various ways to take state observations in consideration, and two of them are suggested in [3] and [4]. While the latter uses state observations for the purpose of control and demonstrates that supervisor existence and constructing problem for DES with event and state observation may be reduced to the same problem in the context of event observation only, the former embraces them for fault events diagnosis. In [1] supervisor non-rejecting property preservation for the model from [4] has been considered. In what follows we examine both models using the the method of logical-algebraic equations (LAE-method).

Lying at the intersection of system dynamics, algebra and logic, the LAE-method is a method of mathematical systems theory which serves to synthesize criteria for preservation properties of systems connected by special mappings called morphisms. One of the main applications of the preserving criteria obtained is the reduction of studying some complex system, say $S$, to studying a much simpler one, say $S'$. To exploit the LAE-method [5], a property of the system under consideration is treated as a property of an algebraic system, name it $\mathfrak{A}$. Due to the complex nature of dynamical systems, the process of algebraizing of their models usually leads to many-sorted algebraic systems (MAS) where the basic sets have the meaning of a state space, a time scale, etc. Moreover, in [5] the notion of a general many-sorted algebraic system of finite type (GMAS) $\mathfrak{A} = \langle A, \Omega_F, \Omega_P, \Omega_E \rangle$ was introduced, where $A = \{ A_\lambda | \lambda = 1, k \}$ is a family of basic sets, $\Omega_F = \{ F_\beta | A \} \times \{ S_\beta | A \} \times \{ S_n | A \} \rightarrow S_{n+1}|A \}, \beta = 1, k, F \}$ a set of functions, $\Omega_P = \{ P_\gamma A \} \times \{ T_\gamma A \} \times \{ T_n A \}, \gamma = 1, k, P \}$ a set of relations, $\Omega_E = \{ E_{\delta} | U_{\delta} A \}, \delta = 1, k, E \}$ a set of distinguished elements. The elements of the set $\Omega_{F \cup \Omega_P \cup \Omega_E}$ are defined on extended Bourbaki steps $S[A]$ over the family $A$. Omitting detailed description of the extended step notion, note that step is a set formed from the basic sets $A_\lambda$ with the help of operations of cartesian product, boolean and sequence forming, called schemes [1], [5].

Let a family of mappings $\varphi = \{ \varphi_\lambda A \lambda \rightarrow A'_\lambda, \lambda = 1, k \}$, (1) maps the basic sets of GMAS $\mathfrak{A}$ to the basic sets $A' = \{ A'_\lambda | \lambda = 1, k \}$ of the GMAS $\mathfrak{A}' = \langle A', \Omega_F', \Omega_P', \Omega_E' \rangle$ which is of the same type as $\mathfrak{A}$. The “same type” means that the powers of the sets $A$ and $A'$, $\Omega_F'$ and $\Omega_F$, and so on accordingly match, and the step $S'_{1\beta}[A']$ respectively from the sets $A'_\lambda$ with the same scheme as $S_{1\beta}[A]$ ($S_{2\beta}[A]$, $T_{1\gamma}[A]$, $U_{\delta}[A]$ respectively) from the sets $A_\lambda$.

The LAE-method considers either a logical-algebraic equation $X_{\land} F \Rightarrow F'$ or $X_{\land} F' \Rightarrow F$. Here $F$ is a formula

MIPRO 2017/CIS
1367
predicate which describes the studied property of the system \( \mathcal{A} \), \( \mathcal{F}' \) is a property of another algebraic system \( \mathcal{A}' \) corresponding to the system \( \mathcal{S}' \), and \( \mathcal{X} \) is the subject for searching. The second equation corresponds to the case of preservation of the property in the direction which is opposite to the direction of mappings \( (1) \). We describe the considered system property with a formula predicate \( \mathcal{F} \frac{df}{ \equiv } \mathcal{F}(x_1, \ldots, x_p) \) of the signature \( \sigma \) of the chosen GMAS \( \mathcal{A} \), where \( x_\mu \) is a free variable, \( \mu = 1, p, p \geq 0 \). Without loss of generality, the formula \( \mathcal{F} \) is considered to be formed of literals (concluding statements, or c-formulas) \( \mathcal{F}' \), that is, atomic formulas \( \mathcal{F}'_\varepsilon \) or their negations \( \mathcal{F}'_\delta \), with the help of connectives \( \& \), \( \lor \), and type quantifiers \( \alpha \frac{df}{ = } \forall z_\alpha : Z_\alpha \frac{df}{ = } \forall z_\alpha (Z_\alpha \Rightarrow \lor) \) (universal type quantifier), \( \alpha \frac{df}{ = } \exists z_\alpha : Z_\alpha \frac{df}{ = } \exists z_\alpha (Z_\alpha \& \lor) \) (existential type quantifier), \( \alpha = \Gamma, n, \nu = \Gamma, M \). Such formulas, unlike positive formulas used, for example, in general algebraic system theory, are referred to as \textit{generalized positive formulas}.

A solution, name it \( \mathcal{R} \), of the chosen LAE is constructed algorithmically. Such a solution in place of \( \mathcal{X} \) guarantees preserving the truth values of formula predicate \( \mathcal{F} \) under the mappings of many-sorted algebraic system \( \mathcal{A} \) to \( \mathcal{A}' \). \( \mathcal{R} \) is constructed in the form of traditional morphisms, i.e. it is of the meaning of preservation operations and relations only. Morphisms of dynamical systems proved to be especially useful, for example, for those procedures of studying stability and other dynamic properties that require changing variables, since we should ensure that the property under consideration in old variables is equivalent to that one in new variables, or at least guarantee its unidirectional preservation. In [6] classes of properties which are preserved by the morphisms of the same class were defined. Exploiting these results, in what follows a connection between properties which are basic for supervisory control implementation, of specification languages for DES with event and state observation and specification languages for a common DES, will be investigated.

II. The notion of controlled DES

Let \( \mathcal{G} = (Q, \Sigma, \delta, g_0, Q_m) \) be a discrete event system modeled as a generator of a formal language [7]. Here \( Q \) is the set of states; \( \Sigma \) is the set of events; \( \delta : \Sigma \times Q \rightarrow Q \) the transition function; \( g_0 \in Q \) the initial state; \( Q_m \subset Q \) the set of marker states. As usual, \( \Sigma^* \) denote the set of all strings over \( \Sigma \), including the empty string \( \varepsilon \). Function \( \delta \) is naturally extended on strings. Language generated by \( \mathcal{G} \) is \( L(\mathcal{G}) = \{ w : w \in \Sigma^* \} \) and \( \delta(w, g_0) \) is defined), while language marked by \( \mathcal{G} \) is \( L_m(\mathcal{G}) = \{ w : w \in L(\mathcal{G}) \} \) and \( \delta(w, g_0) \in Q_m \).

The Ramadge–Wonham supervisory control framework assumes the existence of a means of control \( \mathcal{G} \) presented by a supervisor [7]. Let \( \Sigma_c \) be arollable event set, \( \Sigma_{uc} = \Sigma \setminus \Sigma_c \), \( \Sigma_c \cap \Sigma_{uc} = \emptyset \). The supervisor switches control patterns so that the supervised discrete event systems achieve a control objective described by some regular language \( K \). Let \( \mathcal{G} \) be partially observable, i.e. a set \( \Sigma_o \) of observable events is distinguished from all events, \( \Sigma_{uo} = \Sigma \setminus \Sigma_o \), \( \Sigma_c \cap \Sigma_{uo} = \emptyset \). The observation function is usually defined as the natural projection \( P : \Sigma^* \rightarrow \Sigma_o^* \) which just erases unobservable events. The supervisor observes only events from the \( \Sigma_o \) and, basing on this information, disables events in \( \Sigma_o \). Formally, a supervisor is a pair \( \mathcal{J} = (\mathcal{S}, \phi) \) where \( \mathcal{S} = (X, \Sigma_o, \xi, x_0, X_m) \) is a deterministic automaton with input alphabet \( \Sigma_o \), \( \mathcal{S} \) is considered to be driven externally by the stream of observable event symbols (words) generated by \( \mathcal{G} \) (i.e. words from \( P(L(\mathcal{G})) \)), while \( \phi : X \rightarrow \Gamma \) is a function that maps supervisor states \( x \) into control patterns \( \gamma \in \Gamma \subseteq 2^\Sigma \). If \( \sigma \in \gamma = \phi(x) \), then \( \sigma \) is enabled, while if \( \sigma \notin \phi(x) \) then \( \sigma \) is disabled (prohibited from occurring). Note that, unlike DES models with forced events, enabled events should not necessarily occur. Because uncontrollable events cannot be disabled, it is required \( \Sigma_{uc} \subseteq \gamma = \phi(x) \).

Extend the function \( \delta \) to the function \( \delta_e : \Gamma \times \Sigma \times Q \rightarrow Q \) assigning control patterns as

\[
\delta_e(\gamma, \sigma, q) = \begin{cases} 
\delta(\sigma, q), & \text{if } \delta(\sigma, q) \text{ is defined and } \sigma \in \gamma; \\
\text{undefined, otherwise.} & \text{if } \delta(\sigma, q) \text{ is defined and } \sigma \notin \gamma.
\end{cases}
\]

Construct the function \( \xi \times \delta_e : \Sigma \times X \times Q \rightarrow X \times Q \), where \( (\xi \times \delta_e)(\sigma, x, q) = (\xi(\sigma, x), \delta_e(\phi(x), \sigma, q)) \) is defined if \( \delta_e(\sigma, q) \) is defined, \( \sigma \in \phi(x) \) and \( \xi(\sigma, x) \) is defined. Denote \( L(\mathcal{J}/\mathcal{G}) \) a language generated by the closed-looped behavior of the plant and the supervisor: \( L(\mathcal{J}/\mathcal{G}) = \{ w : w \in \Sigma^* \} \) and \( \xi \times \delta_e(w, x, q) \) is defined. Let \( L_m(\mathcal{J}/\mathcal{G}) \) denote the language marked by the supervisor: \( L_m(\mathcal{J}/\mathcal{G}) = \{ w : w \in L(\mathcal{J}/\mathcal{G}) \} \) and \( \xi \times \delta_e(w, x, q_0) \in X_m \times Q_m \).

Supervisory control and observation problem. Given a plant \( \mathcal{G} \) over an alphabet \( \Sigma \), a language \( L_A \subseteq L(\mathcal{G}) \), a language \( L_E \subseteq L(\mathcal{G}) \), and sets \( \Sigma_o, \Sigma_c \subseteq \Sigma \), construct a supervisor \( \mathcal{J} \) for \( \mathcal{G} \) such that \( L_A \subseteq L(\mathcal{J}/\mathcal{G}) \subseteq L_E \).

Since the above problem face high computational complexity, it is often substituted by the less complex problem of finding such control patterns that the language marked by the supervisor is equal to some required language. Thus, the special case of the supervisory control and observation problem is to construct such supervisor that \( L_m(\mathcal{J}/\mathcal{G}) = K \) where \( K \) is called a \textit{specification language}. The notions of controllable and observable languages are essential in solving this problem.

Let \( L \subseteq \Sigma^* \). The \textit{closure} of \( L \) is the set of all strings that are prefixes of words of \( L \), i.e. \( \overline{L} = \{ s | s \in \Sigma^* \text{ and } \exists t \notin \Sigma^* : s \cdot t \in L \} \). Symbol \( \cdot \) denotes string concatenation and is often omitted. A language \( L \) is closed if \( L = \overline{L} \). If \( \mathcal{G} \) is any generator then \( L(\mathcal{G}) \) is closed.

\textit{Definition 1 ([7])}: \( K \) is controllable (with respect to \( L(\mathcal{G}) \) and \( \Sigma_{uc} \)) if

\[
\overline{K \Sigma_{uc} \cap L(\mathcal{G})} \subseteq K.
\]

We have that \( K \), thinking of it as the admissible behavior of the system, is controllable if occurring of any uncontrolled event after prefix of the word from \( K \) leads to a word from \( K \), i.e. still admissible.

\textit{Definition 2 ([4])}: \( K \) is observable (with respect to \( L(\mathcal{G}) \) and \( P \)) if

\[
\forall s, t \in \Sigma^* (P(s) = P(t) \rightarrow \text{consis}(s, t)),
\]
\( (\forall \sigma \in \Sigma)(s\sigma \in K \& t\sigma \in L(G) \& t \in K \rightarrow t\sigma \in K) \).

Definition of observability means that if two strings look the same, then they must be consistent in the sense that no conflict of one event continuability after one string but not continuable after the other should occur. Supervisor existence criterion sounds as follows: given \( K \subseteq L(G) \), there exists supervisor \( J \) such that \( K = L_m(J/G) \) iff \( K \) is controllable and observable w.r.t. \( L(G) \) and \( P \). Note that it is also required \( K \) to be \( L_m(G) - \text{closed} \), i.e. \( K = K \cap L_m(G) \) \([7]\).

III. DES with State Observation

Assume that in addition to event observation, supervisor also possesses some information on the states of \( G \), provided by some sensors installed in the system of interest. For a given string generated by \( G \), there is a unique sequence of states visited by this string. Define \([3]\) the sensor maps \( h_j : Q \rightarrow Y_j \), \( j = 1, M \), where \( M \) is the number of sensors, \( Y_j \) is a set of outputs of \( j\)-th sensor, and a global sensor map defined as \( h(q) = (h_1(q), h_2(q), \ldots, h_M(q)) \). To use sensor information \( G \) may be transformed to a new system \( \tilde{G} \) where sensor outputs are explicitly exploited. In \([3]\) this transformation is as follows. Let \( q' = \delta(q, \sigma) \) with \( q, q' \in Q, \sigma \in \Sigma, h(q) = y, h(q') = y' \). Then

1. if \( \sigma \in \Sigma_o \) then \( \sigma \) is replaced with the new event \( \langle \sigma, y' \rangle \) and let \( \tilde{\delta}_1(q, \langle \sigma, y' \rangle) = q' \);  
2. if \( \sigma \in \Sigma_{uo} \) and \( y = y' \), then \( \sigma \) is left unchanged in \( \tilde{G} \) and \( \tilde{\delta}_1(q, \sigma) = q' \);  
3. if \( \sigma \in \Sigma_{uo} \) and \( y \neq y' \), then new event \( \langle y \rightarrow y' \rangle \) and new state \( q_{new} \) are introduced and let \( \tilde{\delta}_1(q, \sigma) = q_{new} \) and \( \tilde{\delta}_1(q_{new}, \langle y \rightarrow y' \rangle) = q' \).

Define \( Q_{new} = \{ q_{new} \} \), \( |Q_{new}| \leq |Q| \). Let \( \tilde{G}_1 = (\tilde{Q}_1, \tilde{\Sigma}_1, \tilde{\delta}_1, \tilde{q}_{0,1}, \tilde{Q}_{m,1}) \) with \( Q_1 = Q \cup Q_{new} \), \( \Sigma_{uc,1} = \Sigma_c \), \( \Sigma_{uo,1} = \Sigma_{uo} \) and \( \tilde{\Sigma}_1 = \{ \sigma, y', \langle y \rightarrow y' \rangle \} \) where \( \sigma \in \Sigma_o \), \( y \neq y' \), \( q_{0,1} = q_0 \), \( \tilde{Q}_{m,1} = Q_m \), and \( \tilde{\delta}_1 \) is constructed according to rules 1) – 3) above.

In \([4]\) for the supervisor construction problem \( G \) is modified in the other way. For each \( q \in Q \) new state \( q_{new} \) is defined. Let \( \tilde{\Sigma}_2 = \Sigma \cup Y, \tilde{Q}_2 = Q \cup Q_{new}, \tilde{Q} = \tilde{Q}_2 \cup Y \), \( |Q| = |Q_{new}| \) and given \( \delta(q, \sigma) = q', h(q) = y \), define \( \tilde{\delta}_2 \) according to rules:

1. \( \tilde{\delta}_2(q, \sigma) = q_{new} \) for \( \sigma \in \Sigma, q \in Q \), whenever \( \sigma \) is observable or not;  
2. \( \tilde{\delta}_2(q, y) = \tilde{\delta}_2(q, \sigma) = q \) for \( q \in Q \);  
3. \( \tilde{\delta}_2(q_{new}, y) = q_{new} \) for \( q_{new} \in Q_{new} \);

and everything else is undefined. The artificial events in \( Y \) are considered to be observable and uncontrollable. Denote \( \tilde{G}_2 = (\tilde{Q}_2, \tilde{\Sigma}_2, \tilde{\delta}_2, \tilde{q}_{0,2}, \tilde{Q}_{m,2}) \) a DES with \( \tilde{\Sigma}_2 = \tilde{\Sigma}_o \cup \tilde{\Sigma}_{uo}, \tilde{Q}_{m,2} = \tilde{Q}_m \cup Y, \tilde{\Sigma}_{uo} = \tilde{\Sigma}_{uo} \cup \tilde{\Sigma}_{uc,2} = \tilde{\Sigma}_{uc} \cup Y, \tilde{q}_{0,2} = q_{0,new}, \tilde{Q}_{m,2} = Q_m, \) and \( \tilde{\delta}_2 = (\tilde{\Sigma} \cup Y) \times (Q \cup Q_{new}) \rightarrow Q \cup Q_{new} \) is constructed according to rules 1') – 3') above.

To compare these two constructions consider Fig.1, there a part of an automaton for \( G \) is presented. Fig. 2 presents modifications \( \tilde{G}_1 \) and \( \tilde{G}_2 \) for \( G \).

Here only \( \sigma_1 \) is observable, \( y_1 = y_2, y_2 \neq y_3 \). Note that structure of \( \tilde{G}_2 \) is not affected by observational properties of events or equality of outputs. If a word \( v = w\sigma_1\sigma_2\sigma_3 \) is generated by \( G \) which gives observation \( P(v) = P(w)\sigma_1y_1y_3 \), then \( \tilde{G}_1 \) gives the string \( v_1 = w(\sigma_1, y_2)\sigma_2\sigma_3(y_2 \rightarrow y_3) \), or projection \( P(v_1) = P(w)\sigma_1y_2y_3 \). It should be noted that appearance of \( y_1 \) in \( v_1 \) depends on previous string \( w \). For the same string \( \tilde{G}_2 \) gives \( v_2 = w(\sigma_1, y_1)\sigma_1y_2(\sigma_2y_2)^*y_2(\sigma_3y_3)^*y_3 \) and a projection \( P(v_2) = P(w)\sigma_1y_2y_3 \) if we unable to recognize multiple occurrence of the same outputs.

The example shows that approaches providing \( \tilde{G}_1 \) and \( \tilde{G}_2 \) are quite close. Since the latter one is more stable in the sense of generator structure, in what follows we focus on it, leaving the former one for future investigation.
output $y$ is inserted before each occurrence of event. Such supervisor realizes a mapping $\theta_e : P(L(\tilde{G}_2)) \rightarrow 2^{\Sigma_L \cup Y}$. Note that the language generated and marked by $\tilde{G}_2$ may be defined via the language generated and marked by $G$ [4]. For this define $e : \Sigma^* \rightarrow (\Sigma \cup Y)^*$ as follows:

$$e(\varepsilon) = h(q_0),$$
$$e(w \sigma) = e(w) \sigma h(\delta(w \sigma, q_0)),$$

which is different from [4] but we believe it is more correct. Here, unlike [4], we do not repeat insertion of the output, since it is redundant to form control pattern. The following lemma may be easily proved in the same way as in [4].

**Lemma 1:** If $L(G)$ is not empty, then

1. $L(\tilde{G}_2) = e(L(G))$,
2. $T(L(\tilde{G}_2)) = L(G)$,
3. $L_m(\tilde{G}_2) = e(L_m(G))$,

where $T : (\Sigma \cup Y)^* \rightarrow \Sigma^*$ is the projection.

Let $K$ be a nonempty language that describes, for instance, the control objective for the system modeled by $G$. In [4] it is suggested to extend $K$ till language $K_s$, such that

$$K_s = T^{-1}(K) \cap L_m(G).$$

**Lemma 2:** [4] Assume that $K$ is $L_m(G) - closed$. Then

1. $K_s = T^{-1}(K) \cap L_m(\tilde{G}_2)$,
2. $K_s = \bar{K} \cap L_m(\tilde{G}_2)$,
3. $T(K_s) = \bar{K}$.

In order to include state observation in $G$ directly, the observation mapping may be presented by the extended projection $\hat{P} : L(G) \rightarrow ((\Sigma_0 \cup \{\varepsilon\}) \times Y)^*$ recursively defined as

$$\hat{P}(\varepsilon) = (\varepsilon, h(q_0)),$$
$$\hat{P}(w \sigma) = \hat{P}(w)(P(\sigma), h(\delta(w \sigma, q_0))).$$

Again, unlike [4], multiple occurring of the artificial events corresponding to the output is not included in this definition. Only one pair $(\sigma, y) \in \Sigma \times Y$ is added to the observation sequence, since adding more than one output is redundant for control purposes. Since $S$ is now driven by the words of $L(G)$ after observation provided by extended projection, a supervisor realizes a mapping $\theta_e : \hat{P}(L(G)) \rightarrow 2^{\Sigma_c}$. Here $\theta_e(\hat{P}(w))$ is interpreted as a set of events enabled by $\theta_e$ after observing $\hat{P}(w)$, $w \in L(G)$. $\theta_e$ should guarantee that $L_m(\theta_e/\tilde{G}) = K_s$. In [4] it was proved that non-blocking $\theta_e$ such that $L_m(\theta_e/\tilde{G}) = K_s$ exists iff $\theta_e$ such that $L_m(\theta_e/\tilde{G}) = K_s$ exists and an existence condition for $\theta_e$ is expressed in terms of controllability and observability of $K_s$. In the next section we use the LAE-method to show the connection between these two properties of $K$ and $K_s$ because they are basic for supervisor existence.

**IV. LANGUAGE PROPERTIES PRESERVATION**

**A. Controllability**

The definition of controllability plays a key role in characterizing those languages that can be generated by the closed-loop structure plant–supervisor. Controllability property (Definition 1) may be expressed with the formula of the first-order predicate calculus language

$$\forall w \in \bar{K} \forall \sigma \in \Sigma_{uc}(w \cdot \sigma \in L(G) \rightarrow w \cdot \sigma \in \bar{K}).$$

(2)

Transform (2) to a generalized positive form and in the notation of the language $L(G)$ because we are going to consider LAE $\forall K \forall F' \Rightarrow F$ with $F$ describing controllability of the language $K_s$ w.r.t. $L(\tilde{G}_2)$ which will be denoted from now on as $L(G_s)$ for simplicity. This leads to the formula

$$F_1 = \forall w_s : \bar{K}_s(w_s) \forall \sigma_s : \Sigma_{uc}(\sigma_s) (\neg L(G_s)(\neg(w_s, \sigma_s)) \lor \forall \bar{K}_s((w_s, \sigma_s))).$$

(3)

In what follows we do not distinguish relations and predicate symbols, i.e. $\bar{K}_s(w_s)$ is true iff $w_s \in \bar{K}_s$. While in general DES is treated as a many-sorted algebraic system with the sets of events, states and so on as basic sets, the property of controllability may be dealt with as the property of the single-sorted algebraic system $A = \{\Sigma, \Omega_F, \Omega_p, \Omega_E\}$, where $\Sigma = \{\Sigma \cup Y\}$, $\Omega_F = \{\}$, $\Omega_p = \{K_s, \Sigma_{uc}, L(G_s)\}$, $\Omega_E = \emptyset$. But nevertheless it remains general. Indeed, since $\bar{K}_s, L(G_s) \subseteq (\Sigma \cup Y)^\Omega$, the scheme $\hat{N}(a)$ is associated with the predicates $\bar{K}_s$ and $L(G_s)$. Therefore the operation of a sequence forming, corresponding to the scheme $\hat{N}(a)$ [5], is used to build $A$, which is a specific feature of GMAS.

Let $A' = \{\Sigma', \Omega'_F, \Omega'_p, \Omega'_E\}$ be the GMAS of the same type as $A$ with $\Sigma' = \{\Sigma\}$, $\Omega'_F = \{\}$, $\Omega'_p = \{\bar{K}_s, \Sigma_{uc}, \bar{L}(G)\}$, $\Omega'_E = \emptyset$. i.e. $F'$ describe controllability of the language $K$ w.r.t. $L(G)$. The family of mappings (1) then consists of a single function

$$\varphi : \Sigma \cup Y \rightarrow \Sigma.$$
2) \( \mathcal{I} = \bigcup_{S[A]} \mathcal{I}_S[A] \), where \( S[A] = |v| \), \( v \) are all variables \( z_\beta \) or \( x_\mu \) that enter the equalities \( z_\alpha \equiv v \), which are included in c-statements \( = \) or type conditions of the universal quantifiers \( \exists z_\alpha \), and \( z_\alpha \) is a defining variable;

3) \( \Omega_{P^+} \setminus \Omega_{P^+} = \emptyset \).

Recall that \( z_\alpha \) is called a defining variable, if in \( \mathcal{F}(\pi) \) the domain of the type quantifier \( z_\alpha \) is larger than the domain of the type quantifier of the variable \( v \). If \( v = x_\mu \) then defining variable is \( z_\alpha \). The \( t_1 \equiv t_2 \) denote any of the equalities \( t_1 = t_2 \) or \( t_1 = t_2 \), while symbol \( = \) (resp. \( = \)) denote entrance of the symbol = in positive (resp. negative) literal (c-formula) of the initial formula \( \mathcal{F}(\pi) \). The formula (3) obviously belongs to \( \mathcal{MI}_\rightarrow \) class. It does not contain equalities so the set \( S[A] \) in this case is empty.

Definition 4: Let \( \Theta \) be a set of relation symbols, \( \Theta \subseteq \Omega_P \).

The family of mappings (1) is said to be \( \mathcal{I} \)-injective \( \Theta \)-homorphism GMAS \( \mathfrak{A} = \langle A, \Omega_P, \Omega_{P^+}, \Omega_E \rangle \) to \( \mathfrak{A}' = \langle A', \Omega'_P, \Omega'_{P^+}, \Omega'_E \rangle \), if

1) \( \langle \varphi \rangle S_{n+1, \beta}[A](P_{n+1}^\theta(z_1, \ldots, z_n)) = \langle \varphi \rangle S_{n+1, \beta}[A](z_1, \ldots, z_n) \) for all \( z_1 \in S_1[\beta], \ldots, z_n \in S_n[\beta, A], \beta = \overline{1,F}; \)

2) \( \langle \varphi \rangle T_{1}[A] \times \ldots \times T_{n, \gamma}[A](P_{n, \gamma}) = \langle \varphi \rangle T_{1}[A] \times \ldots \times T_{n, \gamma}[A](P_{n, \gamma}); \)

and for all \( \gamma = \overline{1, k_F} \)

\( \langle \varphi \rangle T_{1}[A] \times \ldots \times T_{n, \gamma}[A](P_{n, \gamma}) \subseteq \langle \varphi \rangle T_{1}[A] \times \ldots \times T_{n, \gamma}[A](P_{n, \gamma}); \)

if \( P_{n, \gamma} \) correspond to a predicate symbol \( P_\gamma \in \Theta \),

\( \langle \varphi \rangle T_{1}[A] \times \ldots \times T_{n, \gamma}[A](P_{n, \gamma}) \)

if \( P_{n, \gamma} \) correspond to a predicate symbol \( P_\gamma \in \Omega_P \setminus \Theta \), and mappings \( \varphi_\lambda \) are injective for all \( \lambda \in \mathcal{I} \).

Theorem 1 (6f): Let \( \mathcal{F}(x_1, \ldots, x_q) \) be a formula of the class \( \mathcal{MI}_\rightarrow \) with free variables \( x_1, \ldots, x_q, q \geq 0 \). Then satisfiability of \( \mathcal{F}(f(x_1), \ldots, f(x_q)) \) implies satisfiability of \( \mathcal{F} \) under \( \mathcal{I} \)-injective \( \Omega_{P^+} \setminus \Omega_{P^+} \)-homorphism of GMAS \( \mathfrak{A} \) to GMAS \( \mathfrak{A}' \).

Symbol \( \varphi[x_1](x_i) \) denotes the canonical expansion of mappings (CEM) \( \varphi \) on the step \( S[A] = [x_i] \) to which variable \( x_i \) belong [5]. To use Theorem 1 for obtaining conditions for the controllability property preservation it is necessary to show that (4) may be specified as \( \Omega_{P^+} \setminus \Omega_{P^+} \)-homorphism. Let us start with condition 1) of Definition 4. The functional symbol \( \cdot \) is associated with triple occurring of the scheme \( N(a) \), and for all \( v_s, w_s \in (\Sigma \cup Y)^N \) an equality

\[ \varphi[N(v_s \cdot w_s)] = \varphi[N(v_s)] \cdot \varphi[N(w_s)] \]

should be valid, since the operation of concatenation is the same in both \( \mathfrak{A} \) and \( \mathfrak{A}' \). It actually has a place 1) if we define \( \varphi \) in as follows:

\[ \varphi(\sigma_s) = \begin{cases} \sigma, & \text{if } \sigma_s \in \Sigma; \\ \varepsilon, & \text{if } \sigma_s \in Y, \end{cases} \]

where \( \varepsilon \) is an empty string, or null event. This definition obviously corresponds to the projection \( T : (\Sigma \cup Y)^* \rightarrow \Sigma^* \).

Since for \( (3) \Omega_E = 0 \), we skip the condition 2) and consider elements of the set \( \Omega_{P^+} \setminus \Omega_{P^+} = \{ \Sigma_{uc}, L(G_s) \} \). To satisfy Definition 4, it is necessary to guarantee

\[ \langle \varphi \rangle (A^N) \subseteq L(G) \]

since the scheme \( N(a) \) is associated with the predicate \( L(G_s) \).

Proposition 1: If \( K \) is controllable then \( K_s \) is controllable.

Definition 5: \( \mathcal{MI}_\rightarrow \) class is a class of general positive formulas \( \mathcal{F}(x_1, \ldots, x_q) \) which satisfy the following conditions:

1) predicates in type conditions of quantifiers do not contain functional symbols;

2) \( \mathcal{I} = \bigcup_{S[A]} \mathcal{I}_S[A] \), where \( S[A] = |v| \), \( v \) are all variables \( z_\beta \) or \( x_\mu \), which enter to equalities \( z_\alpha \equiv v \), which are included in c-statements \( = \) or type conditions of the universal quantifiers \( \exists z_\alpha \), and \( z_\alpha \) is a defining variable;

3) \( \Omega_{P^+} \setminus \Omega_{P^+} = \emptyset \).

Since the formula (3) does not contain equalities, it belongs to \( \mathcal{MI}_\rightarrow \) class as well as \( \mathcal{MI}_\rightarrow \), with an empty set \( S[A] \).

Definition 6: Let \( \Theta \) be a set of relation symbols, \( \Theta \subseteq \Omega_P \).

The family of mappings (1) is said to be a mighty \( \mathcal{I} \)-injective \( \Theta \)-homorphism GMAS \( \mathfrak{A} = \langle A, \Omega_P, \Omega_{P^+}, \Omega_E \rangle \) to \( \mathfrak{A}' = \langle A', \Omega'_P, \Omega'_{P^+}, \Omega'_E \rangle \), if 1) and 2) of Definition 4 is satisfied and for all \( \gamma = \overline{1, k_F} \)

\( \langle \varphi \rangle T_{1}[A] \times \ldots \times T_{n, \gamma}[A](P_{n, \gamma}) \subseteq \langle \varphi \rangle T_{1}[A] \times \ldots \times T_{n, \gamma}[A](P_{n, \gamma}); \)

if \( P_{n, \gamma} \) correspond to a predicate symbol \( P_\gamma \in \Theta \),

\( \langle \varphi \rangle T_{1}[A] \times \ldots \times T_{n, \gamma}[A](P_{n, \gamma}) = \langle \varphi \rangle T_{1}[A] \times \ldots \times T_{n, \gamma}[A](P_{n, \gamma}) \)

if \( P_{n, \gamma} \) correspond to a predicate symbol \( P_\gamma \in \Omega_P \setminus \Theta \), and mappings \( \varphi_\lambda \) are injective for all \( \lambda \in \mathcal{I} \).

Theorem 2 (6f): Formulas of the class \( \mathcal{MI}_\rightarrow \) are preserved under mighty \( \mathcal{I} \)-injective \( \Omega_{P^+} \setminus \Omega_{P^+} \)-homorphism of GMAS \( \mathfrak{A} \) to GMAS \( \mathfrak{A}' \).

To prove that (4) is also a mighty \( \Omega_{P^+} \setminus \Omega_{P^+} \)-homorphism it is sufficient to show that \( L(G) \subseteq \varphi[N(L(G_s))] \) and \( \Sigma_{uc} \subseteq \varphi[(\Sigma_{uc})^* \subseteq L(G)] \). Since these inclusions are obviously satisfied, combination of Theorem 1 and Theorem 2 implies
**Proposition 2:** $K$ is controllable if and only if $K_s$ is controllable.

The proposition states that controllability is not affected by the state observation. This fact was previously demonstrated in [4] but its proof considerably differs from the one presented here.

**B. Observability**

The observability property (Definition 2) of the language $K_s$ may be described by the generalized positive formula
\[ F_2 = \forall v_s : (\Sigma \cup Y)^* (v_s) \land \forall w_s : (\Sigma \cup Y)^* (w_s) \land \neg (P_s(v_s) = P_s(w_s)) \land \neg L(G_s)((w_s, \sigma_s)) \land \neg \neg K_s((v_s, \sigma_s)) \]

In this case consider $\mathfrak{B} = (B, \Omega_F, \Omega_P, \Omega_E)$ with $B = \{ \Sigma \cup Y \}$, $\Omega_F = \{ \cdot, P_s \}$, $\Omega_P = \{ \cdot, Y \}^*, \Sigma \cup Y, K_s, L(G_s) = \cdot$, $\Omega_E = \emptyset$. Note that predicates $\Sigma \cup Y$ and $\Sigma \cup Y^*$ are artificial elements which introduced to embody the formula in the language of GMAS. Let $2^B = (B', \Omega'_F, \Omega'_P, \Omega'_E)$ be the GMAS of the same type as $\mathfrak{B}$ with $B' = \{ \cdot, P \}$, $\Omega'_P = \{ \Sigma^*, \Sigma, K, L(G_s) = \cdot \}$, $\Omega'_E = \emptyset$. In signature of $2^B$ (5) describe the observability property of the language $K$. Here $P_s : \Sigma \cup Y \rightarrow (\Sigma \cup Y)^*$ and $P_s : \Sigma \rightarrow \Sigma^*$. Again, the family of mappings (1) includes the single function $\varphi : \Sigma \cup Y \rightarrow \Sigma$.

In case of (5) and $2^B$ $Q_{ex} = \emptyset$, $Q_{all} = \{ (\Sigma \cup Y)^*, \Sigma \cup Y \}$, $pos(F_2) = \{ (K_s), neg(F_2) = \{ =, K_s, L(G_s) \}$,
\[ \Omega_{P+} = Q_{ex} \land pos(F) = \{ K_s \}, \]
\[ \Omega_{P-} = Q_{all} \cup neg(F) = \{ (\Sigma \cup Y)^*, \Sigma \cup Y, =, K_s, L(G_s) \}, \]
\[ \Omega_{P+} = \Omega_{P+} \land \Omega_{P-} = \{ K_s \}. \]

Though the formula (5) contains an equality, the set $I_s[A]$ is still empty. As in the case of (3), $F_2$ belong to both $\mathcal{MT}_-$ and $\mathcal{MT}_+$ classes. Therefore we proceed to check if $\varphi$ is the morphism we need. In company with the condition on the symbol $\cdot$, previously obtained, for the functional symbols $P$ and $P_s$ the equality
\[ \varphi|N(P_s(w_s)) = P(\varphi|N(w_s)) \]

is valid, what may be easily checked. We skip the trivial equalities $\varphi((\Sigma \cup Y)^*) = \Sigma^*$, $\varphi((\Sigma \cup Y) = \Sigma$, and consider predicate $\sim$. We now state that
\[ [P_s(v_s) = P_s(w_s)] \Rightarrow [P(\varphi|N(v_s)) = P(\varphi|N(w_s))]. \]

Indeed, as far as the output symbols $y \in Y$ are inserted regardless of observability of the symbols from $\Sigma$, this implication is true.

Thus, all conditions of Definition 4 are satisfied and (4) is a $\Omega_{P-} \setminus \Omega_{P+}$ morphism. Therefore, according to Theorem 1, if $K$ is observable then $K_s$ is also observable. However, the property is not preserved in the opposite direction. According to Theorem 2, it should be valid
\[ [P(\varphi|N(v_s)) = P(\varphi|N(w_s))] \Rightarrow [P_s(v_s) = P_s(w_s)]. \]

But this is not the case. Indeed, let two words $v_s = y_1a_2b_2yc \in (\Sigma \cup Y)^*$ and $w_s = y_1a_2b_2y_3c \in (\Sigma \cup Y)^*$ are given, where $b_0$ and $b_2$ are unobservable. Then $\varphi(v_s) = ab_1c$, $\varphi(w_s) = ab_2c$ and $P(\varphi(v_s)) = P(ab_1c) = ac$, $P(\varphi(w_s)) = P(ab_2c) = ac$. But $P_s(v_s) = y_1a_2b_2y_3c$ while $P_s(w_s) = y_1a_2b_2y_3c$. So we formulate

**Proposition 3:** If $K$ is observable then $K_s$ is observable while the opposite is not the case.

**V. Conclusion**

In this paper an application of the LAE-method to prove system properties preservation under its mapping into another system has been demonstrated. This method combines algebraic and logical approaches and may be of considerable interest to the audience. The theorems concerning the classes of the properties which are preserved under the similar type morphisms allow one to easily obtain preservation criteria, basing just on the structure of the formula and omitting some numerous formal manipulations. Although the presented results are quite simple, they illustrate the power of the LAE-method. The LAE-method allows to generalize the properties preservation conditions for different dynamical systems and the only stipulation of its applicability is the issue of algebraization of a dynamical system model.

Note that there are still a lot of open problems in the theory of DES, especially partially observed and decentralized DES, therefore new approaches and methods are needed. For solving some problems of DES supervisory control theory seems perspective. To apply the calculus of positively constructed formulas [8] which proved to be effective means of solving problems of dynamic systems control.

Abstract—The approach to the first-order logic formalization of discrete-event systems based on the positively constructed formulas calculus is presented. Main concepts of the calculus are given and an example of logical deductions which model the behavior of a discrete-event system under supervisory control is presented.

I. Introduction

The calculus of positively constructed formulas (PCF) was originally developed by Russian scientists S.N. Vassilyev and A.K. Zherlov [1], [2] while describing and solving control theory problems. In [2] the proof of soundness and completeness of the PCF calculus as first-order logical formalism is presented (further development may be found in [3]).

Being both machine-oriented with interactive capabilities for a proof search, the PCF calculus is naturally aimed at solving problems of dynamic systems control due to its features, such as modifiability of semantics (constructive, nonmonotonic, temporal, etc.) and an ability to construct intuitionistic inferences of some non-Horn formulas while explicit usage of \( \forall \)– and \( \exists \)–quantifiers, since the skolemization procedure is not required. Constructive semantics is important since we need to extract some knowledge (for example, action plans) from the proofs, nonmonotonicity and a treat of time help to construct plans in dynamically changing subject areas. Interactive properties of the PCF calculus, its application for dynamic systems control and action planning are described in [2] with the examples of elevator group control, mobile robot action planning and telescope guidance. Problems of automatic theorem proving software (called provers) design and implementation are briefly considered in [4].

The current paper presents PCF calculus application in the field of supervisory control of discrete-event systems (DES). During the last 40 years, to investigate poorly structured and poorly formalized control systems discrete-event approach is widely used. Among other things, DES are extensively exploited in group control, for example, to describe the behavior of groups of autonomous mobile robots [5]. In hierarchical control systems DES may model lower level of control to ensure safe movement of each unit [6] as well as upper levels, which are responsible for planning actions of a unit or a whole group [7].

Almost all existing methods of formalizing DES (automata models, Petri nets, Markov chains, queuing systems, generalized semi-Markov processes, minimax algebras and so on) have the possibility of influencing the behavior of the system. To control DES presented in form of automata, the method of supervisory control [8] is used, proven itself in many applications and widely recognized.

Computational complexity of the problem of supervisor construction, usually based on system model and behavior specification method, especially for partially observed DES [9], and NP-hardness of supervisor minimization problem [10] are well known. New methods are needed to check systems properties essential for supervisor existence, to construct supervisors, and to simplify them. For example, the method of logical-algebraic equations may be successfully applied in this field [11], [12]. In what follows a new logical approach basing on PCFs to solve problems of DES supervisory control theory is suggested.

II. Preliminaries

Let us consider the basic ideas behind PCFs and their calculus. The language of PCFs is a restricted variant of the language of first-order logic (FOL), which consists of first–order formulas (FOFs) built out of atomic formulas with operators \&, \lor, \neg, \rightarrow, \leftrightarrow, quantifier symbols \( \forall \) and \( \exists \), and constants \textbf{True} and \textbf{False}. The concepts of atom, literal, and term are defined in the usual way.

Let \( X = \{x_1, \ldots, x_k\} \) be a set of variables, \( A = \{A_1, \ldots, A_m\} \) a set of atomic formulas, and \( F = \{F_1, \ldots, F_n\} \) a set of subformulas. Then formulas (\((\exists x_1 \ldots \exists x_k)(A_1 \& \ldots \& A_m \rightarrow (F_1 \lor \ldots \lor F_n))\)) and (\((\forall x_1 \ldots \forall x_k)(A_1 \& \ldots \& A_m \& (F_1 \& \ldots \& F_n))\)) are denoted as \( \forall_X A : F \) and \( \exists_X A : F \) respectively, keeping in mind that the \( \forall \)–quantifier corresponds to the disjunction of all subformulas, and \( \exists \)–quantifier corresponds to the conjunction. If \( F = \emptyset \) then above formulas turn to the form \( \forall_X A : \emptyset \equiv \forall_X A \rightarrow \textbf{False} \) and \( \exists_X A : \emptyset \equiv \exists_X A \& \textbf{True} \), since the empty disjunction is understood as \textbf{False}, as usual whereas the empty conjunction is understood as \textbf{True}. Let \( \forall_X A \) and \( \exists_X A \) be abbreviations of such formulas. If \( X = \emptyset \) then \( \forall A : F \) and \( \exists A : F \) are analogous abbreviations.

The set of atoms \( A \) is called \textit{conjunct}. Variables from \( X \), bound by corresponding quantifiers, are called \( \forall \)–variables and \( \exists \)–variables, respectively. In \( \forall_X A \), a variable from \( X \) that does not appear in conjunct \( A \) is called \textit{unconfined} variable. Note that \( \forall \emptyset \equiv \forall \emptyset : \emptyset \equiv \forall \textbf{True} \rightarrow \textbf{False} \equiv \emptyset \).
Constructions $\forall X A$ and $\exists X A$ are called positive type quantifiers (TQ), because $A$ is a conjunction of positive atoms only and referred to as type condition for $X$. In practice, these constructions denote phrases such as “for all $X$ satisfying $A$ there is...”, “there exist $x$ satisfying property $A$ such that...”, and so on; for example, “for all integer $x, y, z$ and $n > 2$ there is $x^n + y^n \neq z^n$”. Originally, the term “type quantifier” was introduced by N. Bourbaki [13] as a part of notation for formalization of mathematics.

A. PCF Language Explicit Definition

Definition 1 (Positively constructed formulas (PCF)). Let $X$ be a set of variables and $A$ a conjunct. Then

1) $\exists X A$ and $\forall X A$ are $\exists$-PCF and $\forall$-PCF respectively.
2) If $F = \{F_1, \ldots, F_n\}$ is a set of $\forall$-PCFs, then $\exists X A : F$ is a $\exists$-PCF.
3) If $F = \{F_1, \ldots, F_n\}$ is a set of $\exists$-PCFs, then $\forall X A : F$ is a $\forall$-PCF.
4) Any $\exists$-PCF or $\forall$-PCF is a PCF.

This form of logical formulas is referred to as positively constructed formulas (PCFs), as they are written with only positive type quantifiers. The formulas contain no explicit logic negation sign. Without loss of generality only closed formulas will be considered. Any FOF can be represented as PCF [2].

A PCF starting with $\forall \varnothing$ is called a PCF in the canonical form. Any PCF can be represented in the canonical form. If $F$ is a non–canonical $\exists$–PCF then $\forall \varnothing : F$ is the canonical PCF since $\forall \varnothing : F \equiv \text{True} \rightarrow F \equiv F$. If $F$ is a non–canonical $\forall$–PCF then the canonical PCF is $\forall \varnothing : \{\exists \mathcal{O} : F\} \equiv \text{True} \rightarrow \text{True & F} \equiv F$. Type quantifiers $\forall \mathcal{O}$ and $\exists \mathcal{O}$ are called fictitious, since they do not influence truth value of an original PCF and do not bind any variables. They are used to regularize PCFs, i.e. transform them to canonical ones.

PCFs are usually represented as trees for easier reading. i.e. $Q X A : \{F_1, \ldots, F_n\}$ is represented as

$$Q X A \quad \begin{array}{c} F_1, \ldots, F_n; \end{array}$$

where $Q$ is a quantifier. Tree elements have conventional names: node, root, leaf, branch, etc. As the quantifier $\forall$ corresponds to a disjunction of formulas $\{F_1, \ldots, F_n\}$ (quantifier $\exists$ corresponds to conjunction), then each $\forall$–node is considered as disjunctive branching, and each $\exists$–node corresponds to conjunctive branching.

Parts of canonical PCF are named as follows:

1) The root of a PCF’s tree-view $\forall \varnothing$ is called a PCF root.
2) Each PCF root child $\exists X A$ is called a PCF base, conjunct $A$ is called base of facts, and a PCF rooted from base is called a base subformula.
3) PCF base children $\forall Y B$ are called questions to the parent base. If a question is a leaf of a tree then it is called a goal question.

4) Subtrees of questions are called consequents. If a question has no consequent then the question is referred to as goal question, and it is identical to False.

Example 1. Consider a PCF representation of a FOF $\mathcal{F} = \neg(\forall x \exists y P(x, y) \rightarrow \exists z P(z, z))$.

An image $\mathcal{F}'$ of $\mathcal{F}$ in the PCF language is $\mathcal{F} = \forall: \varnothing \{\exists: \varnothing \{\forall: \varnothing \{P(x, y), \forall z: \{P(z, z) \{\exists: \text{False}\}\}\}\}\}\}$. The tree-like form of the latter is as follows:

$$\forall: \varnothing \quad \exists: \varnothing \quad \exists: y \{P(x, y)\} \quad \forall z: \{P(z, z) - \exists: \text{False}\}$$

B. The Inference rule

Definition 2 (Answer). A question $\forall Y D : \mathcal{Y}$ to a base $\exists X A$ has an answer $\theta$ if and only if $\theta$ is a substitution $Y \rightarrow \mathcal{Y}$ $\subseteq X$ and $D \theta \subseteq A$, where $\mathcal{Y}$ is Herbrand universe based on constant and function symbols that occur in corresponding base subformula.

Definition 3 (Splitting). Let $B = \exists X A : \mathcal{Y}$, and $Q = \forall Y D : \mathcal{Y}$, where $\mathcal{Y} = \{\exists X C_1 : \Gamma_1, \ldots, \exists X C_n : \Gamma_n\}$ then $\text{split}(B, Q) = \{\exists X C_1 : \Psi \cup \Gamma_1', \ldots, \exists X C_n : \Psi \cup \Gamma_n' \} \cup \{B, \forall Y D : \varnothing\}$, where ‘’ is a variable renaming operator.

We say that $B$ is split by $Q$. Obviously, $\text{split}(B, \forall Y D) = \text{split}(B, \forall Y D : \varnothing)$.

Definition 4 (Inference rule $\omega$). Consider some canonical PCF $F = \forall \varnothing : \Phi$. Let there exists a question $Q$ that has an answer $\theta$ to appropriate base $B \in \Phi$, then $\omega F = \forall \varnothing : \Phi \{B, \forall Y D : \varnothing\}$.

In other words, if a question has an answer to its base, then the base subformula is split by this question. In the case of a goal question, we say that the basic subformula is refuted because $\text{split}(B, \forall Y D) = \varnothing$. The refuted base subformula $B$ removed from the set of base subformulas $\Phi$, since $\Phi \{S\} \cup \varnothing = \Phi \{\{\} \cup \{S\}\}$.

As soon as all the bases subformulas from $\Phi$ have been refuted, the formula $F$ is also refuted, since $\forall \varnothing : \Phi \equiv \text{False}.

The PCF language and the inference rule $\omega$ form the calculus oriented to refutation of a negation of an original formula. The only axiom of PCF calculus is $\forall \varnothing : \varnothing$, i.e., False.

III. Supervisory Control of Discrete Event Systems

Let $\mathcal{G} = (Q, \Sigma, \delta, q_0, Q_m)$ be a discrete event system modeled as a generator of a formal language [8], also called a plant. Here $Q$ is the set of states $q; \Sigma$ the set of events; $\delta: \Sigma \times Q \rightarrow Q$ the transition function; $q_0 \in Q$ the initial state; $Q_m \subseteq Q$ the set of marker states. As usual, $\Sigma^*$ denote the set of all strings over $\Sigma$, including the empty string $\varepsilon$. $\delta$ is easily extended on strings from $\Sigma^*$. Language generated by $\mathcal{G}$ is $L(\mathcal{G}) = \{w : w \in \Sigma^* \text{ and } \delta(w, q_0) \text{ is defined}\}$, while language marked by $\mathcal{G}$ is $L_m(\mathcal{G}) = \{w : w \in L(\mathcal{G}) \text{ and } \delta(w, q_0) \in Q_m\}$.

The Ramadge–Wonham supervisory control framework assumes the existence of a means of control $\mathcal{G}$ presented
by a supervisor [8]. Let $\Sigma_c$ be a controllable event set, $\Sigma_{uc} = \Sigma \setminus \Sigma_c$, $\Sigma_c \cap \Sigma_{uc} = \emptyset$. Let $K$ be a nonempty language that describes the control objective for the system modeled by $G$. A supervisor should switch control patterns so that the supervised DES generates exactly $K$. Formally, a supervisor is a pair $J = (S, \phi)$ where $S = (X, \Sigma, \xi, x_0, X_m)$ is a deterministic automaton with input alphabet $\Sigma$. $S$ is considered to be driven externally by the words from $L(G)$, while $\phi : X \to \Gamma$ is a function that maps supervisor states $x$ into control patterns $\gamma \in \Gamma \subseteq 2^\Sigma$. Because uncontrollable events cannot be disabled, it is required $\Sigma_{uc} \subseteq \gamma = \phi(x)$.

Define $\delta : \Sigma \times Q \to Q$ accounting control patterns as

$$\delta_c(\gamma, \sigma, q) = \begin{cases} \delta(\sigma, q), & \text{if } \delta(\sigma, q) \text{ is defined and } \sigma \in \gamma; \\ \text{undefined}, & \text{otherwise}. \end{cases}$$

Construct the function $\xi \times \delta_c : \Sigma \times X \times Q \to X \times Q$, where $(\xi \times \delta_c)(\sigma, x, q) = (\xi(\sigma, x), \delta_c(\phi(x), \sigma, q))$ is defined iff $\delta(\sigma, q)$ is defined, $\sigma \in \phi(x)$ and $\xi(\sigma, x)$ is defined. Denote $L(J/G)$ a language generated by the closed-looped behavior of the plant and the supervisor: $L(J/G) = \{ s : s \in \Sigma^* \text{ and } (\xi \times \delta_c)(s, x, q) \text{ is defined} \}$. Let $L_m(J/G)$ denote the language marked by the supervisor: $L_m(J/G) = \{ s : s \in L(J/G) \text{ and } (\xi \times \delta_c)(s, x_0, q_0) \in X_m \times Q_m \}$. The main goal of supervisory control is to construct such supervisor that $L_m(J/G) = K$.

The definition of controllability plays a key role in characterizing those languages that can be generated by the closed-loop structure plant–supervisor. Let $L \subseteq \Sigma^*$. The closure of $L$ is the set of all strings that are prefixes of words of $L$, i.e. $\bar{L} = \{ s | s \in \Sigma^* \text{ and } \exists t \in \Sigma^* : s \cdot t \in L \}$. Symbol $\cdot$ denotes string concatenation and is often omitted.

Definition 5. $K$ is controllable (with respect to $L(G)$ and $\Sigma_{uc}$) if

$$K \Sigma_{uc} \cap L(G) \subseteq K.$$  

If $K$ represents the admissible behavior of the system, $K$ is controllable if occurring of any uncontrollable event after prefix of the word from $K$ leads to a word from $K$, i.e. still admissible. Only controllable languages may be exactly achieved by the joint behavior of the plant and supervisor.

Supervisor existence criterion sounds as follows: given $K \subseteq L(G)$, there exists supervisor $J$ such that $K = L_m(J/G)$ iff $K$ is controllable and $L_m(J/G)$ closed, i.e. $K = \overline{K} \cap L_m(J/G)$ [8].

Example 2 (DES model of AUV mission). Consider a simplified general DES model of autonomous underwater vehicle (AUV) functioning during some mission implementation (Fig. 1). For this DES $Q = \{ \text{ready, check, complete} \}$, corresponding to AUV readiness for a mission, hardware and software checking, and mission completion, respectively, $\Sigma = \{ \text{start, tuning, perform, end} \}$, corresponding to a start of AUV functioning, AUV systems' checking, mission performing and operation quitting, respectively, $q_0 = \{ \text{ready} \}$, $Q_m = Q$. Suppose $\Sigma_c = \{ \text{start, tuning, perform} \}$.

![Fig. 1. Generator $G$](image1)

Suppose that specification on AUV behavior requires that after first AUV systems' checking procedure AUV will return for tuning or sensors calibrating before the main mission implementation. The automaton generating the specification language $K$ is shown on Fig. 2.

![Fig. 2. Specification $K$](image2)

In this case it is easy to check that $K$ is controllable and $L_m(J/G)$-closed therefore supervisor $J = (S, \phi)$ such that $K = L_m(J/G)$ exists and may be constructed on the base of the automaton for $K$ [14]. Non-reduced $S$ will have five states $X = \{ x_0, x_1, x_2, x_3, x_4 \}$, all marked, and its structure coincides with the structure of the automaton for $K$. The function $\phi$ is shown in Table I. Dashes there denote that it does not matter if event is enabled or disabled.

IV. PCF Presentation of Supervised DES

In this section it will be shown how above example of DES may be formalized using a PCF. The following predicates are needed. \( E(x) \) will be interpreted as “\( x \) is an event”, \( S(x, y) \) will denote “\( x \) is a current sequence of events in a state \( y \)”. The function symbol “\( \cdot \)” will denote the strings concatenation, and the “\( \epsilon \)” symbol will be for an empty string. To save the space event names will be contracted to its first letters and denote states ready, check, complete as \( s_1, s_2 \) and \( s_3 \), correspondingly. The generator \( G \) (corresponding to Fig. 1) is described by the following single base of PCF:

\[
\exists B \quad \forall \sigma E(s), S(\sigma, s_1) \implies S(\sigma \cdot s, s_2) \\
\forall \sigma E(t), S(\sigma, s_2) \implies S(\sigma \cdot t, s_1) \\
\forall \sigma E(p), S(\sigma, s_2) \implies S(\sigma \cdot p, s_3) \\
\forall \sigma E(e), S(\sigma, s_3) \implies S(\sigma \cdot e, s_1)
\]

Here, \( B \) is the conjunct \( \{ E(t), E(s), E(p), E(e), S(\sigma, s_1) \} \)

Let’s go through first steps of this formula’s inference to demonstrate the strategy that will generate the language \( L(\mathcal{G}) \) in the base conjunct \( B \) as first arguments of atoms \( S \). At the beginning of the inference search, there is the only one possible answer \( \{ \sigma \rightarrow \epsilon, x \rightarrow s_1 \} \) to the first question, that will add \( S(s, s_2) \) to the \( B \). Next steps include answers to the second and the third questions, that will add \( S(t, s_1) \), \( S(p, s_3) \) to the \( B \). Note that after these last additions, there will be the new possible answer to the first question, and an extra answer to last question. But we will not use those until the next cycle of questions bypassing, so the inference rule is applied one time to each question in one cycle. The first cycle of question bypassing will end with the answer to the last question, adding the \( S(s, s_1) \) to the \( B \). The next cycle starts with three possible answers to the first question as there are three \( S \) atoms, with the constant argument \( s_1 \) in the base. One of those answers is the same as the very first one used, generating \( S(s, s_2) \) that will be consumed by existing one in the base, thus, our strategy will not use answers that was already used. Going on further, the base will be updated with atoms \( S(p, s_2), S(s, s_2) \) then \( S(s, s_1), S(p, s_3), S(s, s_1) \) and so on.

The language constructing PCF of the supervisor (Fig. 2) is the following, where \( B_x \) is \( \{ E_x(t), E_x(s), E_x(p), E_x(e), S_x(e, x_1) \} \):

\[
\exists B_x \quad \forall \sigma E_x(s), S_x(\sigma, x_0) \implies S_x(\sigma \cdot s, x_1) \\
\forall \sigma E_x(t), S_x(\sigma, x_1) \implies S_x(\sigma \cdot t, x_2) \\
\forall \sigma E_x(s), S_x(\sigma, x_2) \implies S_x(\sigma \cdot s, x_3) \\
\forall \sigma E_x(p), S_x(\sigma, x_3) \implies S_x(\sigma \cdot p, x_4) \\
\forall \sigma E_x(e), S_x(\sigma, x_4) \implies S_x(\sigma \cdot e, x_0)
\]

Junction of the supervisor and the system guarantees that the specification language is constructed. The PCF imitating the concurrent work of the supervisor and the system will be as follows.

\[
\begin{align*}
\forall \sigma E_x(s), S_x(\sigma, x_0) & \implies S_x(\sigma \cdot s, x_1) \\
\forall \sigma E_x(t), S_x(\sigma, x_1) & \implies S_x(\sigma \cdot t, x_2) \\
\forall \sigma E_x(s), S_x(\sigma, x_2) & \implies S_x(\sigma \cdot s, x_3) \\
\forall \sigma E_x(p), S_x(\sigma, x_3) & \implies S_x(\sigma \cdot p, x_4) \\
\forall \sigma E_x(e), S_x(\sigma, x_4) & \implies S_x(\sigma \cdot e, x_0)
\end{align*}
\]

Let’s discuss the inference of the above formula. It consists of two groups of questions, and the first one corresponds to the supervisor, and the second to the initial system with the supervisor atoms added. Latter do not allow incorrect answers that could have added those atoms to the base that contain sequences of events that do not belong to the specification language \( K \).

V. Conclusion

This paper is the starting point in developing a novel approach to formalizing and solving various control problems for important class of dynamic systems known as DES. With the simple example of AUV mission control basic concepts of PCF calculus implementation was shown.

Computational complexity of inference search of PCFs is rely strongly on the complexity of the inference rule application. The application of the PCFs inference rule for the formulas presenting DES has the polynomial, close to linear complexity, since the obtained structures are quite simple and the answers search procedure (consuming the most of time) is also not so hard.

Further investigations will include, among other issues, subsets of controllable and observable events choosing for uncontrollable languages, supervisor reduction problem solving, sensors activation policies investigation. Obtained results will be exploited in group control, for instance, for supporting AUV missions.

Abstract—In the present paper we estimate how long it will take state-of-the-art combinatorial algorithms to enumerate all possible mutually orthogonal diagonal Latin squares of order 10. For this purpose we first evaluate the performance of DLX algorithm and contemporary algorithms for solving SAT in application to finding orthogonal mates of an arbitrary diagonal Latin square of order 10. Then we estimate the number of diagonal Latin squares of order 10 and use this information in combination with some techniques for exploiting symmetries and equivalences to approximate the amount of time it would take to process them using existing hardware.

I. INTRODUCTION

Latin square of order \( n \) is a square table \( n \times n \) filled with elements from the set \( \{0, \ldots, n-1\} \) in such a way that all elements within a single row or single column are distinct [1]. A Latin square is called diagonal if both its main diagonal and main antidiagonal contain all elements from 0 to \( n-1 \). Two Latin squares \( A = (a_{ij}) \) and \( B = (b_{ij}) \) of the same order are called orthogonal if all ordered pairs \((a_{ij}, b_{ij})\), \( i, j \in \{0, \ldots, n-1\} \) are distinct. A set of at least two Latin squares that are mutually orthogonal is often called a set of MOLS.

Latin squares represent one of the most widely known, well studied and easy to understand combinatorial designs. However, even for relatively small values of order \( n \) there remain exceptionally hard open problems. Probably, the most famous of them is to prove the existence or non-existence of a triple of MOLS of order 10.

In the present paper we focus on diagonal Latin squares of order 10. The existence of orthogonal pairs of these squares was determined in [2]. They present an interesting case of Latin squares because mutually orthogonal diagonal Latin squares (MODLS) are quite rare compared to MOLS. That is why we can hope that their number is relatively small. Nevertheless the problem outlined in the title appears to be very hard. We want to estimate how hard it is from the point of view of state-of-the-art combinatorial algorithms. In particular, we estimate the runtime of the simple algorithm, which generates all diagonal Latin squares of order 10 and for each square determines if it has orthogonal diagonal mates. From empirical evaluation it is clear that the second part of the algorithm is much harder than the first, so we consider it in detail and analyze two approaches to the problem of finding orthogonal mates of a specific diagonal Latin square: the approach based on reducing this problem to Boolean satisfiability problem (SAT) [3], and the approach that employs the DLX algorithm proposed by D. Knuth [4].

Let us present the brief outline of the paper. In the second section we give necessary definitions and outline in more details the general algorithm for enumerating all possible MODLS of order 10. In the third section we consider SAT-based and DLX-based approaches in the context of the general Euler-Parker approach [5] to finding orthogonal mates and analyze their effectiveness. In the fourth section we apply the Monte Carlo method [6] to estimate the number of diagonal Latin squares of order 10 and construct our runtime estimation. After this we review related works and discuss how our research fits into general picture. In the last section we make final conclusions regarding the obtained results.

II. PRELIMINARY INFORMATION

There are several terms and definitions that we will use throughout the paper. Let us introduce them first. A transversal of a Latin square of order \( n \) is a set of \( n \) of its entries, in which there are representatives of each row, column and value [1], [7]. In practice for a specific Latin square \( A \) of order \( n \) by transversal we mean an \( n \)-tuple \( T = (t_0, \ldots, t_{n-1}) \), where pairs \((i, t_i)\), \( i = 0, \ldots, n-1 \) mark the coordinates of corresponding elements in \( A \). It is known that a Latin square of order \( n \) has an orthogonal mate if and only if it can be partitioned into \( n \) disjoint transversals (we can effectively construct the corresponding orthogonal Latin square based on this set of transversals). This fact is often used to find MOLS [5], [8], [9]. Diagonal Latin squares impose an additional constraint in this context: for a diagonal Latin square to have diagonal orthogonal mate, all of its disjoint transversals must intersect exactly once with its main diagonal and exactly once with its main antidiagonal [2], [10]. Let us refer to transversals that satisfy this condition as to diagonal transversals. It is easy to see that the set of all possible transversals of a Latin square of order \( n \) actually coincides with the set of all possible permutations of \( n \) elements \( \{0, 1, \ldots, n-1\} \). Meanwhile, the number of diagonal transversals is significantly smaller than that. For \( n = 10 \) the number of transversals is 3 628 800 among which only 494 080 are diagonal. This fact is the main reason why MODLS are rare: for example, the second square from the first pair found in [2] has 5 504 transversals, of which only 866 are diagonal.

For the purposes explained later it is convenient to split the space of all possible diagonal Latin squares into relatively large chunks. It can be done in various ways. In the context of the present paper we follow a simple path and consider the
sets of Latin squares which have the same values of elements in the first several rows. In particular, let us denote by $LS_n^k$ ($DLS_{10}^k$), $k < n^2$ an incomplete Latin square (diagonal Latin square) of order $n$ in which only first $k$ elements (traversing a Latin square from left to right, from top to bottom) are known. It is then natural to consider all Latin squares (diagonal Latin squares) constructed by filling the remaining $n^2 - k$ elements.

For convenience we consider only normalized diagonal Latin squares, i.e. Latin squares in which the elements of the first row are in ascending order. An arbitrary diagonal Latin square can be represented in such form using simple transformations that do not violate any conditions. It also reduces the search space by the factor of $n!$. In more detail we will consider the ways to reduce the search space in the end of Section 3.

A. General outline of the algorithm for finding MODLS of order 10

We consider a basic algorithm for solving the considered problem. It looks as follows.

1) Generate all possible diagonal Latin squares of order 10.
2) For each generated diagonal Latin square check if it has diagonal orthogonal mates.

From a practical point of view this basic algorithm can be viewed as a computational scheme involving two main parts:

- algorithm for generating diagonal Latin squares of order 10;
- algorithm for finding orthogonal mates of a specific Latin square (or for proving that there are none).

It means that to construct the runtime estimation for this algorithm we need, first, to estimate the number of diagonal Latin squares of order 10, and, second, to estimate the speed with which we will be able to process them.

To estimate the number of diagonal Latin squares of order 10 we can use the Monte-Carlo method [6] in the following form: first for a specific $0 < k < n^2$ we compute (or estimate) the number of all possible $DLS_{10}^k$. Then using a random sample of $DLS_{10}^k$ we compute an estimation of the expected value representing the average number of diagonal Latin squares that share the same $DLS_{10}^k$. Then by multiplying these two numbers we will obtain our estimation. In detail we will address this problem in Section 4.

The two stages of outlined computational scheme can be viewed as independent (of course in practice it is reasonable to generate and analyze Latin squares in batches of relatively small size). Since there are known algorithms for generating diagonal Latin squares that make it possible to construct about $10^6$ squares per second on one core of mainstream PC [11], in the remainder of the paper we assume that the bottleneck of the general algorithm lies in finding orthogonal mates. Our empirical evaluation showed that this point of view is justified. That is why we want to consider it in more detail in the following section.

III. Computational approaches for finding orthogonal mates

The problem of finding orthogonal mates for a specific Latin square of order $n$ has a history of its own. As it is outlined in Chapter 7 of [12], two main approaches have been formed for solving this problem. To the first one we can informally refer as to Paige-Tompkins approach. In it we fill the cells of the second (potentially orthogonal) square in some order to satisfy all the constraints (imposed by Latin square conditions, orthogonality condition, etc.).

The second one is usually referred to as Euler-Parker approach [5]. It implies that we first construct all transversals of a considered Latin square and then search for subsets of $n$ disjoint transversals in a constructed set, considering it as an instance of exact cover problem. After thorough analysis D. Knuth makes a conclusion that Euler-Parker approach is much more effective, therefore we will employ it in the remainder of the paper. Since it represents a kind of a general framework and does not specify any particular algorithms, we implemented several state-of-the-art combinatorial algorithms within its context and compared their effectiveness. In particular, we used for this purpose state-of-the-art SAT-solving algorithms and DLX. Let us first address the exact cover problem and then describe the algorithms employed in more detail.

A. Finding orthogonal mates of a Latin square as exact cover problem

In the context of Euler-Parker approach we can consider both the problem of finding transversals of a Latin square of order $n$ and the problem of finding sets of $n$ disjoint transversals as instances of exact cover problem. This problem is formulated as follows: given a set $X$ and the collection of its subsets $S = \{S_0, \ldots, S_k\}$, $S_i \subseteq X$, $i \in \{0, \ldots, k\}$, $k < 2^{|X|} - 1$ to find such subcollection $S^*$ of sets from $S$ that each element from $X$ is contained exactly in one subset of $S^*$. Note that when searching for transversals we need to find all possible solutions of this problem.

To reduce the search for transversals to exact cover we represent the problem in the following form. Let $A = \{a_{ij}\}$, $a_{ij}, i, j \in \{0, \ldots, n - 1\}$ be an arbitrary Latin square of order $n$. Let the set $X$ contain $3 \times n$ elements $\{x_0, \ldots, x_{3n-1}\}$. The elements $x_0, \ldots, x_{n-1}$ correspond to rows, $x_n, \ldots, x_{2n-1}$ to columns, and $x_{2n}, \ldots, x_{3n-1}$ to values of Latin square cells. Then the collection of subsets $S$ will have exactly $n \times n$ subsets, that correspond to Latin square cells in the following way: with the cell $a_{ij}$ we associate the subset $S_{i \times n+j} = \{x_i, x_{n+j}, x_{2n+j}\}$. If we want to search only for diagonal transversals we need to introduce slight modifications. Remind that we call a transversal diagonal if and only if it has exactly one entry from the main diagonal and exactly one entry from the main antidiagonal. The modifications are as follows: first, we add to $X$ two more elements $x_{3n}, x_{3n+1}$ that correspond to main diagonal and main antidiagonal, respectively. After this we add $x_{3n}$ to subsets corresponding to Latin square cells on the main diagonal, and add $x_{3n+1}$ to subsets corresponding...
to cells on the main antidiagonal. It is easy to see that each solution of this problem will yield a transversal (diagonal transversal) of a considered Latin square.

The representation of the problem of finding \( n \) disjoint transversals in a set of transversals \( T^A = \{ T_1, \ldots, T_k \} \) is similarly straightforward. In this case the set \( X \) contains \( n \times n \) elements \( x_0, \ldots, x_{n^2-1} \). Here an element \( x_{i+n-j} \), \( i, j \in \{ 0, \ldots, n-1 \} \) corresponds to a Latin square cell with coordinates \((i, j)\). The subset corresponding to transversal \( T_k = \{ t^0_k, \ldots, t^{n-1}_k \} \) is formed by elements \( x_{t^0_k}, x_{t^1_k}, \ldots, x_{n \times (n-1) + t^{n-1}_k} \). To find diagonal orthogonal mates we need to find exact cover solution containing only subsets corresponding to diagonal transversals.

It is interesting that we can specify an exact cover instance, all solutions of which will yield all possible normalized diagonal Latin squares. Moreover, the corresponding instance can be adapted to produce only Diagonal Latin squares that share some particular \( LS^2 \) (\( DLX \)). Let us now consider the algorithms that we employ.

### B. SAT approach

Boolean satisfiability problem (SAT) is the historically first NP-hard problem. Despite this fact there are many areas in computer science in which state-of-the-art SAT solving algorithms, usually referred to as SAT solvers, are successfully applied [3]. SAT approach was used to solve problems related to Latin squares, for example, in [13]. We, too, carried out a computational experiment in the volunteer computing project SAT@home\(^1\) aimed at finding MODLS of order 10 [14]. However, in all these works the SAT encoding used was in a way implementing the Paige-Tomkops approach. Possibly because of this reason we managed to find only about 50 pairs of MODLS of order 10 in several months. In the present paper we apply SAT approach in the context of Euler-Parker approach.

For this purpose we need to reduce exact cover instances to SAT. By SAT instance it is usually meant a Boolean formula in Conjunctive Normal Form (CNF). CNF is essentially a conjunction of clauses, where clause is a disjunction of literals. By literal we mean either Boolean variable or its negation. Thankfully, the transition from exact cover instance to SAT is very simple. First we associate with each subset \( S_k \) of a set \( S \) a Boolean variable \( b_k \). Then for each \( x_i \in X \) we form a set \( X_i \) that contains all \( b_j \) such that \( x_i \in S_j \). A SAT instance we need will be formed by the set of constraints specifying that in each set \( X_i \) exactly one variable can take the value of True. This constraint can be written in CNF in several different ways. In our experiments we used pairwise scheme. Note that given a CNF \( C \) a SAT solver either finds its satisfying solution or reports that a CNF is unsatisfiable. It is easy to see that from a satisfying assignment we can effectively extract the solution to exact cover problem. Note that to find all solutions we need to implement an iterative process in which we restrict each found solution and search for different ones until a CNF becomes unsatisfiable, meaning that we found all solutions.

### C. DLX approach

The DLX algorithm proposed in [4] is the most widely known algorithm for solving exact cover problem. It is a recursive depth-first backtrack algorithm that heavily relies on the use of special technique called ‘Dancing Links’ to represent data in the computer memory. It takes as an input a description of exact cover problem that does not need any adjustments. While there are available implementations of DLX\(^2\), we implemented our own simple version. Since it almost directly corresponds to the algorithm described in [4] we believe that its performance is comparable to that of other existing implementations.

### D. Comparison and performance evaluation

All the experiments described below were carried out on one core of Intel Core i7-3770k with 16 Gb RAM (Windows 10). All considered algorithms were implemented in C++ (Microsoft Visual Studio 2015). To solve SAT instances we used the MINISAT 2.2 solver [15]. We made a wrapper for MINISAT and introduced small changes in standard SAT solving procedure in order to find all satisfying assignments without having to reload SAT instance each time. The source code of the application can be found online\(^3\).

An important stage of experiments consists in generating diagonal Latin squares of order 10. Existing implementations, for example the one described in [11] make it possible to generate about 1 million of them per second on one processor core. We found out that by applying DLX to a set cover instance for this problem we get the generation speed of about 300 000 diagonal Latin squares of order 10 per second. This speed was satisfactory for our purposes.

Apart from SAT and DLX-based algorithms for finding transversals and orthogonal mates we also implemented a straightforward depth-first backtrack algorithm for both purposes to evaluate their performance better. In Table I we show how the algorithms fared against each other. The total time required to process the sample is averaged for 10 samples of size 100 000 diagonal Latin squares of order 10 each. The samples were produced by generating first 100 000 diagonal Latin squares for a randomly selected \( DLX_{10}^2 \). In ‘Finding Transversals’ we measured total time required only to find all diagonal transversals for each square from the sample. In ‘Finding orthogonal mates’ we measured total time spent on both finding transversals and subsequent finding disjoint sets of them. The entries SAT and DLX imply that we employed the corresponding approaches for both finding transversals and searching for their disjoint sets. In SAT + DLX we find transversals using DLX and search for orthogonal mates using SAT.

Let us comment the obtained results. It is clear that DLX definitely wins in all categories, with SAT being from 4 to

\(^1\)http://sat.isa.ru/pdsat/

\(^2\)http://koti.kapsi.fi/pottonen/libexact.html

\(^3\)https://github.com/veinamond/LS_search/
40 times worse. When finding transversals, SAT loses even to simple backtrack search. The explanation here is simple: to find, say, 100 transversals using SAT approach we need to launch SAT solver 101 times, each time restricting it from encountering already found solutions. Meanwhile DLX (and Backtrack search) simply traverses the search space without stops and restarts. We can modify the SAT solver to imitate such behavior by incorporating the so-called warm restarts technique, but judging by the overall picture, it won’t make much difference. Another interesting observation is that more than 90% of time spent on checking orthogonal mates the algorithms spend to search for transversals. It is surprising because in both papers [12], [9] the corresponding process takes much less time. One possible reason for this is the fact that most diagonal Latin squares of order 10 in these random samples have relatively small number of diagonal transversals (about 100) and do not have orthogonal mates.

Overall, it means that for the purpose of our runtime estimation we will use DLX results. In particular we will assume that it can process roughly 900 diagonal Latin squares per second on one mainstream processor core. It is more or less similar to the performance achieved in [9], where the authors used special algorithms for enumerating all MOLS of order 9.

E. Correctness of results

To safeguard from possible errors, we cross-checked the results of our computational experiments. In particular, we compared on random samples of diagonal Latin squares the output of transversal finding procedures. We even went one more step in this direction and made a fourth implementation of this procedure based on lookup. We did the same in application to procedures for finding orthogonal mates. It was less trivial due to the fact that the majority of diagonal Latin squares of order 10 from random samples do not have orthogonal mates. That is why for this purpose we tested the implemented methods on diagonal Latin squares found in SAT@home\(^4\) and in [2].

F. Symmetries and equivalence classes

Taking into account various symmetries and equivalence classes can greatly impact the performance of any algorithm operating with combinatorial designs. A good example of how it is used in computational experiments can be found in [16]. In the case of Latin squares there are several variants of constructing equivalence classes, covered in detail for example in [9]. However, diagonal Latin squares present a special case. While they can be normalized effectively (transformed to a form where the first row is in ascending order), many simple transformations used to produce isotopic/isomorphic Latin squares lead to violation of a diagonality constraint. Surprisingly, the question of constructing isomorphic diagonal Latin squares is well studied in the research area related to magic squares. A magic square is an \(n \times n\) table filled with integer numbers in such a way that the sums of numbers in each row, each column and also in the main diagonal and main antidiagonal are all equal to the same so-called ‘magic constant’. It is clear that each diagonal Latin square is a Magic square. Unfortunately, we could not trace the original references to the ideas on constructing isomorphic Latin squares presented below, despite the fact that they became a sort of common knowledge. Let us briefly describe them.

So, we are interested only in transformations of a diagonal Latin square of order \(n\) that make it possible to produce other diagonal Latin squares of order \(n\). Note that when we change the order of rows or order of columns in a Latin square, the square remains Latin and has the same number of orthogonal mates as an original Latin square. However, as a result we can violate the diagonality constraint. This is not true for the case of renaming elements. However, since we consider only normalized diagonal Latin squares (i.e. with the first row in ascending order), we can not use it to produce isomorphic squares. It means that we need to find such combinations of rows/columns permutations that preserve the contents of main diagonal and main antidiagonal. In total there are three kinds of such transformations of which the second and third are the so-called M-transformations.

- The first class of such transformations is formed by 4 transformations that are produced by mirroring a diagonal Latin square with respect to its main diagonal or main antidiagonal and also horizontally or vertically.
- The first kind of M-transformations contains all transpositions of two columns that are positioned symmetrically with respect to the middle with simultaneous transposition of two symmetrically positioned rows, for example, transposition of 0-th and \((n - 1)\)-th columns with simultaneous transposition of 0-th and \((n - 1)\)-th row. The number of such transformations for \(n = 10\) is \(2^5\) (equal to the number of all subsets of a set with 5 elements).
- The second kind of M-transformations consists of all transpositions where we choose two columns in the left half of a Latin square and transpose them and simultaneously transpose the two columns positioned symmetrically with respect to the middle in the right half of a square with simultaneous similar transposition of

rows, for example transposition of 0-th column with 1-th column, (n − 2)-th column with (n − 1)-th column, 0-th row with 1-th row and (n − 2)-th row with (n − 1)-th row. The number of these transformations for n = 10 is 5! (equal to the number of permutations of a set with 5 elements because by transposing pairs we form all possible permutations).

It is easy to see that each of the above transformations preserves the contents of main diagonal and main antidiagonal. Note that we can normalize (by renaming elements) each diagonal Latin square produced as a result of the above transformations. Thus, we can produce for n = 10 exactly $5! \times 2^5 \times 4 = 15 \times 360$ normalized isomorphic squares. Also if we sort all isomorphic squares lexicographically and choose the first one – we can use it as a representative associated with this isomorphism class (the corresponding square is usually referred to as canonical form of an original square).

It is currently unclear if it is feasible to construct canonical form for each diagonal Latin square to be checked, but our preliminary evaluations show that it should be possible to employ the outlined technique to significantly reduce the search space.

IV. ESTIMATING THE NUMBER OF DIAGONAL LATIN SQUARES OF ORDER 10

Since we have evaluated the performance of state-of-the-art combinatorial algorithms in application to the considered problem, the only thing we need to do in order to construct our runtime estimation is to estimate the number of diagonal Latin squares of order 10. Basically it means that enumerating all possible diagonal Latin squares of order 10 in reasonable time is out of question. Thus we will have to resort to the Monte Carlo method. As we mentioned in the introduction, we can compute the number of possible variants of incomplete diagonal Latin squares of order 10 comprised of the first k elements (we refer to them as $DLS_{10}^k$) and use probabilistic experiment to estimate the expected value of a number of diagonal Latin squares produced by completing arbitrary $DLS_{10}^k$.

Since we consider only normalized diagonal Latin squares, we can safely fix the first row to 0123456789. An important part of the Monte Carlo method is that we have to choose species representatives randomly according to the uniform distribution. Assume that we need to randomly choose $DLS_{10}^k$, $10 < k < 100$ and that we have a procedure that can enumerate all possible $DLS_{10}^k$ in a fixed order in a reasonable time. We first count the number of corresponding $DLS_{10}^k$, let us refer to it as $N_{10}^k$. Then for a fixed random sample size u choose according to the uniform distribution over the set $[0, \ldots, N_{10}^k]$, u values $\alpha_0, \ldots, \alpha_u-1$. After this we can repeat the $DLS_{10}^k$ generation procedure to output the instances of $DLS_{10}^k$ with numbers $\alpha_i$, $i = 0, \ldots, N_{10}^k$.

In our experiments we used the modified version of the algorithm proposed in [11] to enumerate $DLS_{10}^k$. To produce proper estimation we need to choose k in such a way that $N_{10}^k$ can be computed fast, and at the same time the number of squares that share a specific $DLS_{10}^k$ on average can be enumerated in reasonable time. Computing the number of possible $DLS_{10}^{20}$ requires quite significant effort, and the corresponding number $N_{10}^{20}$ is 284 086 571 712. However, to compute the number of Latin Squares produced by completing arbitrary $DLS_{10}^{10}$ it takes several days on one core of state-of-the-art processor. Therefore we chose $k = 32$ and computed our estimation using this value. The number of $DLS_{10}^{32}$ is 12 611 543 636 160. We generated a random sample of size 10 000 $DLS_{10}^{32}$ instances and used it to estimate the expected value of the number of diagonal Latin squares of order 10 with fixed $DLS_{10}^{32}$. The corresponding expected value was equal to 11 931 268 344.

By multiplying the two values we can estimate that the number of normalized diagonal Latin squares of order 10 is 150 471 711 355 040 or about $1.5 \times 10^{23}$. Following the optimistic scenario that we can exploit the features outlined above we can divide this number by 15 360 thus having to process about $9.8 \times 10^{18}$ distinct diagonal Latin squares. Taking into account the fact that we can process about 900 squares per second it means that the runtime estimation on one mainstream processor core is about $1 \times 10^{16}$ seconds or 345.15 million years. If we employ the second best supercomputer (Tianhe-2) in Top500$^6$, that has 3 120 000 cores, it will take us about 110.6 years to enumerate all MODLS of order 10.

V. RELATED WORKS

There is a significant interest to enumerating various combinatorial designs, reflected in the existence and popularity of OEIS (The On-Line Encyclopedia of Integer Sequences)$^5$. It has over 40 entries directly related to Latin squares, 5 of which are about diagonal Latin squares, and also about 100 more entries that concern related combinatorial designs. We would like to mention the most relevant of them. They are A266166 (Number of reduced pairs of orthogonal Latin squares), which was obtained as a result of research described in [9], A000315 (Number of reduced Latin squares of order n) that is a result of cumulative effort of many research groups throughout the world, and A274171 (Number of diagonal Latin squares of order n with first row 1..n), the authors of which recently finished a large scale computational experiment on enumerating all diagonal Latin squares of order 9 in the volunteer computing project Gerasm@home$^7$. Note that there is little to no available information regarding enumeration of (diagonal) Latin squares or MODLS of order 10.

Ideologically, one of the most closely related works is [9] in which authors managed to enumerate and classify all MOLS of order 9. Note, that they used completely different approach based on special combinatorial properties of specific objects. The performance of their computational algorithm seems to be more or less similar to that of our DLX implementation since they comment that they process about 1200 Latin squares of order 9 per second on a mainstream PC (supposedly, on

3http://oeis.org
4http://oeis.org
5http://gerasm.boinc.ru/
one core). They also consider some problems related to Latin squares of order 10, in particular to construct the triple of Latin squares closest to being a triple of MOLS of order 10, however, they do not study specifically diagonal Latin squares of order 10.

Constructing runtime estimations for solving hard problems is performed quite often, especially for problems found in cryptography. We are not aware of other attempts at constructing runtime estimations for finding specific configurations of MOLS or MODLS of order 10.

Despite the fact that both SAT and exact cover problems are NP-complete, there exist state-of-the-art combinatorial algorithms that manage to solve many instances arising in practice relatively fast. DLX algorithm proposed by Donald Knuth in [4] is the de facto algorithm for solving exact cover problem. In case of SAT while there are many different directions of development, the majority of algorithms are usually based on the Conflict-Driven Clause Learning concept [17]. SAT approach was successfully applied in [13] to solve several algebraic problems. Also the author of [13] noted that he searched for a triple of MOLS of order 10 using SAT solvers for several years without any success.

Usually the problems related to Latin squares are encoded to SAT using the so-called naive encoding, which represents Latin square as a set of its cells with specific constraints over them. It is described, for example, in [14]. We applied this encoding to search for MODLS of order 10 in the volunteer computing project SAT@home, and managed to find about 50 previously unknown pairs. Currently, we believe, that while SAT approach using naive encoding might be good for finding specific cases of Latin squares which satisfy a lot of additional constraints, it is inferior to the one employed in the present paper for a systematic search or enumeration purposes. In our recent work [10] we applied SAT approach using naive encoding to prove that there is no triple of MODLS of order 10 with fixed values of the first 45 elements. It took about 38 minutes of multithreaded SAT solver on 32 cores to solve the corresponding SAT instance. Meanwhile using the DLX implementation from the present paper we can do it in about 42 seconds on one processor core.

Conclusions and future works

The constructed runtime estimation for enumerating MODLS of order 10 means that, unless there are some theoretical constructions that make it possible to significantly reduce the search space or to drastically improve the effectiveness of the algorithms for traversing it, it is completely unrealistic and pointless at the present moment to launch the corresponding computational experiment or expect that it will be finished at least in the course of one lifetime. In particular it means that the problem of finding triples of MOLS of order 10 will most likely require a different approach. Nevertheless, the technical progress, especially in supercomputing, is evident and it is possible that in a decade or two new algorithms and hardware will make it possible to reconsider the current evaluation. In the nearest future we plan to apply DLX approach to finding triples of diagonal Latin squares of order 10 that are closest to being triples of MODLS of order 10.

Acknowledgment

The research was funded by Russian Science Foundation (project No. 16-11-10046). The authors would like to thank Eduard Vatutin, Alexey Zhuravlev, Maxim Manzyuk, and citerra (Russia team at Boinc.ru) for helpful discussions. We are also grateful to Sergey Belayev for sharing his implementation of straightforward backtrack search implementing Euler-Parker approach and to Alexey Belishev for information about M-transformations and canonical forms of diagonal Latin squares.

Abstract—In this paper we study several discrete models of collective behavior based on Synchronous Boolean Networks. For these models we consider a number of related problems that we solve by reducing them to Boolean satisfiability problem (SAT) and applying state-of-the-art parameterized SAT solving algorithms. We describe a greedy algorithm that exploits the features of functions used to recalculate network nodes weights and interconnections between neighborhoods of network nodes. This algorithm in combination with several specific propositional encoding techniques, makes it possible to significantly reduce the size of propositional encoding. We compare the effectiveness of SAT solving algorithms on the new encodings with that on previously employed encodings and evaluate the total performance gain achieved by using state-of-the-art tools for finding efficient SAT solver parameters.

I. INTRODUCTION

Many hard combinatorial problems arising in different areas of science can be reduced to Boolean satisfiability problem (SAT) and solved using state-of-the-art SAT solving algorithms called SAT solvers. Since SAT is NP-hard, it means that these algorithms heavily employ different heuristics and have many parameters. In the recent years there appeared several tools that make it possible for specific classes of problems to find effective values of these parameters that significantly improve SAT solvers performance on these problems compared to that of SAT solvers with default parameters values. Another relatively active direction of research in the area of SAT consists in development of new techniques for propositional encoding — methods used to reduce original combinatorial problems to SAT.

In the present paper we apply both propositional encoding techniques and parameterization algorithms to improve the effectiveness of SAT approach in application to analysis of discrete models of collective behavior. In the corresponding models we observe a system of a number of agents in discrete time steps. A system of agents is specified by simple graph, where vertices (associated with agents) have Boolean weights. All weights are recalculated and refreshed synchronously using Boolean functions associated with each agent (vertex). We consider one special class of these functions, that can be used to model the so-called conforming behavior. It means that for each graph vertex we need to count the number of vertices with weight ‘1’ in its neighborhood. In propositional encoding we use sorting networks for this purpose. We propose two improvements to the previously used encoding. In the first one we analyze the interconnections between neighborhoods of network vertices in order to process their ‘intersections’ once (instead of multiple times) and thus reduce the redundancy of the encoding. For this purpose we employ a specially designed greedy algorithm. The second improvement consists in using the recent findings related to encoding of cardinality constraints to significantly reduce the number of comparators in encoded sorting networks. In total, it is possible to reduce the size of propositional encodings up to several times depending on the graph structure. After this we figure out if the improvements of encodings translate into the improvements of effectiveness of solving. In particular, on this stage we apply state-of-the-art parameterization algorithms in order to find good values of parameters for each of constructed encodings and evaluate the total gain.

Let us give a brief outline of the paper. In the next section we formally define the studied discrete models of collective behavior and describe the previously used propositional encoding. In the third section we consider sorting networks in somewhat more detail, discuss their specific features from the SAT perspective, and then propose two improvements to the existing scheme. In the fourth section we use state-of-the-art parameterization tools to optimize SAT solvers parameters and improve their effectiveness on the constructed encodings, thus comparing the encodings between each other. In the two last sections we consider related works and draw conclusions.

II. SAT APPROACH TO ANALYSIS OF DISCRETE MODELS OF COLLECTIVE BEHAVIOR

The discrete models of collective behavior that we study in this paper have been considered in detail in [1], [2]. Let us describe the general idea on which we built them. It was first expressed in the classical paper [3].

A. Discrete model of conforming behavior

Assume that we have \( n \) distinct agents. We want them to show conforming behavior – meaning that the decisions of each agent should conform to the decisions of other agents from its neighborhood. It is interesting to view the spread of decisions of agents in a system in the course of several discrete time moments, assuming that all agents re-evaluate their decisions synchronously. In the simple case each agent...
can decide either to act (1) or not to act (0). Then we can assign each agent a special parameter \(c\) called conformity level and say that this agent decides to act at the next time step if and only if at least \(c\) agents from its neighborhood act at the current time step.

Formally, it is convenient to define the network of agents by a simple directed graph \(G = (V, E)\), where a set of vertices \(V, |V| = n\), corresponds to a set of agents, and a set of edges \(E\) reflects the interconnections between agents. Consider discrete time moments \(t = 0, 1, \ldots, k\). At each time moment associate with each vertex \(v_i\) its weight \(w_i^t \in \{0, 1\}\). We define the neighborhood of vertex \(v_i\) as the set of vertices \(N_i\), from each of which there is an edge to \(v_i\) \(N_i = \{v_u \in V | (v_u, v_i) \in E\}\). Assume that with each vertex \(v_i\) we also associate the conformity level \(c_i, c_i \in \{1, \ldots, |N_i|\}\). Then we can define the function for recalculating the value of each vertex as follows:

\[
w_i^{t+1} = \begin{cases} 
1, & \sum_{v_j \in N_i} w_j^t \geq c_i \\
0, & \sum_{v_j \in N_i} w_j^t < c_i
\end{cases}
\]

The model defined this way despite its simplicity makes it possible to study a lot of different phenomena in a way it is done in agent-based modeling, when we define simple rules for each agent and then see how a collective of such agents develop in different conditions. In the present paper (similar to [2]) we focus on the following combinatorial problem. First we introduce special kind of agents called instigators. Their distinctive feature consists in the fact that they are usually active (i.e. the corresponding \(w_i^t = 1\) for each possible value of \(t\)). Assume that at initial time moment \((t = 0)\) only instigators are active in a network. Then for an arbitrary graph \(G = (V, E), |V| = n\), with specified conformity levels \(C = (c_1, \ldots, c_n)\) we consider the following problem: to find a disposition of at most \(S\), \(S < n\) instigators (assuming that we replace some agents by instigators) in such a way that after \(k\) time steps at least \(F\), \(F > S\) agents in a network are active.

On the one hand, it is easy to see that in the general case the proposed problem is very hard. On the other hand, essentially Boolean weights of graph vertices and simple nature of the function used to recalculate them allow for the natural reduction of this problem to SAT [4]. For practical purposes, SAT is formulated as follows: for a system of logical equations to find its solution or to prove that there is none. Usually, the system of logical equations is represented in the conjunctive normal form (CNF). Let us now consider how we can reduce the problem of analysis of the discrete model of collective behavior outlined above to SAT.

B. General Outline of Propositional Encoding

Assume that we have a system of \(n\) agents. Without the loss of generality, let us consider only the transition from one time step to the next, in particular, from \(t = 0\) to \(t = 1\). It means that essentially we need to write a system of logical equations that specifies how we move from Boolean variables \(w_i^0, \ldots, w_i^m\) to \(w_i^1, \ldots, w_i^n\) according to (1).

Again, without the loss of generality let us focus on encoding the transition from \(w_i^0\) to \(w_i^1\). From the (1) it is clear that we need to somehow count the number of 1’s among Boolean variables \(W_i^0(N_i) = \{w_i^0 | v_j \in N_i\}\). It can be done in several different ways: for example, we can write logical equations that encode computing the sum of corresponding variables viewed as binary numbers. Or we can construct for \(W_i^0(N_i)\) its sorted version \(S(W_i^0(N_i)) = (t_1, \ldots, t_{|N_i|})\), where \(t_1, \ldots, t_{|N_i|}\) are auxiliary Boolean variables, \#\(\{t_j = 1\} = t_j \in S(W_i^0(N_i))\) \#\(\{u_j = 1\} = 1w_j^0 \in W_i^0(N_i)\) and \(t_u > t_{u+1}\), \(u = 1, \ldots, |N_i| - 1\). We believe that the second path (with sorting) is more convenient and effective due to several reasons, arising from how state-of-the-art SAT solving algorithms work. We will discuss them in more detail in the next section. Once we have \(S(W_i^0(N_i)) = (t_1, \ldots, t_{|N_i|})\), it is clear that, \(w_i^1 \equiv t_{c_i}\). If there are at least \(c_i\) ones in \(W_i^0(N_i)\) then \(t_{c_i} = 1\) and according to (1) it follows that \(w_i^1 = 1\). If there are less than \(c_i\) ones in \(W_i^0(N_i)\) then \(t_{c_i} = 0\) and \(w_i^1 = 0\) too. Thus the problem is to construct for an arbitrary \(W_i^0(N_i) = \{w_i^0 | v_j \in N_i\}\) the sorted array \(S(W_i^0(N_i)) = (t_1, \ldots, t_{|N_i|})\). It can be done using several methods, developed in recent years for encoding so-called cardinality constraints to SAT [5], [6]. In [1], [2] we used sorting networks for this purpose, and we continue to use them in the present paper, albeit in a more efficient manner.

III. IMPROVING PROPOSITIONAL ENCODING

From the layout of the function (1) it is easy to see, that for most graphs \(G\) there exist \(i, j \in \{1, \ldots, n\}, i \neq j\) that \(N_i \cap N_j \neq \emptyset\). It means, that when counting ones from \(W_i^0(N_i)\) and \(W_j^0(N_j)\), we can actually count ones in \(W_i^0(N_i \cap N_j)\) once, and thus reduce the redundancy of the procedure. Of course, the benefit is the larger the more common elements we find, however, there is no effective algorithm for this purpose. Nevertheless, having in mind several special constraints imposed by the use of sorting networks, it is possible to propose a greedy algorithm specifically for this purpose. To progress further let us give some details about sorting networks.

A. Sorting Networks from SAT Perspective

In computer science, sorting networks are constructions, that are built to sort fixed number of values. They comprise of so-called wires. Modules called comparators connect pairs of wires. When a pair of values corresponding to connected wires move through a comparator, they switch wires if their order is not desirable, and remain on their wires otherwise. The example of sorting network for 8 inputs is shown in the left lower part of Fig. 1. On most depictions it is assumed that input values are on the left and output values are on the right.

The advantages of sorting networks from SAT perspective compared to other variants of counting ones in an array of Boolean values were considered in detail in [5]. Let us mention those that we see as the most important. First is that sorting networks are easy to encode. In the context of propositional encoding, by \texttt{comparator}(a, b, c, d) we mean two logical equations: \(e \equiv a \lor b, d \equiv a \land b\). Second, propositional encodings
of sorting networks allow propagation of partial knowledge, i.e. if the values of several input variables are already known, it makes it possible to derive values of several output variables (depending on several additional factors). The same can not be said regarding, for example, the variant when we compute the sum of Boolean variables.

There are several algorithms that can be used to construct sorting networks for \( n = 2^k \) inputs [7], [8]. In the present paper, as in [1], [2] we use Batcher’s odd-even merge algorithm [7]. Essentially, the algorithm presents the construction, that makes it possible to merge two sorted sequences of \( n/2 \) numbers into one sorted sequence of \( n \) numbers. Since a single comparator can be used to sort a sequence of length 2, it means that by recursive application of merging procedure we can sort any sequence of length \( n = 2^k \). The merging procedure, to which we will refer as Merge is defined as follows (the description is taken from [6]).

\[
\text{Merge}(a_1, b_1, c_1, c_2) \leftrightarrow \text{comparator}(a_1, b_1, c_1, c_2).
\]

\[
\text{Merge}(a_1 \ldots a_n, b_1 \ldots b_n, (d_1 \ldots d_{n-1}, e_n)) \leftrightarrow
\]

\[
\bigwedge_{i=1}^{n-1} \text{comparator}(e_i, d_{i+1}, c_2i, c_2i+1).
\]

There are at least two papers (see [6], [5]), which study in detail how to encode sorting networks to SAT, however, focused on working with cardinality constraints (constraints of the kind \( a_1 + a_2 + \ldots + a_k h \leq \leq, = \), \( h \leq k \), where \( a_i \in \{0, 1\} \)). Nevertheless, a lot of methods from these papers can be adapted to our needs.

B. Improvements in Encoding Sorting Networks

In previous works [1], [2] when we needed to encode sorting network to sort \( l \) inputs, we constructed a sorting network for \( 2^{\log(l)} \) inputs, encoded it to SAT and fed inputs with number > \( l \) the Boolean variable, assigned with the False (0) value. It means, that, for example, if we needed to sort only 33 values — we nevertheless encoded the full sorting network with 64 inputs and 64 outputs. In the present work we decided to adapt the algorithm for constructing sorting network to our means. In particular, it is convenient for our purposes to group comparators of the sorting network into mergers. By merger of size \( l \) we mean the construction, that takes as input two sorted sequences of size \( l/2 \), merges them into one sorted sequence of size \( l \) and outputs it. Each merger directly corresponds to the application of Merge procedure. It is easy to see that mergers naturally form layers, and the number of layers coincides with \( \log(l) \): in the first layer there are \( \lceil l/2 \rceil \) mergers of size 2 (with 2 inputs and 2 outputs, i.e. comparators), on the second layer \( \lceil l/4 \rceil \) mergers of size 4, etc. The last layer always consists of one merger of size \( 2^{\log(l)} \). On the first glance it may seem that this construction provides no benefits compared to the one when we generate the whole sorting network at once. But let us consider as an example the network of mergers for 5 inputs, that is shown in the right part of Fig. 1. Dashed lines correspond to void values. The third merger of size 2 in the first layer has only one input — it means that to produce its output we do not need to introduce new comparators at all: the output of the merger will be the non-void value and void value. Now let us proceed to the second merger in the second layer. Since it has only output of one merger as an input — it does not need to introduce new comparators as well, only to add to the sorted sequence of one nonempty value and one void value two more void values. By combining these two techniques we now can construct sorting networks for an arbitrary length of input sequence, which do not have comparators that are never used. Also, we modified the previously used procedure for introducing comparators in such a way, that if one of comparator input values is void, it does not add new comparator at all, just puts non-void value (if any) as first output and void value as second.

Now let us return to the idea, where we want to reduce the redundancy of our encoding by careful processing of neighborhood intersections. The use of networks of mergers imposes one welcome additional constraint that we will use to our advantage: indeed we are interested only in neighborhood intersections with sizes equal to powers of 2.

C. Using Greedy Algorithm to Determine Neighborhood Intersections

At first we need to determine all neighborhood intersections of size 2 that should be processed. In order to do it we use the following greedy algorithm. Assume that we have \( n \) agents. Then as an input our algorithm takes \( n \) neighborhoods \( N_i, \ N_i \subseteq \{1, 2, \ldots, n\}, i = 1, \ldots, n \). It outputs two sets. One is the ordered and numbered set of pairs \( R \). Second is the set of sets of pairs \( NU \). It has size \( n \) components, and each component \( NU[j] \) is the set that contains pairs from \( R \) included in the corresponding \( N_j \). Then we perform the following algorithm.

1) Introduce auxiliary sets \( WS_i = N_i, i = 1, \ldots, n \).
2) Construct all possible pairs of elements from \( WS_j: P = \{(a, b) \exists j : (a, b) \in WS_j\} \).
3) For each pair \((a, b) \in P\) count how many \(WS_j\) contain it: \(W[(a, b)] = \#\{WS_j : (a, b) \in WS_j\}\).
4) Choose pair \((a^*, b^*) \in P\) for which \(W[(a^*, b^*)]\) is maximal.
5) If \(\text{Max}_{(a, b) \in P}(W[(a, b)]) = 1\) then return \(R, NU\).
6) Remove \((a^*, b^*)\) from \(P\) and add it to resulting set \(R\) and \(NU\).
7) For each \(j : (a^*, b^*) \in WS_j\)
   a) Add \((a^*, b^*)\) to \(NU[j]\).
   b) Remove \((a^*, b^*)\) from \(WS_j\).
8) Go to 3.

Let us refer to the set of obtained intersections of size 2 as \(R^2\), and the set detailing which pair is included in which neighborhood as \(NU^2\). In order to obtain intersections of size 4 we can use the same greedy algorithm. Indeed, assume that we order all pairs in \(R^2\) and assign them numbers from 1 to \(|R^2|\). Then for each \(N_i\) we construct set \(N_i^2 = \{j : (a, b) \in NU[j]\}\).

Then we give the constructed \(n\) sets \(\{N_i^2\}\) as an input to our greedy algorithm. It is easy to see, that from its outputs \(R^4, NU^4\) using information about numbers assigned to pairs from \(R^2\) we can extract all intersections of size 4 constructed from intersections of size 2. We can repeat this process until the resulting \(R^2 = \emptyset\).

Of course, by means of this greedy algorithm we do not obtain the optimal solution for the problem. But it works relatively fast (with proper implementation), gives us the result that is suitable for our needs (i.e. only intersections of sizes equal to powers of 2) and is easy to implement.

Now we can use the obtained sets \(R^2, R^4\), and \(NU^2, NU^4\) to reduce the redundancy of networks of mergers. Assume that we first introduce the mergers for all \(R^2\), then for all \(R^4\), etc. Note that, for example, each set of size 4 in \(R^4\) is comprised of two pairs from \(R^2\) by definition. It means that we use outputs of mergers for corresponding pairs as inputs for merger of size 4, etc. Of course, in general case not all mergers of smaller size are used to construct mergers of larger size. Assume that we now construct network of mergers for an agent \(j\). Then we fill its network of mergers by already constructed mergers corresponding to entries in the corresponding \(NU^2[j]\), \(NU^4[j]\), \ldots (put in the proper order). After this we introduce mergers for all elements that are not covered by existing ones, etc.

Let us consider one more improvement which consists in adapting the sorting network generation procedure to specific value of conformity level parameter.

D. Using Advanced Sorting Network Construction Procedures

There are several ways, how we can take into account the value of conformity level to reduce the size of propositional encoding. The most drastic effect we can achieve by noticing that conformity levels \(c_i = 1\) and \(c_i = |N_i|\) do not require to construct any sorting network at all. Indeed, \(c_i = 1\) means that if there is at least one agent \(v_j\) with \(w_i^j\) in the neighborhood of agent \(v_i\) at time moment \(t\), then \(w_i^{t+1} = 1\). It is easy to express it by simple logical equation \(w_i^{t+1} = \vee_{v_j \in N_i} w_i^j\). Following the similar reasoning, for \(c_i = |N_i|\) the logical equation looks as follows: \(w_i^{t+1} = \bigwedge_{v_j \in N_i} w_i^j\). It also means that we do not need to process the corresponding neighborhoods by our greedy algorithm described earlier.

Now, for the cases when \(1 < c_i < |N_i|\) we can use the information about conformity level value to a lesser, but quite significant extent. For this purpose we combine one simple heuristic with a method for reducing the size of sorting network outlined in [5]. It is used in that paper to construct cardinality constraints. Essentially, it proposes that if for a sorting network that sorts \(2^h\) values, we are interested only in the first \(2^h\) outputs, \(h < l\), then we can use a simplified merging procedure to merge sorted sequences of size \(2^h\) into sequences of size \(2^h\). It is defined as follows:

\[
\text{SMerge}(a, b, (c_1, c_2)) \leftrightarrow \text{comparator}(a, b, c_1, c_2)
\]

\[
\text{SMerge}((a_1, a_2, \ldots, a_n), (b_1, b_2, \ldots, b_n), (d_1, d_2, \ldots, d_{n+1})) \leftrightarrow \text{SMerge}(a_1, a_2, \ldots, a_{n-1}, b_1, b_2, \ldots, b_{n-1}, d_1, d_2, \ldots, d_{n+1}) \wedge \text{SMerge}(a_2, a_3, \ldots, a_n, b_2, b_3, \ldots, b_{n-1}, d_2, d_3, \ldots, d_{n+1}) \wedge \ldots \wedge \text{SMerge}(a_n, b_n, d_n) \wedge \text{comparator}(c_1, d_{n+1}, c_2, 2^h+1)
\]

We use it as follows. Consider an agent \(v_i\) with conformity level \(c_i, |N_i| = k_i, c_i < k_i\). We construct a network of mergers, and if \([\log(c_i)] < [\log(k_i)]\) then we replace each merger which takes as input sequences of length \(2^{[\log(c_i)]}\) by simplified merger. The resulting sorting network has much less comparators than original. At the left part of Fig. 2 we show full sorting network with 16 inputs and 16 outputs at the top, and sorting network with 16 inputs and 4 outputs, constructed using simplified mergers at the bottom.

Another small improvement consists in the following: in fact, we only need one output of the sorting network for our purposes – the \(c_i\)-th one. It means that we can discard all comparators that do not influence the value on the \(c_i\)-th wire.
Interesting and relatively counter-intuitive observation consists in the fact, that for Batcher sorting networks the application of this technique gives different results depending on whether we use simplified mergers or not. As an example, we assume that $|N_i| = 16$ and $c_i = 3$. The results of application of the proposed technique to the sorting networks with 16 inputs constructed using mergers and simplified mergers are shown in the right part of Fig. 2: the top variant corresponds to removing redundant comparators from the standard network constructed using mergers, and the bottom variant corresponds to processed sorting network constructed using simplified mergers.

E. Comparison of Encodings on Random Graphs

To measure the effect of proposed encoding techniques, we need to specify the problem and define graphs specified above. Assume that we consider a graph with $n$ vertices. We encode to SAT the following problem: to determine the disposition of at most $[0.15 \times n]$ instigators at the initial time moment (remind, that only instigators are active at the initial time moment), so that after 15 time steps at least $[0.8 \times n]$ agents in the network are active. We compare the encoding techniques in application to two series of random graphs generated according to different random graphs model: Erdős-Rényi model [9] and Barabási-Albert model [10]. We will not specify how the graphs are constructed since it was covered in detail in many sources, including [1]. In Table I we show the sizes of propositional encodings for outlined problems for graphs with $n = 250$ vertices. Graphs corresponding to Erdős-Rényi model are referred to as ‘GNP’ and were constructed using parameter $p = 0.05$. Barabási-Albert model does not have explicit parameters per se, and the corresponding graphs are referred to as ‘BAR’. As for encodings, ‘OLD’ stands for the encoding method employed in [2], [1], ‘BASE’ – to the new encoding method without employing greedy algorithm and techniques for removing redundant comparators, ‘GR’ – to the encoding produced using greedy algorithm, ‘RED’ - to the encodings produced using techniques for removing redundant comparators, ‘GR-RED’ – to the encodings fully benefiting from all techniques proposed in this paper. For each random graph model we generated 100 instances and show the average size in megabytes. Also to show that greedy algorithm works best when the graph is dense, we show the statistics for a complete graph with 250 vertices (referred to as ‘Complete250’ in the Table I). For each graph, conformity level of each agent $v_i$ was generated according to the uniform distribution specified on $[1, |N_i|]$. It is easy to see that our old scheme used in previous works was very redundant. It is also worth mentioning that the size gap in the transition from ‘OLD’ to ‘BASE’ should not theoretically translate into easier problems for SAT solvers (unlike that for other cases) because it is achieved mainly by techniques for constructing sorting networks of specified size instead of that of size equal to closest power of two (see subsection III.B). Overall, it should be noted that the results are quite remarkable: proposed techniques make it possible to significantly reduce the size of encodings. The impact of greedy algorithm is the larger the denser is the graph, as it is illustrated by 3 times difference between the sizes of ‘GR’ and ‘BASE’ encodings for complete graph. As for techniques that ‘prune’ sorting networks based on the value of conformity level – they generally work quite well, however, it is possible that their effect will be worse the higher (on average) the conformity levels are.

IV. USING STATE-OF-THE-ART TOOLS TO OPTIMIZE SAT SOLVERS PARAMETERS

Now let us compare the effectiveness of SAT solving algorithms on the constructed encodings. In particular, for this purpose we use the LINGELING SAT solver [11] (version bbc-9230380-160707) and employ the SMAC tool [12] (version 2.10.03) for optimizing solver parameters. As a computing platform we use cluster nodes of the computing cluster ‘Aca-demician V.M. Matrosov’ of Irkutsk supercomputing center SB RAS 1, one node equipped by two 16-core AMD Opteron 6276 CPUs and 64 Gb RAM. We disable one of 331 LINGELING parameters (‘mem-lim’), thus SMAC has to vary the remaining 330. The LINGELING solver is a single-threaded application, while SMAC is multi-threaded. For each test series when SMAC had to optimize parameters values it was launched for two days with time limit of 5000 seconds on several nodes, using 8 CPU cores within a node (so that solvers do not run out of memory) with enabled option –shared-model-mode, allowing SMAC instances to exchange data.

In the first series of experiments we applied SMAC+LINGELING to 8 series of 100 tests corresponding to 4 encodings for ‘BAR250’ and ‘GNP250’, discussed in the previous section. For each series we randomly chosen 10 instances as training set, for which SMAC optimized parameters, and the remaining 90 as test set. It means that we performed 8 separate experiments with SMAC. In Table II we show the results of LINGELING on the test set with default values of parameters and with tuned parameters. It is clear that the benefit is very substantial and the ‘GR-RED’ encoding is the best or very close to the best.

After this we (following [2]) applied the parameter values found for graphs with 250 vertices to the corresponding problems for graphs (of the same model) with 500, 1000 and 2000 vertices. We show the results for ‘BASE’ and ‘GR-RED’ encodings (see Table III). Note that for the case of 2000 vertices we generated only 10 SAT instances with ‘GR-RED’ since their size is very large. Also, because Erdős-Rényi model

to SAT. New procedures are heavily optimized in a sense that we reduced the amount of redundant repeated actions to minimum, thus making encodings more compact and less difficult for SAT solvers. The optimizations of the algorithm use both new (however, relatively simple and problem-specific) methods, such as greedy algorithm to figure out neighborhood intersections and removing redundant comparators that do not influence specific outputs of a sorting network, and the results from known works, such as Simplified Merge procedure [5].

VI. CONCLUSIONS
In this paper we significantly improved the effectiveness of procedures that can be used to study several discrete models of conforming behavior using SAT approach. We tested it on two families of random graphs, generated according to Erdős–Rényi and Barabási–Albert models. The decrease in size turned out to be from 30 % to 70 %. The corresponding effect on SAT solving algorithms was good as well.

Abstract – The table-organized data can be analyzed by various algorithms; some of them are capable of generating IF THEN decision rules which comprises of condition attributes and decision attributes. However, it is possible to reduce the set of condition attributes but without information loss. By analysis of the condition attributes set and cuts histogram obtained by discretization and rule consistency, it is possible to choose condition attributes. This paper gives some directions and the practical example.

I. INTRODUCTION

This paper presents the process of attribute selection in order to generate IF THEN rules from table-organized data. The problem is recognized by the CRISP-DM standard [1], which clearly separates Data Understanding from Data Preparation. Data Understanding is an activity that uncovers the very essence of the data, while the Data Preparation includes more activities dealing with lost information, simpler and better data processing. The problem of choosing data for research is especially present in the field of Big Data.

There are situations when the result of data classification obtained by IF THEN rules is good. However, if we analyze the consistency of this set, we can conclude that there are situations when the rules are not precise enough. If the OR logical operator is included in the THEN part of the rule, the rule is inconsistent and imprecise, while classification is often good. The possibilities of further detailed selection of condition attributes will be considered based on Rough Set Theory [2], and by attribute histogram analysis as well.

II. ROUGH SET THEORY

The Rough Set Theory has been developed having in mind data analysis and information systems [2]. The basic purpose of these sets is the approximation of unfamiliar knowledge using the familiar one [3]. Based on the principle of indiscernibility relation of objects and the concept of approximation, this theory enables recognition of inter-dependability between the decision attributes and condition attributes [4].

In the rough set theory, an information table [5], consisting of ordered quadruple \( S = \langle U, Q, V, f \rangle \), is defined, where:

- \( U \) is the finite set of objects - universe;
- \( Q = \{q_1, q_2, \ldots, q_m\} \) is a finite set of attributes;
- \( V = \bigcup_{q \in Q} V_q \), where \( V_q \) is the domain of attribute \( q \) (attribute values);
- \( f = U \times Q \rightarrow V \) is the total function, such that \( f(x, q) \in V_q \) for each \( q \in Q, x \in U \) and is called information function.

Each object \( x \in U \) is described by the vector:

\[
\inf_q(x) = [f(x, q_1), f(x, q_2), \ldots, f(x, q_m)]
\]  (1)

which defines the values of object \( x \) attributes.

If \( P \) is a non-empty subset of attribute set \( Q \), then the relation \( I_P \) is defined on the objects from the universe \( U \), in the following way:

\[
I_P = \{(x, y) \in U \times U : f(x, q) = f(y, q), \forall q \in P\}
\]  (2)

Relation (2) is called indiscernibility relation. If \( (x, y) \in I_P \), we say that the objects \( x \) and \( y \) are \( P \)-indiscernible. The indiscernibility relation is the equivalence relation and it generates the partitions – equivalence classes. [6]. The family of equivalence classes, generated by \( I_P \), are marked with \( U/I_P \).

Equivalence classes generated by relation \( I_P \) are called \( P \)-elementary sets, and the equivalence class containing the object \( x \in U \) is marked with \( I_P(x) \) or \([x]_P\).

For the set \( X \), a non-empty subset of \( U \), called a rough set, and for \( \emptyset \neq P \subseteq Q \), the following are defined:

\[
P(X) = \{x \in U : I_P(x) \subseteq X\}
\]  (3)

\[
\overline{P}(X) = \bigcup_{x \in X} I_P(x)
\]  (4)

\( P(X) \) is the \( P \)-lower approximation, which means that the objects certainly belong to \( X \), and \( \overline{P}(X) \) is the \( P \)-
upper approximation, which means that the objects may belong to the set $X$ \[7\].

$P$-boundary of subset $X$ in $S$ is defined as follows:

$$Bn_p(X) = \overline{P}(X) - P(X)$$  \hspace{1cm} (5)

Graphical interpretation of $P$-boundary is shown in Fig.1. It cannot be said with certainty that the elements from the boundary region belong to the set $X$ – so it is said that they are the elements of the set $X$ approximation \[8\].

This research will use simple calculation of consistency and reduct sets, which are used for IF THEN rules generation. Consistency is defined on the basis of generalized decision function $\delta_p(x_i)$ in the rough set theory. Moreover, a direct implication of inconsistent table can be observed: it is the decision rules which in IF part have the same conditions, and in THEN part various decisions. Information reduct, or just reduct is intuitively recognized as a minimal subset of condition attributes which keep the discernibility between the objects \[9\]. The reduct set includes only these condition attributes which are sufficient for evaluation of the decision attribute value.

The variation of the Johnson’s algorithm \[10\] will be used for calculating the minimal simple implicants of Boolean function, so that IF THEN classification rules will be generated by single reduct set. Johnson’s algorithm is a simple greedy heuristic algorithm, often applied to discernibility functions to find a single reduct. The algorithm first sets the current reduct candidate, to the empty set. Then, it evaluates each conditional attribute appearing in the discernibility function according to the heuristic measure. This measure is usually a count of the number of appearances an attribute makes within clauses. The algorithm adds the attribute with the highest heuristic value, removing all clauses in the discernibility function containing this attribute at the same time \[11\].

After reduct set calculation, it is possible to determine rules of the IF $a$ THEN $b$ form. Here $a$ denotes a conjunction of attributes from some reduct set and their corresponding values: attribute value or subinterval obtained through discretization. The $b$ consists of decision attribute and corresponding value.

III. HISTOGRAM

Histogram is a well-known mathematical tool for graphical presentation of object distribution, i.e. frequency of certain data values. Its advantage in presenting data is firstly in the fact that the graphical presentation can show the center of distribution, the spread of distribution, shape of data distribution, as well as noticing of some unusual data characteristics. If a distribution has only one peak, then the middle of such a distribution is usually at the peak. The shape of distribution is usually used in recognizing the data patterns \[12\]. Unusual characteristics often refer to certain breaks in histogram, as well as in isolated values (Fig. 2). Some distributions can be similar to a mathematical distribution, while a significant data set often comes in the form of an irregular multimodal distribution (Fig. 3).

![Figure 1. P-boundary of set](image)

![Figure 2. Histogram edge peak data distribution](image)

![Figure 3. Histogram multimodal data distribution](image)

Previous to rough set theory application, the data values need to be prepared so that all values are discrete and the consequent histogram is a suitable for data analyses.

IV. THE RELATION OF HISTOGRAM AND DATA DISCRETIZATION

In the domain of Data Mining, numerous Machine Learning methods can work only with the discrete attribute values. This is the reason why it is necessary to transform the continuous attribute values into the discrete ones, before machine learning process. This process of data discretization is an essential task in preprocessing of data. The result of discretization is the set of cuts by which the data are classified into intervals \[13\].

A. The relation of data distribution and discretization algorithm

The relation of data distribution and large databases has been observed within the algorithm of maximal discernibility, by using median \[5\]. Paper \[14\] suggests the usage of the incremental algorithm for data streams, in order to modify the data distribution. The algorithm for estimating a histogram density based on the MDL principle (MDL Histogram Density Estimation) uses the entropy to generate the histograms for data regularity. The consequent analysis results enable the discretization \[15\]. Therefore, the MDL based algorithm discovers patterns in the data histogram.
B. Histogram segmentation

Histogram segmentation definition is related to recognition of the thresholds of multimodal distribution. Firstly, the segmentation of multimodal distribution is done by ‘smoothing out’ the existing histogram – so that the distribution function becomes a smooth curve, as shown in Fig. 4 (the figure was taken from Paper [16]). Secondly, based on the cross-section of these smooth curves the threshold point is obtained, dividing the histogram into two parts.

![Original histogram (left) i smooth histogram (right)](image)

Figure 4. Original histogram (left) i smooth histogram (right)

Appropriate histogram segmentation example is described in [16]: Fig. 5 shows the blood cells and the histogram with two thresholds (the figure was taken from Paper [16]). In detail, Fig. 5 shows the picture of blood cells, histogram, smooth curve obtained through the histogram and the picture obtained through histogram segmentation. The first part of segmentation of the interval (0, 128) shows the picture of blood cells. The second part of the interval segmentation (128, 184) shows the blood plasma. Finally, the segmentation of the interval (184, 250) shows the cell membranes.

![Blood cells, histogram, smooth curve, and results obtained through histogram segmentation](image)

Figure 5. The picture of blood (a), histogram (b), smooth histogram (c) and the results obtained through histogram segmentation, blood cells (d), blood plasma (e) and cell membranes (f)

Based on the histogram analysis, the unimodal parts of multimodal distribution can be recognized. In the case of no-peak histograms or the ones with only one distinct peak, the segmentation would not be possible.

C. The idea of choosing the condition attributes on the basis of histogram and cuts

In [13] the significance of histogram segmentation in the processes of discernibility-based discretization is described. The cuts obtained through the algorithm of maximal discernibility, which are closest to the histogram segmentation thresholds, are very important for the preservation of discernibility. Based on this, the algorithm of approximate discretization APPROX MD was developed [13]. It uses the cuts obtained through the maximal discernibility algorithm, which are closest to the multimodal histogram segmentation thresholds. The aim is to define the most significant cuts for all condition attributes.

Consideration of process of choosing the condition attributes for generating IF THEN rules is the extension of the process described in [13]. Since the reduct of the condition attribute set distinguishes those attributes which can describe the entire set, the subject of the research is the analysis of the histogram of the attributes which make up the reduct.

This paper will give the basic directives for the analysis of histogram and cuts obtained from reduct set. The directives are:

- the existence of the histogram thresholds,
- the position of cuts on the multimodal distribution histograms,
- the position of cuts on the unimodal distribution histograms,
- the comparison of the reduct of the entire information table with the reduct of the modified information table obtained through the reduction of certain condition attributes set,
- the comparison of the reduct of the entire information table with the reduct of the modified information table obtained through the enlargement of certain condition attributes set.

Mandatory part of the reduct analysis is the observation of consistency of the IF THEN rules set.

V. Example

The histograms of condition attributes will be shown on the example of Iris database [17]. The database contains 3 classes, 150 instances while each class refers to a type of the flower iris. As a result, a discretization has been done by the maximal discernibility algorithm and a reduct was calculated by the variation of the Johnson’s algorithm. The reduct consists of third and fourth attribute, which satisfies multimodal histogram distribution. First two condition attributes do not satisfy typical multimodal distribution. The histograms of all the condition attributes are presented on Fig. 6 – Fig 9. The cuts are shown on the ordinates by wide black vertical lines.

![Data distribution of the 1. attribute sepal length, with the cut obtained by the maximal discernibility algorithm](image)

Figure 6. Data distribution of the 1. attribute sepal length, with the cut obtained by the maximal discernibility algorithm
multimodal distribution on the reduct set should be researched on the bigger number of the databases.

Abstract—Resource constrained project scheduling problem (RCPSP) is one of the most intractable combinatorial optimization problems. RCPSP belongs to the class of NP hard problems. Integer Programming (IP) is one of the exact solving methods that can be used for solving RCPSP. IP formulation uses binary decision variables for generating a feasible solution and with different boundaries eliminates some of solutions to reduce the solution space size. All exact methods, including IP, search through entire solution space so they are impractical for very large problem instances. Due to the fact that exact methods are not applicable to all problem instances, many heuristic approaches are developed, such as genetic algorithms. In this paper we compare the time complexity of IP formulations and genetic algorithms when solving the RCPSP. We present two different solution representations for genetic algorithms, permutation vector and vector of floating point numbers. Two formulations of IP and and their time and convergence results are compared for the aforementioned approaches.

I. INTRODUCTION

Scheduling is process which all of us use on everyday basis. In scheduling the goal is to allocate resources to tasks over given time periods. Usually the resources that we have have some limitations. For example we have limited project budget, limited number of employees, vehicle capacity etc.

This work will focus on one of the problems with constraints known as resource constrained project scheduling problem (RCPSP). RCPSP is a problem in which one has to deal with two kinds of constraints - precedence and resource. In this scheduling process we define starting point of some activity taking care of its precedence and amount of resources that are available.

RCPSP belongs to class of NP hard problems [1] and that, with fact that it is common problem in everyday world, results with numerous methods for solving it. Which method to use is a decision that has to be made upon the problem characteristics. In literature two different groups of solving methods can be found - exact methods and heuristics [2].

Exact methods search the entire space of feasible solutions and guarantee the optimality [3], but because of size of solution space they are impractical and almost useless for problems with large instance size [4]. Because of that many heuristic methods were developed. Heuristics do not search the entire solution space and do not guarantee the optimality but they are fast and can result with good enough solutions for the specific problem.

Heuristics can be divided into two groups: priority rule-based methods (or constructive heuristics) and metaheuristic-based approaches (or improvement heuristics). Methods in the first group start with empty schedule, and iteratively put in each step one activity based on it’s priority, until unscheduled activities exists. The second group starts with initial complete solution and in each iteration tries to improve it.

In this work we will present two IP formulations as representatives of exact methods, and Genetic algorithm (GA) as representative of heuristics methods. In GA approach two different solution representations will be used. Result comparison and time execution comparison will be given for these methods.

This paper is organized as follows: in section 2 a short overview of solving methods for RCPSP is given. The definition of RCPSP can be found in section 3. In section 4 two different IP formulations are given, and GA adaption for RCPSP is explained in section 5. Experimental results together with implementaion details of this methods are given in section 6. Finally in section 7 a short conclusion is given.

II. RELATED WORK

Many researchers investigate RCPSP and a lot of work for exact and heuristic methods can be found in literature. Exact methods can be divided in four different groups: 1) Integer Programming - using large number of binary variables [5], [6] 2) Implicit Enumeration - using enumeration tree and bounds to reduce the space of feasible solutions [7], [8] 3) Branch-and-bound methods - using trees and lower bounds to eliminate nodes in tree that cannot lead to optimal solution [9], [10] 4) Dynamic programming - divide problem on problems with smaller size and solve that problems, and combine the solution [11].

Some of heuristic methods that can be found in literature are: Genetic algorithms [12], [13], Simulated annealing
RCPSP is a problem in which we need to schedule activities which have their duration and resource demands, while all resources have limited amount that can be used in one time period. Beside of the limited resource amount, there are precedence constraints that have to be satisfied, meaning that every activity has predecessors that need to be finished before it starts. The goal of scheduling is to find a feasible schedule that minimizes some objective, by assigning start times to each activity that satisfies the precedence and resource constraints.

Formally, RCPSP can be defined as a combinatorial optimization problem as tuple [17]:

\[
RCPSP = (A, E, p, R, B, D, c).
\]  

In this tuple \( A \) denotes the set of all activities \( A = \{A_0, A_1, \ldots, A_{n+1}\} \), where activities \( A_0 \) and \( A_{n+1} \) are dummy activities that represent the start and the end of a schedule. Vector \( p \in \mathbb{N}_{0}^{n+2} \) is vector of durations, in which component \( p_i \) is duration of activity \( A_i \). Dummy activities have duration \( 0 \).

The precedence relations between activities are given by set \( E \). Set \( E \) consists of pairs of activities \( (A_i, A_j) \) which mean that activity \( A_i \) precedes activity \( A_j \). The assumption for dummy activities is that activity \( A_0 \) precedes all other activities and that \( A_{n+1} \) succeeds all other activities. So, by determining the start point of \( A_{n+1} \) the total project duration is found.

Resources that are needed for activities are given by set \( R = \{R_1, \ldots, R_r\} \), and amount of each resource that is available in all time period is given by vector \( B \in \mathbb{N}^r \). Demands on resources for each activity are given by matrix \( D \in \mathbb{N}_{0}^{(n+1) \times r} \).

The objective function is \( c : \chi \subseteq \mathbb{R}^{n+2} \rightarrow \mathbb{R} \), where \( \chi \) is a feasible schedule. Sometimes this tuple member is omitted, in which case the objective function which needs to be minimized is project makespan (total project duration). The solution is a schedule \( S \in \chi \), where component \( S_i \) of vector \( S \) represents the start time of activity \( A_i \). When vector \( S \) is known it is easy to find vector of completion times of activities denoted by \( C \), by computing component \( C_i = S_i + p_i \).

If we mark the set of all activities which are active at a time \( t \) with \( A_t = \{A_i \in A : S_i \leq t \leq S_i + p_i\} \), RCPSP can be defined as a problem of finding a feasible schedule \( S \) with minimal makespan \( S_{n+1} \) for which following constraints are satisfied:

\[
S_j - S_i \geq p_i \quad \forall (A_i, A_j) \in E
\]  

\[
\sum_{A_i \in A_t} D_{ij} \leq B_j \quad \forall i \geq 0, \forall R_j \in R.
\]  

For further problem analysis we also need to define set \( E(t) \) - the set of eligible activities at time \( t \). For definition of that set we need to define the following properties of each activity:

- \( ES_j \) - the earliest start time of activity \( A_j \)
- \( EF_j \) - the earliest finish time of activity \( A_j \)
- \( LS_j \) - the latest start time of activity \( A_j \)
- \( LF_j \) - the latest finish time of activity \( A_j \).

To calculate mentioned properties the horizon (the total project time) \( T \), must be known. If it is not given, it can be calculated by some heuristic or using the formula

\[
T = \sum_{j=1}^{n} p_j.
\]  

With setting \( ES_0 = EF_0 = 0 \) for calculating \( ES_j \) and \( EF_j \) we can use the following formulas:

\[
ES_j = \max\{EF_i : i \in P_j\}
\]  

\[
EF_j = ES_j + p_j, j \in \{1, \ldots, n\},
\]

where \( P_j \) is set of activities that directly precede the activity \( A_j \).

Similarly, for calculating \( LS_j \) and \( LF_j \) we set \( LF_n = LS_n = T \) and use formulas:

\[
LF_j = \min\{LS_i : i \in F_j\}
\]  

\[
LS_j = LF_j - p_j, j \in \{n-1, \ldots, 1\},
\]

where \( F_j \) is set of activities that directly succeed the activity \( A_j \).

Now we can define \( E(t) \) as:

\[
E(t) = \{A_j : A_j \in A, ES_j + 1 \leq t \leq LF_j\}.
\]

IV. IP FORMULATION OF RCPSP

IP is a method in which number of binary variables are introduced and used for creating a schedule. In this section two different IP formulations of RCPSP will be given.

A. Formulation I

The first IP formulation was given by Pritisker et al. [6] in 1969. In this formulation, the solution of RCPSP is represented with series of zero-one variables \( x_{jt} \), \( j \in J \) (\( J \) is set of activity indexes), \( t \in [EF_j, LF_j] \). Variables are defined as:

\[
x_{jt} = \begin{cases} 
1, & \text{if activity } A_j \text{ is completed at the end of period } t \\
0, & \text{otherwise.}
\end{cases}
\]

The variable \( x_{jt} \) can have the value 1 just in a time period in which the activity \( A_j \) can be completed so it is introduced just for \( t \in [EF_j, LF_j] \). Time in which activity \( A_j \) finished is given by:

\[
\sum_{t = EF_j}^{LF_j} t \cdot x_{jt}
\]
IP formulation for RCPSP can be now given as:

\[
\text{subject to:} \quad \sum_{t = EF_i}^{LF_i} t \cdot x_{jt} = 1, \quad j \in J
\]

\[
\sum_{t = EF_i}^{LF_i} (t - p_j) x_{jt} - \sum_{t = EF_i}^{LF_i} t \cdot x_{it} \geq 0, \quad j \in J, i \in P_j
\]

\[
\sum_{j \in E(t)} \sum_{q = \max\{t \cdot LF_i\}}^{\min\{t + p_j - 1, LF_i\}} u_{jr} \cdot x_{jq} \leq a_r, \quad r \in R, t \in [1, \ldots, T]
\]

\[
x_{jt} \in \{0, 1\}, \quad j \in J, t \in [EF_i, LF_i]
\]

From (11) it is clear that in this formulation one minimizes the completion time of the last activity (makespan). If the completion time of the last activity is minimal then the completion time for all activities is minimal too. Constraints (12) and (15) ensure that the activity can be completed exactly in one time period. Constraint (13) ensures that all predecessors of activity \( A_j \) are completed before it starts with execution, and constraint (14) ensures that in each time period the amount of resources being used is smaller or equal to the available amount of resources.

B. Formulation 2

RCPSP can be formulated as IP using variables \( y_{jt} \), which can also only become 0 or 1 for \( j \in J, t \in [ES_j + 1 - p_j, LF_j] \) and are defined in the following way:

\[
y_{jt} = \begin{cases} 
1, & \text{if activity } A_j \text{ is completed at the beginning of period } t \text{ or earlier} \\
0, & \text{otherwise.} 
\end{cases}
\]

For activity \( A_j \) there is vector with \( LF_j - ES_j - 1 + p_j \) components with two blocks: the first consists of zeroes, and the second consists of ones. Time period in which change between these two blocks happens is the time point in which activity \( A_j \) started. In accordance with that, the time point in which activity \( A_j \) starts is given with:

\[
LF_j - \sum_{t = ES_j + 1}^{LF_j} y_{jt}
\]

IP formulation of RCPSP with introduced variables is:

\[
T - \sum_{t = ES_n + 1}^{LS_n} y_{nt} \to \min
\]

subject to:

\[
y_{jt+1} - y_{jt} \geq 0, \quad j \in J, t \in \{ES_j + 1, \ldots LS_j - 1\}
\]

\[
y_{t, t-p_j} - y_{jt} \geq 0, \quad j \in J, i \in P_j, t \in \{ES_j + 1, \ldots LF_j\}
\]

\[
\sum_{j \in E(t)} (y_{jt} - y_{jt, t-p_j}) \leq a_r, \quad r \in R, t \in [1, \ldots, T]
\]

Objective function is given with (17) and minimizes makespan. Constraints (18) and (21-23) ensure that activity \( A_j \) starts in one time point only. Constraint (19) ensures that all predecessors \( A_i \in P_j \) of activity \( A_j \) start at least \( p_i \) time units earlier. Constraint (20) ensures that resource usage in every time period satisfies the amount of resource which can be used.

V. GA FOR RCPSP

In this section, genetic algorithms and how they work will briefly be explained.

The idea for genetic algorithms (GAs) came from the principles of natural selection and genetics. Because of that, certain terms in GAs are equal to the terms one can see in genetics. In GAs decision variables are coded as finite dimensional vectors which come from an alphabet of some cardinality. Those vectors are called chromosomes, parts of the alphabet are called genes, and the values of the genes are called alleles. E.g. for the Traveling Salesman Problem (TSP), one chromosome represents a route and one gene represents a city in a route [18]. In GAs solutions can be represented in various ways. Some of them are [19]: array of bits, permutation array, matrix representation, floating point vector, integer vector etc.

In order to get better solutions in the process of natural selection, there should exist some measure which will determine which solutions are better than the others and then lead to better solutions in GAs. Genetic algorithms use population of solutions rather than only one solution to find optimum of some problem. It is necessary to determine the optimal size of population, which is an optimization problem by itself. After determining the size of population and chromosome coding as well as some fitness measure for solution candidates, algorithm can start to evolve solutions for a given problem using the following steps [18]:

1) Initialization: initial population of solutions is generated randomly, or if some additional information about solution space is known, that knowledge is incorporated in generating better initial population

2) Evaluation: after initialization, the fitness of each population member is evaluated
3) Selection: selection chooses few of the better solutions and that way one can secure survival of the fittest
4) Crossover: crossover operators combine parts of two or more parents in order to create one or more children solutions
5) Mutation: mutation modifies existing solution in order to keep diversity in population
6) Replacement: population of children obtained in selection, crossover and mutation, replaces old population of parents

After that, evaluation, selection, mutation and replacement are repeated until some of stopping criteria is met.

GAs can be sequential and parallel [19]. Sequential GAs can be steady-state GA or generational GA. Steady-state GA chooses two parents from population, makes one child, mutates it and evaluates it. Child can then be inserted in population (in that case some other solution candidate gets thrown out) or rejected. In generational GA in every step whole new population of children is created which replaces old parent generation. If in that process one does not want to lose best found solution, elitism can be introduced, i.e. the best current known solution is always put in child population. In GA implementation used for this work, a sequential steady-state GA with elitism is used.

VI. EXPERIMENTAL RESULTS

A. Integer Programming

For solving IP problems it’s common to use cutting plane methods and variants of the branch and bound method. In this work Gurobi [20] was used for solving IPs. The solvers in the Gurobi Optimizer use parallelism while solving problems. The process of solving can be divided in two phases: presolving and solving. Presolving phase is a phase in which problem is simplified which can significantly reduce the time needed for solving problem. Methods that are used in this phase are: removal of empty rows and columns, finding and removing rows dominated by linear combination of other rows etc. In the solving phase Gurobi uses branch and bound and cutting plane methods for solving new reduced problem created in presolve phase.

B. Genetic Algorithm

In GA implementation for this problem two solution representations were used: permutation representation (as proposed in [21]) and floating point vector representation. In permutation representation, every candidate solution is represented as integer vector which contains numbers from 0 to \( n+1 \), where \( n \) denotes number of jobs. E.g. for \( n = 5 \), \( \{0, 2, 3, 5, 1, 4, 6\} \) means that job 2 is executed first, after that job 3 is executed etc. In floating point vector representation, every candidate solution is presented as vector which contains numbers between 0 and 1. The higher the number, the more important it is to start the job earlier. E.g. \( (0.3, 0.95, 0.17, 0.82, 0.5) \) means that jobs should be executed in the following order: \( (2, 4, 5, 1, 3) \). In order to get feasible solutions in the initial population (solutions that meet precedence constraints and resource constraints) for both representations, serial schedule generation scheme has been used which schedules a job in earliest possible time in which both precedence constraints and resource constraints for given job are met. Due to the lack of space, serial schedule generation scheme pseudocode is omitted but can be found in [22].

For GA tests, Evolutionary Computation Framework\(^1\) (ECF) was used with the following setup: 3-tournament selection was used, where in each iteration three random individuals are chosen and the worst of the three is eliminated. A new individual is created using crossover from the remaining two, and is subjected to mutation with a given probability. In the permutation encoding, order-based crossover operators OBX and OX2 as well as cycle crossover where used as crossover operators. The mutation operator randomly chooses two genes in an individual and swaps their positions. For the floating point vector a discrete crossover was used and a simple mutation that randomly recreates a single vector element. More information on the genetic operators is available at the framework website.

A short tuning phase was conducted for both representations, which resulted in using the population size of 1000 individuals and a mutation rate of 0.7 (i.e. on average 7 out of 10 new individuals will get mutated). Rather than using a maximum number of generations or evaluations, the stopping criterion is set to a common time limit (of 8 hours) for the purpose of comparison with the IP solver.

C. Benchmark

Implementation of methods mentioned in this work were tested on problems from PSBLIB Library. This library consists of different sets of RCPSP with their so far known optimal or heuristic results. Problems in PSBLIB Library are divided in 4 groups based on number of jobs. The first group consists of problems with 30 activities, the second with 60 activities, the third one has problems with 90 activities and last group problems with 120 activities. More about this library and generation of problem instances can be found in [23].

D. Result and execution time comparison

Tests were conducted on 48 problem instances from group of 30 activities and on 48 problem instances from group of 90 activities. Results are given in tables I and II.

For IP formulations tables show execution times if solution was found in under 8 hours, otherwise the x is put in corresponding row. To make the comparison fair, for the genetic algorithm the stopping criterion was set at the same time limit or achieving the optimal solution (if it is known in advance). Furthermore, the GA was automatically restarted (under the time limit) if no improvement was achieved in the last 500 generations. The GA results in Tables I and II present the best found solution in the

\(^1\)http://ecf.zemris.fer.hr/
8 hours allotted to the algorithm, regardless of the number of restarts.

It can be seen that when using IP for problems with 90 activities the number of instances that are not solved in under 8 hours is bigger than in problems with 30 activities, which supports the fact that instances of larger size are more difficult to solve. If we compare formulation 1 and formulation 2, we can see that formulation 1 gives results in less time than formulation 2. However, it is worth noticing that there is no problem instance which is solved by one formulation and not by the other.

The tables also show results and execution times for both solution representations in GA. The GA was always able to reach the known optimum solution for 30 activity problems, whereas it did not reach the optimum in ten of the problem instances with 90 activities.

If we compare the two solution representations we can see that the permutation representation obtains slightly better results. This is evident from the deviation of the obtained results from the optimum solutions: for the cases where the optimum was not obtained, the permutation encoding exhibits an average deviation of 7.16%, while for the floating point it averages 8.8%.

To better illustrate the average performance of the two GA representations, Table III shows the results of both variants on the test instances from Table II in which the GA did not manage to obtain the optimal solution. The data in the table indicates the standard statistical properties obtained with 20 repetitions with the stopping criterion of $10^6$ evaluations.

</table>

If we compare IP and GA we can see that for instances in which IP found a solution, GA also found the optimal solution with execution time that is approximately the same as the execution time of IP. For some instances, IP (especially for instances with 90 activities) found solution in less time, but for problems where IP did not find a solution, GA always managed to obtain a solution of an acceptable quality. One can conclude that when dealing with problems with less activities, it would be better to use an IP solver because then one can be sure that the optimal solution is achieved. But when dealing with problems with more activities, GA shows its strength because in a reasonable amount of time one can get a good enough solution for most applications.

VII. CONCLUSION

In this paper two different formulations of IP and GA using two different representations for RCPSP were compared. The results indicate that RCPSP belongs to NP hard problems for which the exact methods are applicable only on smaller size problems and even for that problems there is no guarantee that solution will be found in reasonable time. On the other hand GA shows better results than IP; but for some instances the solving process lasts long considering the fact that there was only 30 or 90 activities and real problems are usual larger than that. Also the downside of both approaches is the fact that these methods are generally not applicable in dynamic environments.

Due to these facts, as future research it is planned to try out other heuristic methods that could give better results,

Balancing academic curricula by using a
mutation-only genetic algorithm

Kadri Sylejmani, Arbnor Halili, Arbnor Rexhepi
University of Prishtina/Department of Computer Engineering, Prishtina, Kosovo
(kadri.sylejmani, arbnor.halili, arbnor.rexhepi)@uni-pr.edu

Abstract - In universities, the academic programs are organized in a number of periods, usually in six or ten semesters, for a bachelor or a master degree, respectively. It usually happens that a given semester is much loaded with courses than the others. This makes it hard for the students to comprehend and deal with a high volume of learning material per certain semesters. This problem is difficult, because some courses have prerequisites (e.g. Math2 should be taught after Math1), and this means that course correlation must be taken into account. Therefore, in this paper, we present an intelligent method that is based on genetic algorithms to optimize the academic curricula of a given program, by trying to dispatch the courses over the available semesters, so that the load of individual semesters, in terms of course credits, is balanced as much as possible. The proposed genetic algorithm explores the search space by means of two mutation operators, which swap or shift courses between the semesters. The algorithm performance is fine-tuned and evaluated by using three state of art instances from the literature. The results show that the proposed algorithm is comparable with the state of the art solutions for the problem at hand.

I. INTRODUCTION

A study curricula (program) taught at some university is commonly structured based on some professional academic domain (e.g., computer science, economics, medicine, etc.). Such study curricula consist of several courses, which are usually dispatched, as even as possible, into several study periods (semesters). Since, some courses are more difficult to comprehend than the others, each course is assigned a number of credits based on learning hours needed to grasp the required material. In addition, some courses might not be taught before some other courses, due to prerequisites a course might have (e.g. in an economic study program the microeconomics course is taught before the macroeconomics course). An intuitive intention in such situations would be to have the courses distributed into semesters so that the load of the students (in terms of learning hours) over different semesters is as balanced as possible. This problem in the literature is known as Balanced Academic Curriculum Problem (BACP) [1]. Another extension is the Generalized BACP (GBACP) [2] problem, where two new concepts are introduced, explicitly allowing multiple study programs (curricula) and consideration of professor’s preferences about the terms (winter or spring) they want to teach the courses. In this paper, the earlier version of BACP problem is considered.

The remaining of this paper is organized as in the following. Section II presents a literature review of approaches solving the BACP problem; Section III presents the mathematical definition of the problem; Section IV presents the proposed approach; Section V shows the computational experiments; and Section VI concludes the paper.

II. LITERATURE REVIEW

In the literature, there is a plethora of approaches that tackle and solve the BACP problem by means of deterministic and non-deterministic algorithms. Castro & Manzano [1] solve the BACP problem by using constraint programming techniques, where parameter values and variables are ordered based on some specific heuristics. Lambert et al. [3] present a hybrid approach consisting of genetic algorithms and constraint propagation techniques, by employing some elementary functions that can be parameterized and used by different search strategies. Castro et al. [4] present a genetic local search approach that uses an operator that is based on the simulated annealing algorithm. Further, in [4], with the aim of making the BACP problem more realistic, new diverse evaluation functions are introduced by considering different mathematical models. The Generalized BACP problem is tackled by Chiarandini et al. [2] through applying several local search heuristics, where also a new alternative objective function is introduced. Rosas-Téllez et al. [5] present a tabu search metaheuristic for the BACP problem, by utilizing short-term memories to escape from local optima. Rubio et al. [6] solve the BACP problem by means of Ant Colony Optimization approach, in particular by employing the version of Best-Worst Ant System.

III. MATHEMATICAL MODELLING

The mathematical formulation for balancing the academic curricula problem is done based on [1], which is an Integer Linear Programming (ILP) model that uses a range of parameters and three decision variables, as described below:

Parameters:
- \( m \) – Number of courses
- \( n \) – Number of academic periods
- \( a_i \) – Number of credits of course \( i \), \( i = 1, \ldots, m \)
- \( \beta \) – Minimum credit load allowed per period
- \( \gamma \) – Maximum credit load allowed per period
- \( \delta \) – Minimum number of courses per period
- \( \varepsilon \) – Maximum number of courses per period

The remaining of this paper is organized as in the following. Section II presents a literature review of approaches solving the BACP problem; Section III presents the mathematical definition of the problem; Section IV presents the proposed approach; Section V shows the computational experiments; and Section VI concludes the paper.

II. LITERATURE REVIEW

In the literature, there is a plethora of approaches that tackle and solve the BACP problem by means of deterministic and non-deterministic algorithms. Castro & Manzano [1] solve the BACP problem by using constraint programming techniques, where parameter values and variables are ordered based on some specific heuristics. Lambert et al. [3] present a hybrid approach consisting of genetic algorithms and constraint propagation techniques, by employing some elementary functions that can be parameterized and used by different search strategies. Castro et al. [4] present a genetic local search approach that uses an operator that is based on the simulated annealing algorithm. Further, in [4], with the aim of making the BACP problem more realistic, new diverse evaluation functions are introduced by considering different mathematical models. The Generalized BACP problem is tackled by Chiarandini et al. [2] through applying several local search heuristics, where also a new alternative objective function is introduced. Rosas-Téllez et al. [5] present a tabu search metaheuristic for the BACP problem, by utilizing short-term memories to escape from local optima. Rubio et al. [6] solve the BACP problem by means of Ant Colony Optimization approach, in particular by employing the version of Best-Worst Ant System.
Decision variables:

\[ x_i = \text{equals 1, if course } i \text{ is set in period } j, \]
\[ \text{otherwise it is 0, } \forall i = 1, \ldots, m, \forall j = 1, \ldots, n \]
\[ e_j = \text{Credit load of period } j, \forall j = 1, \ldots, n \]
\[ c = \text{Maximum credit load of all periods} \]

Objective function:

\[ \min c = \max \{c_j\}, \text{ where } c_j = \sum_{i=1}^{n} \alpha_i x_{ij}, \]
\[ \forall j = 1, \ldots, n \] (1)

Constraints:

\[ \sum_{j=1}^{n} x_{ij} = 1, \forall i = 1, \ldots, m \] (2)
\[ x_{ij} \leq \sum_{r=1}^{n} x_{ir}, \forall i = 1, \forall j = 2, \ldots, n \] (3)
\[ c_j \leq \beta, \forall j = 1, \ldots, n \] (4)
\[ c_j \leq \gamma, \forall j = 1, \ldots, n \] (5)
\[ \sum_{i=1}^{m} x_{ij} \geq \delta, \forall j = 1, \ldots, n \] (6)
\[ \sum_{i=1}^{m} x_{ij} \leq \epsilon, \forall j = 1, \ldots, n \] (7)

In the above mathematical formulation, Equation (1) represents the objective of optimizing the problem, which is minimizing the credit load of the most loaded period, in terms of the academic credits assigned to it. Constraint (2) makes sure that all courses are assigned to some period, whereas Constraint (3) ensures that the perquisites of individual courses are complied. Constraints (4) and (5) guarantee that the minimum and the maximum credit load is respected, whilst constraints (6) and (7) confirm that the rule for the minimum and the maximum number of courses per period is enforced.

IV. SOLUTION APPROACH

In order to obtain a real time response when balancing the academic curricula, it would be required to design an algorithm that computes the results in period of less than one second, while ensuring that the quality of the solutions stays at a high level. Genetic Algorithms (GAs) [7] have been successfully applied in different domains, to optimize problems like flow shop scheduling [8], determining multiple routes [9], aircraft sequencing [10], etc. Hence, in this paper, we solve the problem of balancing the academic curricular by using a genetic algorithm that generates new individuals only by utilizing mutation operators. At each iteration, GAs make the three basic steps, namely selection of the parents for constructing the new population, mutating the parents to breed new children, and updating the population for the next generation.

A. Representation

The representation of a candidate solution (i.e. a member from the population P) is done by using a one dimensional array, where each member of the array is a list. The length of the array equals the number of periods (n), whereas the length of each list (that represents a single member of the array), is determined by the number of assigned courses at a certain period. In the following, we present a sample member representation of a scenario of an academic curriculum with 10 courses and 4 periods, where it can be seen that the first and the second period contain three courses each, whereas the other two periods contain only two courses each.

\[ I = \{\{1, 3, 4\}, \{2, 6, 10\}, \{7, 5\}, \{8, 9\}\} \]

B. Mutation operators

The mutation mechanism of the algorithm consists of two operators, namely swap and shift, where the earlier swaps two courses belonging to distinctive periods, while the later shifts a course from some period to some other period.

As presented in Algorithm 1, in order to apply a number of swaps between different courses of a given individual, the swap operator iterates through a loop for a number of iterations (as specified by sw parameter). During the course of a single iteration, initially, two distinct periods (i.e. p and q) are selected randomly, and then, their respective feasible courses (i.e. courses that satisfy the perquisite constraint) are enlisted (i.e. \( CL_p \) and \( CL_q \)). Afterwards, the first pair of courses, which is obtained by combing courses from \( CL_p \) and \( CL_q \) lists and that produces a feasible mutation (i.e. courses that meet other hard constraints), is used to mutate the current individual \( I_m \) by swapping the places of the selected courses. In case, no feasible swap can be achieved, the operator continues with next iteration.

Algorithm 1 Swap operator procedure

Input: individual \( I \), swap mutate intensity \( sw \)
Output: mutated individual \( I_m \)

1. \( I_m = I \)
2. \( i = 1 \)
3. repeat
4. \( p = \text{Random period from } I_m \)
5. \( q = \text{Random period from } I_m \text{ different from } p \)
6. \( CL_p = \text{Get courses that can be swept from } p \)
7. \( CL_q = \text{Get courses that can be swept from } q \)
8. repeat
9. \( I_m = \text{Mutate } I_m \text{ by randomly swapping a course from list } CL_p \text{ with a course from list } CL_q \)
10. until a feasible swap cannot be found
11. \( i = i + 1 \)
12. until \( i > sw \)

Algorithm 2 Shift operator procedure

Input: individual \( I \), shift mutate intensity \( sh \)
Output: mutated individual \( I_m \)

1. \( I_m = I \)
2. \( i = 1 \)
3. repeat
4. repeat
5. \( p = \text{Random period from } I_m \)
6. repeat
7. \( c = \text{Get a random course from } p \)
8. until no course provides a feasible shift
9. until no period provides a feasible shift
10. \( PL_c = \text{Get periods that can accept course } c \)
11. if \( PL_c \) is not empty then
12. \( q = \text{Random period from } PL_c \)
13. \( I_m = \text{Mutate } I_m \text{ by shifting course } c \text{ from period } p \text{ to period } q \)
14. \( i = i + 1 \)
15. until \( i > sh \)
The shift operator (see Algorithm 2) is also executed for several iterations, as specified by $sh$ parameter. During the progress of a given iteration, initially, a random period is selected, and then, one of its courses (i.e. course $c$) is picked as a course that will be shifted in some other period, while leaving the current period in a feasible state. Next, the periods that can accept course $c$ (i.e. $PL_c$ list) are initially outlined, and then, one of them is selected randomly as the period that will accept the envisioned course. In case there are no periods that can feasibly accept the selected course, the operator proceeds with the next iteration.

C. Initialization

In a typical instance of the academic curricula balancing problem, courses are (or can be) ordered based on the number of prerequisites they have, where courses with no prerequisites are placed first then courses with one prerequisite and so on.

At the beginning (see Algorithm 3), in order to start with a balanced curricula, in terms of the number of courses, each period is set (estimated) to accept equal number of courses, unless there is an odd number of courses, which requires that some of the periods have an additional course. Next, in the first phase of the algorithm (lines 3 to 17), by following the ascending order of the number of prerequisites, the courses are dispatched into the available periods, subject to the constraints of min/max credit load and course perquisites. If during this phase, a given course cannot be settled at some particular period, due to the hard constraints, it gets shifted into one of the next available periods. As a result, the end of this phase will produce an individual that satisfies all the hard constraints foreseen by the problem modelling.

Further, in the second phase (lines 18 to 24), with the aim of incorporating some randomness on the initial solution, subject to the parameter of randomness intensity, a couple of feasible swaps are made between any two selected courses belonging to distinct periods.

D. Evaluation and Selection

The evaluation of a given candidate solution is done by using Equation (1), which returns the credit sum of the courses within the period that has the maximum load. In the case of the running scenario with 10 courses and 4 periods, for the specific example presented in the previous subsection, the load of the individual periods, in terms of course credits, is 4, 11, 5 and 8, respectively, hence the evaluation of the solution is 11.

The process of the selection of the parents that will take part in breeding the next population is completed by using the tournament selection algorithm. This algorithm initially selects a number of individuals (as specified by the tournament size parameter) at random from the population, and then, from those that are selected, it finds the best fit individual.

E. Genetic Algorithm

The implementation of the proposed algorithm has a generative nature, meaning that its population will be totally renewed at each generation. As shown in Algorithm 4, the envisioned approach has 7 parameters, which can be used for fine tuning the performance for different problem complexities and sizes. Besides the default genetic algorithm parameters, such as population size ($ps$), maximum generations ($mg$) and tournament size ($ts$), the implementation at hand uses three so called “intensity” parameters, namely initial solution randomness intensity ($is$), swap mutate intensity ($sw$) and shift mutate intensity ($sh$), for specifying the number of times a certain operator (i.e. swap or shift) will be applied when called upon. In addition, the algorithm uses a special parameter (i.e. operator alternation frequency – $af$) to change the mutation operator from swapping to shifting and vice versa every $af$ number of generations.

At the very start of the algorithm, a list of two possible operators to be used is defined, which is made of swap and shift operators. Then, a population $P$ of $ps$ individuals is created by using the procedure for creating the initial solution explained above. Next, in the repetitive phase of the algorithm, at each iteration, the following steps are undertaken:

- Evaluation of all individuals. In case a new best individuals is found, it is saved as the best solution found so far,
- Formation of the new population by selecting the parents based on tournament selection and by
Algorithm 4 Genetic algorithm

Input: academic curricula \(C(m, n, \alpha, \beta, \gamma, \delta, \epsilon)\), population size \(ps\), maximum generations \(mg\), tournament size \(ts\), initial solution randomness intensity \(is\), swap mutate intensity \(sw\), shift mutate intensity \(sh\), operator alternation frequency \(af\)

Output: \(S_b\)

1: Operators = \{Swap, Shift\}
2: \(P = \{\}\)
3: \(i = 1\)
4: \(\text{repeat}\)
5: \(P = P \cup \text{Random Individual (C, is)}\)
6: \(i = i+1\)
7: \(\text{until } i > ps\)
8: \(S_b = \text{Best solution from } P\)
9: \(k = 1\)
10: \(j = 1\)
11: \(\text{repeat}\)
12: \(S_1 = \text{Best solution from } P\)
13: \(\text{if } S_1 \text{ better } S_b \text{ then}\)
14: \(S_b = S_1\)
15: \(Q = \{\}\)
16: \(i = 1\)
17: \(\text{repeat}\)
18: \(I = \text{Select Individual (P, ts)}\)
19: \(\text{Mutate} = \text{Operators (k)}\)
20: \(Q = Q \cup \text{Apply Mutate (I, sw, sh)}\)
21: \(i = i+1\)
22: \(\text{until } i > ps\)
23: \(P = Q\)
24: \(k = (i / af) \% 2\)
25: \(j = j+1\)
26: \(\text{until } j > mg\)

mutating them through the operator (i.e. swap or shift) used in the running iteration

- Before the next generation commences, based on the \(af\) parameter, one of the two operators is picked for acting as a mutation operator in the next stage.

The algorithm terminates when the maximum number of foreseen generations is achieved.

V. COMPUTATIONAL EXPERIMENTS

In this section, we initially present the test set used for experimentation, and then, we show the experimental results for fine tuning algorithm parameters, as well as presentation of the comparative results of the proposed approach against the known optimal solutions.

**Table 1: Details of Test Instances**

</tbody>
</table>

The algorithm is developed by using C# programming language that is part of Microsoft Visual Studio 2012 development environment. The experiments are done by means of a machine with CPU of type Intel Core i5 2.2GHz with 16GB of RAM memory, while running on a Windows 10 Operating System. Since, the proposed approach is a non-deterministic one, every experiment constitutes of 10 independent executions of the algorithm.

**A. Test set**

The evaluation of the proposed approach is done by using a widely used test set from the literature that consists of three instances, which are taken from the CSPLib online library [11]. This basic details of individual instances are given in Table 1, where it can be noticed that the range of periods varies from 8 to 12, whereas the number of courses and credits goes from 46 to 66 and 133 to 204, respectively. In terms of course interrelationship, the courses that are the most constrained in Instances 8, 10 and 12 have 4, 3 and 5 prerequisites, respectively.

**B. Parameter settings**

Based on some preliminary algorithm execution, for each of the seven algorithm parameters (i.e. \(ps, mg, ts, is, sw, sh\), and \(af\)), four best performing values are chosen (as presented in second the column of Table 2). Then, a
systematic computation, by using the three above described test instances, is performed, with the aim of finding out which value of the range, for a given parameter, yields to better algorithm results.

In Table 2, we present the computation outcome for different parameters, where the results are averaged over the complete test set. The best performing values for specific parameters are emphasized in bold. In overall, the results show that the algorithm is more sensitive for the general parameters (i.e. ps, mg and ts) of the genetic algorithms, than for the specific parameters (i.e. is, sw, sh, and af) introduced here for this particular problem. As a result, in the forthcoming experiments, the best parameter value sets are utilized.

With the aim of illustrating the level of sensitivity of algorithm performance for different runs, in Fig. 1, we show the results of Instance BACP8, for 10 different runs, by using the best parameter values. As it can be seen, in each and every run of the algorithm, the optimal solution is found, while the running time at most goes to 500ms. In all of the cases of the algorithm execution, a solution with fitness 18 (which is one more than the fitness of the optimal solution), is found within 100ms of computation time.

C. Comparative results

In this section, we compare the results of the proposed approach, denoted as the Mutation only Genetic Algorithm (MGA), against the known approaches from the literature, namely Variable and Value Ordering (VVO) [1], Hybridization of Genetic Algorithms and Constraint Propagation (HGACP) [3], Tabu Search (TS) [5] and Ant Colony Optimization (ACO) [6]. For the three data sets presented above, the optimal solutions, obtained from some of the state of the art solutions described above, read as in the following: BACP8=17, BACP10=14 and BACP12=17.

Table 3 presents a comparison, in terms of the quality of solutions, of the results of the proposed approach against the state of the art approaches in the given test set. The results are averaged over 10 different algorithm executions. The computational results show that the performance of the proposed approach is equal (for Instance BACP8) or better than the performance of VVO approach, which does not find the optimal solutions for instances BACP10 and BACP12. While, the proposed approach produces the same results as HGACP, TS and ACO approaches for instances BACP8 and BACP10, it can be noticed that, for instance BACP12, the results are for 6% worse than the optimal solution, which is obtained by ACO approach. In overall, it can be stated that the proposed approach can be used to balance complex academic curricula (such as BACP12 instance with 12 periods), in average, in less than one second. Furthermore, the results outline that for more complex problems (i.e. BACP12 instance), the algorithm can provide good quality solutions, although not always the optimal ones.

In addition, Table 4 presents the results of the computation time of all state of the art approaches, along with computation time of the proposed approach. Nonetheless, the results should be taken more as informative rather than comparative, since all of the envisioned approaches utilise distinct computation machines when doing the experiments, hence no direct comparison can be made between specific approaches in this respect. However, the last column of Table 4 shows that the proposed approach is able to solve any of the described instances within a period of less than one second.

VI. CONCLUSIONS

In this paper, we presented an approach for balancing the academic curricula based on genetic algorithms, where two mutation operators are employed alternatively for exploring the search space. The swap operator exchanges two courses between two distinct periods, whereas the shift operator shifts a single course from one period to another period.

The computation results showed that the algorithm is not sensitive to the set of values of the new parameters introduced for this particular problem. When the parameters are fine-tuned, the algorithm is always able to find the optimal solution for instances BACP8 and BACP10, whereas for instance BACP12, the algorithm

Figure 1 Solution improvement over time for different algorithm executions in the case of BACP8

MIPRO 2017/CIS 1405
finds solutions that are for 6% worse than the optimal solution.

Since for more complex problems, such as instance BACP12, the algorithm seems to get caught in local optima, as part of future work, it would be interesting to investigate other variants of the swap and shift operators, such as for example swapping one course with a set of other courses, or shifting a set of courses from one period to another one. In addition, it could be worthwhile developing new mutation operators, such as for example a rotation operator, which could for instance, select a number of courses from distinct periods and rotate them based on the their actual placements in the periods.

Abstract—The prediction of protein secondary structure is the method of finding the way in which an amino acid sequence causes the protein structure to fold and bend into \textit{alpha helices}, \textit{beta strands} and other shapes. Until today, the problem of finding protein secondary structure is not fully resolved. Classification or clusterization based methods have an accuracy rate of circa 80 percent and they mainly work on a reduced set of shapes and folds. It is very difficult to predict how a local sequence of amino acids is going to behave and in which way it is going to affect the future of protein structure. Based upon the predicted secondary structure of the protein, the tertiary and quaternary predictions show the real nature and function of the protein as a whole. In this paper, we address the problem of the secondary structure prediction of protein and propose a new hybrid method based on the usage of multiple neural networks with the use of a consensus function and compare our approach with other efficient methods.

Keywords—Bioinformatics, Protein Secondary Structure Prediction, Hybrid Method, Neural Networks, Machine Learning

I. INTRODUCTION

Bioinformatics is an important interdisciplinary field in which information technologies are used to successfully solve existing biological problems in the world today. Usually, the most accurate ways to solve these kinds of problems are through experimental methods. Some of those approaches are described in [1]–[3]. The main obstacle, which undermines the significant progress of experimental methods, is the high cost of the entire process. One of the reasons for the high cost is the high amount of pure protein required to perform experiments on, not to mention the required amount of computational power. On the other hand, information technologies are rapidly improving and spreading over various fields, which opens up the space for new approaches in solving biology problems. These kinds of approaches are typically referred to as \textit{ab initio} approaches since they usually focus on solving problems "from scratch" rather than using existing structures obtained through experimental methods. According to [4], some of those methods can achieve up to 75% to 80% accurate results, while the theoretically highest possible accuracy lies at 90%.

The problem that has proven difficult to solve efficiently is the prediction of protein structures. Predicting the protein structure and function does not solely include predicting classes and structures, but also predicting the environmental and other potential influences, protein-protein interactions etc. The problem is rather complicated to be precisely determined only with machine learning and other mathematical-based methods. However, a combination of different algorithms merged together and combined with some biology field knowledge might just give good results. This fusion of different experimental and mathematical approaches represents the domain of hybrid algorithms and it is proven to be an efficient way to improve existing algorithms.

In this paper, we focus on the improvement of the machine learning algorithms which are typically referred to as \textit{in silico} methods, especially neural network approaches. The accuracy of neural network based methods is around 60% [5] and the results largely depend on the protein that is being analyzed. We try to increase this accuracy and also overcome the large oscillations that can occur if the input datasets which contain a large number of differently structured proteins. Our focus is the identification and exact classification of the two most common secondary structural classes, \textit{alpha helices} and \textit{beta sheets} (Fig.1). Other structures that can form during the process are aggregated in the \textit{coil} class. We present a new hybrid method based on multiple neural networks combined together through a census function. The networks that compose the ensemble are trained with different parameters which are determined empirically, through analysis of benchmarking results. The local results obtained from the neural networks are analyzed and, through a majority voting process, combined into a global ensemble result. This ensures the higher consistency and accuracy of the method in comparison to the single network approach, regardless of the diversity of the input dataset. The accuracy of our method is 65% for all the datasets used.

This paper is organized as follows: Related work regarding different machine learning approaches is briefly reviewed in section II. In section III a new, neural network based, hybrid method for protein secondary structure prediction is proposed. The implementation of the proposed method and discussion of the achieved results are stated in section IV. We conclude the paper in section V with appropriate remarks.
were acquired through experimental methods, the structures available at the time. As more secondary structures statistically, one residue at a time. Those methods were also prediction methods, amino acids had been mostly observed was the fairly consistent methods for secondary structure prediction had much more example data to work with. One of the first methods also advanced in consistency and accuracy as they were implemented and elements of machine learning were observed. More advanced statistical approaches to improve drastically as higher degree interactions between elements were also constrained by the small amount of predetermined protein structures available at the time. As more secondary structures were acquired through experimental methods, the in silico methods also advanced in consistency and accuracy as they had much more example data to work with. One of the first fairly consistent methods for secondary structure prediction was the Chou-Fasman method [6] which combined different statistical and heuristic rules. The main problem with this method was the mentioned inspection of isolated amino acids in the chain which couldn’t exactly reflect the real state of the protein as a whole. This issue was resolved in the GOR [7] [8] method where the surrounding of the amino acids was also included in the secondary structure prediction.

After the initial simple approaches, the algorithms began to improve drastically as higher degree interactions between elements were observed. More advanced statistical approaches were implemented and elements of machine learning were integrated in the methods. Advanced methods make use of nearest neighbor approaches and fuzzy logic [9]–[11], hidden Markov models [12] [13], support vector machines [14] [15], neural networks etc. Today, approaches that only predict protein structure from a single organism are getting more popular since they avoid the need for generalization and therefore offer higher accuracy in prediction. One example is the specified structure protein interaction for the yeast species Saccharomyces Cerevisiae is described in [16].

One of the more interesting approaches is the usage of neural networks. The network is trained with a primary structure and the corresponding secondary structure later predicts secondary structural classes for protein with unknown secondary structure. There are many different ways to tackle the defined problem using different types of neural networks, sometimes in a combination with other algorithms as described in [17]–[20]. The deep learning algorithms are also gaining popularity as described in [21]–[24]. They emphasize the learning process of the networks and achieve more accurate results.

III. NEW HYBRID METHOD

The problem of the secondary structure prediction is one of the most challenging problems in bioinformatics. The neural networks “style” of problem solving is a one way of solving this problem. We formalize the main steps of the modeling process for our method as:

(A) Window length selection
(B) Binarization of inputs and outputs
(C) Construction of the neural network as a classifier
(D) Ensemble construction

The first two steps offer a detailed description of the data preparation process with focus on the inclusion of the immediate surroundings of each residue. After the input and output data format is established, available datasets are pre-processed and divided into appropriate training, validation and test sets. The main contribution of our method is in the next two steps, where we introduce network selection and ensemble construction. Based on achieved results for different parameters, the best performing networks are chosen and a diversified ensemble is constructed. The voting process which unifies single neural network results is implemented. In the end, a series of tests containing data from different datasets than the ones used in the training process are carried out to measure performance of the algorithm. The next subsections offer detailed description of all individual steps of the process.

A. Window Length Selection

Looking at a single amino acids individually does not get good results. The interaction between residues in the chain needs to be preserved in some way. For example, if the window size is 11 and an amino acid at the $n^{th}$ position in the chain is in focus, elements at positions $\{n-5, ..., n, ..., n+5\}$ also need to be taken into consideration as depicted in Fig. 2. In [25], it is shown that there are many factors in successfully determining the optimal window size, but it largely depends on the protein in focus. Many protein secondary structures depend on factors such as hydrophobicity, motifs, b-factors etc. and that makes it difficult to find the general optimal sliding window size for all the protein in existence. For example, the transmembrane proteins have the average of one transmembrane alpha helix spanning through the membrane so the optimal size should be around 20 residues. The only way to determine the optimal window size is empirical and thus multiple neural networks with different windows must be constructed, trained and evaluated.

Fig. 2: Sliding window size.

B. Binarization of Inputs and Outputs

The string representation of the amino acid chain is simple for people to understand, but difficult for machines to process. Because of that, we need a fitting transformation of the input in order to model a neural network and gain efficiency in terms of
This indicates that the input needs to be at least a 20xn matrix where m is the number of amino acids in the chain. Because of the sliding window size that needs to be incorporated into the input, the matrix also needs to have n residues on each side of the current amino acids. Therefore, the final input matrix needs to be a (20*ws)xmn matrix where ws represents the sliding window size. For example, if we use a window with a size of 17, the final input matrix will be 340x(n−16). The 16 elements that are subtracted are the first and last 8 elements of the amino acid sequence, that are ignored because the window size can be applied only at the 9th position. That leads to the conclusion that some of the elements of the primary structure will not be included in the prediction of the secondary structure which is one of the disadvantages of this surrounding-inclusive approach. The input data has grown in dimensionality since it went from a simple string to a fairly big matrix but in this format it is much easier for the computers to process and also an excellent fit for the input of a neural network.

The same principle of binarization can also be applied for the output. The main difference is that there are only three classes to represent. The alpha helix labeled A, the beta sheet labeled B and the coil labeled C.

\[
\text{bout}(c) = \begin{cases} 
[1 \ 0 \ 0]^T & \text{if } c \text{ is alpha helix} \\
[0 \ 1 \ 0]^T & \text{if } c \text{ is beta strand} \\
[0 \ 0 \ 1]^T & \text{if } c \text{ is coil}
\end{cases}
\]

The c represents the resulting structural class, and \(\text{bout}(c)\) represents the output binarization function which translates the three structural classes from the string into the binary format.

C. Construction of the Neural Network

Multilayer feed-forward neural networks with backpropagation learning algorithm are suitable for advanced classification problems [26] as the one that is being treated in this paper.

1) Neural Network Architecture: In a feed-forward network the output of a node y is described as a function of the input x. The input to a given node is a sum of previous nodes and their associated weights:

\[
X = \sum_{i=1}^{n} x_i w_i
\]

where n is the number of neurons and \(w_i\) is the associated weight. This value is then passed through a sigmoid activation function:

\[
\text{Y}_{\text{sigmoid}} = \frac{1}{1 + e^{-X}}
\]

which guarantees that the neuron output is bounded between 0 and 1. If we consider equation (1), the activation of the nodes \(y_i\) can be defined as:

\[
y_i = f_i(X) = f_i(\sum_{i=1}^{n} x_i w_i)
\]

For any dataset given as input and the corresponding weights, there is a certain error measured by an error function. Since the backpropagation learning rule is applied, there are two contrary directions of information flowing across the network. Input signals \((x_1, x_2, ..., x_n)\) are propagated from the left to right and the error signals \((e_1, e_2, ..., e_n)\) from right to left. Error signals are calculated for the output of each neuron and the general error function for one epoch is defined as the sum of the squares of the differences between all target node outputs and actual node outputs:

\[
E_p = \frac{1}{2} \sum_{n}(t_{jn} - w_{jn})^2
\]

where \(t_{jn}\) is the target activation value for the node n and p marks the current epoch. Given the equation (4), the networks overall error is simply calculated by summing all of the \(E_p\) values for a given set of training patterns. The respective formula and the standardized version, the MSE (abbr. Mean Squared Error) equation are shown below.

\[
E = \sum_{p} E_p = \sum_{p} (t_{jn} - w_{jn})^2
\]

\[
\text{MSE} = \frac{1}{2PN} \sum_{p} (t_{jn} - w_{jn})^2
\]

The MSE shows the difference between the correct output and what’s estimated. Since the algorithm uses the backpropagation learning rule, which is based on the Widrow-Hoff delta learning rule, the main goal is to adjust the neural network parameters in a way that the MSE is minimized below a certain threshold. As that is not always bound to happen, an additional maximum epoch number is given after which the algorithm terminates regardless of the current MSE value.
2) Important Parameters of the Neural Network: One of the important factors in this algorithm is the configuration of the parameters that suits the secondary structure prediction problem. Three neurons make up the initial hidden layer. By increasing this number, more accurate results can be achieved, but there is also the risk of overfitting. The neural network can get too adapted to the training data and try to memorize the previous examples instead of learning how to generalize and adapt its structure to successfully solve unknown structures that show up as the input after training ends. All the different layers and the previously described backpropagation learning flow of data inside a neural network is depicted in Fig 3.

![Fig. 3: Neural network architecture and data flow.](image)

For the training of the networks in the ensemble the Rost-Sander RS121 [27] and the FC699 datasets [28] are used, since they contain a wide range of different protein primary structures and their corresponding secondary structures. This makes the selection of datasets justifiable for the initial training. Through the k-fold cross-validation method of determining training, validation and test sets, the individual datasets are split and translated into the correct input matrix format with a split ratio of 70-15-15 for all the sets, respectively. Other parameters that have a significant impact on the networks performance are also: the training algorithm, number of neurons in the hidden layer, number of input vectors etc.

D. Construction of the Ensemble

The idea of creating a learning ensemble is relatively simple. Since the neural network largely depends on the quality and diversity of the input data, it cannot provide the correct prediction all the time. This is especially true within the structure prediction problem since a wide range of protein families exists. That is why multiple networks are created and their results are combined through one of the consensus methods. Individual networks can have different architectures, different number of neurons in their layers, different window sizes etc. The important aspect is that the output is one of the structural classes. In this way, if \( H_n \) is the hypothesis space of one of the ensemble members, multiple hypothesis spaces narrow down the possible solution space with their intersections as depicted in Fig. 4. This limits the search space for the optimal solution marked as \( h_{best} \). Thus, the best classification rule is constructed through approximation of multiple classification rules. One important factor is the aggregation of multiple outputs. There are many different approaches, however in this paper we used majority voting method to determine the final output. If one or two networks fail to correctly classify a structural class, other networks with correct predictions can override the bad result. It all depends on the way other networks are constructed and trained. Therefore, the entire ensemble will give incorrect results only if the majority of the networks fails to identify the correct structural class. The ensemble approach in our method can add some additional security to the classification that is sometimes needed to provide satisfactory results.

The complete pseudo code for our hybrid method, based on multiple neural networks working together within an ensemble, can be formulated as in Algorithm 1. The method requires certain parameters which are usually determined empirically as described in the previous sections. The first two lines of the for loop represent on of the advantages of the method as pre-processed datasets with diversified data are given as inputs to neural networks to ensure the stability of the ensemble.

![Fig. 4: Multiple hypothesis space intersection.](image)

Algorithm 1 Hybrid Method based on an Ensemble of Multiple Artificial Neural Networks

```python
function PREDICTPROTEINSECONDARYSTRUCTURE
    Require:
    size - Size of the ensemble;
    ws - Sliding window size;
    datasets[] - Datasets used for training;
    annParameters[] - Network parameters;
    inputSequence - Amino acid chain;
    k - k-fold cross-validation parameter;
    for \( i < size; i \leftarrow i + 1 \) do
        binIn = binarizeInputs(datasets[i], ws);
        binOut = binarizeOutputs(datasets[i]);
        dataset = combine(binIn, binOut);
        [tr,te,val] = crossValidation(dataset, k);
        ann = constructANN([tr,te,val], annParameters[i]);
        results[i] = ann.predict(inputSequence);
    end for
    secondaryStructure = consensusMethod(results);
    return secondaryStructure;
```

1410  MIPRO 2017/CIS
IV. RESULTS

The algorithm described in previous chapters was implemented in MATLAB version 8.5.0 (R2015a) using the Neural Network Toolbox. The datasets used for training were the RS121 and FC699. The dataset used for testing was a combined dataset containing parts from the 25PDB [28] and CB513 [29] datasets and other proteins and their respective secondary structures which did not occur in the training sets. The standard \( Q^3 \) or Average Percentage Accuracy method was used as the quality measurement of the results. The results that were achieved for a single neural network with different parameter combinations are listed in Table II. Throughout all runs, the highest percentage achieved is at about 61% with 10 neurons in the hidden layer and a window size of 17. It is also visible that, with these configuration parameters, the network has big oscillations, since the accuracy for window size of 3 lies little below 35%. That makes these results not trustworthy.

**TABLE II: Q3 accuracy results for a single neural network.**

</tbody>
</table>

According to the measurements, the best and most consistent results are achieved with a window size of 17 and 20 neurons in the hidden layer. If Table II is translated into a percentage bar chart for the most successful parameter configurations, the correlation between the window size and the prediction accuracy becomes visible. That leads to the conclusion that the optimal empirical values for the window size are between 17 and 20, depending on the protein structure.

These results show that the isolated neural network performance possibilities lie at around 60% as shown in Fig. 5. Of course, these numbers can be increased by implementing some advanced network improvements as mentioned in Section II, but in this paper we focus is on the ensemble and integration of methods. The described ensemble method is tested by executing 20 runs with 20 different test sets than the ones used to train the neural networks. The results achieved through the whole process of testing the proposed method are as shown in Table III. The highest and lowest accuracy is also marked.

The average accuracy lies at approximately 65.3% which shows the improvement made by simply combining differentiated neural networks together. If the datasets that caused the two best, two worst and a near-average performance in the ensemble are given as input in a single neural network and Naive Bayes classifier, a good accuracy comparison can be made. As depicted in Fig. 6, the proposed hybrid method solves the structural classification much more efficiently than the single neural network approaches and the common classification methods such as the Naive Bayes classifier [30]. That is to be expected because of the lack of diversity in network training and the previously described problems with purely statistical approaches cannot cover all the processes within the secondary structure formation process.

**TABLE III: Q3 accuracy results for a network ensemble.**

<table>
<thead>

<td>57.1%</td>
<td>59.1%</td>
<td>46.8%</td>
<td>48.9%</td>
<td>56.2%</td>
</tr>
</tbody>
</table>

It is also worth noting that the isolated neural networks work well under the additional pressure of differentiating datasets. That means that, for all the individual neural networks, a good parameter configuration is chosen and that the networks are capable of good generalization. The common problems that can arise, such as overfitting and underfitting, are thereby successfully avoided.
V. CONCLUSION

The search for a universal algorithm for the protein secondary structure prediction is not an easy problem to solve. However, in this paper, a hybrid, multiple neural network ensemble approach is proposed which shows promising results of improving the accuracy of existing algorithms. Through a simple aggregation of different prediction methods, this approach narrows down the possible hypothesis space in which the optimal solution is located and therefore increases the time that is needed to find the optimal solution. That also makes it more likely that the optimal solution will be found, i.e. that the MSE parameter will drop down below the given accuracy threshold within the set number of epochs.

The proposed method, based on multiple differently trained neural networks achieves around 65% accuracy of successfully predicted secondary structures. The final evaluation was based upon creations of different smaller datasets partially derived from the 25PDB and CB513 datasets and other protein structures gathered for the purpose of testing. The input data was formed by combining data from different sources, which proves that our method, along with the accuracy increase, is stable in prediction of diverse protein structures. Since the accuracy of methods based solely on neural networks lies around 60% [5], and those methods can have oscillations for differently structured protein than those used for training, our proposed method is suitable for classification of protein secondary structures. Also, it offers a good example on how to combine different methods and, more importantly, how to properly train and incorporate these elements into a bigger, more advanced algorithm for secondary structure prediction.

Hardware-in-the-Loop Architecture with MATLAB/Simulink and QuaRC for Rapid Prototyping of CMAC Neural Network Controller for Ball-and-Beam Plant

Vjosa Shatri*, Lavdim Kurtaj* and Ilir Limani*

* Faculty of Electrical and Computer Engineering, University of Prishtina "Hasan Prishtina", Prishtina, Kosova
✉ lavdim.kurtaj@uni-pr.edu

Abstract - Cerebellar Model Articulation Controller (CMAC) is type of neural network inspired from part of the brain named cerebellum. It has long history in control applications, in simulated or in real-time implementations. MATLAB/Simulink is used for rapid building of CMAC neural network controller prototypes than can run in real-time. To run the controller in the same personal computer, QuaRC is used as real-time operating system that will execute controller task along Windows operating system. Hardware-in-the-loop architecture was used to test CMAC controller in real ball-and-beam physical plant from Quanser. Library of developed Simulink functional blocks enable easy exploration of different structural aspects of CMAC neural network controller, including selection of receptive field types, receptive field widths, Albus overlays, and fully interconnected multi-dimensional receptive fields. Same CMAC controller can be used also for controlling model of the plant, which can serve as means for controller to acquire knowledge before operating with real plant. CMAC controller learned to control the plant, and progressively became main control signal generator, while control signal from primary proportional-derivative controller almost vanished. Developed library can serve as easy startup for working with CMAC networks also for other types of applications.

I. INTRODUCTION

All technical systems that are built to serve in fulfillment of some intended functional behavior that can be described with desired output quantities. Some of these quantities can be requested to maintain constant value, while for others may be requested to follow some time trajectories. To achieve acceptable performances plant must be driven with proper command inputs. But the trivial cases, complexity of these commands necessitates appending the plants with other functional blocks that in a concerted ways will generate them in an automated fashion without permanent human intervention. These functional blocks are generally named as controller [1]. Designing and building proper controller for desired certain plant and desired reference behavior is main task of automatic control.

Most widespread type of controller in use is PID (proportional-integral-derivative) controller [2], where not all of three types of action must be present, resulting in different versions of the controller, like P, PI, PD. For plants with more complex dynamics PID controller will not be able to achieve satisfying performance. Many other types of the controllers have been devised to aid in this task. One family of these controllers tries to emulate some working principles of animal's nervous system, named neural network controllers [3]. In general, even they were inspired from real neurons and neural systems, they evolved as a separate family of controllers with many functional variations, not necessarily biologically based or not yet proven they exist. An attractive feature of neural network controllers is ability of learning [4] control task from past and present information they get from inputs of the plant to be controlled and from outputs they generate to act on that system. This contrasts with rigid structure of classical PID controller that can not give long run satisfactory performance, without retuning [5], when system parameters or working conditions change.

One practical and safe way for testing new controllers is by simulations. Usual simulations will require also the model for plant to be controlled [6]. Accuracy of plant model will influence the final results of the controller, when it goes to real implementation and gets installed to work with real plant. To have more accurate and realistic data, especially the one related to timing aspects of controller action, simulation can be made to interact with real plant. In this case controller will be "built" in the simulation environment, with all commodities that it offers, but simulation runs will happen in real-time interacting with real plant to better emulate real working conditions. In cases when using real plant could be very costly, or dangerous to use, hardware plant simulators [7], [8] can be used. These would provide similar interface as the real plant has, and from controller point of view it would behave like real one. Since most control structures form a closed loop including controller and plant, this technique of simulation is termed hardware-in-the-loop (HIL) [9], and is used for rapid prototyping of some functional part of bigger system [10], [11], controller in this case, like in [11]-[13].

Neural network controller that has long history in control applications, in simulated or in real-time
implementations is the one inspired from part of the brain named cerebellum [14], with resulting Cerebellar Model Articulation Controller (CMAC) [15]. Processing of information on layers of the cerebellum and development of corresponding Simulink models are shortly described in Section II. Results of simulations with ball-and-beam plant model and with HIL simulations with real plant are contained in Section III. Paper in the end concludes with Section IV.

II. CMAC SIMULINK MODEL

Since it was introduced CMAC [15] was attractive for real time applications, as a consequence of simple logical operations needed for implementation. It enabled very modest microcomputer systems to handle all computations for real time operation [16]. To experiment with different CMAC configurations and performance on different plants, availability of the model for more general tools would ease analysis and design process. MATLAB is powerful tool for numerical computing that enables graphical programming in common form of block diagram through tightly integrated Simulink environment. It enables automatic generation of C source code that can be targeted to wide range of hardware platforms for operation in real time. With additional real-time operating system, like QuaRC from Quanser, models can be run in real-time on platforms with Windows operating systems, including the same platform where MATLAB/Simulink is running.

Simulink CMAC model generation can follow several approaches. Authors of [17] used MATLAB S-function implementation that can be included in models developed in Simulink. Approach of this paper is to preserve visual layered structure, and in same time to leave open possibilities of customizing final structure, in creating averaged cerebellar structures, like standard CMAC [15] or Cerebellar elementary Processing Unit (CePU) [18].

A. CMAC Mossy Fiber Input

Information carried by mossy fibers, during most of the simulations, usually is in form of receptive fields (population code). On the other side, standard form of information in other parts of the system is in form of continuous values lying in a specified range (rate code). Blocks of this layer will convert rate coded signals to population coded signals, with specified bases function for receptive fields. First three rows of Simulink block library, Fig. 1, show blocks for generation of mossy fiber input. First three rows of Simulink block library, Fig. 1, show blocks for generation of mossy fiber input, with multiplication operation, from inputs x1 to x4. Unused input dimensions should be tied to constant 1. Standard CMAC [15] will use this block. Second one corresponds to CePU model [18], and will create multidimensional receptive fields, from inputs mf1 to mf4, modulated with mf_ldt rate coded input. PC block models Purkinje cell with synapses if makes with parallel fibers, represented with weights. CF input represents climbing fiber input, and guides learning. It is assumed that CF input carries error information. DCN block models deep cerebellar nuclei as simple summation of inputs.

B. CMAC Granule Cell Layer

This layer will create multidimensional receptive fields from (assumed) one-dimensional receptive fields of several dimensions. Most of the granule cells have 4 dendrites that receive information from mossy fibers. We assume that idealized elementary granule cell-Golgi cell processing circuit (GrC-GoC) [18] is a group of several thousand granule cells, inhibited from same Golgi cell, [14] that receive information from up to four groups of population coded mossy fibers, corresponding up to 4-dimensional input space. Bottom two rows of library contain two blocks that perform function of this layer, 4D_BF and GrC-GoC blocks. First one will create standard up to four dimensional receptive fields, with multiplication operation, from inputs x1 to x4. Unused input dimensions should be tied to constant 1. Standard CMAC [15] will use this block. Second one corresponds to CePU model [18], and will create multidimensional receptive fields, from inputs mf1 to mf4, modulated with mf_ldt rate coded input.

C. CMAC Purkinje Cell Layer

Single Purkinje cell with synapses it makes with parallel fibers is part of this layer, PC block of library in Fig. 1. Purkinje cells in CMAC model are modeled as simple perceptron with adjustable weights. Block has PF input that mimics Purkinje cell inputs from parallel fibers. Other input, CF, matches climbing fiber input to Purkinje cell and will guide learning. Usual assumption is that CF input carries error information. Initial values for weights are set with input w0, whereas w output will show current weight values. Output PCaxon of this block is in the same time output of standard CMAC model Mask of the block can be used to set learning rate and update period.
D. CMAC Deep Cerebellar Nuclei

In standard model of the CMAC deep cerebellar nuclei are not modeled. Every output would have one Purkinje cell model. In current version, block DCN of library in Fig. 1, model will be simple summation of all signals in the incoming vector, usually outputs from several Purkinje cells, inputs from some set of mossy fibers, and from some climbing fibers, inputs PC, mf, and cf respectively.

III. SIMULATIONS AND RAPID PROTOTYPING WITH CMAC

Inclusion of the neural controllers as part of the general control system usually goes jointly with some form of conventional controller [20], but it can be used also as a standalone controller [21]. Neural controller will acquire knowledge about the system to control during learning or training phase. This phase can be accomplished off-line or on-line. When on-line mode is used, it can last some time and then stop, or if can be active all the time adapting itself to possible changes of plant behavior. Different types of neural network manifest quite different behavior at different phases of their operation, during initial, during, or after learning [22], i.e. influence that "fresh" network has on system behavior, how fast it gains knowledge during learning phase where learned and adaptive behavior are intertwined, and final quality of learning when learning stops. Conventional controller used along neural one is some version of PID family of controllers [2].

Figure 2 show diagram for building of full overlaid CMAC and for CMAC with Albus overlays from library blocks. When building Albus CMAC, receptive fields of the same layer should not overlap, achieved by proper parameters of corresponding blocks, blocks with names starting with lL_TBF_Width. According to signal dimensions from figure, number of receptive fields for each dimension of each layer is 26. Number of two-dimensional receptive fields on each layer is 26*26=676. Total number of two-dimensional 4-quanta wide receptive fields for this 4-layer CMAC is 4*676=2704. Same resolution with full overlaid CMAC would have (4*26)*(4*26)=104*104=10816 two-dimensional receptive fields. Block implementation is meant to correspond directly to defining equations, for easy understanding and building different models that mimic connections in real biological version of the cerebellum. This has consequences in calculation time, and directly influencing size of CMAC that can be used during HIL simulation. QuaRC will report error if calculation time exceeds fundamental sample time selected for simulation. Size of the CMAC is not limited for offline simulations, but it will directly influence simulation speed.

CMAC was used as secondary controller along PD primary controller for position of the ball, in cascade control structure of Quanser the SRV02 Ball and Beam plant. Used CMAC had two dimensions, ball position error and ball speed error. These same signals usually serve as input to standalone fuzzy controllers [21]. Output of PD controller was used by Purkinje cell during learning. Fig. 3a shows connection of the CMAC controller. Iside this block is subsystem from Fig. 2a.

Figure 2. Diagrams for realization of Simulink CMAC models from library blocks: a) full overlaid model, b) Albus overlaid with 4 layers. Only part from rate coded inputs up to parallel fibers is shown. Model around Purkinje cell is the same for both models. Part with matrix viewer and reshape blocks is used only for offline simulations. Switches are used to select mode of operation: Learning On/Off and Dead Zone On/Off, respectively.

Testing was done with sinusoidal reference signal. First 50 seconds are controlled with PD controller alone. From Fig. 3c we see that control signal from CMAC is zero (red, thick solid line). When CMAC starts learning error drops considerably, traces on Fig. 3b, caused by CMAC taking main control, followed by reduction of control from PD, Fig. 3c. Color map of the weight space for this simulation and one with step reference are given in Fig. 4a and Fig. 4b, correspondingly. Number of the receptive fields for second case was 101 for each dimension was 8-quanta wide.

Any simulation CMAC model that is build can be compiled and run in real-time with QuaRC, if hardware platform can handle all processing timely. All we have to do is change simulated plant with interface to physically real plant (or physical model of real plant), under condition that interface signal are of the same type and range. Quanser provides simulated plant and interface to physically real SRV02 Ball and Beam plant. Behavior of physical plant under sinusoidal or triangle reference signal was very different, with unpredictable sticks [23] and jumps. This can be caused by not modeled dynamic effects, and by limits of control components. To control sinusoidal 5 cm reference signal, amplitude of reference angle to inner control loop is only $\pm 2^\circ$. Gear backlash under this condition can easily deform final behavior. Looking to components of control part of the problem, simulated control voltage that will drive motor for this...
control voltage swings between about 0 to 12 mV, where only 1 quantum is used for both positive and negative side, number of quanta would come close to that provided by 12-bit digital-to-analog converter resolution of control board, 3333 vs. 4096. Under this conditions CMAC controller in most of cases, if some dead-zone for error was not set, it came to the solution with high oscillatory motion around reference path, which in some form solves stiction problem, thought not the desirable one. Same can happen with simulated plant with no dead-zone in learning. Situation is more favorable with square wave condition is only ±0.12 mV, where much approximation capabilities for that specific type of fuzzy control is to hold at constant level activities of edge receptive fields. Receptive fields of same type were used through this paper, where half of total activity on active receptive fields can be used for purpose of position and width adaption of same. As desirable value of total activity would be normalized value equal to 1. For generation of Fig. 5 scope block provided by Quanser (Time Figure) was used, that can show whole range in same plot during real-time HIL simulation. Two first periods of the simulation in Fig. 5 are controlled with PD controller alone. For time after 40 second CMAC learning is on and contributes to control process. We notice dampening of oscillation after jump change in the reference input. Initial overshoots did not change considerably. Most of behavior is preserved after switching learning off, signifying that CMAC has acquired knowledge for controlled plant. For lower values of learning rate, set from mask of Purkinje cell block, speed of learning is proportional learning rate parameter value. When values become larger control action of CMAC can contain considerable amount of adaptive behavior and less learned one. At these conditions, control can be with small errors during learning on phase, but it can increase significantly when learning is switched off. CMAC neural controllers are in good position of fast learning and preserving knowledge [22], if high values of learning rates are avoided and with structure of design that suits to the problem it will control for best generalization capabilities [18]. Not every problem can be solved efficiently with same uniform type of network; even thought approximation capabilities for that specific type of
neural network are proved to be general. Specific structure can lead to much simpler network, with much better generalization. Brain that served as inspiration and still inspires can serve as an example, by having different structures at specific part of it, presumably serving different purposes.

Same library can be used for any type of target selected for development, and for more intensive computations stand-alone target can be used, where pure hardware based implementations with complex programmable devices, like field programmable generic arrays (FPGA), would offer superior performance. Initial tries for preserving block based building, by performing operations on specific limited group that would correspond to active receptive fields did not provide significant improvement in performance. It may be that selection process takes about same time as for operation being performed uniformly on all receptive fields. The reason behind can be to optimized structure of MATLAB and Simulink for working with vectors and matrices. At this stage simplicity of structure was favored, with possibility of building general neural networks with biological similarity, and more specifically cerebellar structures, but with non-spiking averaged signals.

IV. CONCLUSION

Cerebellum was an inspiration from the time that its neuronal circuit was constructed [24], [25]. Initially thought uniform structure inspired theories of cerebellar functioning, and models that would be used for solving problem of coordinated motion, as one of main functions that was thought to be carried by cerebellum. Modern view of possible functions where cerebellum is involved is very broad, up to cognition and emotion.

To be able to develop behavioral models of the cerebellum that would follow some functionally specific group of neuronal circuit, library of functional blocks with models of specific cerebellar structures was developed. Library includes blocks that provide interface to real signals, and converts them in appropriate form to provide compatible inputs to the cerebellar model. Development had in mind to use same development environment for practical control applications, with simulated and real physical plants. This objective is achieved with library of block developed in Simulink, and same can be used in real-time applications through QuaRC. Library blocks were used to build Cerebellar Model Articulation Controllers (CMAC) with full or with Albus overlays. They were used in simulation with simulated and real Quanser SRV02 Ball and Beam plant. Results with simulated plant proved effectiveness and flexibility of the different CMAC models built with library blocks, and proved good learning abilities. During simulations with physical plant, nonlinearities that were not modeled in simulated plant, like static friction and backlash, generated very “fuzzy” signals that necessitate different approach for interfacing them to CMAC. Parts where signals are of comparable quality to simulated one, like in the inner position control loop of cascaded control strategy, results were similar.

Abstract - One can evidence an increased and complex dynamic in the today’s society in terms of technology that is being used, amounts of data that are being collected and processed by computers, and the resulting information overloads. The main challenge is how to address such a change with regard to the design of information systems and how those information systems are aligned with the change in human behaviour. This paper aims to address the issue of designing information systems that support Science 2.0 – a new phenomenon of interrelated sociotechnical interactions in which communication is the heart of science and the environment that enables critiquing, suggesting and sharing ideas and data in real time with almost no costs. This paper underlines problems related to the institutionalisation of knowledge transfer and its weaknesses. It also pinpoints John Dewey’s primary and secondary experience as a point of departure which provides theories, theoretical frameworks and models such as information behaviour, documents and communities of action, the quadruple Helix model, activity theory, evolutionary learning and knowledge sharing communities. All these can be utilised for designing adaptive information systems that support better knowledge transfer.

Keywords - adaptive information systems, science 2.0, information behaviour, socio-technical systems, open innovation, information and communication sciences

I. INTRODUCTION

Humanity evidences major social, technological, economic and cultural transformations producing a new kind of society: network society [1]. Such an environment is described as turbulent, and is more complex, with higher uncertainty and with more interdependence.

In such contextual turbulent environment, technocratic bureaucracies, with its mechanical authoritarian control structure of the organisational form, cannot absorb or reduce such environmental turbulence. The absorption and reduction are necessary, opening the way to a viable human future [2].

Information systems can be understood as the “extension of meaningful engagement practice through mediating and organising social interactions” [3].

Empirical evidence of such a proposition can be found in a recent massive-scale experiment on Facebook users in which the emotional state of the user changed accordingly to the amount of positive or negative content in their news feed placed without their acknowledgment [4]. Besides emotions, patterns of the information system use can configure cognition and behaviour of a user in the process of accomplishing work-related tasks [5].

It is also important to discuss how new principles of information system design will succeed in overcoming separation between technology, work and organization.

If an information system consists of social, technological and informational components, which are not separate but interrelated [6], and the social component of such a system changes according to patterns of behaviour, whereas there is an inherent inseparability between the technical and the social [7], can we search for causality between those patterns and adaptiveness of the information technology?

Human and material agencies are shared building blocks of routines and technologies, but by being isolated, neither of them (human or material agencies) are important. Namely, what is essential is the moment when they become imbricated, i.e. interlocked in a particular sequence, and as a whole they produce, sustain, or change routines and technologies [8]. To observe this phenomenon and to find an answer to the aforementioned question, the particular sequence of the relationship between human and material agencies, the inherent inseparability between the technical and the social, and the complexity of real situations should be examined, rather than analysing separate aspects [9].

II. SCIENCE 2.0 AS A SOCIO-TECHNICAL SYSTEM

In a recent proposal for development of science based on socio-technical progress, the term Science 2.0 emerged as a new phenomenon of interrelated socio-technical interactions, claiming that socio-technical systems are best studied at scale, in the real world, by rigorous observation, carefully chosen interventions and ambitious data collections [10]. In such an environment, which is fruitful for critiquing, suggesting, sharing ideas and data,
communication is the heart of science, the most powerful tool ever invented for correcting errors, building on colleagues’ work and fashioning new knowledge [11].

To understand technology in society, we have to treat it as an action system, where its subfunctions could be performed by humans or technical objects (human or material agencies) acting as subsystems. This allows us to transform the abstract action system into a socio-technical system by conceiving an object for every suitable acting function and by integrating them into the human acting or working relations [9].

Software to be run on such a socio-technical system must be able to sense, interpret and respond [12] to patterns of system behaviour that emerge according to internal system properties or reflections to the environment.

III. SECONDARY EXPERIENCE RESEARCH

The aim of this research is to investigate and eventually enable the exchange and (re)use of scientific papers created on the universities in the Danube region with their wider external environment including public, private and non-governmental organisations.

Scientists working at the universities publish scientific papers and get the papers’ reflection according to the usage of the outside environment including public, private and non-governmental organisations. The main research question is, can we build an artefact in form of an information system that supports such an exchange and reflection?

In a critical review of the literature related to university governance of knowledge transfer, institutionalisation of linkage between universities and industry is defined as a new phenomenon, underlying various forms of knowledge transfer activities, ranging from collaborative research projects involving universities and companies (e.g. research contracts), intellectual property rights and spin-offs, labour and student mobility, consultancy etc., as well as “soft” forms of knowledge transfer, such as attendance at conferences and creation of electronic networks.

Universities’ governance of knowledge transfer applies only to research contracts, intellectual property rights and spin-offs, but most university knowledge is transferred via traditional channels such as personnel exchanges, publishing, consulting and conferences. However, these types of knowledge transfer activities have not been institutionalised and little attention has been paid to their management and governance [13]. We believe that an intervention into this area by designing an adaptive information system could extend the capabilities of human and material agencies.

As a starting point for the conceptualisation of our research, we use primary and secondary experience proposed by John Dewey. The primary experience is the one with “minimum of incidental reflection”, while secondary experience is described as “what is experienced in consequence of continued and regulated reflective inquiry... experienced only because of the intervention of systematic thinking”. Dewey contrasted two different kinds of experience, primary and secondary, proposing that objects in secondary experience “get the meaning contained in a whole system of related objects; they are rendered continuous with the rest of nature and take on the import of the things they are now seen to be continuous with” [14].

To successfully transfer knowledge an information system is needed that supports better exchange of scientific papers between the academia and the environment, but which also enables acquiring feedback based on reflections from the environment.

In our view, the primary object in designing an information system is the one in which the observed object is excluded from the context with other objects, while secondary objects are those objects which are observed as a part of the higher-level system, consisting of the object itself and its relationships and behaviour in interaction with other related objects. Such a higher-level system includes an information system itself, but also its users and their information behaviour observed as a whole.

To design such an information system, we have to understand the information behaviour in socio-technical systems consisting of technologies that support the interaction between scientists, organisations they are working for, and published papers. The environment consists of public, private and non-governmental organisations.

Those three sectors together with the academic actors create a Quad Model [15] or Quadruple Helix [16] creating a framework for EU Digital Agenda for Europe in which government, industry, academia and civil participants work together [17].

To do so we have to extend our research not only to the design of the information system, but also towards the information behaviour research in such a socio-technical system.

We have to research what type of information resource (e.g. abstract, full paper etc.), and what type of media (e.g. scientific journal, conference proceedings, web pages etc.), are being utilised, but also what are the patterns of information seeking behaviour in the process of accessing information resources.

Those three research variables (type of information resources, type of communication channels and information seeking patterns) will provide us with insight into the phenomena of impact and usage of already published scientific papers by their environment (public, private and NGO). Such an insight is essential for the design of such an artefact, i.e. information system.

Another research inquiry is the area of interaction, or precisely speaking, what are the motivation drivers and factors that influence the interaction between scientists and their environment. If we understand the motivation drivers and factors that influence interaction, we can implement them into the design of an information system.

But we cannot know the effect of such functions in the information system, unless we incorporate them and put them into use.
IV. THEORETICAL BACKGROUND OF RESEARCH

Main theoretical background of this research is in the Activity theory [18], describing the three-way relationship between a person (the subject), an object, to which an activity is directed, and the tools or instruments used in the activity. A further theoretical extension is in different models of information behaviour [19], which will provide us with the framework for collecting data about the usage of already published scientific papers existing in the area of interaction between universities, public, private and NGO organisations.

In our research we will use the Documents of Action concept [20], which gives us an analytical framework to analyse usage, interaction and co-operations around already published scientific papers. Another theoretical concept used in this research is Evolutionary Learning [21], suggesting that sustainability requires collaboration among governments, businesses and civil society.

A clear distinction was made between growth, development and evolution, where growth is the increase in size or quantity, development is an amelioration of conditions or quality, and evolution is a tendency towards greater structural complexity and organisational simplicity, more efficient modes of operation and greater dynamic harmony.

Another theoretical contribution to this research is based on knowledge sharing communities [22] and communities of action [23] providing us with detailed frameworks for an information system functionality that supports both, social and technical, aspects of information behaviour.

Also different social cybernetic concepts about self-organisation, self-reference, self-steering, autocatalysis and cross-catalysis and autopoesis [24] will be used in researching feedback between the information system and its users. This proposed research also contributes to the discipline of information system design science [25-27] and contributes to the extended definition of the information system, seen as an artefact which consists of information, social and technical elements, creating a whole which is greater than the sum of its parts [6].

Two papers have already been published with regard to this very particular research – one paper dealing with the possibilities of developing an information system based on the recognition of usage patterns [28]. In another paper, the authors provided an overview of the scientific communications models that are present for the last 50 years and suggested a synthesised model [29].

V. CONCLUSION

We evidence a trend of blurring the line between technological and social in information system research, moving the focus from deterministic to more casual logic in their design. Main aim of our research is to search for feedback from users’ socio-cognitive behaviour that could be used as a signal that triggers information system adaption.

One of the theoretical fields we are currently exploring is information behaviour, which results in patterns of that behaviour. As the dynamic of patterns is observable by a machine, we believe that there is a possibility to use this signal to automatically (or semi-automatically) trigger restructuring of the information system, to generate new functions to support existing and create new information system goals.

We perceive an information system as a system consisting of informational, social and technological components acting as a whole, and that is aligned with findings from related theoretical and empirical studies presented in this paper.

Those components interact between each other and such an interaction, which is not only deterministic but casual, could provide fundamentals for adaptive information systems which evolve along their usage. Researching interaction around scientific papers by universities, public, private and non-governmental organisations could provide us with valuable information on where and how to intervene in such a system.

Building an artefact in form of an information system for the purpose of the research could provide us with empirical insights which of the interventions and interactions give optimal results in terms of information system performance.

For example, if we knew what types of documents have the most impact on the environment and trigger the cognitive, communicative and co-operation processes [30] (with public, private, non-governmental organisations), we could further design amplification towards this area of the system which could then produce change in dynamics of information behaviour and related patterns.

New patterns will open up new areas of research interests, which then again could be amplified or attenuated. In that way we could design feedback loops in the information system which could enable deterministic but also casual properties.

Abstract — Captology is an acronym, derived from Computer As Persuasive TechnOLOGY, where the instance persuasive, (lat. persuasibilitas - enticing), refers to the convincing persuasion caused by computer technology. Transitive and interactive technologies as intelligent systems, have imposed, by their persuasiveness, "the cult of information", after which the information became type of goods that as utilitarian resource need to be quickly and efficiently exploited. Such widely accepted fact resulted as hype, presenting perspective that approach to large amount of information and faster "digestion" of their content and sense will enable users to quickly get desired knowledge. Intelligent systems are ubiquitous in almost all segments of society and life, although there are no relevant researches to confirm the claims of all their acceptability. The paper presents the results of research and testing processes of computer persuasion to show that its success is primarily dependent on its factors. The design for "cloud work", interactive computer programs, web, desktop and other factors directly affect the user, and its attitudes, beliefs, learning and behavior. That impact can be positive or negative.

Keywords — Artificial intelligence, AI, intelligent technology, ILLG, intuition, persuasion, permission, expert systems.

I. INTRODUCTION

Studies have shown that artificial intelligence, (AI), contributes to development of the human mind, through its products, "smart" creations, [1]. Researches of AI from the very beginning of its recognition, (the end of 40-ies of the last century), had a much more complex relationship to philosophical researches related to the science, all to find the methodological guidelines and practical tools for self-analysis and synthesis, simultaneously providing a comprehensive theory of human nature, [2-9]. AI seen as a "new philosophy", but as "anti-philosophy", as well, defined the human being and its place in the universe, with a radically new empirical approach, (Herbert Simon, Alan Turing and Margaret Boden), [10-19]:

- AI with its content, goals and methods produces "smart" creations that simulate and reproduce quasi-cognitive characteristics, ( quasi-abilities), of people to reduce symbol manipulation by captological access through the application of specific formal rules.

- By symbol processing, AI emphasizes the key role of cognitive processes calculation and their criteria as crucial intellectual foundations.

- Recognition of AI within technologically-intelligent multitude related to informatics, ensured the required start for intelligence assessment beyond the conceptual point of view.

- The link established between AI and informatics is extended to engineers of knowledge, designers of creations whose successes must be judged based on their performance, regardless these processes are used by AI and whether any similarity with the corresponding human processes is found.

- "Smart" creations of AI, whether a computer program, computer itself or the intelligent system, are assessed through their activities, which are compared with the human mind.

A. The concept of expert system for processing

In technical sciences, field of computing, there is a branch of artificial intelligence. One of its products is an expert system. Model of such system is simply displayed with three components, (database, base of knowledge and inference mechanism). When the expert system is being compared with information processing type, problem solving and decision making related to human cognition and mental potential, a parallel with intuition and intelligence can be drawn, Fig. 1.

Fig. 1 - Mental competences - model of expert system

The base of knowledge is "cognitive" dependent, based on the symbolic representation and is identical to the intelligence. For the sake of purposefulness, it is necessary to undergo both databases and knowledge to the mechanism of reasoning. In the biological sense of identification with the functioning of the human brain, (way of thinking), latter suggests that the
The purposeful use of intuition and intelligence need some sort of trained strategy, (intuigence). That was confirmed through detailed studies results conducted since 2008 till today, and these findings are groundwork for this paper, [20].

II. CAPTOLOGIES - CONDUCTED RESEARCHES
A. 3P-Model of intelligent technologies and empathy

The strategy development of world computer production and sales, confirmed the promoted 3P-model, [20], (Persuasive / Permissive / Pervasive). Within this model, persuasive, (lat. persuasibilibus - enticing), is associated with convincing and suggestive influence by the intelligent system, while permissive, (compliant), is linked to the educational approach that does not require the implementation of almost any control, (the effort of meeting all wishes and requirements); and lastly, pervasive, (permeate), is associated with indicators of developmental disorders, (PDD). The common product of latter results as impact on empathy loss, in psychology described as a process of direct involvement to emotional states, opinions and behavior, as well as the ability to understand the emotions of other people, (the way they are reacting to perceived emotions). As a basic emotion, empathy is extremely important for healthy emotional and moral development. Two levels exist therein: emotional and rational, (it is possible to feel what others feel, but also understand rationally).

Apart from being partly inherited through genetics, empathy may be encouraged and learned as any other skill much needed in society. As a skill that develops, it depends on the environment in which lives. It is well known that empathetic people are more successful and happier and have more friends. Empathy is a positive emotion and it's highly advised to develop. By strengthening empathy, the connection between people strengthens and the ability of emotional tolerance is achieved.

A prerequisite for a positive impact on empathy is primarily interest in other people and sincere desire to overcome internal borders. The most difficult task herein is learning to listen others without judgment. Since the characteristic of human mind is that it constantly classifies something, defines, shares, asks - developing empathy is a very demanding task, although is one of the ways of self-development. By listening the other person, it's needed to involve parallely within its inner world and truthfully understand its point of view. If alongside listening comes words reasoning, then the subject of conversation becomes susceptible for approval or disapproval, understanding and misunderstanding, which leads to the conclusion that much other is made but mere hearing. Speech and hearing are greatly suppressed with the presence of intelligent technology. Examples of studies conducted show that speech is lost in the flood of images and messages that quickly disappear because they cannot be memorized over created archetypes, [21].

B. Persuasive addiction and the human mind

The perfidy of persuasion in the context of information treatment and understanding, comes to the fore when the relative value of each information on network, via intelligent systems, including "cloud-work", (e.g. the ubiquity of web-information), and is evaluated by two factors:

- the number of incoming links information, (page), attracted,
- the authority of the pages from which these links originate.

Studies have confirmed that this is about "third-party tools for experiments on users", [22]. Software algorithms evaluate and rank the value of all information on networks from these databases. Ever since the beginning of the new millennium so called A/B testing have been introduced. By that case, millions of users were informed about 6,000 conducted experiments annually on the search mode with 10, 20 and 30 links. Within five years, more than 450 changes are made in search algorithms and page layout. Therefore, it is not surprising fact that over 300 trials are conducted daily and about 200 signals are continuously carried out therein, all to have effect on the maintenance of "freshness" and speed of collecting, dissecting and transferring data, which is directly related to provider’s profit of information services, [23]. Although rarely mentioned, but persuasively successful, captological arsenal was discovered as:

- Cognitive biases, (from more than 170 of cognitive biases, stresses the "risk aversion in time deficit", and which is led by persuasive message),
- The weapon of persuasion, (this is a persuasive technique that rely on the "principle of scarcity" and the "theory of authority acceptance"),
- Productive laziness, (confirmed by the fact of the of the human mind laziness and skipping preferences or careless reading, which, because of persuasive guidance result in unwanted consequences),
- Fatigue of the decision, (associated with the depletion of user by persuasive excessive offers that encourage the application of the least resistance line), [24].

The human mind evolved thanks to the unfailing desire to try and change, while the desire to follow only "reliable and truthful" answers is not the case.

Brain stimulation usually happens while new situations are about to occur, such as: solving new problems, seeing new places, seeing new shows, meeting new people. A larger beneficial of eclectic energy is created due to the novelty of mental or motor stimulus, rather than when it comes as already familiar knowledge.

Although interesting insight as to when learning occurs at the cellular level of the brain, cellular learning and behavior of individuals differ significantly. It is possible to learn good learning processes from books, and to not produce any outward signs of acceptance and application of acquired knowledge. Behavior change that is the result of learning is dependent on numerous factors such as emotional state, previous knowledge, daily fluctuations in brain chemistry, the amount of peptide hormone and captology.

The result of learning should be a human intelligence. The brain is a structure, and mind is what the brain does, (function). The mind is a process. Nowadays, psychometric studies confirmed that the brain can continually create new connections to increase mind learning. The learning capacity of the brain is
huge and designed for more demanding intellectual activity than those in which it is usually involved. The human brain has two independently acting systems, for receiving and for thinking. The leading one is in the left half of the brain and it analyzes, writes, reads, speaks and receives logic. The main center for emotions is in the right half of the brain and acts more completely, emotive, and associative - intuitive. Selected activities of the left and right hemispheres of the brain helps the brain learn by pairs model, (challenges and feedback).

Right side of the brain uses for intuitive problem processing based on two components:

- simple provisional rules used by provisional order to recognize the most important information, but ignore everything else, which enables quick response.
- Predispositions of brain evolved abilities - skills acquired genetically or by learning, all to make these predispositions into competences.

The real question seeks how human mind is progressing thanks to the unfailing desire to try and change, and not through desire to follow only "reliable" answers. It also includes the question if the brain development can be achieved when captologies are not new but uniform, deadening situation.

C. Example of the study

In support to abovementioned persuasive addictions, the results of the "Tests / Exercises" can be joined, as educational material originally developed through course “Intelligent Systems” at the Electrical Department of Zagreb University of Applied Sciences, (TVZ). It is basically about learning and reasoning components through the knowledge base and databases of expert and agent system, [25]. The conclusion is carried out by applying the acquired knowledge of distributed artificial intelligence in correlation with human intelligence and social predetermined. The instruction accurately describes the task which each student receives in envelope. The teacher reads instructions out loud before the beginning of the task, in front of the students at the initial location of the implementation. Two groups are solving the task shortly after given instructions, at two different locations. Students are reminded that they have the ability to cooperate with each other, where this is exactly the object of exercise. Five simple questions are conceived that must be answered in a way that all students participate and create a common, identical answer. The guideline text is divided in three parts, (description of the assignment, approach to the resolution and guidelines for the solution). Through four educational periods in three academic years, 148 students took part in this task and in any case the task has not been solved.

The reason such a simple task is not solved lies in the data, (information), hyper-offer. Students are taught that with the help of information technology comes fast data browsing. Therefore, task understanding comes down to short view and is very shallow, which makes the easy way to create oversight in the understanding of approaches to solve task. Too much data distract from deep and lasting engaging in any single argument, fact or idea. Too much details and characters nullify each other. Hence, students are prone to shorten sometimes exhausting search and move toward each connector, (link): Thusly piled but seemingly interesting data are the start of the interruption in current potential of available human concentration. Thence, the externally generated interference of human attention and lack of cooperation is performed. As in browsing and search within vastness of data the case is to cause users to quickly come and go, the same effect is achieved within the messy text. Rapid collection and transmission of data causes cognitive efficiency loss. Furthermore, a multitude of confusing information and parameters that draw attention, fragment, impede and impair the flow of thoughts finally end up as distractions. Self-efficacy is heavily influenced by intelligent technology and therefore under the pressure. Part of the human mind, in charge for critical thinking, analysis of reality and which should be used daily is not evident and has a lack of understanding. It should be used as a form of thinking when solving problems, but also in social interaction when used to connect to the outside world. That element has been lost in captology for it does not follow the sequence of evaluation, Fig. 2., which is the process where mind through stages of gathering information and understanding them acquires the higher forms of evaluation.

D. Example of understanding while meeting other people

One example of understanding related to learning to understand while meeting other people was carried out by William Outhwaite, who observed the situation meeting other people through four categories:

1. Category of physical facts that can be observed, (how people look like and where that result come from). These are understandable phenomena’s in the relevant sense when seen as a mark of something not physical from last time or something related with the mental state.
2. Category of mind states at others that may be identified immediately, or can be concluded based on previous findings.
3. Category of others actions, (detection of what others do and what they consider they’re doing), is described through three subcategories:
• Action identification accessed from distance,
• Acceptance of what is said about on the same elemental level,
• Sorted judgment on the actual significance of what it is or what is really meant by what is said about it.

4. Category of questions about why certain things work, and what motivates people to do so.

The difference is tried to be made through abovementioned categories, (especially between third and fourth category, i.e. the difference between motives and "hermeneutic understanding"). The psychological understanding of human mind mental states can be observed based on three conclusions about people motives and their intentions, and they are: a), visible signs, b), explicit statements and c), knowledge of the "situation facts", which is in fact confirmed by the psychology of the situation, [26]. From latter examples, the complexity of understanding knowledge can be seen, which is theoretically processed, and mere social process of knowing people, is incorporated as algorithm on a subconscious level, [27].

E. Example of understanding while reading out loud

For confirmation of this research is useful to consider the adoption of understanding through example of literacy development research. This case leads to the conclusion that central process in learning to read actually to understand the text and active search for meaning and purpose, as Whitehurst & Lonigan determined. The process of reading, i.e. reading comprehension, comes down to understanding encryption and decryption, which is nowadays included in media environment, Fig. 3.

On that basis, data processing parallel to reading takes place with five concurrent methods, known as the “Model of 5 babushkas”, developed by R. J. Marzano and D. E. Paynter, which includes:

1. Understanding the reading goal,
2. Assessment read data conformity with the goal,
3. The meaning of smallest thought units, (assertions),
4. Recognizing the meanings of words,
5. Recognizing sense of what was read.

Reading, listening, watching and pronunciation are learning modes, and each one has a different contribution to what is learned. According to the learning mode, left and right cerebral hemisphere is activated, but the emotional center of the brain as well, Table I, [20].

a. Left brain hemisphere; b. Right brain hemisphere; c. Emotional brain center

Understanding the learning by reading, (reading aloud), is a strategy that along with understanding involves understanding development, voice sensitivity development and motivation development. These examples, in particular data processing operation when reading, is an important basis for different types of reading analysis, such as:

• matured reading,
• linear text reading - printed book,
• linear text reading - e-books,
• reading by text search - computer,
• hypertext reading – computer.

It is necessary to distinguish the reading from search, which being influenced by captotlogy is turned into an addictive need, because they held worthless power over digital information flow. Imposed "Internet Ethics" as the media, results in persuasive addiction that manifests through:

• stimulation and "thirst" quench for small segments of short-lived information,
• curious dependence on uninterrupted progress which is updated in real time, "updated status" that loses concreteness already few moments after the announcement and
• desire to speed up the flow of information.

These events do not have any contributions for the storage of learned, for nothing has been taught. There was a disturbance and activation of the brain hemisphere nor emotional center of

In fact, the presented is mere concept of expert system functioning, groundwork for explanation and processing. Researches on the reading impact has set the foundations for mechanism of reading explanation, which are:

• comparison,
• memory recall,
• connecting what is seen and what is heard, (or being heard),
• identifying the relevant data and discarding redundant.
the brain hadn’t been recognized, which nowadays can be confidently confirmed by psychometric tests, [28].

F. Examples of hermeneutic understanding

Accepting the presented facts, human as a rational being can observe its understanding on two levels. The first is a subjective level or psychological level of participation, and the other is an objective level, or the level of intellectual participation. Thusly, an objective understanding of the meaning and subjective understanding of the motives and intentions can be distinguished. Next to it, basic and higher forms of understanding can be recognized, (graph in Fig. 2). The elementary forms of understanding are regulated by the concept of objective mind or spirit, which guarantees the possibility of inter-communication at the basic level.

"Higher forms of understanding" act confrontative with an internal difficulty or contradiction with what is already known. Therefore, recall and input of all living structures is necessary, (establishment of relations between life and expression of its mental content), whose foundation can be found in the hermeneutic understanding, [29].

Hence, it is possible to conclude that the hermeneutics is universal theory of understanding where is no misperception for hermeneutic understanding is not an interpretation or explanation. The ancient interpreters of hermeneutics confirm latter by saying: "sensus non est inferendus, sed eferendus", i.e. meaning must be parsed from the outside, not from the text, [30].

Studies that processed captological components of intelligent interactive technology are confirmed through examples of human thinking simulation by computer in the field of cognitive science. Model of expert system has processed numerous examples of research studies. The research results show that style of thinking and information processing develops and modifies over long period. On a slightly higher level of flexibility, mental skills which process information intuitively and analytically can be acquired, [31]. These findings, along with persuasive context and information technology close the "hermeneutic circle of artificial intelligence", which requires certain psychoculture, Fig. 4.

G. Psychoculture and captologies

The term "psychoculture", according to [32], calls for culture, (lat. colere – to breed, nurture; cultos - cultivation), which represents an integrated system of attitudes, beliefs and behavior patterns typical for members of society, and which are not the result of biological heritage, but the social product, transmitted and maintained through communication and learning. The function and meaning of culture are assistance, extension and development of human society. Culture arises from the people’s need to master the nature and to control the animal part, hence not only external nature is cultivated but its own, which realizes the humanization process. Under various influences and thusly captological ones, culture is the subject of collective mind programming that differs members of one community from others. Psychoculture, which is associated with the cultivation of the soul, is mentioned in ancient times, e.g. by Cicero, (lat. cultura anima). Developing and training noble qualities, but also the creation of a collective mentality in society can be achieved by dominant ideology that directs the social and political processes. Every individual has own ideology or value system and environmental landmarks that use as directions in life, but also determine the behavior that can be influenced by captology. Socio-cultural neuroscience enables better insight into the complex interactions between the socio-cultural and neural structures and processes, and thus the biological mechanisms that underlie social and cultural phenomena and people behavior, including all components of existentialism.

From these findings is useful to point out, according to [33], the structure of neural networks of the cerebral cortex is the biological basis of our mental abilities. In adulthood, new knowledge and skills are simply acquired, without changing the structure of the neural network. Education, psychological, social and emotional environment during development change structure of the neural network, especially in parts of the brain essential for adoption of the most complex brain functions. This includes the affective modulation of emotional expression, conceptualization of the own mind, mentalization, cognitive flexibility and working memory. Captological impact is confirmed on the mental and cognitive abilities of people, at a sufficient level of psychometric tests, but the results of these impacts are not transparently recognized, therefore initiated research continues, [34-37].

III. CONCLUSION

When education, psychological, social and emotional environment connect with the presence and intimacy of intelligent technology, it leads to confirmation of their multiple influence hypothesis, as in a positive way by raising level of integrated development knowledge of the human mind, thus in the negative way through insights about origin of the neuropsychiatric diseases development. Biomedical and social concept is one of the main subjects of continuing debate between advocates of selective, as opposed to design theory of mental processing, unfortunately, only present at the expert level of medical profession. This topic arises an important question: how to use the mind and intelligent technology in modern times? One
part of the human mind is responsible for critical thinking, analysis of reality, and as a way of thinking, it is used daily to solve problems, but also in social interaction, when used to connect to the outside world. The second part of the mind is used for imagination and can be operated when the analytical thinking is excluded. The realization that imagination and analytical thinking are not two opposing forms of thought, but two kinds of thinking with different functions, is a result of intelligent technology contribution, whose use must be decided by human intelligence.

Abstract - This paper aims to propose and discuss concepts of how users can recognise information seeking behaviour
automatically and what implications such an automatic recognition can have. The authors develop the discussion
around variables proposed in Wilson's second model of information behaviour and state how they can collect data
necessary to recognise information behaviour automatically. The authors give an overview of different parts of Wilson’s
second information behaviour model such as activating mechanisms (stress/coping, risk/reward, and self-efficacy),
intervening variables, different stages in the information acquisition process, and types of information seeking. They
also discuss streams of data that can be collected and processed automatically. From a set of thought experiments,
the authors propose that by processing computer log files and recognising user affective states, which employ affective
computing techniques, it is possible to recognise information seeking behaviour. Analysis also shows that Wilson’s second
model of information behaviour can be used as a reference model in designing automatic information behaviour
systems. By quantitatively describing the information behaviour sequence, such a description could be implemented
into the computer algorithm, and that process of information searching could be replicated reducing the
time needed to satisfy information needs. Modern society is one step closer to making the trails Vannevar Bush
proposed a reality.

Keywords - data mining, information behaviour, systems modelling, adaptive information systems, information and
communication sciences

I. INTRODUCTION

This paper aims to propose conceptual ideas related to automatic information behaviour recognition. As a
fundamental block of this very analysis, the authors use T. D. Wilson’s second model of information behaviour [1]
and discuss different sets of variables that it proposes in terms of how they could be used to recognise behaviour
automatically.

The authors discuss two main techniques used in collecting data necessary to recognise information
behaviour. One is computer log file processing, and another is affective computing. In their view, instead of
observing the user or sources of the information separately, it is necessary to observe “patterns” of the
interaction of the user with the sources of information (stored in an information system).

The authors define “patterns” as a time sequence happening between the moment a user experiences
information, i.e. when structured data become information and the information seeking process starts, until the
moment the user stops interacting with the information source as the user satisfies his information needs. Such a
process can occur in social and technical domains [2].

This is a working definition describing the scope of the analysis. Such a proposition can connect with the concept
of trails proposed by [3]. The authors would also like to propose that every interaction of the user, described as a
“pattern”, and the source of information is observable as an open system of interest.

Patterns, as defined above, are a dependent variable of system behaviour, and the user’s affective states
accompany them.

The authors believe in the importance of such a view, as system behaviour is not quantitative, which makes it
hard to collect and process data automatically. But by observing the user’s log files created while interacting
with the information resources and using affective computing techniques, one can describe “patterns” with
rich quantitative data sets.

The main question the authors would like to raise and discuss is – how can different variables from Wilson’s
second model be used to facilitate automatic information behaviour recognition?

II. INFORMATION BEHAVIOUR

Information behaviour is “the totality of human behaviour in relation to sources and channels of
information, including both active and passive information seeking, and information use” [4].

Different people may engage in different types of information behaviour even when faced with similar tasks
and circumstances [5]. Information behaviour can be understood as an adaptive mechanism [5] that responds to
changes in the environment, creating complex system behaviour.

There are two descriptions that can help to understand complex systems: state descriptions and process
descriptions. The former characterises the world as sensed, and the latter characterises the world as acted upon
[6].
Reference [6] indicates that this distinction is an essential condition for the survival of the adaptive organism – in this case, an adaptive system of the user and the information source – and it should develop correlations between goals in the sensed world and actions in the world of process. When such correlations become conscious and verbalised, it is possible to find differences between them.

The task is to discover information behaviour sequences resulting in changes in state and process descriptions, and this changes are goal-driven. For example, if a person starts seeking for information by using an information system, then the person’s affects states will be different at the moment when the person starts to seek for information (one state description) and at the moment when the person has found the information (another state description) [7].

Observing the changes in the process description enables one to recognised when the information need is satisfied.

By observing how log files in the information system change while a user is performing information seeking, it is possible to determine when the process is finished, as there are no new log files being produced.

Central parts of Wilson’s second model are two activating mechanisms and intervening variables. An activating mechanism is what prompts someone to engage in activities, and intervening variables are factors that influence those activities [5].

The activating mechanisms and intervening variables can help in describing the sequence of a process description. State descriptions tell about the information need, i.e. the initial state, and about satisfying this need, i.e. the goal state.

There are correlations between goals in the sensed world (information need and information need satisfaction) and actions in the world of process (activating mechanism and intervening variables).

But if there is no awareness of those correlations – i.e. the satisfaction of the information need and the corresponding satisfying actions – and the difference between the two isn’t recognisable, then the information system does not produce much of value to the user in terms of adaptiveness to particular user information needs.

For instance, let us assume that there is a new librarian working in a library and he does not know on which shelf a particular book is. A new visitor enters the library and he is looking for this very book and finds it by himself. The librarian recognises only that the visitor found the book and that his information need is therefore satisfied. But the librarian does not know the steps the visitor took to find the book he was looking for. Consequently, when another user comes to look for the same book a few hours later, the librarian cannot help. But if the librarian knew the process the first visitor followed to find the book, then he could easily help a second user to find it.

How the process description, i.e. the sequence of events or steps the first visitor used to find a book, is verbalised will influence the quality of its transition to the state description, i.e. the instructions on how to find a particular book.

So if one understands information behaviour as a process description and if one is able to recognise it automatically, then it is clearly possible to translate it into the state description.

In other words, the more one knows about information behaviour, the easier it gets to move users from process (actions) to state (goals) descriptions.

According to Wilson’s second model, when an information need arises, a system, which consists of a user and a source of information, starts with the process of acquiring information.

There are two activating mechanisms. The theory of stress and coping explains the first activating mechanism [1]. Stress is a relationship between the person and the environment, and the person appraises such a relationship through his reflection on the resources available to him and his wellbeing [1]. Coping is cognitive and produces behavioural effects to master, reduce, or tolerate the internal and external demands that stressful situations create [1].

Reference [1] indicates that various states will exist as a result of intolerance to uncertainty and arousal. If one looks at the user and the source of the information as one open system, uncertainty is important as the information that enters the system reduces it. It is possible to understand the arousal as an intention of the system to move into the steady state, and it is done by inputting new information into the system.

Reference [8] states that a living organism maintains a disequilibrium called the “steady state of an open system”. Characteristics of an open system in the steady states are that it can do work [8], and such a state is reachable by equifinality, that is, a process specific to open systems in which a system may reach the same state from different initial conditions, and only the system parameters determine it. In this case, such parameters will depend on properties of the user and the information system that stores information resources.

Such changes may occur since the living system initially is in an unstable state and tends towards a steady state, such as, roughly speaking, the phenomena of growth and development [8].

In terms of information behaviour, when a user experiences an information need and starts to interact with the information sources, and if one perceives these two entities, i.e. the user and the information source, as an open system, in the beginning, it is in an unstable state, but as information needs become satisfied, such a system moves towards a steady state. And the closer it is to the steady-state system the more it develops and the more it is capable of doing better work.

For example, when a student has to pass an exam, the information need begins, as he starts the process of seeking and searching for information. And the more relevant papers he finds and reads, the more he knows about a specific subject, whereas his chances of passing the exam increase, being more capable of doing work.
At the same time, if the information system – that stores those papers and acts as an information source for the student – could recognise student information behaviour and adapt accordingly to the student’s information needs, it would also develop and would be capable of performing better. And if one understands this distinct joint environment, which consists of a student and an information system storing relevant papers, as an open system, such a system will evolve and develop too.

III. AUTOMATIC INFORMATION BEHAVIOUR RECOGNITION

An important question emerges – how can an information system that acts as an information source to the user automatically recognise user information behaviour?

The authors believe that doing this automatically is possible if two sets of techniques are applied. The first is by collecting, analysing, and interpreting computer log files, and the other is affective computing, which is the study and development of systems and devices that can recognise, interpret, process and simulate human affects [9].

Those thoughts derive from recent researches that are based on behavioural computing and which are pointing out the distinct differences between demographic and behavioural data, and which show how they are structured for the purpose of conducting analyses. Such a data structure is essential for developing specific algorithms on top of the data which represent the user behaviour [10-11].

Any change in the emotional states of the user and change in the information system’s interaction patterns could signal that there are changes in the information need [7].

If stress/coping theory explains the first activating mechanism in Wilson’s second model [1] and involves user affective states, recognising user emotions in the process of seeking and searching for information is important and could be done automatically.

The next group of variables proposed by Wilson relate to the psychological, demographic, role-related, environmental, and source characteristics of the user who is interacting with the information system while seeking and searching for information [1].

Data describing those variables can be found in many sources. If seeking and searching happen in an organisation that has an information system with functions that support human resources management, then most of the data needed is already in those systems.

Other sources are social media platforms, but it is also possible to collect relevant data through sensors (e.g. biofeedback, ubiquitous computing). In today’s communication environments, one can gather lots of data from the interaction between users (user to user, user to system, user to system to user). It is also possible to collect data related to time spent while interacting with the system and, for instance, geo-locations of the system users. By collecting those data and comparing them with the log files that describe patterns and affective states, one can develop various computing techniques that automatically recognise an information need.

The types of information seeking [1] proposes are passive attention, passive search, active search and ongoing search. The authors hold that those four types of search are easily recognisable by observing log files collected from users interacting with the information source, since different log files probably correlate to different types of searches.

In Wilson’s second model, the second activating mechanism is described as risk/reward and self-efficacy [1]. The risk/reward model is essential for understanding information seeking behaviour.

User behaviour will depend on the risk/reward ratio, and such a risk is not only evaluated through financial resources, but also through psychological and physical resources.

But how can one recognise and measure the risk/reward ratio from the signal, i.e. the stream of data, one can capture from the user-information system interaction?

Components that are included in risk are performance risk, financial risk, physical risk, social risk, ego risk, safety risks and time-convenience loss [1]. If one recognises the type of information seeking behaviour from the log files, it is possible to build models that can help one to automatically recognise and connect different types of risks with different seeking behaviours.

For example, if a student is looking for exam-related information at the information kiosk (i.e. information system) in the university hall, and if the system is able to recognise that particular exam within a certain timeframe (e.g. 10 minutes from the moment a student starts to interact with the information kiosk), then the main goal of the information system is to reduce the performance risk by providing the student with basic data (e.g. in plain text format) for fast information retrieval.

But if the system knows that the student, that is looking for exam-related information, had already failed the exam a few times, and has to pay additional exam fees if he fails again, then the system should reduce the student’s financial risk by offering him more extensive and relevant data, such as books to read, in order to decrease the chances of failing the exam once more.

And let us assume that the information kiosk has sensors that can detect a student’s stress level, and if such a level is high, then the system might play relaxing music to reduce the student’s physical risk.

By observing log files while a student is searching for information, the system can detect if the student is not focused and therefore cannot find information, and adapt accordingly. Also, by comparing log files of a student’s search process with the log files of his colleagues, the social risk will possibly be reduced.

By using trails [3] that are already stored in the information kiosk, the system can reduce time/convenience ratios by employing implemented
recommendation techniques, which can improve the person's state of happiness, i.e. can reduce ego risk.

Another part of the second activating mechanism is related to the self-efficacy, as an “individual may be aware that use of an information source may produce useful information, but doubt his or her capacity properly to access the source” [1].

There is a link between self-efficacy and coping strategies, as people are more likely to act, or in this case to search for information, if they are convinced in their own effectiveness. It will also influence the amount of effort invested in the process.

According to [12], efficacy expectations are based on performance accomplishments, i.e. carrying out the actions oneself; vicarious experience, i.e. learning from others; verbal persuasion, i.e. which may include self-instruction; and physiological states, particularly emotional arousal.

The authors believe that it is possible to recognise from log files whether the student is looking for information in order to learn by himself (e.g. by searching for papers), from others (e.g. by searching for students that already passed an exam and by looking up their contact information), or from postings to find the date of the next exam.

By using affective computing techniques, one can recognise different levels of emotional arousal. Reference [1] proposed the following stages in human computer interaction for the purpose of the information acquisition process: intelligence, intention or goal formation, design, choice or selection, information extraction (and integration), and review or evaluation.

Breaking down and observing the process of student interaction with the system (for example the information kiosk) throughout these stages, one can hypothesise that it is possible to recognise behaviour by observing interaction log files and data describing the student’s affective states.

IV. CONCLUSION

The authors briefly demonstrated that Wilson’s second information behaviour model can be very useful as a rich source of variables that describe the process of satisfying information needs.

Following Wilson’s second model the authors describe the sequence from the initial state to the goal state. The sequence can be described quantitatively by implementing computing techniques that collect and process data related to the user’s stress/coping, intervening variables that influence the behaviour, different types of associated risks, and different stages in information acquisition.

Such a description could be implemented into an algorithm, reducing the time needed to go from the initial state to the goal state. By doing so, the “recipe” for how to find information (or trails) is stored in the system.

Through observing the user and the information system he interacts with as one open system, one can compare and analyse different systems and test how different “recipes” (or trails) perform. And the ones that perform well can be implemented into the design of the information system.

REFERENCES

Abstract - The paper analyzes the semantics of adjectives in sentences in English language. The goal is, based on the analysis of individual sentences and the method of induction, to show the semantic relationship between the adjective and other word types by using the method Nodes of Knowledge (NOK). The NOK method is used for formal knowledge representation expressed in text, i.e. to represent the knowledge network. The method incorporates the enrichment of representation with hidden semantics contained in the context of an individual sentence. The paper analyzes and graphically represents the location of the adjective in a sentence using the NOK method diagram (DNOK). DNOK graphically shows the knowledge network, which can be computer-implemented into the knowledge base as a part of the construction of intelligent information systems. The construction of intelligent information system is not possible without a complete metamodel of language and this work is a contribution to the research.

I. INTRODUCTION

One of the unsolved problems in the field of the development of database and programming tools is the input of language and knowledge of the language in a computer system which could understand the language and communicate intelligently. In addition, there is also the problem of machine translation of languages. Both problems are being addressed through the construction of intelligent software product and a corresponding knowledge base [1].

From a series of necessary properties, from the standpoint of communication with human, an intelligent system is any system that has the following properties [2], [3]:

- the system must communicate with humans and other intelligent systems in a friendly manner – therefore, it uses natural language and speech.
- such communication involves handling ambiguities and grammatically incorrect sentences.

Knowledge representation (KR) began to develop in the area of artificial intelligence in 1970-ies and remained one of the strongest sub-areas of artificial intelligence [4], [5].

There are numerous ways to display knowledge [6]. Schemes for knowledge representation can be divided into four basic approaches [7], [8]: network schemes, logical schemes, procedural schemes and framework theories. There are also other approaches to represent knowledge such as: object-oriented approach, descriptive logic, taxonomies, ontologies and others.

Semantic network [9] is a network scheme for knowledge representation that represents knowledge in the form of a graph. Nodes mark objects or concepts, their properties and corresponding values. The arcs mark the relationships between nodes. Nodes and arcs generally have names (arcs have weight). Nodes can represent concepts, objects, events, features, time and so on [5], [8], [10]. The NOK method belongs to the group of semantic networks. A comparison of the NOK method to other methods is given in [11].

Here we can provide a short comparison of the NOK method to two other methods for knowledge representation: Quillian's model of semantic memory [12], [13] and Minsky's frame theory [14].

In Quillian's model of semantic memory, each word is stored along with the configuration of the pointer to other words, and this configuration represents the meaning of the word. For example, if we want to store the following statement: "Canary is a yellow bird.", then the word "canary" is stored in memory, which has the pointer to the word "bird" (the category name of canary) and pointer to "is yellow" (representing a property of canary). The NOK method also has pointers to other words but these pointers have a semantic identifier which indicates the reason for the existence of the pointer (or link). Semantic identifier is represented by a question. In the example of the statement "Canary is a yellow bird.", the NOK method would record the words "canary", "is", "yellow", "bird", the links between them, as well as questions that represent the reason for the existence of links ("canary" - (who?) - "is" - (what?) - "bird" - (what kind?) - "yellow").

In Minsky's frame theory, the frame is a data structure (which is stored in slots) that stores information such as: Facts or Data, Procedures, Default Values and Other Frames or Subframes. Table 1. shows the statement "Boy is a male person under 12 years.". It can be seen that this type of representation results in the loss of the semantic relationship between words that exists in the sentence, which does not occur with the NOK method.
The NOK method starts from verbalized knowledge, which is composed of parts and has structure and content, and can be presented as such in the form of knowledge network. In the process of the formation of the network, the network is explicitly enriched with hidden implicit contextual knowledge contained in sentences [15].

The NOK method uses two elements for the graphical representation, node and link. Links between nodes allow grouping into complex expressions. A detailed description of the NOK method is presented in [15]–[17].

In the beginning of the development of the NOK method, verbs were selected, as separate word type, and a special symbol in the form of an ellipse was introduced for their modelling. Other word types are treated equally. This paper analyzes adjectives and suggests their modelling in the context of the NOK method.

Based on the NOK method, a special formalized language for knowledge representation was developed (FNOK) [18] by which knowledge can be stored and processed using a computer program [19], [20].

The application of the NOK method can proceed towards the development of QA system, Chatterbot system (Elize, ALICE, Evi, Wolfram Alpha) and more recently digital assistant system (such as Google Assistant, Apple Siri, Amazon Echo) [19], [21]–[26]. All these systems have a myriad of problems and will require further research and development.

II. THE NOK METHOD

This paper deals with knowledge representation formalisms and with problems of natural language semantic representation. It introduces a new method for knowledge representation named Nodes of Knowledge (NOK). The NOK method has a graphic representation form, a diagram (DNOK). The NOK method uses two elements for graphical representation, nodes and links. Different kinds of nodes are used for terms representation. Links between nodes enable grouping terms into more complex expressions. Process node is introduced as an aggregation point for representation of knowledge described in sentences. Furthermore, an array of interconnected process nodes can represent knowledge expressed in a sequence of sentences.

![Graphical concepts in the NOK method](image)

Our idea was to define a method that can capture natural language semantics, but simple enough to allow efficient reasoning and learning process implementation. The goal of the NOK method is to represent a knowledge network of knowledge written in a textual form. Furthermore, the NOK method can capture different kinds of knowledge: knowledge from dictionaries and encyclopaedias, knowledge from existing databases, knowledge embedded in business processes, knowledge stored in business documents, etc.

Concepts of the NOK method are used for modelling knowledge. In the NOK method, nouns are independent nodes, verbs are independent processing nodes and adjectives are a special type of nodes that belong to nouns [15]. Basic graphic symbols are visible in Fig.1. Verbs and adjectives are separately marked, while other word types are displayed as a rectangle.

Let us observe the sentence "Mark drives a car." With the proposed symbols of the NOK method, the semantics of the sentence is represented using a diagram as shown in Fig. 2. The following discussion will use the version of the NOK method with a single link.

III. ADJECTIVES AS ENTITY ATTRIBUTES

This paper will briefly present basic facts about adjectives. It should be noted that the detailed descriptions are given in other papers. Adjectives fall into the category of open word classes, that is, the category which can acquire new members (either by borrowing from other languages or by coining new words).

Persons, places, things and ideas are collectively called entities. A noun is a word type (term), which appoints entities (persons, places, things or ideas). For example, thing "house" in objective reality is named with the word "house". Entities may have some properties (or attributes). The properties of entities are also appointed by nouns. The house has the following properties: number of rooms, colours, etc.

In English language, an adjective is "a word that describes a noun or pronoun" [27]. In Croatian language, adjectives are defined as "words which express the characteristics of persons, places, things and ideas" [28]. From the viewpoint of database modelling, in regard to the definition of adjectives in both languages, adjectives specify the values of entity (noun) attributes or relationships between persons, places, things and ideas. The adjective is the value of a certain property of the entity. For example, for the noun "house", we can ask the following: what size it is and what colour it is. The answers
are adjectives: small and blue. Therefore, adjectives additionally describe a noun or highlight some of the possible values of a chosen property.

The most common inherent adjective category is the comparison (lat. comparatio) [29]. From the viewpoint of comparison, adjectives are changeable word types in both languages. One of the inherent properties of adjectives is also Motion (lat. moito, mobility), according to which the number of adjectives depends on the number of grammatical genders of the adjective (Croatian, Latin and German have three grammatical genders, French two, English none) [30]. In the Croatian language, as well as some other languages, adjectives are additionally changeable according to: number and case. In addition, the Croatian language also differentiates adjectives for describing living and non-living things in masculine gender. In some grammatical cases there is also a difference between definite and indefinite adjectives. Both languages have three degrees of comparison.

According to function, adjectives can be classified as [31]:

- Adjectives which can occur in attributive function, i.e. they can premodify a noun, appearing between the determiner and the head of a noun phrase (e.g. a round table).
- Adjectives which can occur in predicative function, i.e. they can function as subject complement (e.g. he is diligent) or object complement (e.g. I consider him diligent).

According to the semantic features of adjectives, they can be classified as:

- Static/dynamic adjectives. Adjectives are characteristically static, but some can be seen as dynamic. In particular, adjectives that are susceptible to subjective measurement can be dynamic. For example, funny can be static (He is funny) or dynamic (He is being funny).
- Gradable/nongradable adjectives. Gradability of adjectives is manifested through comparison, and most adjectives aregradable. However, certain adjectives are nongradable, such as sheer, British, etc.
- Inherent/noninherent adjectives. An inherent adjective applies the meaning directly. For example, a wooden cross implies that the cross is made of wood. Noninherent, on the other hand, implies an allegorical meaning (a wooden actor is not made of wood).

Therefore, adjectives can fall into two categories at the same time. For example, in the phrase “a perfect stranger”, perfect is an attributive and noninherent adjective.

Adjectives can be compared. Comparison of adjectives is a grammatical category that has three degrees (three states) as follows: positive, comparative and superlative.

What follows is an overview of representing adjectives in sentences using the NOK method.

IV. CREATING DNOP FOR ADJECTIVES

Let us analyze the semantics of the sentence "John is a good programmer" and propose a corresponding NOK model. This sentence is represented in three versions A, B and C in Fig. 3.

Let us analyze version A. Nouns "John" and "Programmer" are independent nodes (rectangle symbol). The verb "is" brings together the two nouns into a thought "John is a programmer", because the verb is transformed into a process node named "is P", which is linked with single links towards nodes. The thought John and thought programmer are included into the thought "is P" and form a unique whole, a new thought. John is, therefore, a programmer, and then we can ask: what kind of a programmer? The adjective Good is associated with Programmer through a single relationship "What kind". This means that the adjective is passive and that it gives its characteristic of “good” to the noun, and the noun "Programmer" is active in this relationship because it receives the property from the adjective.

The adjective "good" is linked to the noun "programmer", and thus we attribute “good” to the noun programmer. Then we link the noun which is characterized by the adjective to the person John. Thus, we say that John is a programmer, a programmer who is good.

Other possible forms of DNOP are shown in versions B and C. The B version emphasizes that John is good, and only then that he is a good programmer. In version C dual links emphasize that John is a programmer and the adjective is added as an attribute of the process relationship, thus “good” is transferred to both John and programmer. Therefore, versions B and C are poor solutions since they do not reflect the semantics of the starting sentence.

A. General Rules of Writing and Reading Knowledge on DNOP

Let us point out the differences and similarities of the three ways to store knowledge: in mind, in textual records and in the DNOP. In the text, the terms are written and all
the interpretation is given in the mind of the person reading it. In DNOK terms are written in a network of related terms in an effort to represent their relationship. The meaning of certain terms in the network is given by the reader, and the relationships between them are shown with the structure of DNOK.

Reading the DNOK network cannot directly lead to same sentences from which the network was created, but it leads to the same meaning. The situation is similar in the mind of a man listening to a story; he/she remembers the elements and relationships between elements. When asked to retell the story told in his/her own language, new sentences are created, that convey the same knowledge in a new way. An even clearer example is a teacher who can successfully lecture the same lesson in completely different ways.

In the text, the same noun (or verb, adjective) referring to the same concept can be repeated several times. Noun John can be written twice in two sentences, as is natural for a language made up of sentences. In DNOK, the noun does not have to be re-written, and it can be seen that the same John is included in a set of skills that apply to him. DNOK has no limitations which are typical for the textual record. In DNOK, a noun representing the same concept (e.g. John) is drawn only once. We repeatedly draw the same concept only for clarity of figures and put a label (*), but it is understood that this is the same concept. John is a genuine entity in reality and in thoughts, and in DNOK, it represents a unique implementation of the concept from mental reality.

The question is how to show relationships of nouns, verbs and adjectives in DNOK? For example, let us observe a simple sentence "John has a big house." The verb Has and adjective Big, unlike nouns John and House, are not objects in reality, but merely mental concepts. Verb and adjective used in this sentence are a unique implementation (application) of general terms in the language of the particular sentence and they represent original terms from mental reality in DNOK and therefore unique concepts in DNOK. Thus, every adjective, e.g. Big, is an original word in all sentences, and it can therefore be said that no two sizes are the same. They have the umbrella term adjective Big that connects all of them, but when that word is used in a particular sentence, its original meaning is of a special "size". This is also true for verbs and other types of words. Thus, "having" a house by John is a completely original "having", different from other "having" of the house of all other people.

If new sentences express new knowledge related to John, it is added to DNOK by expanding the network. For example, for the sentence "John is diligent, fast and wise programmer", we would add three new adjectives for "programmer" in Fig. 3.A.

The sentence has a beginning (initial capital letter of the first word), duration and end (a full stop at the end of the sentence). DNOK does not have the beginning of the sentence, word order or the end of the sentence. In DNOK there is a relationship between words that has a unique meaning and no homonymous meaning.

To clarify the above statements, let us observe the following sentences:

- John has a house. The house is big.
- Mark has a beautiful and big garden and a beautiful house.

Let us analyze the sentences and their representation on DNOK (Fig. 4). Mark and John’s house is not the same house, so two nodes are generated in the diagram. The verb “has” results in two process nodes for having a house and one process node for having a garden, because it involves a different possession, of another house belonging to another person.

In human language and in text, it is implied that the reader understands it out of the context. To build a network of knowledge, this is not enough, and it is necessary to represent every verb as a different concept on the model.

Texts in language abound in such "implicit" homonyms and they do not present a problem because human intelligence interprets it in the context of the sentence. For a computer system, it is necessary to resolve the homonyms by introducing different process nodes for verbs.

It is similar for adjectives. The adjective "big" (and "beautiful") itself outside the sentence context is the same umbrella term, but in every sentence it is an original term associated with something specific. Every word in the dictionary, therefore every adjective represents one umbrella term. And each used adjective in a sentence represents the implementation of the term from the dictionary in a sentence and is drawn using an arrowed line from the contextual umbrella term to its implementation.

B. Variants of Modelling Adjectives

There are two basic forms of DNOK model for adjectives: adjective "subordinate" to the noun and the adjective "nonsubordinate" to the noun. Mostly, attributive adjectives are subordinate, while predicative are nonsubordinated forms in the DNOK diagram, with few
Figure 5. DNOK model for adjective (positive)

exceptions. For subordinate form, an analysis of the diagram shape in the example of "John is a good programmer" was conducted. DNOK form is shown in Fig. 3A. Let us take two simple sentences, the first representing the subordinate and the second nonsubordinate form:

- Mark is beautiful.
- Beautiful Mark.

These sentences are represented with DNOK in Fig. 5. Since "beautiful" is an attributive adjective, an adjective that is semantically associated with and subordinate to the noun, then the question in Fig. 5 is "Which?" instead of "what kind?".

The adjective from the viewpoint of comparison has three forms, namely: positive, comparative and superlative. Fig. 5 shows a form of DNOK for positive of the adjective. Let us take the example of a sentence for comparative of adjective "Mark is more beautiful than Noah" and example of a sentence for superlative of adjective "Mark is the most beautiful." DNOK form for this sentence is shown in Fig. 6.

Fig. 6 shows the way of translating sentences in DNOK that have the comparison of adjectives. For comparative, it can be seen that every word in the sentence represents a separate node. Links between nodes Mark and Noah are single links and go from the verb "is".

The model with the comparative is an aggregate of three relationships: 1. Who? - the one talked about is Mark, 2. What kind? - that particular somebody is beautiful and 3. Than who? - This particular somebody is something more than Noah.

For comparative of adjectives, the verb "to be" is superior to three nodes: the first noun which the adjective belongs to, the adjective describing the first noun and the second noun that is compared with the first noun. At the same time, the proposition "than" is linked as a subordinate node of another noun with which it makes a unity.

Figure 6. Comparison of adjectives using the NOK method

There may be other variant solutions for the comparative, which would follow the implementation and only practice can show the advantages of the solution, such as:

- Link node "Noah" with "more beautiful" using the question "Than who". The argument for this version is the ability to ask the question "Who is Mark more beautiful than?"
- Introduce a comparative process node "than" linked to three nodes that correspond to the question of who?, what kind? and than who?.

The superlative is resolved in the same manner as the positive, i.e. as an adjective nonsubordinate to the noun.

V. CONCLUSION

The paper graphically presents modelling adjectival sentences using the NOK method. Based on the analysis of individual sentences, the semantic relationship of adjectives to nouns and verbs is identified.

For subordinated adjectives, there is a special relationship between an adjective and a noun where the adjective is "subordinate" to the noun and there is no verb between them. For nonsubordinated forms of adjectives, there is the verb "to be" which is superior to the noun described by the adjective, as well as to the adjective itself.

Comparative is presented by a process node that links the three nodes, where the two words "than Noah" represent a semantic whole.

The NOK method, in addition to the nodes that contain words in a sentence, adds links that represent semantic relationships between words. Each link is named with questions that examine the relationship between words and thus enriches the graph in relation to the starting sentence.

Based on the DNOK, it is possible to build a formalized language to record sentences into the knowledge base, the so-called FNOK, required for the construction of intelligent information systems.

After the development of the system prototype, an initial test was conducted using 42 sentences and 88 questions. The obtained results (82% correct answers) indicate that the direction in which the development of the prototype is headed is correct. The authors are currently upgrading the prototype by installing knowledge of modeling adjectives and other relationships in a sentence. The success of the new prototype will be tested using a larger sample of sentences and authors will try to find ways to increase the established success.

Further expansion of the NOK method requires resolving two important types of words: pronouns and conjunctions. Automation of the proposed transformation process of sentences into a new record is a particular problem that the authors are addressing and it is important for the massive input of articles into the knowledge network.

The construction of an intelligent information system is not possible without the knowledge base and precise knowledge representation in accordance with the selected
method, and the proposed research is only part of the process.

Abstract – Although the protection of ownership and the prevention of unauthorized manipulation of digital images becomes an important concern, there is also a big issue of image source origin authentication. This paper proposes a procedure for the identification of the image source and content by using the Public Key Cryptography Signature (PKCS). The procedure is based on the PKCS watermarking of the images captured with numerous automatic observing cameras in the Trap View cloud system. Watermark is created based on 32-bit PKCS serial number and embedded into the captured image. Watermark detection on the receiver side extracts the serial number and indicates the camera which captured the image by comparing the original and the extracted serial numbers. The watermarking procedure is designed to provide robustness to image optimization based on the Compressive Sensing approach. Also, the procedure is tested under various attacks and shows successful identification of ownership.

Keywords – digital watermarking, digital signature, public key, TrapView, watermarking

I. INTRODUCTION

Development of new ICT technologies improved the ease of creation and access to digital information. However, ease access to digital information increases the doubt about who is the creator or owner of the digital content, as well as its authenticity. Namely, by using various digital tools, digital media copies can be distributed with changed information about source, author or owner. The public key digital signature (PKCS), embedded into the digital media, can provide services for strong origin authentication and reliable content integrity of digital image. PKCS technology is reliable and strong in terms of protection on hacker attacks, but it is fragile for use in environments where digital images are subject to modification or exposed to communication noise during transport to receiver. Therefore, this paper proposes the watermarking procedure that aims in preserving the embedded part of the PKCS, even if the digital image is exposed to the various attacks.

Watermarking techniques provides indication of ownership, and/or indication of the identity of a licensed user, by embedding the information in the digital object [1]-[12]. This information may be visible or hidden, but the security properties of this technology are limited due to possible malicious attacks on the original image. Image watermarking techniques usually embed the security information throughout the digital pixels in a manner that does not impact its normal use [1],[11]-[13]. There is always the requirement that the watermark should be capable of surviving routine transformations to the image, such as blurring, cutting or compression. Adding digital signature in cover work of the watermarking techniques could highly improve safeguarding against malicious source origin change and unauthorized image modification.

In the proposed procedure, part of the PKCS – a serial number (SN), is used for embedding. The SN, that is available in the hexadecimal form, is transformed into the 32-bit binary form. Based on the binary form, logo is created and embedded into the image as a watermark. Watermarked image is transmitted through the network and may be exposed to the attacks. At the receiver side, the watermark detection extracts 32-bit binary sequence. This sequence is then compared with the original sequence, i.e. with the SN corresponding to the camera device that captured the observed image. This original SN is available through the Certification Authority system.

The procedure of watermarking and camera identification is tested on the images from the TrapView pest monitoring system [14],[15]. The TrapView system is consisted of traps distributed through the fields/orchards with a purpose of monitoring pests captured in those traps. The images of caught insects are sent regularly to the TrapView cloud that later provides pest recognition and pest occurrence statistics. When the number of insect specimens becomes too large, trap has to be renewed. The SN-based watermarking procedure helps to locate the trap that has to be renewed, by revealing the SN of the camera device.

Having in mind that the images has to be regularly uploaded to the cloud, and that they are of high resolution,
the image size optimization has to be done prior it is sent over mobile network. The optimization is done by using the Compressive Sensing (CS) approach [16]-[23]. By randomly selecting only small number of image samples from its frequency domain, the image can be successfully reconstructed at the receiver size by using an optimization algorithms. The SN has to be preserved after the random samples selection and optimization. In other words, the proposed watermarking procedure should be robust to the CS attack.

The paper is organized as follows. The TrapView system and image optimization by using the CS is described in the Section 1. Theoretical background on the image watermarking is provided in the Section 2. Section 3 describes the proposed watermarking procedure, while in Section 4 the experiments are given. Conclusion is in the Section 5.

II. THEORETICAL BACKGROUND

TrapView pest monitoring system is a platform that provides information about occupancy of traps distributed through the fields/orchards. The system captures and uploads the images to the TrapView cloud, at daily basis. An automated pest monitoring is useful in cases when there is need for monitoring large areas [14], [15]. Each TrapView camera has its own PKCS, and part of the PKCS is the SN. System is illustrated in Figure 1.

In order to be able to detect which camera captured the observed image, the SN is embedded into the image. The SN embedding can be added to the standard TrapView system after image capturing, as it is shown in the Figure 1. As the TrapView captured image is around 1MB large, our goal is to reduce its size without loss of quality and by preserving the SN embedded in each captured image.

Let us firstly describe the size optimization approach. The optimization is done by applying the CS method. The CS aims at recovering data from the small set of available samples [11]-[13], [16]. Signal can be intentionally undersampled, or samples corrupted by noise or some other environmental factors can be considered as missing. Random selection of the signal coefficients, in the domain where signal has dense representation, assures successful reconstruction from the small number of acquired samples. If an N-dimensional signal \( x \) has a sparse representation in the certain transform domain \( \Psi \):

\[
x = \sum_{j=1}^{N} X_j \psi_j = \Psi x,
\]

where \( X_j \) is a transform domain coefficient and \( \psi_j \) is a basis vector, then the vector of acquired samples \( y \) is defined as [11]:

\[
y = \Phi x = \Phi \Psi x = \Lambda x.
\]

The matrix \( \Lambda \) denotes the measurement (CS) matrix, while the matrix \( \Phi \) models random selection of the coefficients. The signal is reconstructed by solving the set of linear equations (2), using an optimization algorithm, i.e., finding the sparsest solution of the system. In the case of 2D data, commonly applied method for the optimization problem solving is the TV optimization, based on minimization of the image gradient [11]-[13],[15],[23].

For solving the system (2), the minimization over \( X \) of the regularization function \( J(X) \) is performed [12],[23]:

\[
J(X) = \frac{\mu}{2} \| y - \Lambda x \|^2 + \lambda R(X),
\]

where \( \lambda \in (0,\infty) \), \( R(X) \) is the TV of the signal \( X \):

\[
R(X) = \| d_X \|_1,
\]

\[
d_{i,j}X = \begin{bmatrix} X(i+1,j) - X(i,j) \\ X(i,j+1) - X(i,j) \end{bmatrix},
\]

and \( d \) is a gradient operator.

The TV optimization is applied on the TrapView images. The TrapView camera, placed in the field, takes pictures of insects captured in the trap and sends them to the cloud. Before sending, the image is transformed in the discrete cosine transform (DCT) domain and undersampled. Therefore, the vector of measurements \( y \) is consisted of the DCT coefficients. The optimization problem is defined as:

\[
\min_{X} \text{TV}(X) \text{ subject to } y = \Lambda x,
\]

Or, in the discrete form:

\[
\text{TV}(X) = \sum_{i,j} \sqrt{(X_{i+1,j} - X_{i,j})^2 + (X_{i,j+1} - X_{i,j})^2}.
\]

III. THE PROCEDURE FOR TRAPVIEW IMAGES WATERMARKING AND CS OPTIMIZATION

A. TrapView image watermarking

The watermarking procedure is based on embedding of the SN, part of the digital certificate, that corresponds to certain camera device. Digital certificates are issued from
the Certification Authority (CA), and each issued certificate has its own and unique SN, validity period and a subject to whom is issued. The SN provides the name or source origin of the image, stored in register of digital certificates issued by CA, and consequently identifies the camera which is the source of the captured image.

The SN consists of 32 bits grouped in 8 hex numbers, thus forming unique digital identifier for a subject. In the proposed procedure, the group of 8 hex numbers is firstly modified from its original form and binary sequence is created, as it is shown in the Figure 2.

Each symbol is represented with 4 bits, which results in 32-bit sequence. After hex-to-binary conversion, each bit from the sequence is represented in the $n \times m$ matrix form. Therefore, one hex symbol forms an $n \times 4m$ matrix (see Figure 2). After all of the 8 symbols are converted into the matrix form, the binary logo image is created.

In order to increase robustness to different watermark attacks, the logo image is repeated and new binary image with repeated logos is created. This binary image is of the same size as the original image. The starting logo is chosen to be embedded 4 times, in the image corners, as it is shown in Figure 2.

The next step is logo embedding. The original logo is spread into the several bit planes, and only part of the logo is embedded into each plane. If we assume that the image coefficient is represented with $B$-bits, then $B$ bit planes are available. We chose $L=4$ bit planes for embedding and four $n \times 4m$ matrices in the image corners are used. Middle bit planes are considered [9], in order to provide robustness and, at the same time, to avoid the influence of the watermark to the image quality. The logo is divided into the $L$ parts (layers), by using a unique security key, i.e. a unique random matrix $\hat{A}$ [9]. The matrix is separated on $L$ layers, and each layer contains values from the certain interval - there are $L$ non-overlapping intervals. Therefore, the random matrix $\hat{A}$ and the threshold values, together with selection of the bit planes, form a security key. The complete logo is obtained after summation of the $L$ layers (Figure 3).

If $W_k$ denotes the $k$-th layer of the logo $W$, $B$ number of bit planes, $M$ and $N$ are image sizes and $\theta_k$ are the threshold values for the layers, then logo creation procedure can be defined within the Table 1.

**Table 1: Procedure for logo creation**

$$k \in \{1, \ldots, B\}$$

- for $i=1:M$
  - for $j=1:N$
    - if $\theta_{k-1} < \hat{A}(i, j) < \omega_k$ then
      - $W_k(i,j) = W(i,j)$
    - else
      - $W_k(i,j) = 0$
  - end if
- end for
- end for

The threshold values are chosen by using an equidistant rule, which is one way of secrecy providing. In our case, the elements of the random matrix $\hat{A}$ take values from the interval $(0, 1)$ and the threshold values for the corresponding layers are $(0, 1/4)$, $(1/4, 1/2)$, $(1/2, 3/4)$ and $(3/4, 1)$. If we denote the observed image with $x$, the embedding can be described within the Table 2.

The watermark extraction is done on the receiving side. Depending on the attack to which image is exposed during transmission, the logo will be degraded at certain degree. The SN is extracted from the received logo. Since the logo is consisted of 4 small logos at the image corners, the 4 SN will be extracted. If we find at least one SN corresponding to the embedded original SN, and if we have successful comparison between original and received SN, we are
proving the source origin. The details for the original SN are requested from the Montenegro Public Certification Authority – Post CG CA.

**Table 2: Procedure for logo embedding**

<table>
<thead>
<tr>
<th>k {0, ..., B}</th>
</tr>
</thead>
<tbody>
<tr>
<td>for i = 1:M</td>
</tr>
<tr>
<td>for j = 1:N</td>
</tr>
<tr>
<td>if W(i,j) = 1</td>
</tr>
<tr>
<td>x(i,j) = W(i,j)</td>
</tr>
<tr>
<td>else</td>
</tr>
<tr>
<td>x(i,j) = x(i,j)</td>
</tr>
<tr>
<td>end if</td>
</tr>
<tr>
<td>end for</td>
</tr>
</tbody>
</table>

The procedure for logo extraction starts by observing the bit planes where watermark is added, and is described in the Table 3:

**Table 3: Procedure for logo extraction**

<table>
<thead>
<tr>
<th>k {0, ..., B}</th>
</tr>
</thead>
<tbody>
<tr>
<td>for i = 1:M</td>
</tr>
<tr>
<td>for j = 1:N</td>
</tr>
<tr>
<td>if W(i,j) = 1</td>
</tr>
<tr>
<td>wk-1 &lt; A(i,j) &lt; wk</td>
</tr>
<tr>
<td>W_k^{ext}(i,j) = W_k(i,j)</td>
</tr>
<tr>
<td>else</td>
</tr>
<tr>
<td>W_k^{ext}(i,j) = 0</td>
</tr>
<tr>
<td>end if</td>
</tr>
<tr>
<td>end for</td>
</tr>
</tbody>
</table>

Logo extraction cannot be done unless the random matrix A, together with the thresholds and the bit plane order numbers, are known.

### B. CS as a watermark attack

A special attention is devoted to the CS attack of the watermarked image [12], [13]. After the SN embedding, the CS is applied to the captured image, with an aim to decrease the amount of transmitted information. Certain percent of the pixels from the watermarked image is selected. Selection is done at a random manner [11],[12],[15],[16]. After that, the selected pixels are transmitted and the image is reconstructed at the receiver side. High image quality after the CS reconstruction is important for:

- image post-processing;
- SN extraction.

Post-processing of the images means counting the number of captured insect specimens, based on counting algorithms [14],[15]. Therefore, it is of great interest to save the quality of the reconstructed image as better as it is possible, in order to minimize the possibility of error occurrence during counting. As it was mentioned previously, an accurate SN extraction is important for the camera device location.

### IV. EXPERIMENTAL RESULTS

Let us consider the SN-based watermarking of the TrapView images. The overview of digital certificate for certain user/device is shown in Figure 4.

The observed SN is in the hexadecimal form: 4C F9 DF CA. The first step of the proposed procedure is hexadecimal to binary conversion. Therefore, after the conversion, the following sequence is obtained: 0100 1100 1111 1001 1101 1111 1100 1010. The next step assumes forming matrix from each bit in the sequence. This part of the procedure results in binary logo formation, as it is shown in Figure 2a. The logo is created as a binary image of equal size as the original image. The sizes of the logos that are embedded into the image corners are 50×48.

The logo is repeated 4 times (see Figure 2b), prior it is embedded into the 4 bit planes (the coefficients of the image are represented with 8 bits). In order to determine the positions of sub-images pixels used in watermarking procedure, the random matrix A is exploited and it has to be known at the receiver side.

![Figure 4: Overview of digital certificate with serial number details](image)

The original TrapView image is of 2MB size. In order to reduce the procedure complexity, we have observed only part of the original image – part of 256×256 size. The 4 logos of size 50×48 are embedded into the observed image part. The same watermarking procedure can be applied to the whole image, or only to the selected image part.

The original and the watermarked images are shown in Figure 5. As it can be seen, the watermark does not degrade the image quality. In order to decrease the number of transmitted samples per image, as well as to increase transmission and upload speed, only 21% of randomly transmitted SNs are considered.
selected samples per image are chosen (14000 samples out of the total number of 256×256 samples).

TV-based optimization is done at the receiver side and the image is reconstructed. After the optimization, the logo and SN are extracted. The CS reconstructed image is shown in Figure 6a, while the extracted logo is shown in Figure 6b. The obtained peak signal to noise ratio (PSNR) is 30.0082 dB, which numerically proves satisfactory reconstruction quality. Therefore, we can conclude that the CS approach will not affect the process of specimens counting.

The SN is detected by using the extracted logo. Based on counting the “1” and the “0” in each n×4m matrix and taking the value that correspond to the greater number of occurrences, the decision on serial number’s bit is made and the extracted SN appears in binary form.

The SN extraction is done from all 4 logos, because if only one bit from 32 sequence is modified, the identification fails. Therefore, we check the extracted SN 4 times, and if match with the original SN is obtained just once, we can say that the camera device identification is successful. In this case, all 4 extracted logos provide the exact SN. Beside the CS, the robustness of the watermarking procedure is tested under other commonly appeared attacks in real applications. The success of the SN extraction is observed, and the results are given in the Table 4.

V. CONCLUSION

The procedure for image watermarking, based on the Public Key Cryptography Signature and serial number embedding, is proposed in the paper. The images captured with an automatic observing cameras in the Trap View pest monitoring system, are used. Each camera has its own serial number, based on which the device identification is done. The images are watermarked in order to ease the camera identification that captured the observed image. Based on 32-bit PKCS serial number, the binary logo is created and embedded into the captured image. Detection of the watermark is done at the receiver side, and indicates the camera which captured the image by comparing the
extracted serial number with an original one. The watermarking procedure is defined in a way that provides robustness to CS-based image optimization. The 80% of the image samples can be avoided and image can still be reconstructed, preserving the embedded serial number. The robustness of the procedure is also tested under other common watermarking attacks and shows successful serial number extraction in all considered cases.

ACKNOWLEDGMENT
This work is supported by the Montenegrin Ministry of Science, project grant funded by the World Bank loan: CS-ICT “New ICT Compressive sensing based trends applied to: multimedia, biomedicine and communications”. The authors are thankful to Mr. Matej Štefanič, the director of EFOS, for providing us test images.

Abstract - Generally speaking, anti-computer forensics is a set of techniques used as countermeasures to digital forensic analysis. When put into information and data perspective, it is a practice of making it hard to understand or find. Typical example being when programming code is often encoded to protect intellectual property and prevent an attacker from reverse engineering a proprietary software program.

Through this paper the focus will be on anti-forensics methods which in sense is how information obfuscation is affecting digital forensic investigation. The paper will describe some of the many anti-forensics methods used under the broad classifications of data hiding, artefact wiping, trail obfuscation and finally attacks on the forensic tools themselves.

With any modern-day investigation relying more and more on digital forensics, investigators are required to deal with anti-forensics methods on a daily basis. This paper will explore the challenges investigators and forensic practitioners are facing when conducting investigations. The methods used will be separated into low-tech and high-tech techniques, how they are being used, how they are affecting digital forensic investigation and what the mitigation possibilities are. Focus will be on high-tech techniques that will not stop the investigation but rather prolong or make the process extremely time consuming and therefore not possible to complete in a timely manner or be cost effective.

Index Terms - information, obfuscation, artefacts, anti-forensics, digital forensics

I. DIGITAL FORENSICS

Digital forensics (sometimes known as digital forensic science) is a branch of forensic science encompassing the recovery and investigation of material found in digital devices, often in relation to computer or mobile device crime. The term digital forensics was originally used as a synonym for computer forensics but has expanded to cover investigation of all devices capable of storing digital data. With roots in the personal computing revolution of the late 1970s and early 1980s, the discipline evolved in a haphazard manner during the 1990s, and it was not until the early 21st century that national policies emerged. Digital forensics investigations have a variety of applications. The most common is to support or refute a hypothesis before criminal or civil (as part of the electronic discovery process) courts. Forensics may also feature in the private sector; such as during internal corporate investigations or intrusion investigation (a specialist probe into the nature and extent of an unauthorized network intrusion) [1].

The technical aspect of an investigation is divided into several sub-branches, relating to the type of digital devices involved; computer forensics, network forensics, forensic data analysis, mobile device forensics and new emerging cloud/internet or cyber forensics. The typical forensic process encompasses the seizure, forensic imaging (acquisition) and analysis of digital media and the production of a report of collected evidence. Later it will be shown how obfuscation directly affects each of these steps.

As well as identifying direct evidence of a crime, digital forensics can be used to attribute evidence to specific suspects, confirm alibis or statements, determine intent, identify sources (for example, in copyright cases), or authenticate documents. Investigations are much broader in scope than other areas of forensic analysis (where the usual aim is to provide answers to a series of simpler questions) often involving complex time-lines or hypotheses. To make this harder or impossible to do, information obfuscation is used.

Obfuscation is method used for obscuring intended meaning in communication, making the message or content confusing, willfully ambiguous, or harder to understand. It may be intentional or unintentional (although the former is usually connoted) and may result from circumlocution (yielding wordiness) or from use of jargon or even argot (yielding economy of words but excluding outsiders from the communicative value). Unintended obfuscation in expository writing is usually a natural trait of early drafts in the writing process, when the composition is not yet advanced, and it can be improved with critical thinking and revising, either by the writer or by another person with sufficient reading comprehension and editing skills. Conventionally, obfuscation is commonly tied to encryption since it is the main way of making any type of information unreadable unless the cypher is known. Nevertheless, information can be obscured in many other ways that will be described later on [1][2][3].

The combination of information obfuscation methods and digital forensics form anti-forensics techniques.

II. ANTI-FORENSICS

Anti-forensics was first defined by Ryan Harris in 2006 in his paper “Arriving at an Anti-forensics Consensus: Examining How to Define and Control the Anti-forensics Problem” as “Attempts to negatively affect the existence, amount, and/or quality of evidence from a crime scene, or make the examination of evidence difficult or impossible to conduct”. He was also one of the first to produce classification of common anti-forensics methods as described in the table below [4]:

TABLE 1 Classification of common anti-forensics methods

In his paper Ryan reflected only on several methods but in today’s world many new have emerged and the ways how data is being hidden or obfuscated has changed. This paper will go much further than this. Still, the goal of anti-forensics remains the same, avoid detection of the true meaning of data, disrupting information collection, increasing time needed to conduct the investigation, trail obfuscation, information modification, data hiding, data saturation and general casting doubt on the forensics report or testimony. Anti-forensic techniques aimed towards digital forensics tools are especially of interest, since they exploit shortcoming of tools that are the main means of giving broader meaning to data. It is important to mention that in the period when this paper was written an average storage capacity of a computer is about 1TB of data and personal computers hold about 8GB or Random Accesses Memory (RAM). On the other hand, mobile devices have at least 16GB of data while the top capacity phones now stretch up to 256GB of data. The amount of data that must be examined is truly vast and the only way of putting any meaning to it, in a reasonable amount of time, is to use digital forensic tools that accelerate the process. Manually going through such high capacity storages would be too time consuming for police officers and the back log (number of cases waiting to be processed) would be vast, while in the perspective of corporate investigations, it would be financially unprofitable.

As mentioned earlier, there are many ways of making information hard or impossible to interpret. To build on previously mentioned classification, means of obfuscation will be separated into two main classes, low tech and high tech. As their names suggest, low tech requires basic knowledge of computing and electronics while high tech requires excellent conversance of computing/programming and electronics.

III. LOW TECH ANTI-FORENSICS TECHNIQUES

A. Physical data destruction

The simplest method of them all that doesn’t require any special knowledge is complete physical data destruction. Typically, this means taking data holding media such as computer hard drive or USB thumb drive and smashing it with a hammer. In some cases, this procedure can be used as an official procedure for media destruction when certain hardware becomes obsolete or is due for replacement/upgrade. Besides using a hammer, criminals will do some of the following:

- Use a power drill and bore through the hard drive plates or through memory chips
- Throw the media in water – nearby pond, toilet, pour water over electronic parts
- Use power press to completely crush the media
- Use strong magnets to demagnetize the media
- Pour acid over the media

In today’s modern world, these very primitive methods are not used very often since if applied, the media will become unusable and what is even more troublesome is the fact that data will be destroyed even for the criminals to use again. Today even the media can be somewhat expensive to replace but the data can be irreplaceable. Because of these facts, criminals will tend to use other techniques that will allow them to access the data after it was investigated by the legal authorities.

B. Hard drive scrubbing

Besides physical data destruction, next low tech method that is commonly used is Hard Drive (HDD) scrubbing or wiping. This is easy to implement since modern HDD’s and file system will do this automatically when data is being deleted from a digital source. Basically, a user will delete everything he doesn’t want others to find. This can be a full HDD wiping – writing zeros to the whole HDD or just deleting important files. Since this is also a destructive method on a logical form where data is being completely destroyed, persons usually go for less destructive method where they can still retrieve the data for the same reason described in the section above. The most common and fastest
method is quick formatting. By doing a quick format, only index that contains information where the data is located is deleted, but data still resides on the media. If untrained investigator performs a preview of the media he will not see any data and disregard it when in reality, everything is still there but “hidden” from the operating system.

Data deletion is commonly used by low level criminals but even an average investigator will know that soft deleted data can be retrieved by all digital forensic tools and how to do it. What is also important to state is that data deletion often implies guilt and intention to destroy evidence. Furthermore, often absence of information can be evident itself. To explain on an example, it would be very strange to see a mobile phone that doesn’t have any pictures on it since everybody takes pictures and it would be anticipated to find at least some. Another example would be to find an older computer that has no user files on it while there are traces of past user activities. Same would be if someone is buying a 5 year old car that has very low mileage – for experienced buyer a definitive sign of mileage count manipulation.

C. Artefact wiping

Continuing with the previous section, besides actual information deletion or partial deletion which is very destructive mechanism persons can delete artefacts that make digital forensics analysis more difficult. This can be considered as removing metadata – information that describes other information. To accomplish this, users can utilize various free programs used for fixing or clearing up space on computers as CCleaner, Clean Master, BC Wipe or Eraser. These programs are advertised as PC optimization tools, speeding up systems, clearing up space, safe browsing, privacy protection etc [5]. In reality what they do is remove browsing history, delete cache files, delete operation system files, wipe slack and unallocated space and “clean” registry files. All this information is used to create a better picture of what the person was doing on the system, what was their intention and if they were trying to hide their true goal. For example, by wiping artefacts investigators can find an incriminating picture but they don’t have the information on who was the original author, to whom was it sent to or how did it get on the system.

Mitigating this method is relatively easy. No tool is perfect and therefore “anti-forensic” tools are not perfect and will leave something behind that could be used during the investigation. As before, the mere presence of the tool will raise suspicion with the investigator and make him dig deeper into analysis.

D. Steganography

A bit of history… Roots in hiding data/information begin with steganography - the practice of concealing messages or information within other non-secret text or data [5]. When put into digital information perspective, steganography can be used on computers and networks through steganography applications that allow for someone to hide any type of binary file in any other binary file, where image and audio files are today’s most common carriers. To put it simple, hide pictures in MS Office PowerPoint or word document or hide a message in a spam email. Persons can go even one step further by covering picture, table or text block under a white block so if the document is quickly reviewed it would be hard to spot. Most modern digital forensic tools will detect most of these anti-forensics methods since they unpack and index documents with their metadata [6][7]. Of course, this can also be a high-tech technique if data is being embedded in an audio file or inside the picture, null cyphers can be used to select a pre-determined pattern of letters from a sequence of words or similar. These methods are rarely used since they are hard to implement, take time to do and also require lot of time to decode. Steganography is especially hard do implement on data that is accessed often.

E. Cryptography

Cryptography is a very easy and commonly used technique to hide data. Sometimes it is also described as an ultimate anti-forensics tool since if properly implemented, will put the digital forensic investigation to a complete halt. It is very easy to implement since there are variety of tools, both paid and free that have excellent encryption algorithms and are simple to install and use. Most commonly known programs widely used all over the globe are Truecrypt, Veracrypt and Bitlocker for Windows and Linux machines while Apple devices use proprietary encryption FileVault. They can be implemented in two ways – full disk encryption or file/container encryption.

If full disk encryption is used, whole media (hard drive, memory card, USB thumb drive) will be fully encrypted, first to last byte and without a password no data is accessible or retrievable. If less known product is used for encryption, even with knows password it can be troublesome to retrieve the data.

Other type is file or container encryption. This method will create an encrypted file or encrypted container that can store other files and acts as a vault. Everything stored in this container will be fully encrypted but rest of the files on a system or media will be readable. Digital forensics tools will often detect encryption but don’t have any means of decrypting the data without the proper password. There are tools that will attempt to break the encryption by trying to guess the password, but this method of decryption is a very time consuming process and with no guarantee of success. The table below represents the number of combinations per number of letters in a password.

<table>
<thead>

<td>6.0956894e+15</td>
</tr>
</tbody>
</table>

| TABLE 2 Password combinations |
This table is only for English dictionary and does consider capital letters, numbers or special characters which make up total of 94 different characters:

- numbers (10 different ones: 0-9)
- letters (52 different ones: A-Z and a-z)
- special characters (32 different ones)

Usual password length today is 6-8 characters with requirement for at least 1 small and 1 capital, and 1 number. As seen from the table, even with today’s powerful computers that can compute 100,000 passwords per second, for 6 character password it would take several years to guess the password [8][9].

Encryption can be implemented not only on stored data but also to hide data/information that is being transmitted over the network. This can be implement through various ways such as PGP, encrypted VPN, TOR networks and similar. Again, if an investigator is collecting network traffic, all data will be fully encrypted and not possible to interpret.

Similarly to data deletion, encryption in respect to the circumstances, can be interpreted as intention to hide data and raise suspicion which for suspects is an undesirable effect since it will cause investigators to dig deeper into the case. On the other hand, encryption it widely used as a necessity, corporate or government rule or is turned on by the manufacturer by default. Usage of encryption can be debated but it not the subject of this paper.

IV. HIGH TECH ANTI-FORENSICS TECHNIQUES

Most of low tech methods can be utilized with various free tools and do not require any special interaction from the user except running the tool and making few selections. The main issue they have in common is that they raise suspicion from the investigator side, since they leave noticeable traces and it’s very easy to spot something is wrong, missing or hidden.

On the other hand, high tech methods are not destructive and are focused more on hiding data, breaking digital forensics tools and process, or causing prolongation of the whole investigation. These methods will try to confuse the automated process of evidence discovery and basically make the whole investigation last longer and therefore making it not financially profitable. To better understand how this is achievable, the regular forensic process must be defined. These are common steps that are part of any digital forensic investigation:

1. Collection – gathering all relevant evidence from the crime scene
2. Preservation – respecting the chain of custody. Marking and transporting the digital evidence from the scene to the lab
3. Identification – reviewing and identifying gathered evidence and determining what and how it should be processed
4. Analysis - performing digital forensic analysis of collected evidence
5. Presentation – creating a report on the findings

Each of this basic steps will be challenged with the goal not to prevent the forensics from happening but rather just slowing down the examination process down until the data loses its value or intelligence or cost.

There are many high tech anti-forensics methods and this paper will mention just some of them since they are very technical and as mentioned before, require a lot of advance knowledge of computing.

A. Data saturation

To start simple, it is very easy to create problems in collection phase of investigation - own a lot of media. Simply, persons will never throw out old hard drives, USB drives, memory cards, phones, laptops or any storage media. When investigators come to the scene, they will find all this media that they cannot neglect and must either review on the scene, image or take with them to the laboratory. This will prolong the time needed to image all storage media before it can be processed and examined.

To mitigate this, investigators must parallelize the acquisition process – utilize multiple duplicators and machines. Also, investigators can use the suspects hardware against them to preview the evidence prior to imaging.

In the later investigation phase, data saturation can also be applied by creating or owning a lot of false data or senseless data. This method will again prolong the investigation since the investigator must divide false from real data and later on come to some concrete conclusion. The same is often used when one is trying to conceal its public information by creating vast number of false information.

Mitigation technique involves having as much as possible data about the case so that through analysis investigator can easily pinpoint desired information. Never the less, there will always be cases where data croscheck will be required.

B. Hiding data

Similar to steganography where binary data is hidden in other binary data, the same effect can be accomplished in numerous ways. This section will address only few that are very common and appear in many digital forensics investigations.

Most common would be hiding data in virtual machines. In computing, a virtual machine (VM) is an emulation of a computer system. Virtual machines are based on computer architectures and provide functionality of a full physical computer. Their implementations may involve specialized hardware, software or a combination [10]. Even an average personal computer today is capable of running virtual machines and software for creating them is very easy to use. Persons that want to hide their activity create VM’s and use them for malicious or secret work while the host machine is used for everyday work. These machines can also be fully encrypted or password protected for strengthen security.

Next possibility of hiding data can be accomplished by storing data in other user disk spaces, closed sessions on compact discs and public or shared servers. By storing data away from the original machine where it is actually being used, if not all data storage spaces are inspected it can easily be omitted. Furthermore, analysis of such data can be tedious work since it can be difficult to determine the owner of the information. This poses a serious problem for digital forensic
investigator since data today can very easily be transferred and received over the network to and from a remote location. In cases where data is being stored on remote servers outside the person’s country, police officers usually don’t have any jurisdiction over that kind of data and is often inaccessible.

To mitigate this, investigators must perform live machine analysis and dawn raids where persons of interest don’t have time to delete, disconnect or close their sessions to remote data. When data is stored in such way, there is always some data leftovers that will provide clues to investigators on what was going on and how the user was operating.

C. Hiding data in slack and unallocated space

Over 80% of computers today are running Windows OS which implies that the most used file system is Windows New Technology File System (NTFS) [11]. When formatting a hard drive to NTFS users have a choice of how many partitions they want to create, e.g. if they want to format the whole drive or create several partitions. After partition is created, certain portion of hard drive space will be reserved for file system files and there will be partitions that will remain unused by the file and operating systems. Some of these protected and unused areas are Master Boot Record (MBR), Host Protected Area (HPA), Device Configuration Overlay (DCO), unallocated hard drive space. These areas are never used by regular user and are by default inaccessible, but for skilled user they can be used for storing sensitive data or for data exchange between users. If storage media is not properly examined, it is very easy to omit these areas.

Main stream digital forensic tools will always examine most of these areas for data but some, such as HPA and DCO, must be explicitly reviewed if any trace of hidden data exists. If investigator is performing a manual analysis, it is very easy to overlook.

D. Nonstandard RAID configurations

RAID or redundant array of independent disks provide a way of storing the same data in different places (thus, redundantly) on multiple hard disks (though not all RAID levels provide redundancy). By placing data on multiple disks, input/output (I/O) operations can overlap in a balanced way, improving performance. Since multiple disks increase the mean time between failures (MTBF), storing data redundantly also increases fault tolerance [12]. In order to create a RAID array, users must define stripe patterns, block sizes and various other parameters. By using nonstandard parameters, if investigators image or confiscate the drives, before they start the analysis they must rebuild the RAID array. If parameters are not known this is not possible. RAID arrays commonly need not only proper parameters to function but also dedicated hardware. If nonstandard hardware is used, this will also cause issues during investigation.

To mitigate, investigators can de-RAID volumes on suspects machines, create images on suspect machine or preview the data. It would be recommended to image volumes rather than physical drives and therefore worry only about copying data to destination drive. Recording configuration of the suspects machines is a necessity.

E. File signature masking

All digital forensic tools work with file signature rather than file extensions. This basically means that all files will be analysed and handled by their binary header and/or footer (signature) rather than the file name extension which is easily changed just by renaming the file with a single click. In the past, this method was widely used to hide data on the system, but today it would be detected automatically by forensic tools. To make it harder, users can “hollow out” a file and store wanted data inside it. To go even one step further, data that is pasted in the middle of the other file can be encrypted. This method is sometimes also called transmogrify since the original file is being significantly changed. Other method would be to change the file header/footer rather than the file extension to confuse the digital forensic tool. For an example, all *.jpg picture files have header FF D8 in hexadecimal representation and by changing it to e.g. 00 00 00 14 66 74 79 70 would mask it as Quick Time movie file. If somebody tried to open such modified file, they would get an error.

Mitigating file signature masking can be accomplished with usage of fuzzy hashing. In order to understand this, general file hashing must be explained. A hash function is any function that can be used to map data of arbitrary size to data of fixed size. The values returned by a hash function are called hash values, hash codes, digests, or simply hashes. Put simple, hash function is a mathematical formula that takes any value as an input and returns a fixed size result. If the input changes even by one digit or one byte, the resulting output will be a completely different number. In forensics, most common hash functions used are MD5 which returns 128-bit value and SHA-1 which returns 160-bit value. Hashing in computing is mostly used to find and/or compare data. This will be discussed later. Going back to fuzzy hashing, it is a concept which involves the ability to compare two distinctly different items and determine a fundamental level of similarity (expressed as a percentage) between the two. Chances are that the person or suspect chose a file from his own system and copied it or hollowed it out. By analysing recent files investigators can easily spot suspicious activity such as opening system file as rundll.dll with Excel. Also during analysis when fuzzy hashing produces results that specific file is very similar to notepad.exe. One other mean of mitigation is to use National Software Reference Library (NSRL) which is a large database of known files with their hash values. NSRL database contains large physical collection of commercial software packages (e.g., operating systems, off-the-shelf application software as MS Office, Adobe etc.), detailed information, or metadata, about each file that makes up each of those software packages and smaller public dataset containing the most widely used metadata for each file in the collection that is published and updated quarterly [13] Investigators use NSRL libraries to filter out “typical” files from the evidence so that only unknow remains. This process is sometime called De-NISTing.
F. NSRL Scrubbing

In previous section NSRL database was introduced. As investigators use NSRL on regular basis to reduce the amount of data needed to be analysed, suspect will try to disable the usage of this database by modifying system, program and other files in general. As mentioned before, if only a fraction of input data is changed, the resulting hash value will be completely different and therefore it will not match the record in the database. This is accomplished by modifying strings or insignificant part of files. Furthermore, by turning off Data Executing Prevention (DEP) which is a set of hardware and software technologies that perform additional checks on memory to help prevent malicious code from running on a system, hashes will again be changed and no longer match with the NSRL databases.

There is no easy way of mitigation for this technique of masking files and therefore obfuscating information they hold. There are some guidelines investigators can follow not to omit important information. Instead of using blacklisting, whitelisting approach is preferable – approach that looks for things that match. Investigators are encouraged to identify useful files rather than eliminating them.

G. Scrambled MACE Times

Timing is everything. Same can be said for digital forensics investigations. It is of utmost importance to establish proper timeline of events. Investigators will also utilize dedicated tools for creating histograms in addition to timelines of events in order to create a better picture of what and when something happened. All files on computer store multiple timestamps:
- Modified - the last time file was modified or written to
- Accessed - the last time file was read
- Created - the file’s creation date
- Entry - the last time the Master File Table (MFT) entry was updated

As it can be seen above, these four times form MACE acronym. By changing these times either manually or by randomizing them, investigators will have hard time in determining the proper timeline of events. Time changes can be also accomplished by changing BIOS time, turning off “Last Access” update in Windows or by changing time zone of the system.

Mitigation process involves ignoring MACE times and creating new timeline by determining proper ones. As an example, suspects will rarely go to such lengths of changing all possible times on the system and since majority of systems are connected to the internet, investigators only need to find times that are correct by comparing them to real time. Log files will usually be sequential and therefore anything that is off can be considered to be changed intentionally. Also, identifying small sets of similar times can prove to be helpful since investigator only needs to determine the time offset to the real time. All times that are completely scrambled can be ignored. Scrambled MACE times is one of the most difficult anti-forensic techniques to mitigate since it can be very hard to determine when something happened to the second, since that information can be crucial to any case.

H. Restricted filenames

Since this paper is addressing information that is stored in a digital form, in order for that to be possible a storage media is needed. Every storage media must be formatted to a specific file system to hold data. In computing, a file system or filesystem is used to control how data is stored and retrieved. Without a file system, information placed in a storage medium would be one large body of data with no way to tell where one piece of information stops and the next one begins. By separating the data into pieces and giving each piece a name, the information is easily isolated and identified [14]. A filename (or file name) is used to identify a storage location in the file system. Most file systems have restrictions on the length of filenames. In some file systems, filenames are not case sensitive (i.e., filenames such as FOO and foo refer to the same file); in others, filenames are case sensitive (i.e., the names FOO, Foo and foo refer to three separate files). Most modern file systems allow filenames to contain a wide range of characters from the Unicode character set. However, they may have restrictions on the use of certain special characters, disallowing them within filenames; those characters might be used to indicate a device, device type, directory prefix, file path separator, or file type (File system, 2016). As mentioned earlier, most widely spread file system is Windows NTFS. This file system has specific restricted file names such as:
- CON
- PRN
- AUX
- NUL
- COM1, COM2, COM3, COM#
- LPT1, LPT2, LPT#

Furthermore, file names cannot have nonstandard or hidden characters as 0xFF ‘e, ~u or similar. If file has a restricted file name or file name contains nonstandard or hidden characters, it will not be accessible through the operating system and will confuse the digital forensic tools. Also, some functions in tools will not work properly such as exporting files. This again will not stop the investigation but will cause prolongation of the data analysis since live preview and live analysis will not be possible until the data is properly imaged and analysed in a forensic tool.

Mitigation is relatively easy since the only requirement is to process all acquired data in a digital forensic tool. Files with such modified file names must be exported with different files names or with file ID number as a name.

I. Circular references

As defined in the previous chapter, file system not only has file name restriction but also file location restrictions. Users can also exploit this restriction for hiding data. Folders have a limit of 255 characters for the full file path. If file is stored with a file path longer than 255 it will become inaccessible to the operating system and therefore to the investigator. File path can also contain “junctions” or “symbolic links” that change the actual file location. File can be represented to the operating system in way that the actual file location is in a completely different location than reported. Users can also use circular references in a way that the file is being stored in...
file path as: C:\Parent\Child\Parent\Child etc. to confuse the investigator or they can be stored in multiple nested folders to cause the tool to run into an infinite loop or throw errors during acquisition or analysis [15].

As in previous case with restricted filename, mitigation is relatively easy. Just knowing about this method will help investigator circumvent it. Investigators should always work from digital forensic images and be mindful about this anti-forensic method when dealing with a live system.

J. Broken log files

In addition to file MACE times, logs can also be vital evidence. Logs will show important information such as when a user logged in to the system, when did he log out, what programs were used, when did the system restart, how application was used and in general will lay out an audit trail. To hide their activity and make the information hard to retrieve, users will make changes to log files as described in artefact wiping, file signature masking or restricted filenames sections of the paper. This will confuse certain data parsers and make them throw errors [16].

To mitigate broken log file method, investigators first must ask themselves whether they actually need the log file. Usually there should be sufficient data to gather all necessary information from evidence files – try to prove a point without logs. If there is a necessity for examination of the log file, they can potentially be parsed in portions (parts that are needed), create custom small scripts that will perform automatic parsing or zero in on the specific records that are of interest rather than parsing the whole log.

K. Portable systems and programs

With the introduction of restricted user profiles that don’t have administrator privileges and no possibility to modify the system (eg. install new programs or change settings), many portable software’s have emerged ranging from simple programs as file browser to full portable operating systems. These applications and systems can be simply copied to a portable USB thumb drive and used on whatever system is available. Most common usage would be in public internet shops or libraries. Person just plugs the USB thumb drive into computer and boots into his own operating system, usually Linux. There he has a full control over all hardware that is available. After he is done, he simple takes his USB and boots back to the original operating system leaving almost no trace on the host machine. Similar can be done with programs. Portable version of internet browser can be run directly from the USB. In this way majority of data will be stored on USB drive itself and therefore very little will be left on the machine hard drive for investigators to go through.

Mitigation method requires thorough preparation before going to field. On the scene, machines must be imaged live, computer memory must be captured and all media storages must be confiscated. This procedure will ensure that investigators have all possible data sources that will enable them to perform full analysis.

L. Non standard program usage

The last method that this paper will address is based on usage of nonstandard tools. As mentioned multiple times throughout this paper, what was addressed were the most common operating systems, file systems, programs etc. Digital forensic tools parse best “common” data that is coming from common programs or sources. To lay out an example, there is excellent support for parsing artefacts coming from Microsoft Office but few coming from LibreOffice. All Microsoft Windows operating system versions are supported but not all Linux operation systems are supported. The same can be said for smaller types of software such as internet browser, encryption programs, communication programs etc. It is easy to spot an emerging pattern that is exploited by users. By using non-popular programs, it is very easy to hide activity, information or intentions since tools will not parse data coming from non-popular/standard sources.

Mitigation of this method can only be achieved by constant education and by following current trends. Investigators should train themselves to spot suspicious applications and educate on how they work. Unfortunately, investigation of such data should be performed manually and will definitely prolong the overall investigation time.

V. CONCLUSION

In today’s modern world where almost all information is exchanged in a digital form, digital forensics plays a big role. Conceiving true form of information, person’s intention, information destination or source are just some of the ways data and therefore information is being manipulated and therefore making discovery and data analysis hard or impossible to perform. In digital forensics, anti-forensics methods are trying to confuse investigators and their tools in accomplishing their task. Over the years, goal of anti-forensics changed from trying to completely deny access to information, to just making it too hard to obtain or being cost effective. The main reason for this change is that the lack of evidence is evidence itself and intentional (obvious) hiding of information, raises unwanted suspicion. It is also necessary to mention that complete data destruction is not an option since in today’s world, information is money.

Taking all methods that were explained throughout this paper into account and considering that there are many more available, it can be concluded that it is very easy to disrupt digital forensic investigation. There are also other factors that make investigation hard to perform, one of them being data stored in the cloud that takes it out of current investigators jurisdiction and making it hard to obtain and investigate. The future with everyday development of hardware and encryption possibilities will bring even more obstacles in conducting investigations. The only method that can help investigators to come on top of this never-ending battle is education. Knowing about these and other methods and their mitigation is to only way investigators will be successful in their jobs.

Analysis of Mobile Phones in Digital Forensics

Sengul Dogan* and Erhan Akbal*
* Department of Digital Forensics Engineering, Firat University, Elazig, Turkey
sdogan@fırat.edu.tr

Abstract – Nowadays, the need to tackle rapidly increased crimes is increasing day by day to help ensuring justice. Digital forensics can be defined as the process of collecting, examining, analyzing and reporting of digital evidence without any damage. Digital forensics requires a detailed examination of devices such as computers, mobile phones, sim cards, tablets that contain digital evidence regardless of whether the crime is large or small. Among these devices, mobile phones take an important place in digital forensics because of their widely usages by every individual. The importance of examining of the data called as evidence in mobile phones has increased with advances in technology, operation capacity, storage capacity and functionality. In a forensics case, mobile phones must be examined by authorized persons and the data obtained from the device must be brought to standards that can be used forensically. In this study, examination and analysis of mobile phones in terms of digital forensics is evaluated. At the same time, data that can be obtained from mobile phones through a sample application has been investigated.

Keywords: Mobile Phone, Digital Evidence, Digital Forensics.

I. INTRODUCTION

Digital forensics is defined as the analysis of data, such as audio, video, video, etc., obtained after the examination of electronic devices, to help the legal process [1,2]. Today, with the advancement of technology, electronic devices are diversified such as tablet, flash memory, memory cards. At the same time, the storage capacities of devices are increasing day by day. People use these devices widely in many areas such as facilitating their work and following social environments [3]. It is an important issue to properly store and analyze this increased data in the electronic environment. Digital forensics aims to examine these devices and data to help the legal process. When forensic analysis is performed, the data on these devices must be evaluated unchanged and not destroyed [4-6]. The obtained results can be used in the judicial process with this condition. Digital forensics is divided into sub-disciplines as given below [3,7,8].

- Computer Forensics
- Mobile Forensics
- Memory Forensics
- Network Forensics
- Malware Forensics
- OS Forensics

Digital forensics has become a discipline that needs to be examined in detail at sub-disciplines because of different operating conditions of each device, progress of technology, storage structure.

After a crime occurred, digital forensics consists of four important processes: collection, examination, analysis and reporting as shown in Figure 1. The detailed planning of these steps and use of effective software and hardware tools ensure quickly and accurately assessment of the case [2].

![Figure 1. The process of digital forensics](image-url)

1. Collection: The evidence is collected and the image is taken.
2. Examination: The method is selected for the evidence to be examined.
3. Analysis: The stage of analysis is to obtain findings from digital evidence in accordance with the information required by judicial authorities.
4. Reporting: The reporting phase is the preparation of the documentation to be submitted to the judicial authorities.
Among available devices, mobile phones are one of the most used devices. Mobile phones meet the general needs of people like a computer with the cheaper and widespread use of the Internet. In terms of digital forensics, mobile phones that people do not separate from themselves can contain important evidences [3].

In this study, the evidence that can be obtained by examining mobile phones containing important data in digital forensics is presented.

II. MOBILE FORENSICS

Mobile devices have the ability to store and process data in a variety of methods. Mobile forensics, which is called examination of mobile devices, is a difficult area for the judicial process because it includes devices such as different brand-model mobile phones, smartphones, tablets [9,10]. Different models, hardware, memory structure, operating systems of each of these devices are available. These structures are removed from the standard when every device is examined in the light of digital forensics. However, just as digital forensics, mobile forensics also consist of basic steps as shown in Figure 2 [11].

![Diagram showing the processing steps for mobile phone examination](image)

Figure 2. The processing steps for mobile phone examination

The basic information obtained from mobile phones is given in Figure 3, despite the device differences [9,11].

![Diagram showing the basic data obtained by mobile phone examination](image)

Figure 3. The basic data obtained by mobile phone examination

The threats detected on mobile devices can be classified as direct attacks, malware, data interception, exploitation and social engineering. At the same time, it is among the most important security issues that users have insufficient knowledge of technology. There are many software and hardware tools developed for use in judicial cases in the detection of all these problems. The basic software and hardware tools used in mobile phone examinations are given in below [12,15]:

- Cellebrite
- Paraben’s Device Seizure
- XRY
- EnCase Neutrino
- Oxygen Forensic
- MOBIledit
- Faraday
- Tarantula

On the basis of all these programs, evidence has to be obtained without harming the data in the mobile phone to help the judicial process [3,15].

III. FINDING AND RESULTS

In this study, the data that can be obtained by a mobile phone examination are presented. For this purpose, the phone having android operating system examined for the computer with the features given in Table 1 is analyzed with Oxygen Forensic and MOBIledit programs.

<table>
<thead>
<tr>
<th>TABLE I. THE SYSTEM FEATURES</th>

</tr>
<tr>
<td>Simcard Serial Number</td>
<td>-</td>
<td>✓</td>
</tr>
<tr>
<td>SHA-2 Hash</td>
<td>✓</td>
<td>✓</td>
</tr>
</tbody>
</table>

At the same time, the findings with mobile phone examination can be listed as follows:

- **Device Information**
  - Retail Name
  - Manufacturer
  - Platform
  - IMEI
  - Software Revision
  - Network Information
  - Device Information, etc.

- **Sim card information**
  - IMSI
  - PIN
  - PUK
  - ICCID
  - LAI, etc.

- **Contacts**
  - Phonebook
  - Event Log (Incoming, missed call, outgoing)
  - Messages
  - Applications
  - E-mail
  - Groups, etc.

- **Timeline of events made during phone use**
- **List of web browsers entered from the phone**
- **The available files on the phone**
- **Passwords stored on the phone**
- Phone calendar events
  - Meetings
  - Appointments
  - Anniversaries, etc.
- Applications installed on the phone
- Cloud account information and data
- Device log information
- User Data
  - Photo
  - Videos
  - Audio
  - Sound recordings,
  - Document, etc.
- Deleted data
- Location information
- Wi-Fi connection logs

According to the information obtained above;

- It is necessary to act on the dump in order for the case to be able to help the legal process.
- Live analysis can damage the evidence. For this reason, live analysis is not recommended in the judicial process. Choosing a program to perform on the dump is important for judicial cases.
- If the number of evidences is too high, the program should be selected according to the need for fast processing.
- Mobile forensics programs have advantages and disadvantages. For this reason, the correctness and diversity of the findings must be revealed by using different programs

IV. CONCLUSION

Almost everyone in today's world has a mobile phone. In the past, mobile phones were only used for voice communication, but now people are using a lot of fields such as writing messages, data transferring, socializing, data storing. The widespread use of mobile phones has made these devices the most important factor applied in judicial events. For this reason, mobile forensics, a subdivision of digital forensics, has emerged. At the same time, the development of hardware and software to provide mobile phone investigations with mobile forensics has been achieved. In this study, the analysis of information obtained from the investigation of mobile phones are evaluated. At the same time, evidences from mobile phones are presented by the investigation. When evaluated in terms of running time, it was observed that MOBILedit program performed faster for this analysis. In addition, Oxygen Forensics advantages over MOBILedit program can be listed as dump analysis, Social graph, Wireless Security Protocol. It has been shown that the results of the analysis can be obtained from a mobile device in terms of forensic information of the user's criminal data.

Security Analysis of Open Home Automation Bus System

Milan Ramljak
University of Zagreb, Faculty of Electrical Engineering and Computing
Unska 3, 10000 Zagreb, Croatia
ramljak.milan@gmail.com

Abstract - Today's modern homes are becoming complex live systems in which virtually all functionality, from lighting and heating control to security and occupancy simulation, is mediated by computerized controllers leading to IoT future. The smart nature of these homes raises obvious security concerns and history has shown that a vulnerability in only one component may provide the means to compromise the system as a whole. Thus, the addition of every new component, and especially new components with external networking capability, increases risks that must be carefully considered. In this paper we examine one of the most active open source home automation framework, Open Home Automation Bus (openHAB) which is used as platform for many other IoT supported devices. First, we go through openHAB security architecture and supported features following the challenge of a static source code analysis of several most used openHAB packages (called bindings) and carefully crafted test cases that revealed many undocumented features of the platform. Next, we exploited security flaws by constructing two proof-of-concept attacks that: (1) openHAB system denial of service; (2) inject custom binding for message bus monitoring and control; We conclude the paper with security best practices for the design of custom openHAB bindings.

I. INTRODUCTION

With the unstoppable advance of technology, most research projects in field of smart homes have been designed to help human and increase their quality of everyday living experience. A home, which is smart, is the technology result used to make all electronic equipment around the home act "intelligent" or more smart. Smart home has advanced automatic rules for lighting, temperature control, security and many other functions. Each and every new home appliance are having embedded intelligence with automation, monitoring and controlling possibilities. Exposing the data outside smart home system, except security concerns, provides wide range of potential benefits for users and companies building those systems. There are many smart home solution that allows reusable automation rules and offers uniform user experience. OpenHAB does not try to replace existing solutions, but rather wants to enhance them - it can thus be considered as a system of systems. A core concept for openHAB is the notion of an “item”. An item is a data-centric functional atomic building block. [1] Under the hood, openHAB does not directly communicate with a physical device. Instead, it communicates with an instance of an “item” that encapsulates a physical device. This approach makes it even easier to replace device communication protocol by another without doing any changes to rules and UBs.

A most advanced aspect of openHAB’s architecture is its modular design giving simple way to extend system at runtime without stopping it. Each feature is developed as completely standalone Java OSGi library also known as openHAB binding. Modular binding approach has been a huge enabler for the active community around openHAB with many engaged contributors [2]. Looking from security side this could lead to many problems in security implementation as different bindings are developed by different users implying that static code analysis is important. Our security analysis explores the above security-oriented aspects of the openHAB framework. Performing the security analysis of an open-source system revealed devastating result of binding documentation. Some bindings are well document but some without any documentation at all, referring to code documentation. For an experienced Java developer is not that hard to dig into the code to get more understanding but some more complex bindings do need significant amount of time. To overcome these challenges, we used a combination of existing static analysis tools and manual analysis on a dataset of 153 bindings that we downloaded in source code form. As openHAB is based on Java programming language for this purpose we used Java enabled analysis tool Find Security Bugs.

II. RELATED WORK

Although the openHAB system analyzed in this article is widely used within the open source community, to day of writing this article, no information of existing security assessments has been found. Still many researchers touched the field of smart home systems and their security implications. Except the analyzed system, there are few other open source solutions such as openHAB [12]:

MIPRO 2017/ISS

1461
• Domoticz – a home automation system with native HTML5 support, developed in C/C++ programming language
• OpenMotics – open source system designed to deliver full wired solution, including software and hardware
• Casaas – full-stack home automation platform, including preconfigured Linux operating system

Search for any structured security analysis documents related to any of above mentioned resulted without success. Most of the security analysis articles focus only to smart home devices and their protocols, building blocks, and barely on the complete system utilizing them. All automation systems support set of widely used smart devices such as switches, thermostats, pin locks. In following part, we show some of security flaws of most popular smart devices. We start with security assessment of smart thermostat, Google Nest, where researchers have revealed how it can be exploited and then used as smart spy device. Vulnerability required physical access to thermostat to load custom software over underlying Linux system. The compromised Nest thermostat acts as an entry point to attack other nodes within the local network exposing the data to the attacker [15].

Another device, where more realistic security issues were identified, is based on Insteon Hub, a network enabled device that can control light bulbs, wall switches, power outlets, thermostats, cameras and more. During a first Insteon Hub setup, user is asked to set up port forwarding from the Internet to the device. System documentation basically led user to expose access to anybody from the Internet. Furthermore, there was no option to enable authentication for the Web service running on the Insteon Hub that receives commands [16].

Smart home system with the most detailed security analysis is the Samsung propriety automation system called SmartThings [13]. Results revealed in SmartThings security analysis were trigger for this paper, and comparing the results similar set of issues is identified although the system is propriety [14]:

• SmartThings application can read all events a device generates if the application is granted at least one capability the device supports
• 42% of applications are granted capabilities that were not explicitly requested or used
• exploited framework design flaws to construct proof-of-concept attacks

On the protocol front, researchers demonstrated flaws in the ZigBee and ZWave protocol implementations for smart home devices [17]. Exploiting these bugs requires proximity to the target home but later can be used in attacks that do not require physical access to the home. Researchers also discussed the presence of some well-known vulnerabilities in home automation systems, such as Cross Site Scripting (XSS). Attacker could embed persistent Javascript in the log pages of one of the products. The researchers also observed that in some home automation systems, every communication between the homeowner and home automation system, both from within the home network and over the Internet, is done in clear text allowing an attacker to eavesdrop on the communication and gather legitimate login credentials [18].

III. OPENHAB SECURITY ANALYSIS

OpenHAB is designed in multilayer ecosystem with OSGi as baseline for its runtime engine showed on Fig 1. In this chapter we put focus on following components:

• openHAB Add-on Libraries
• openHAB REST service
• openHAB HTTP service

The Add-on libraries layer represents most vivid component of architecture also known as openHAB bindings. There are many bindings available, from house heating control to network binding allowing user to check, whether a device is currently available on the network. All bindings communicate with openHAB core through event based message bus. Next architectural component is HTTP service exposed as main management interface for openHAB configuration and administration. Every openHAB binding can be monitored, installed, or removed from this point. Last but not least important component is REST service. Most of the logic of REST service implements JavaScript Object Notation Application Programming Interface (JSON API) providing HTTP endpoints for third-party applications to interface with openHAB. This interface is main point for openHAB Android and iOS mobile applications to communicate towards openHAB event bus.

A. Security analysis of core components

To understand how the community based binding development manifest in practice from security point, we downloaded 153 [4] bindings from the openHAB official
web page and performed a static code analysis. We first present the number of bindings that are potentially vulnerable and then drill down to determine the extent to which apps are over privileged due to design flaws.

Table I shows the result overview of our dataset and most important that not all of these bindings are vulnerable. To show example, we pick few of these bindings to show actual vulnerability. Almost all bindings have some sort of Java coding bugs with resulting on its performance issues. Attaching higher number of bindings to openHAB runtime engine puts more focus on mentioned performance issues leading to process crash. After systems is crashed all openHAB functionality is terminated leading to smart home system which needs to be manually restarted. The same goes for openHAB REST service and mobile applications using it.

Adding more and more bindings to running system is very simple, but having in mind less code quality of some of bindings, could lead to openHAB process crash. From security perspective this is denial of service (DoS). However, this bug can be minimized by configuring openHAB in high availability mode (HA) where two instances are used. If one openHAB instance fails, other will take over and system will remain functional.

Next we show how we can utilize over privilege bindings to perform operations on system without permissions. One of widely used binding is openHAB Exec binding used to execute system scripts or commands directly from binding. Once started on system, this binding lets user to perform a command without any access control. The same goes for remote user using REST interface or using mobile application. Binding requires command in following structure:

```sh
exec="<[/bin/sh@@-c@@command]"
```

where command can be any shell command. To make a DoS showcase this can do remote system shutdown.

```sh
exec="OFF:ssh pi@192.168.1.4 shutdown -p now"
```

Exec binding is not installed by default, but is usually first choice for developers to do quick progress. This exact vulnerability is perfect example of user input validation problem we found by scanning bindings. Most of 153 bindings provide a user to control them by providing input arguments without any validation. Input from untrusted sources must be validated before use. Maliciously crafted inputs may cause problems, whether coming through binding arguments or external sources.

Another result analysis revealed is that some bindings uses direct communication with openHAB message bus. This is not an issue but shows that an attacker can create such binding which can listen for all events on openHAB message bus. Having complete access to all messages exchanged on bus can provide much information, such as security pins and passwords used in bindings connecting to external services such as Gmail Calendar. This kind of attack is not hard to achieve as all openHAB bindings are possible to download from web store where no cryptographic hash integrity functions are used by time of this analysis.

</tbody>
</table>

OpenHAB exposes HTTP based web service using the Representational state transfer (REST) or RESTful protocol. REST-compliant Web services allow requesting systems to access and manipulate textual representations of Web resources using a uniform and predefined set of stateless operations [5].

This kind of service is widely used for many IoT systems as usage is very simple and does not require special programs to be used. RESTful service exposes several predefined operations that can be utilized to integrate openHAB with other systems as it allows read access to items and item states as well as status updates or the sending of commands for items. To access REST service of the running openHAB users simply browse link:

```
http://ip_address:8080/rest
```

where ip_address is IP address of machine running openHAB process. Complete REST schema is based on Swagger specification [6] supporting different media types. The REST service furthermore supports server-push, so one can subscribe client on change notification for certain resources. Reaching REST endpoint returns structured openHAB data such as:

- Bindings
- Binding Discovery
- Items
- Data persistence

Default configuration starts openHAB without any security activated at all. In general, it is advised to use HTTPS communication over HTTP. On the very first start, openHAB generates a personal (self-signed, 256-bit ECC) SSL certificate and stores it in the Jetty Web service keystore. This process makes sure that every installation has an individual certificate, so that nobody else can falsely mimic your server.

Maybe the worst thing regarding openHAB REST interface is that it does not support restricting access through HTTPS for certain users. There is no authentication in place, nor is there a limitation of functionality or information that different users can access. So, once someone has access to openHAB service it has access to all of its functionality. This looks like very bad approach, but the answer why relies on the fact that openHAB uses Eclipse Smart Home code as baseline [7]. Complete HTTP service part exposing REST interface is used from that code so the expected solution needs to be there.
Fortunately, there are few recommended workarounds to overcome this security vulnerability. First is to limit access and only allow REST requests coming from local loopback interface. The default value allows access from all interfaces:

```java
web.listening.addresses = 0.0.0.0
```

and needs to be changed to:

```java
web.listening.addresses = 127.0.0.1
```

to allow requests only from local machine.

Second solution is to run openHAB behind reverse proxy. A reverse proxy simply redirects client requests to the appropriate server. This means we can proxy openHAB request connections to other web service. Running openHAB behind a reverse proxy allows to access openHAB runtime via port 80 (HTTP) and 443 (HTTPS). It also provides a simple way of protecting server with authentication and secure certificates.

The last option is to setup account for openHAB Cloud service which enabled that openHAB runtime tunnels to it hiding all the communication. The main core features of openHAB Cloud are a user-management frontend, secure remote access, remote proxy-access, device registry & management, messaging services and data management & persistence. The openHAB Cloud also serves as core backend integration point for cloud-based features (e.g. IFTTT) and provides an OAuth2 application enablement [4]. Cloud openHAB will proxy home sitemap over HTTPS so the communication to UI is TLS encrypted.

To see how openHAB REST interface is vulnerable we used penetration testing tool OWASP Zed Attack Proxy (ZAP), an open-source web application security scanner intended to be used by both those new to application security as well as professional penetration testers [9]. When used as a proxy server it allows the user to manipulate all the traffic that passes through it, including traffic using https. It can also run in a ‘daemon’ mode which is then controlled via a REST Application programming interface.

Scan discovered four type of issues, two with medium severity (orange) and two with low (yellow) showed in Table II. First issue is related to application error disclosure. Some responses contain an error/warning message that may disclose sensitive information like the location of the file that produced the unhandled exception. This information can be used to launch further attacks against the web application. To solve this bug, review the source code of this page by implementing custom error pages. Consider implementing a mechanism to provide a unique error reference/identifier to the client (browser) while logging the details on the server side and not exposing them to the user. For example:

```javascript
"error": {
  "message": "HTTP 404 Not Found",
  "http-code": 404,
  "exception": {
```

Second detected medium severity vulnerability is that X-Frame-Options header is not included in the HTTP response to protect against 'Click Jacking' attacks. Most modern Web browsers support the X-Frame-Options HTTP header. Ensure it's set on all web pages returned by your site (if you expect the page to be framed only by pages on your server (e.g. it's part of a frameset) then you'll want to use deny, otherwise if you never expect the page to be framed.

Going forward to low severity vulnerabilities we start with XSS protection not being enabled, or is disabled by the configuration of the 'X-SSS-Protection' HTTP response header on the web server. Posting data to REST API could make an attacker to post script which can lead to leakage of some user data. To minimize this kind of vulnerability openHAB web browser’s XSS filter needs to be enabled, by setting the X-SSS-Protection HTTP response header to '1'.

The last but not the least important vulnerability is the X-Content-Type-Options header was not set to 'nosniff'. This allows older versions of Internet Explorer and Chrome to perform MIME-sniffing on the response body, potentially causing the response body to be interpreted and displayed as a content type other than the declared content type. As a solution administrator needs to ensure that the application/web server sets the Content-Type header appropriately, and that it sets the X-Content-Type-Options header to 'nosniff' for all web pages.

B. Exploiting system weaknesses

OpenHAB HTTP server is based on Java Jetty web service. Looking inside Jetty configuration it is noticeable that default configuration is used with no request filtering policy. Default HTTPS connection timeout is set to 30 seconds, giving easy way to produce high load request flooding and cause DoS. To do this test in this paper we used JMeter load generator software build by utilizing Java HttpClient object [8]. This object gives plain implementation of HTTP protocol without overhead resulting in high performance. Used generator is written in

MIPRO 2017/ISS
asynchronous programming style, so that limited threads do not limit the maximum number of users that can be simulated. Generator is configured to start thread pool of 1000 parallel HTTP requests over the network as it gives more realistic performance and latency. Each thread represents unique user. The results revealed that 1000 parallel requests decreased openHAB availability by 30%. Increasing number of parallel requests up to 10000 decreases availability to an extent that openHAB rest service cannot be used where 80 % of sent requests failed. To overcome this vulnerability default Jetty configuration needs to be updated by adding request filter. Filter places throttled requests in a priority queue, giving priority first to authenticated users and users with an HTTP session, then to connections identified by their IP addresses. The DoS filter limits exposure to request flooding, whether malicious, or as a result of a misconfigured client. The DoS filter keeps track of the number of requests from a connection per second. If the requests exceed the limit, Jetty rejects, delays, or throttles the request, and sends a warning message.

Proposed filter is shown here:

```xml
<filter>
  <filter-name>DoSFilter</filter-name>
  <filter-class>DoSFilter</filter-class>
  <init-param>
    <param-name>maxRequestsPerSec</param-name>
    <param-value>30</param-value>
  </init-param>
</filter>
```

where filter limits maximum number of requests per second to 30. The filter works on the assumption that the attacker might be written in simple blocking style, so by suspending requests you are hopefully consuming the attacker's resources. For a high reliability system, it should reject the excess requests immediately (fail fast) by using a queue with a bounded capability. The DoS filter is used to avoid Jetty thread starvation what is of great importance if openHAB runs on embedded system such as Raspberry Pi.

Earlier is showed that delivering openHAB bindings doesn’t incorporate integrity validations, so all bindings downloaded and used directly could be potentially harmful. In this chapter we show how is easy to build an openHAB binding which could be used to expose system protected data over the REST interface. The purpose of a binding is to translate between events on the openHAB event bus and an external system. This translation should happen “stateless”, i.e. the binding must not access the item registry in order to get hold of the current state of an item. Likewise, it should not itself keep states of items in memory. If proposed approach is not followed it is more likely binding will result in system resource starvation and potentially DoS.

To build openHAB binding skeleton we start with delivered project template to create OSGi structured Java project. Once created binding is automatically runnable as any other binding, but without any additional custom logic. For this purpose, to make openHAB event bus exposed, we need to add custom Java code to link event message bus and REST interface. First thing is to implement BindingConfig class over newly created Java class. Extending the class user can make own implementation of processMessage method with custom logic as all events happened on the message bus will pass this point. Logic depends on wanted result, and here we use any information gained on the bus by exposing it to remote REST service under our full control. Any content received on message bus will end up on our web service on the Internet and carefully stored. Working code is:

```java
@override
public void processMessage(String topic, byte[] message) {
    URL url = new URL("http://our.page.com/logger.php");
    HttpURLConnection conn = url.openConnection();
    conn.setDoOutput(true);
    conn.setRequestMethod("POST");
    try {
        DataOutputStream wr = new DataOutputStream(conn.getOutputStream());
        wr.write(message);
    } catch (Exception e) {
        // hide potential trace
    }
}
```

where URL object defines remote logging service which will receive all the event data from custom binding. Remote logging service is plain PHP script which stores all data received by HTTP POST request in local file. Rest of the Java code does HTTP connection and writes every event bus message data to it. It is important to note that code catches all possible exception errors that could notify victim that something is wrong to hide suspicious operations.

Next step in this process is to build custom binding as Java archive library (jar) and put it in openHAB add-on directory. Attacker could potentially upload link to this binary to some of openHAB forums, but for test purposes we skipped this part and installed bindings directly on local instance. Once started binding automatically works and pushes all event bus messages to the remote logger script. To show extent of exposed data we were able to see if house was occupied, motion sensor state changes, security pin codes and much more. Part of logged file looks like following:

```
2016-08-06 18:12 [ItemStateChangedEvent] - Motiondetector_Outdoor_Switch changed from NULL to ON
2016-08-06 18:52 [ExecBinding] - executed commandLine 'sudo ssh admin@192.168.0.106 shutdown -p now'
2016-08-06 19:16 [ItemCommandEvent] - Item 'Volume_Main_Bedroom' received command 0
```

MIPRO 2017/ISS
C. Binding usage best practices

As is the case for openHAB binding repositories, further research is needed on validating available binding for smart homes. A language like Java provides some security benefits, but also has features that can be misused such as input strings being executed without prior validation. We need techniques that will validate openHAB bindings against code injection attacks, over privilege, and other hidden security vulnerabilities (e.g., disguised source code). For this purpose, automated code analysis can be performed by existing tools such as OWASP LAPSE+ or Java Security FindBugs. OWASP LAPSE+ is a security scanner for detecting vulnerabilities of untrusted data injection in Java EE Applications [10] and Java Security FindBugs is plugin for security audits of Java web applications [11].

To overcome intentional vulnerabilities openHAB community will need to introduce integrity validation of all community managed bindings. The other approach is to encourage, not to say force, users to migrate to openHAB Cloud service where installation of new bindings is performed by centrally managed bindings repository. Another solution is to let openHAB web service to validate used bindings and notify users if unofficial binding is found. Strict user confirmation needs to be enforced, similar as Android applications. Smart home devices and their associated binding software will continue to increase and will remain attractive to end user because they provide already developed functionality. However, the findings in this paper suggest that caution is required as well on the part of existing bindings, and on the part of binding designers. The risks are significant, and they are unlikely to be easily fixed via simple security patches alone.

IV. Conclusion

We performed a security evaluation of the popular open source home automation framework for programmable smart homes. No related work has been found available in this area, giving this paper first view over openHAB security issues. At the time of writing this paper results of analysis are not published, but can be retrieved upon user request to the authors.

Analysis of openHAB was a bit easier because all the framework and bindings code is accessible for any user. We performed a static code analysis to process existing bindings and determine how well the bindings quality is from programming perspective. We discovered (a) great number of performance issues in list of 153 existing openHAB bindings followed with incomplete documentation; (b) 9 bindings did use all the permissions by monitoring complete openHAB event bus potentially exposing over privilege to remote users; (c) more than hundred bindings accepts user input without prior validation; (d) 4 different security vulnerabilities, found by OWASP scan tool over openHAB REST service, are documented with proposed solution. We combined these open community flaws with other vulnerabilities and were able to do openHAB REST service load testing with DoS. Next area of interest was development of custom binding which can be utilized to proxy all event bus messages to remote service and monitor user lock pin-codes, motion sensor values, temperature, all without requiring permissions of user. The last part focused on areas of improvements to make openHAB community members more security aware to build ecosystem for future development.

Analysis of Credit Card Attacks Using the NFC Technology

Juraj Jumić, Marin Vuković
University of Zagreb Faculty of Electrical Engineering and Computing
e-mail: Juraj.Jumic@fer.hr, Marin.Vukovic@fer.hr

Abstract – Near field communication (NFC) is a short-range type of communication technology used in various appliances, and more recently in contactless credit and debit bank cards. Most modern smartphones have the capability to receive and transmit NFC signals, which makes them a promising platform for mobile payment. However, payment systems always attract malicious users who try to use the technology to get financial benefits. There is a wide array of smartphone applications and external hardware capable of analyzing NFC systems and traffic that may enable several types of attacks. In this paper, we analyse the existing threats and try to assess whether the users are safe from such attacks and what harm, if any, can such attacks yield.

I. INTRODUCTION

When talking about technology advancement in general, topics are usually focused around some of the well-known industries such as automotive industry, development of newer, faster and more efficient computer components or mobile devices.

But not much thought has been given to the banking sector, which is also introducing new and attractive technologies. In lots of societies, cash is still being used a lot and has traditionally been the most common form of payment, especially for low-amount (micro) transactions. Bancking cheques were rather popular previously as a form of payment designed to avoid physical payment with paper money and meant to be cashed in at any possible bank. The main problem of this type of payment is counterfeiting [1].

After banking cheques, one of today’s most popular form of payment became banking cards. Banking cards come from variety of vendors with different characteristics – Visa, MasterCard and American Express are just some of them. More and more credit card vendors are introducing contactless cards based on NFC technology. The main goal of contactless payments is to speed up the transactions, especially when dealing with micro transactions. In such cases, the protocol does not require additional authorization other than just physically presenting a contactless card. However, when dealing with larger transactions, owner of the card is asked for a PIN (Personal Identification Number) in a more traditional and usual manner to provide a higher level of authorization.

The NFC technology that these cards use is based around radio frequency of 13.56 MHz [2]. It enables communication between the card and a POS (Point of Sales) device only in a range of several centimetres, which is also important from security perspective.

Use of NFC for payments brings many benefits to payment process for both users, vendors, card processors and merchants. But it also has several potential drawbacks, security possibly being one of them, and possible breaches are addressed in this paper.

The rest of the paper is organised as follows. Section 2 gives an overview of NFC working principles to better comprehend the possibilities of attacks. Section 3 discusses related work, while Section 4 describes performed experiments. Finally, we conclude the paper in Section 5.

II. NFC WORKING PRINCIPLES

NFC became the standard in establishing communication between devices in near proximity. It is based on RFID (Radio Frequency Identification) which is used in identification and for tracking various object (such as people, animals, warehouse and shop items) via radio waves.

RFID has several working frequencies that define the reading range and characteristics of the signal, resilience to obstacles and other parameters. NFC, as a subset of RFID, uses radio frequency of 13.56 MHz (with width of 7 kHz) and is based on ISO/IEC 18000-3 standard [2].

In theory, 20 centimetres is the maximum distance from which a reading can be made, but in practice it is closer to 10 centimetres or less, depending on the strength of the antenna and type of NFC tag. Data is transferred at rates anywhere from 106–424 kilobits per second. When examining smartphone implementations, NFC communication requires two NFC enabled devices and distinguishes three working modes:

- **Read/Write mode** where one of the devices (the initiator) generates the radiofrequency (RF) field, and the destination device doesn’t. The destination device is then called a "transponder" and works in the passive transfer mode where the maximum transfer rate is 106 kilobits per second.
  - If both the initiator and the transponder generate a radiofrequency field, then the maximum transfer rate is raised up to 424 kilobits per second
- **Card emulation mode** enables a device to mimic a smart card. A smart card usually contains
sensitive and often confidential data or data defined by its owner (user).

- **Peer-to-peer mode** enables two NFC enabled devices to exchange data on a link level. It can be compared to other technologies such as Bluetooth or a Wireless Local Area Network (WLAN).

There are currently around three hundred smartphone models available which have NFC technology integrated into them, and this numbers are expected to increase over time. Most of them are Android smartphones and it is expected that by the year 2019, the number of transactions made with them using NFC will surpass five hundred million per year [3].

One type of passive NFC devices are NFC tags or smart cards that can be used to communicate with active NFC devices (which can be an active reader or writer in any operational mode) [4]. NFC Forum defines several standards for NFC-enabled smart cards which are categorized into the following categories as shown on Fig 1:

- **Type 1** is based on ISO 14443A standard which enables reading, writing and setting the read-only mode. It contains 96 bytes of memory, expandable up to 2 kilobytes. This type enables maximum data transfer speed of 106 kilobits per second and is most commonly used in Bluetooth connections and one time reservations.

- **Type 2** is similar to the first type, except it consists of only 48 bytes of memory. It is mostly used for low cost transactions such as daily traffic cards and event cards.

- **Type 3** is based on Sony’s FliCa. It contains 2 kilobytes of memory and has maximum transfer speed of 212 kilobits per second. It is typically applied in more complex applications but the price is higher than the previous types. It can be used in e-payment, some types of tickets, electronic identity and house electronics.

- **Type 4** is compatible with ISO 14443A and B standard and are configured upon creation. Variable transfer speeds up to 424 kilobits per second are available, with the capacity up to 32 kilobytes. Offers authentication and increased security, but the downside is its price.

- **Type 5** is based on ISO 15693 specification. It is applied mostly in libraries, parking tickets and entry tickets.

Figure 1. Visualised preview of the NFC Forum defined standards for card modes and types [5].

### III. RELATED WORK

There are several types of attacks and options that attempt to exploit NFC cards and the data they hold.

One possible type of attack is by using code injection with NFC and RFID systems [8]. They use a prepared passive tag which causes SQL (Structured Query Language) injection or a buffer-overflow. However, such attacks are limited, depending on the integrated mechanisms of transfer initiation and parsing.

These attacks are compacted to small pieces so that they can be written onto an RFID tag and executed. One example of this attack would be a simple command `;shutdown` which would make a SQL server shut down or `;drop table <tablename>` which deletes the entered database table.

In late 2009 some of the Nokia phones with extensive NFC capabilities were released (e.g. Nokia 6212 Classic with Type 4 tags [2]), which were used to execute a relay attack. In 2011 a paper was published [10] that analyzes the security vulnerabilities of the NFC features embedded into this Nokia mobile phone and also demonstrates practical attacks via phone's content sharing and NFC Bluetooth pairing features. Some messages were slightly modified and sent to the NFC device which was running in emulation mode as a passive tag. After the user was tricked into touching a malicious tag, it would invoke a Bluetooth channel and installed applications on the phone without user accepting it.

First widely known practical security issue, a relay attack, was demonstrated on Defcon 20 conference in 2012 [6]. One of the guest lecturers was Blackwing's Eddie Lee who made a proof of concept tool **NFCProxy** which helped exploit vulnerabilities of NFC devices and authorized transactions the target was not aware about. He made a presentation [11] describing the process and released the tool as open source software [7]. The tool was (successfully) tested on commercial credit cards such as Visa and MasterCard but was not tested on Discover or Amex. Since then there have been attempts to recreate the attack, which requires specific software and specific...
mobile phones in order to successfully perform the described relay attack.

IV. EXPERIMENTS AND ANALYSIS

A simple flow of communication between the contactless card and the POS device works like this – The POS device, which is used to initiate the payment, communicates with the appropriate card through application protocol data unit (APDU) communication which include APDU queries (commands) and response as described in [4]. This creates a command-response pair.

First the POS terminal sends a APDU command that consists of a 4-byte header and data bytes ranging anywhere from 0 to 65.536. The card then registers the command and generates a response, which again, consists of up to 65.536 bytes of data and a response 2-byte status instead of a header, keeping in mind the limitations of the NFC communication (maximum range of 10 centimetres) which can be seen on Fig. 2.

One of the greatest fears when using NFC communicating devices is that they use air as the transmission medium and there always exists a possibility of eavesdropping. The main attack on which we focus is this paper is the relay attack.

A. Relay attacks

Relay attack is based on redirecting the data transfer. While passive mode is only used for data transfer, the active mode is used mainly for data communication. The attack is conducted as follows. The attacker needs to have two NFC enabled devices, e.g. mobile phones, to execute it. One device needs to be set in reader mode and the other needs to act as a POS device. The communication looks similar to Fig. 2, but the attacker has two devices instead of one and they are both between the actual credit card and the POS device similar to Fig. 5. and act as proxies.

A "normal" transaction without interference consists of direct communication (sending requests and receiving answers) between the POS device and the credit card. One malicious device now communicates with the POS and the other with the unsuspecting owner's credit card, and they both share data between them to finish a transaction.

As described, there are some prerequisites for executing this type of an attack. A relay attack is a subtype of a man-in-the-middle attack and does not alter transferred data.

The attacker simulates the receiver device in order to acquire sent data. It does it so by accessing the target object and communicating with a fake receiver device, thus getting the transponder to think he is actually communicating with the destination device but the communication includes two more (attacker’s) components.

![APDU initiation (red) and response (green) [11].](image1)

Two Android phones are needed for this attack, both containing an application available from [2]. Example described in [1] uses an older version of this application and the requirements are different, but here we use the newest version available (0.1.12).

As described in [1], the prerequisites for this attack consist of some specific requirements, one of them being an Android phone having a narrow range of system images with some unfixed security issues, and the other is that this image is only available on older mobile phones which are currently less available.

One device is set up to operate in the relay mode and the other in proxy mode. The proxy mode operating Android smartphone exchanges data with the payment terminal and the one exchanging data with the card runs in relay mode as seen on Fig. 3.

![NFC tag discovered in a smart banking card on a relaying NFC device.](image2)
B. Unauthorised card reading

Unauthorised card reading presents a possible privacy and security risk and should be carefully assessed. Below are several issues and techniques that might compromise data stored on the card.

**Eavesdropping.** The data can be intercepted between two NFC devices with adequate hardware, as seen on Figure 4. The attacker can use an external antenna to receive the emitted signal as well. Since the NFC protocol has strict specifications defined by the NFC forum, the attacker can try to find a way to read the received data. As mentioned, NFC devices have a practical distance of maximum 10 centimetres space between them. It is not defined how close the attacker needs to be, because it depends on a couple of factors such as radiofrequency field characteristics, strength and quality of the attackers' and receivers' antenna, quality of the decoder, type of communication (whether it's passive or active) and the signal strength emitted from the NFC transponder. In theory, the attacker can intercept data from 10 meters' distance if the NFC devices were in active operational mode or 1 meter if they are in passive mode [15].

![Figure 4: The basic concept of an eavesdropping attack [13]](image)

**Data manipulation** such as inserting, deleting and modifying the data during the communication. This type of an attack is possible if the communication type between the parties is known. This category also includes data corruption in which data cannot be decoded at the receivers' end due to attackers' interference and is also considered a Denial of Service attack (DoS). If data is being manipulated or inserted, the attacker must know the exact time in which pause and no pause frames occur during the NFC communication and accordingly anticipate data [15].

**Man-in-the-middle attack** is almost impossible to execute because of the radiofrequency blocking from both ends of the communication. Let's assume a scenario in which two NFC devices communicate in order to exchange a security key required for establishing a secure connection. First, either device must initiate the key exchange and will generate a radiofrequency field to transfer the request. The receiver receives the request and can only respond when the initiator's RF field is no longer present or it may cause an interference in which case the sender will not be able to read the sent data. Because the RF field switching time needs to be precise, the malicious device in the middle would almost never be able to sync his request between those two time intervals [15] [12]. It also depends on the type of mode (active or passive) in which the devices operate as shown on Fig. 1.

![Figure 5: Man-in-the-middle attack concept [13]](image)

Due to popular rise of Android applications in the Google Play Store, it is possible to download any free application that scans NFC tags or credit cards. We wanted to test if it is possible to scan a credit card just by using our smartphones and legitimate applications downloaded from the official store. The application we used is called "Credit Card Reader" [14].

We should note that this was only used for testing purposes as this application was not meant to be an exploiting app as well as used for stealing, which was also stated on the application's store page (published as an analysis app).

Scanning the credit card was quick and we got the credit card info in just over a second's time. The result can be seen on Fig. 6:

![Figure 6: Scanned credit card information.](image)
The Visa card we had scanned did not have an enabled transaction history (which usually is enabled). We can see an example transaction log from the developer's app page [14] shown on Figure 7.

We should mention that by increasing the distance from the card, it is more difficult to get the proper reading, which is expected. This is similar to real life situations when clothes, wallets and bags are in the way between the two NFC communicating devices, so an attack of this type is possible but also highly unlikely.

![Banking Card Reader](image)

**Figure 7:** Example credit card transaction history [14]

V. CONCLUSION

In this paper we analyse state-of-the-art in NFC technology used for payment. Since there is an increased worry in the public regarding the security of this technology, the goal was to analyse current research and successfully executed attacks and try to assess whether this technology poses a risk to end-users.

There have previously been flaws in the design of some systems based on NFC technology, and some standards were later updated in order to provide higher security level, better on-card encryption, more secure communication between the reader (POS device) and NFC enabled card. There have also been several successful experiments that managed to compromise data during transport, or to just relay the data over a malicious device, as is presented in the paper.

Generally, virtually all systems in digital world, not just the NFC based ones, are possibly and probably vulnerable. New vulnerabilities are being discovered each day and they are patched until a new vulnerability is found and this has become an expected and common practice. NFC systems also had flaws and some standards and systems still do have flaws which result in vulnerabilities. However, from attacker’s perspective, security is always a trade-off between the time and effort required to exploit a vulnerability and potential financial gain. It is the authors’ opinion that NFC systems used in finance offer too low financial gain, especially when having in mind the small amount of unauthorised transaction limit, as opposed to time and effort required to steal the money from NFC enabled cards, organize a malicious point-of-sale that would do the actual transactions and similar.

On the other side, contactless transactions increase speed, do not require the customer to hand over the card to the merchant at any point and have other benefits for banking institutions and customers. Therefore we can conclude that, at this point in time, contactless payments offer many various benefits that outweigh a few drawbacks regarding security. If security is compromised, the banking institutions or the card providers should be accountable for financial damage to the users, although the risk of such compromise is, from our analysis, rather low.

REFERENCES

Abstract – The security of modern web applications is becoming increasingly important with their growing usage. As millions of people use these services, the availability, integrity, and confidentiality are critical. This paper describes the process of penetration testing of these applications. The goal of such testing is to detect application flaws and vulnerabilities and to propose a solution to mitigate them. The paper analyses current penetration testing tools and subsequently tests them on a use case web application, build specifically with present security flaws. The process of penetration testing is described in detail and the performance of each tool is evaluated. In the last section, recommended practices to mitigate found flaws are summarized.

I. INTRODUCTION

The trend in modern application design is to move these applications into a remote server instead of running them locally. This will ensure consistent and quick updates, application monitoring and lower requirements on local hardware performance. A lot of companies are using these advantages for office applications like Google Docs, Sheets, and Slides; or Microsoft Office 365. On the other hand, this infrastructure also has its specific requirements - especially for good quality of Internet connection. Another broadly discussed topic is security.

The first security consideration is data location. Some constraints and legislative requirements specify, whether data can be stored outside a state boundary. The second issue is public availability of servers, which host these well-known services. The risk of attacks on those servers is much higher than on private computers [1]. It is therefore much more important to test these applications for vulnerabilities, for example like in [2] or [3].

The paper is further organized as follows: the second section introduces related work in web application security. The third section briefly summarizes the most used penetration testing tools. These tools are categorized by penetration testing phases. The fourth section presents penetration testing of a use case application with the most common examples of security flaws. The fifth section recommends the correct setting of web application technologies to protect them against the found security flaws.

II. RELATED WORK

Current work in web application security focuses especially on general security flaw analysis, or on implementation of specific security solutions. The approach to improve the evaluation of security characteristics was described in [4]. A precise evaluation is important during all phases of the application life-cycle and can be especially useful in finding the flaws during early stages of the application development. Early detection of the flaws can bring significant financial and time savings.

An analysis of key critical requirements for enhancing web application security was researched in [5]. The authors analysed the following areas: application and infrastructure security, communication and traffic inspection, zero-days attacks, dynamic application policies, sensitive data leakage, and user protection.

The more specific area of web application security – input validation – was researched in [3]. This area includes one of the most dangerous attacks: SQL injection and cross-site scripting. The authors proposed a systematic approach to secure this area using the security patterns approach.

Finally, one of the most important areas of web application security is user authentication. This was thoroughly analysed in [6], where authors compare existing solutions and propose a new scheme for mutual authentication using encryption primitives.

Although the mentioned research aims at specific areas of web application security, there is no research on a process of penetration testing, which would describe the most common security flaws in modern web applications.

III. PENETRATION TESTING TOOLS

The higher security risk of remotely run applications has to be verified, expressed and minimized. This process is known as penetration testing, or ethical hacking. The goal of the testing is to conduct a series of experimental attacks on the application. Based on found vulnerabilities, a level of risks is evaluated and a procedure to improve security issues is created. The main goal of the testing is therefore to improve the application security via pointing out its security flaws.

There are a large number of tools for penetration testing of web based applications. Moreover, most of these tools work on different security layers. Typically, there are two basic phases of the testing - reconnaissance and application exploitation.

A. Reconnaissance phase – passive

The first reconnaissance phase is conducted before the actual testing begins. The goal of this phase is to gather as much information about the target network as possible.
Unlike in other phases, the network itself is not accessed. Instead, only the publicly available databases and search engines are used to gather the useful information like web sub-domains, IP ranges, user emails etc.

**Maltego** [7] is a tool of OSINT (Open-source intelligence) type, which represents a group of tools using publicly available information sources. The tool uses lists of indexes and databases to search for relevant information.

**Discover Scripts** [8] is another tool of OSINT type. It integrates search and scanning utilities present in *Kali Linux* OS and therefore creates an automatized framework. This framework targets the following four areas: recon (used for passive scanning), scanning, web, and misc.

### B. Reconnaissance phase – active

In the second reconnaissance phase, the testing tools interact directly with targeted devices. The goal is to identify used operating systems, running services and potential vulnerabilities. This type of scanning is normally considered as an attack on the network, and has to be authorised by the network owner.

**Ettercap** [9] is an open source multi-platform tool for network traffic sniffing. It allows the capture of packets and analysis of network protocols. In promiscuous mode, it can capture communication between two users located in the network. The *Ettercap* supports both passive and active scanning and contains several modules for the MitM type of attacks. If the unencrypted traffic is used, the *Ettercap* can be used to gather sensitive information like passwords.

**Nmap** [10] is a well-known open source tool used for network scanning. It can find connected networks end devices, their open ports, run services, and it can build a network map. Versions of operating systems, services, and running daemons can be found as well. This information can be used in combination with well-known vulnerabilities found in publicly accessible databases.

### C. Reconnaissance phase – application scanning

The third reconnaissance phase focuses on an automatized scanning of web applications. The results can present a general idea of the application and give some guidance in exploiting existing flaws. On the other hand, common testing tools are often unable to find all the vulnerabilities due to the usage of modern technologies in common web applications. It is therefore often necessary to manually explore the application source code for discovering further flaws.

**Arachni** – Web Application Security Scanner Framework [11] is an automatized multi-platform open sources scanning tool for security audit of modern web applications. The framework has an integrated browser engine, which allows scanning of modern complex web applications using advanced technologies like JavaScript, HTML5, DOM and Ajax. The framework is using asynchronous HTTP requests, parallel processing of JavaScript operations, and multi-thread scanning. The framework therefore maintains a high performance. **Arachni** is also able to generate a detailed analysis report with found vulnerabilities. Its detection abilities are very high with trustworthiness over 90%.

Testing of an application can take up to tens of minutes (depending on the application scale) and during this time, the application performance can be greatly reduced. It is therefore highly recommended not to use this type of scanning on an application used in a commercial sphere deployment.

**OWASP ZAP** (Zed Attack Proxy) Project [12] by OWASP (The Open Web Application Security Project) is a tool for web application scanning and it contains several modules for exploitation attacks. These modules include: *Proxy* (for communication capturing), *Scanner* (passive and active), *Fuzzer* (sequentially sends potentially dangerous payload in order to identify a vulnerability), *Spider* (traverses all the web pages from the initial URL in order to discover new sequences of the application), and *Forced browsing* (discovers direct access to files stored on the server, using dictionary method).

### D. Web Application Exploitation

After the reconnaissance phase is done, the application exploitation phase can begin. This phase can include various tools depending on targeted exploitations. The most common categories and specific tools are described below.

**SQL Tools** like *SQLmap* and *NoSQLMap*. *SQLmap* [13] is a popular open source tool for testing the database part of a web application. A typical exploitation which can be found is the SQL injection. In the case of a successful exploitation, the *SQLmap* can access the operating system shell. The tool can save analysis results and data gathered from the database into a file. The attack itself can take a few minutes, depending on the scope of the database. The supported databases are: MySQL, Oracle, PostgreSQL, Microsoft SQL Server, Microsoft Access, IBM DB2, SQLite, Firebird, Sybase, SAP MaxDB, and HSQLDB.

**NoSQLMap** [14] is an open source tool targeting NoSQL databases. Currently it supports only MongoDB, but extensions for other NoSQL databases like CouchDB, Redis, or Cassandra are planned. The time needed for the testing is similar to *SQLmap* and data can be also saved into a file if the attack is successful.

**Password attacks** – the typical tool for password attacks is the *hashcat* [15] and its derivatives like *oclHashcat* and *cudaHashcat*. The *hashcat* is an open source tool supporting many hash algorithms (including MD, SHA, and bcrypt). The computation can run either on CPU (hashcat) or GPU (cudaHashcat on Nvidia and oclHashcat on AMD). The GPU performance can typically be much higher due to the parallelized architecture of modern graphic cards.

The *hashcat* contains the following attack modes: straight (classical dictionary attack), combination (words connected from multiple dictionaries), brute-force (mask specification allows to omit unused password combinations), permutation (changes positions of each letter in a single word), and table-lookup (each dictionary
A. Web Application for Tools Testing

In this section, the previously described penetration testing tools will be tested on a custom-made web application. The use case application simulates a typical modern web for E-library, and purposefully contains the most common vulnerabilities described in section 3. The application supports three types of accounts: administrator, librarian, and a customer. The application has the following functions:

- Book reservation
- Credit system for limiting the number of borrowed books
- Options to edit books, credits, and profiles
- Real-time chat based on the Socket.IO technology

The web application uses the following technologies: Node.js (web application back-end), Express (extends module for Node.js), Socket.IO (bidirectional communication between a client and the server), MariaDB (relation database for small to middle sized applications), MongoDB (stores unstructured web content), HTML5 (presentation part), CSS3 (design part), jQuery (local processing on a client side), and Ajax (asynchronous request processing, cooperation with jQuery). These technologies are common in modern web applications and they therefore present a good sample for security testing.

B. Testing Plan

To perform a complete penetration test, a testing plan has to be firstly created. There are many existing approaches and guides; one of the most common is the OWASP Testing Guide v4. This section will describe the sections of this plan, and how to test the most common security vulnerabilities. The complete process will be demonstrated on the use case application. As a testing platform, Kali Linux 2.0 was chosen for penetration testing.

The testing plan of a private web application should include the five following scenarios:

1. Server and application scanning
2. Input data validation
3. Authentication and authorization
4. Client side vulnerabilities
5. The level of application configuration security

If the application is publicly available over the Internet, the additional scenario (preceding the server and application scanning) – the passive reconnaissance phase – should be added. This scenario will not be described, because the use case application is not publicly deployed and therefore no information could be found about it.

Server and application scanning is the first phase which conducts a search for vulnerabilities, which could be exploited later.

Server scanning (nmap) - firstly, the web server should be scanned for used operating system, open ports and running services. In the use case application, the nmap tool, suitable for this scanning, discovered the following facts: used operating system (Linux 3.2 - 4.0), open ports (22, 111, 3000, 3306, 27017, 28017, 50892) and running services (OpenSSH, RPC, Node.js, MariaDB). These results are shown in Figure 1.

Application scanning - an application should be scanned for vulnerabilities by a complex tool like the Arachni or OWASP ZAP. If an application contains sections which require a login, it is recommended to use authentication modules. Depending on the application, additional modules should be used. These modules will ensure, that all the application sections will be scanned for vulnerabilities. In our case, the Arachni found 44 vulnerabilities in the following categories: 12 high, 7...
medium, 5 low, and 20 informational. For comparison, the use case application was further subjected to a scan by OWASP ZAP with the Proxy and Spider modules. This testing allowed scanning of data flow (including password exchanges and forms submissions) between the server and a client; and detection of potentially hidden parts of the application. The tool found the following vulnerabilities: 2 high, 4 medium, and 6 low (no informational vulnerabilities were found). The OWASP ZAP was able to detect the more serious threats: XSS and SQL injection, which were not detected by the Arachni. Therefore, in our case, the OWASP ZAP results were more accurate and we recommend using this tool.

**Input data validation** should verify all the application data sources prone to attacks like XSS (cross-site scripting) or injection. The following four scenarios are the most common areas to conduct an input data validation:

REST API (SQL injection) - each REST API source should be manually identified and their methods and parameters tested by the OWASP ZAP with the Proxy module. All the HTTP requests should have a valid session ID in order to verify operations requiring authentication. The testing of the use case application revealed parameters prone to SQL injection in all the REST API sources. These vulnerabilities could result in data leaks, unauthorized modification, or application instability.

REST API (XSS) - the same API should be further tested for stored XSS (api.js file) vulnerabilities. If some vulnerable API is discovered, HTTP requests can be captured using the Proxy module of the OWASP ZAP tool. These requests should then be moved into the Fuzzer module, where a XSS.txt file can be applied on them. This file contains the list of harmful payloads. Each parameter in our application was tested with the harmful payload and compared to response payloads. The comparison was automated with the custom script restAPI-fuzzer, but it can be done manually as well. The script was able to detect several unhandled data inputs.

NoSQL injection - incorrect handling of input data should be tested for appropriate databases such as the MongoDB. This database can be used, for example, for chat as in our application. In this case, the HTTP request for chat API was firstly captured with the Proxy module. The payload was then modified and sent back to the server. This modification allowed listing of all the messages (instead of listing only messages for a specific user).

Input data (Socket.IO) – the process of the Socket.IO communication testing has to be manually customized for every application. In the use case application, we created a testing script (socketio-testclient) and we used the fuzzing method for sending a harmful payload via Socket.IO. This test revealed, that the input data is not secured for XSS, resulting in displaying dialogue windows caused by the harmful payload.

**Authentication and authorization** is the third phase and should contain at least the following four scenarios:

- **Level of login component security** - this scenario verifies vulnerabilities of a login component. Attacks, like SQL injection, could result in a bypass of the login process. The conducted reports from the first phase should already pointed out if the login form is prone to SQL injection attacks. These found vulnerabilities can be further tested by the Burp Suite and its Intruder module, or by the Fuzzer module of the OWASP ZAP. If the vulnerability is confirmed as in our case, the SQLmap can be used for database scheme gathering.

- Access to unauthorized sections of an application – is the OWASP Top 10 A7 vulnerability and should be thoroughly tested. One of the approaches is to use the OWASP ZAP with the Proxy module for user login (with client credentials). Afterwards, all sections available to this user can be accessed. Consequently, the Forced Browse attack can be conducted with the default OWASP ZAP dictionary. In our case, 708 520 requests were sent and the attack found 4 sections, which should be accessible only to the administrator. This indicates, that some sections of the application are not using authorization verification. This was confirmed by the following authorization verification conducted by the Proxy and Intruder modules of the Burp Suite.

- Session hijacking – the goal of this attack is to discover the session ID of a connected client. The attacker can then login to the application without the knowledge of user credentials. In custom applications, the automated scanning tools are typically unable to detect the session ID. This happened in our application as well, due to the different application session signature. In this case, the manual approach via a packet capturing tool (for example the Wireshark) has to be used to discover the session ID.

- Socket.IO authentication – this manual test verifies if the Socket.IO is accessible only after a successful authentication. In the use case application, the customized script socketio-testclient was connected to the URL: http://192.168.0.3:3000. After the script was launched, the console response showed: "Connecting to the socket was successful!", indicating, that no authentication was necessary. This could result in subsequent attacks.

**Client side vulnerabilities** tests an important part of the application security – the client side. Two basic scenarios should be tested:

- XSS vulnerability exploitation - this scenario uses an unsecured input of unfiltered XSS. The BeEF tool with the hook.js script can be used to exploit the vulnerability. In order to run the script, a link to the hook.js file had to be firstly put into the application database. This can be done using many approaches. In our test, we simply sent the link to the user chat. After the successful hooking process, the information about the client's browser and its stored cookies can be gathered. Additionally, the web content can be spoofed as well.

- CSRF (Cross-Site Request Forgery) exploitation – is a malicious JavaScript code, which executes an attack when it is accessed. Such a code was added into the form on the Profile page. If a user is logged into the application and accesses this page (the link can be sent by the chat), the inserted JavaScript executes the attack. Our attack
The level of application configuration security is the last phase and should be tested in the following four scenarios:

Stolen hashed passwords - this test verifies a situation where a text file with hashed password is stolen. Based on the hash password length analysis, the length of the hash function can be determined. In our application, the 40 hex long password corresponds to 40 * 4 (hex) = 160 bits. Then, the used hashed function can be guessed (in our case SHA1). Finally, an appropriate tool can be used to break the passwords. We used the hashcat tool with dictionary rockyou.txt and we also tested various breaking methods. The Straight method was able to break 13 of 25 passwords in 5 seconds. The same number of passwords was broken by the Table-lookup method in 67 seconds. The last method, Combination, was able to break all 6 passwords in 90 minutes (and the remaining time was estimated to 12 hours).

Sensitive data exposure - the test verifies MitM attack, which can capture usernames and passwords when a user is logging into an application via the HTTP. The Ettercap tool can be used for sniffing the connections via the ARP poisoning. In the use case application, this attack was able to capture the username and password for every client logging into the application.

Sensitive data theft - this scenario verifies the possibility of access to sensitive data. Because it depends heavily on the application context, this analysis has to be conducted manually. The Burp Suite can be used to map all the HTTP requests of the application's REST API. In the use case application, the captured JSON files showed hash of the user passwords, which could then be misused.

MongoDB security - if a database is used in an application, its security should be tested. Firstly, the NoSQLMap can be used to scan an application’s sub network for discovering the database’s local IP address and port. The database can then be exploited with the NoSQL Web App attack. In the use case application, the database was successfully found and data was cloned into a local file. All the chat messages could therefore be exploited.

### C. Testing Summary

Tested vulnerabilities and used tools are summarized in the table 1. The scenarios, where threats could be found using automated tools are marked as Automatic, otherwise they are marked as Manual or Combination. In these later cases, the tools had to be combined with methods of manual code analysis, or custom made scripts, requiring the more consistent knowledge about the security issue.

Only the vulnerabilities from the server and application scanning part can be found using automatized tools. The reason why using automated tools in other categories is not enough, is the complexity and novelty of modern web technologies. The automated tools can be able to detect these vulnerabilities only if they are updated frequently, which is not always the case. For this reason, there will always be a delay between the introduction of new web technology and implementation of threat detection into these automated tools.

### V. SECURITY RECOMMENDATIONS FOR THE APPLICATION

Based on the typical vulnerabilities from the section 4, the following recommendations were created to significantly increase the security of web applications.

**Server and application scanning part** - Opened database ports should be disabled for remote access. This can be accomplished by binding these ports on the loopback interface (127.0.0.1). The password autocompletion should be disabled in all the input password fields (set autocomplete parameter to off). To protect all the replies against clickjacking attack, X-Frame-Options should be sent in a reply header. This can be done with the following setting: app.use (helmet.xframe('deny')); To protect the session against the XSS attack, it has to be set to inaccessible for JavaScript. This can be done by setting a HttpOnly flag for all the HTTP responses: cookie: {httpOnly: true, secure: true}.

**Input data validation part** – for elimination of SQL injection attacks, the database queries should use parameter bindings instead of their ad-hoc creation. An alternative is to use “escaping” of input parameters. NoSQL injection should be prevented by using input data validation for example with the mongo-sanitize module and its sanitize function. In the case of numeric input data, these variables should be explicitly cast into numeric data types. Additional data validation can be conducted by using regular expressions, or by the XSS module.

</tbody>
</table>
Authentication and authorization part - The input parameters of all functions should be "escaped" (for example: `conn.escape(req.body.name)`) or used via a parametrized query. Unauthorized access can be mitigated by using an ACL module, or by implementing a custom authorization middleware. Session ID can be effectively protected by using HTTPS and an already mentioned secured cookie. To protect the Socket.IO access via authentication, the module `socketio-auth` should be implemented.

Client side vulnerabilities part - validation of input parameters (manually, or with the XSS module) has to be implemented to protect the application. Prevention against the CSRF attack can be done by implementing a hidden authorization token. This randomly generated number will ensure the uniqueness of every request. The implementation example is the `csrf` module.

The level of application configuration security part - better protection of stored passwords can be ensured by the `password salting`. This will increase the password length and add randomness into the stored passwords. An additional recommended measure is to enforce the password policies like minimal password length, and a need to include lower-case, upper-case, and special characters. To protect against sensitive data exposure, the HTTPS protocol should be used. Exposure of sensitive data is a logical flaw of an application design. This error should be detected and corrected in the application development phase. The Burp Suite, or the OWASP ZAP, can be used to test HTTP requests and responses to detect such flaws. The used databases (MongoDB) should be secured by their binding on the local loopback. If a remote access to the database is required, the database should work in the `secure` mode. This mode will ensure secure authentication of clients accessing the database.

VI. Conclusion

The performed penetration testing verified the usability of current automated scanning tools. While these tools were able to find most of the vulnerabilities, the testing also confirmed, that some vulnerabilities were not detected. This is in most cases, caused by usage of modern web technologies, which are not yet implemented in these scanning tools. Therefore, the usage of modern technologies does not typically ensure the maximal security, if only the automated tools are used for security testing.

Performing high quality penetration testing is a time-consuming task requiring knowledge of various technologies. Automatized scanning tools can be used to quickly gain a general idea about the application security status, but cannot present a complex analysis. To verify all the aspects of the application, more specialized tools have to be used together with manual code analysis, and writing of custom scripts. It is also important to mention the influence of the penetration testing on an application performance. In more intrusive testing, the application should not be deployed in the production.

ACKNOWLEDGMENT

We would like to thank Radek Knytl for his contribution to this paper. This work and contribution is supported by the project of the student grant competition of the University of Pardubice, Faculty of Electrical Engineering and Informatics.

Abstract—Honeypots are used as a security measure both to divert the attention of a potential attackers intentions and to reveal the attacker since the only reason someone would interact with honeypots is if they are looking for a vulnerable target. Honeypots emulate only a part of the machine they are supposed to represent and contain no valuable data. ICS (Industrial Control System) is a term that is used for a system that monitors industrial plants, distributed control systems or other systems that mostly contain PLCs (Programmable Logic Controllers). Conpot is an open source honeypot that emulates PLC devices so it can be used in ICSs. However, Conpot can not emulate complex honeypot networks. The aim of this project is to make a tool that can be used to design a honeypot network which emulates an ICS. A network designed with that tool will be simulated as a part of this project and the data collected during the simulation will be analyzed.

Index Terms—ICS, honeypot, Conpot, IMUNES

I. INTRODUCTION

Devices in Industrial Control Systems (ICS) often use protocols that aren’t secure because, at the time when those protocols were developed, security wasn’t an issue for control systems. Among other, those systems were not connected in any way to the Internet, or accessible via the Internet or any other network outside the premises. But today, things are different. Those old protocols are retrofitted into new ones, ICSs are connected to business networks, and sometimes directly to the Internet. All this means that hackers can access control systems and use flaws in their original protocols to do harm, e.g. disable certain devices or steal data from them. This is a big issue, as evidenced by multiple incidents that happened [1], and the problem is very complex mainly because of the specifics of ICS and historical development that led to the present situation.

Multiple mechanisms are experimented with and applied in order to make ICS more secure. Although honeypots don’t enhance security of the individual ICS directly, they can be used as an indicator of malignant activities on the network, thus protecting the whole network. Honeypots [2] are systems that emulate different devices, operating systems, or services and are used to protect systems from hackers and/or to study hacker’s behavior. Honeypots are placed within the network that should be protected where they emulate vulnerable devices in order to attract the attention of potential attackers and to alert owners of the network that it is being attacked. Conpot is currently the most popular honeypot specialized for ICSs that emulates PLCs. It uses templates to define PLCs that will be emulated, thus making Conpot adjustable to a specific situations. Users can define and use their own custom templates. Honeynets [3] are a form of honeypots that emulate a network of devices instead of a single device, i.e. they can be viewed as a network of honeypots. They have the potential to further slow down the attackers and give the owners of the network more time to react to the attack. Conpot by itself doesn’t provide the functionality to emulate honeynets, but it could be used for such a purpose by having multiple real or virtual machines mutually interconnected with each running a copy of Conpot. But this is something that has to be done manually, requires a lot of time and resources, and is error prone.

In this paper we describe how the IMUNES network simulator/emulator [4] can be expanded to create a honeynet which emulates an Industrial Control System. IMUNES is a network simulator that allows users to define and simulate/emulate networks of almost arbitrary complexity on a single physical or virtual machine. The nodes of the emulated/simulated network are made of virtual nodes. It allows users to customize the virtual nodes and provides them with the tools needed to connect the virtual network to the internet. The Conpot
A honeypot is used to emulate PLCs in the simulated network and the OSSEC tool is used to monitor all activities on the honeypots and alert the owner of the honeynet when something interesting is happening.

The paper is structured as follows. In Section II of the paper, the tools used for this project are described, as well as the purpose they were used. An overview of related work is given in Section III. In Section IV we describe how we built Conpot honeynet. Few experiments done with Conpot honeynet are described in Section V. The paper finishes with conclusions and future work in Section VI.

II. TOOLS USED TO BUILD ICS HONEYNET

ICS is a term that describes systems used in industrial plants and distributed control systems that are composed mostly of PLCs [5]. As stated before, protocols for PLCs rarely provide any security protections so systems that use those devices need to use additional protection mechanisms. Devices in those systems can, and do, exchange important data that the owners of the system don’t want to be interrupted, modified, delayed, faked, etc. Furthermore, because of the processes ICSs are connected to that are controlled by PLCs, any downtime on ICSs could be very dangerous, up to the point of losses of human lives. That is why those systems need to be protected from alterations or any other action by the attacker that would impact its availability and/or integrity.

In the following subsections we will briefly describe three components used to implement honeynet, namely Conpot honeypot, OSSEC host intrusion detection system (HIDS) and IMUNES network simulator/emulator.

A. Conpot

Conpot is a honeypot for Linux that emulates devices commonly used in Industrial Control Systems [6]. It comes with templates that can be used to emulate Siemens S7-200, Guardian AST and Kamstrup 382 PLCs. All of the templates can be customized by the users to suit their needs. Users can also make their own templates to emulate the devices they need. We will be using this property to diversify emulated devices in the network making the honeynet more realistic, specifically we emulate Siemens S7-300 PLCs due to a certain vulnerabilities which would make that device more tempting to potential attackers [7].

Conpot supports emulation of SNMP [8] and Modbus [9] protocols which are commonly used in PLCs. Like with all other honeypots, Conpot has no other function in the network except for luring potential attackers. Therefore, any outside access to it could be considered an attack on the network. That is why, along with emulating a device, Conpot also records all the network accesses to the honeypot and stores it into a conpot.log file. However, Conpot does not provide a means of instantly notifying the user that the honeypot is being attacked. Which will be solved using OSSEC HIDS.

B. OSSEC Host Intrusion Detection System

The problem with monitoring changes on the honeynet nodes is solved by employing OSSEC Host Intrusion Detection System (HIDS) [10]. OSSEC has several functions, one of which is to monitor changes in specified files. We’ll monitor changes in the log file produced by Conpot. Furthermore, OSSEC allows central collection of logs and log monitoring with customizable regular expressions. But, we are not using those features in this version of the ICS honeynet. Users are notified of changes to Conpot honeypot by email.

C. IMUNES

IMUNES is a network simulator and emulator that runs on FreeBSD and Linux [4] and allows configuration and simulation/emulation of number of nodes interconnected with links. For this work we used Linux version of IMUNES and in the following text it is implicitly assumed so. IMUNES is a “lightweight” virtualization system in which all nodes are using the same kernel. File systems are mounted using overlay, union mount file system and the simplest solution is to mount the same file system on all nodes (read-only) and use copy-on-write mechanism for changes. The virtual nodes can emulate different roles, like routers, switches and Linux hosts and servers. Nodes with those roles are shipped with IMUNES, but the system is configurable and it is possible to add new nodes by customizing existing ones or creating a new ones. The reason is that each node is actually a Docker [11] image. The possibility to create new nodes is used in this project, i.e. PC nodes are modified to run Conpot and OSSEC so that they can be used as honeypots in the honeynet.

IMUNES provides an easy to use GUI that enables the users to easily create networks by drawing them on a canvas. All the network settings for nodes, such as protocols being used by the nodes, can also be configured from the GUI.

III. RELATED WORK

The project A Virtual Honeypot Framework (VHF) [12] has some similarities with our project. The VHF
created Honeyd [13], a low-interaction honeypot which can be used to run a network of honeypots on a single machine. When used to run multiple honeypots, Honeyd emulates an arbitrary network. It also provides features that make that network seem more realistic such as latency and packet loss.

There are several differences between Honeyd and the tool described in this paper. The first is that Honeyd isn’t meant to be used for PLC or ICS emulation. Second difference is that Honeyd isn’t focused on defining specific network topologies so it doesn’t provide the users with a tool to design their own topologies. By using IMUNES to design and run topologies, this tool provides more options when it comes to network emulation.

IV. CONPOT HONEYNET

The process of using IMUNES to emulate a Conpot honeynet can be divided into three steps. The first step is modifying the IMUNES PC nodes by installing tools like Conpot and OSSEC on them. This will enable the users to use the virtual nodes as honeypots in a honeynet. The second step is connecting the virtual network to the Internet so that it can be scanned and accessed by potential attackers. Linux provides the tools needed to forward all the network traffic between the internet and the virtual network. The last part is starting all the services, like Conpot and OSSEC, on the virtual nodes and running the honeynet. The whole process of starting the honeynet and connecting it to the internet was scripted to make it easier for users to start their own honeynets.

A. Modifying IMUNES Nodes

In order to add Conpot to the virtual nodes in IMUNES, the vroot-linux git repository was forked and modified [14]. The repository contains all the files needed to build a Docker image that can be used by IMUNES. The utilities.sh script in vroot-linux is used to install tools and all their dependencies on IMUNES virtual nodes so it was modified to install additional tools on virtual nodes. Along with Conpot, the OSSEC monitoring tool was installed on virtual nodes to enable email alerts. Before installing Conpot and OSSEC, dependencies for those tools were added to the Often used tools part of the utilities.sh file. Since the normal OSSEC installation requires user inputs, OSSEC was installed with preloaded variables by using the preloaded-var.conf file so that the user doesn’t have to manually configure the tool during installation. This file is used to define which services will be used, the email address that will receive OSSEC notifications and where the tool will be installed. The utilities.sh file was also used to make any needed modifications to the newly installed tools. After the utilities.sh script was modified, all the specified tools were installed on the virtual nodes using the following command:

```
sudo docker build -t IMUNES/vroot vroot-linux/image/
```

Virtual nodes can now execute Conpot and thus act as honeypots. They also have OSSEC to monitor Conpot log file which will send email notifications to users.

B. Connecting the Virtual Network to the Internet

In order to connect the simulated network to the internet an external connection node was used. That type of node connects the virtual network to the computer that runs the simulation. Figure 1 shows an example network with 3 PLCs connected to a router that is connected to an external connection node.

![Fig. 1. Simple Network With 3 PLCs](image)

The ext0 node creates an interface on the user’s computer that can be used to interact with the virtual network. The ext0 node configuration window enables the user to define the IP of the newly created interface on the host machine. The virtual router connected to the external interface was also configured, setting the external interface’s IP address as a next hop for a default route on the router. That way, when the router receives a packet with an unknown destination address, it will send it to the host machine which will forward it accordingly.
In order for the host machine to route properly packets received from the virtual router, the host OS was configured to forward packets between the virtual network and the internet. This was done by setting appropriate routes on the host, enabling forwarding using sysctl parameter, and using the `iptables` command to setup source and destination NAT as it is necessary to map host’s IP address to IP addresses in virtual network. Additionally, host was configured to forward TCP segments reaching certain ports on the host’s IP address to ports on virtual honeypots, i.e. destination NAT was used. This enables attackers to communicate with the honeypots in the virtual network even though honeypots don’t have public IP addresses.

For example, any TCP segment with destination port 502 and destination IP address of host was forwarded to port 502 of one of the virtual honeypots in the virtual network. Port 502 is used for the Modbus protocol [15]. The same forwarding of ports was done for other ports used by Conpot. This means that one virtual Conpot honeypot would be easily found by port scanning the host’s IP address. Other virtual honeypots weren’t connected to the host machine’s ports but should instead be accessed from machines inside the virtual network.

C. Starting Services on Virtual Nodes

IMUNES provides a few commands which enable the user to interact with the nodes in the virtual network from shell running on the host. In order to execute a command on a virtual node `himage` command is provided. It enables the user to run a command in the virtual node’s shell. For example, Conpot can be executed on the `plc1` node by running the following command:

```
shimage plc1 conpot
```

`himage` could also be used to open a shell on some virtual node. That could be accomplished using `himage <node name>`. IMUNES also provides the `hcp` command, which can be used to copy files between the virtual nodes and the host. This command is useful for fetching `conpot.log` files from virtual honeypots, among others.

In order to make the honeynet more user friendly for users two scripts were added to the forked `vroot-linux` git repository. The `start.sh` script is used to initialize a honeynet defined by a topology file with `sudo bash start.sh -b <topology file>`. The `-e` option can also be used in order to define the ID of the simulation that is executed, otherwise the simulation will be assigned a random ID by IMUNES.

The honeynet can be further customized with the `conpotimunes.conf` file which is used to define which template will be used on which node, as well as the ports on the honeypot nodes that will be forwarded to the host machine. The `conpotimunes.conf` file also defines the IP of the virtual `external connection` node and the interface on the host machine that is used to connect to the internet. The `start.sh` script will initialize the virtual network and then start both Conpot and OSSEC on the virtual nodes. OSSEC will be configured to send email notifications when a change occurs in the `conpot.log` file of a virtual node. The second script, `collectLogs.sh`, is used to fetch `conpot.log` files from honeypot nodes with the `sudo bash collectLogs.sh <node name>` command. This script will use the `hcp` IMUNES command copy the log file to a directory on the host machine. The name of the directory indicates the time and date when the log was fetched in order to make data analysis easier.

V. EXPERIMENTAL WORK

As a part of this project, an ICS was modelled and then initialized. The network used the default Conpot template to emulate Siemens S7 devices. Additionally, the default Conpot template was modified to more closely resemble a Siemens S7-200 PLC. That template was later used to make a new template which could be used to emulate a Siemens S7-300 PLC because those devices had a vulnerability which could easily be reproduced [7].

A. Modifications Made to the Conpot Templates

The default Conpot template can be used to emulate a Siemens S7-200 PLC. In order to do that it has to be modified since the default template will easily be spotted by attackers [16]. This is mostly because it contains hardcoded values for things like the serial number, PLC name, etc. To see some examples of more realistic PLC devices, the Shodan [17] search engine was used. The default template was then modified to resemble a real PLC device. After comparing Siemens S7-200 devices that were classified as honeypots and devices that were classified as ICSs, modifications were made to the default template which resulted in a honeypot that was also classified as an ICS on Shodan.

Listing 1 shows parts of the changed `template.xml` file which is used to define basic honeypot information. Original values for the changed entries were either too specific or weren’t in the right format.
Some entries, like FacilityName, were changed to an empty string because most of ICS examples had that value undefined. Changes were also made to other XML files that define the default template such as s7comm.xml and http.xml. This of course does not mean that the honeypot could fool every hacker, but it is still an improvement to the standard honeypot. Additionally, by using the same method, the default template was further modified in order to emulate a Siemens S7-300 and Siemens S7-400 devices. The changes were mostly made in the s7comm.xml file along with the template.xml file. Listing 2 shows some of the changes in the template.xml file which were made in order to emulate a Siemens S7-300.

The new devices were useful because some Siemens S7-300 devices had a vulnerability which could easily be exploited. The vulnerability was in the hardcoded basisk username and password which enabled anyone to gain control over the PLC. There is also a Metasploit exploit for that vulnerability which increases the chances that a potential attacker would use that vulnerability to attack the virtual network. The S7-300 templates http protocol file http.xml was modified to partially emulate the vulnerability in question. The modification allowed the honeypot to respond to the basisk login attempt and to the memory dump request. The memory dump consisted mostly of random data but it also had IP addresses and ports from other devices inserted into that random data in hopes that it would help the attackers find the other devices in the honeynet.

B. Designing a Control Network

In this section, an example of an Siemens PLC network was partially modelled in IMUNES. Figure 2 shows the selected network which consists mostly of Siemens S7 PLCs [19].

![Fig. 2. An example of a Siemens ICS](image)

The modified IMUNES tool can emulate some of the devices in this network, but not all of them so some modifications were made to the network. Siemens ET 200, Simatic S5, SIMATIC OP and SIMATIC PG are the devices that couldn’t be emulated. Simatic PC is an industrial laptop used for programming PLC devices so it was replaced by a standard pc node. Other devices that can’t be emulated were replaced with Siemens S7-200 PLC. The resulting IMUNES topology is shown in Figure 3.
The Siemens S7-300 ports were connected to the standard ports on the host machine while other devices were connected to random ports on the host machine. The reason for this is the basic vulnerability added to the S7-300 honeypot which would allow the attacker to request a memory dump from that device. The memory dump of that device contains the private IP addresses of other devices which could be used to access those devices from inside the network.

C. Analysis of Obtained Results

In this section the results of running the honeynet are analysed. The experiment lasted for two weeks with a couple of short breaks to adjust honeypot settings. Once the honeynet was initialized, PLCScan [20] was used to check that all the honeypots are working properly.

During the simulation of the network described in the previous section some activity on the honeypots was recorded. Every time a honeypot was accessed OSSEC notified the owner of the network that the conpot.log has changed. Listing 3 shows one example of an OSSEC email.

Listing 3. OSSEC notification about changes in the conpot.log file

OSSEC HIDS Notification.
2017 Feb 09 14:07:50

Received From: plc1->syscheck
Rule: 550 fired (level 7) -> "Integrity checksum changed."

Conpot honeypots recorded all their activity in conpot.log. Parts of the resulting conpot.log can be seen in Listing 4. That specific part is a record of a port scan directed at the modbus 502 port on the hosts IP address.

Listing 4. Activity recorded in the conpot.log file

2017-02-19 02:16:30,279 New modbus session from 185.35.63.142
(e5ac81d6-dad5-4abc-8f42-2e8170738b38)

2017-02-19 02:16:30,280 New Modbus connection from 185.35.63.142:37443.
(e5ac81d6-dad5-4abc-8f42-2e8170738b38)

2017-02-19 02:16:30,280 Modbus traffic from 185.35.63.142: { 'function_code': 43,
'slave_id': 0, 'request':
'00000000005002b0e0100', 'response': ''}
(e5ac81d6-dad5-4abc-8f42-2e8170738b38)

2017-02-19 02:16:30,281 Modbus connection terminated with client 185.35.63.142.

The recorded activity, however, consisted mostly of port scans targeting the modbus 502 port and the http 8080 port of the Siemens S7-300 honeypot. Port scans on the modbus 502 port mostly requested some basic information from the devices and then didn’t explore the device further. Port scans on port 8080 also didn’t result in any further activity, but that is to be expected seeing how that port is not specific to control devices and was meant to be used by attackers that have previously scanned the 502 port or 102 port and found a Siemens device that is potentially vulnerable.

None of the port scans resulted in attacks on the virtual network so there was no activity recorded on the other honeypots in the virtual network. There were also no attempts to exploit the Siemens S7-300 vulnerability. Since the time frame of the experiment was only two weeks, more testing should be done in order to see how successful this particular honeynet is at attracting hackers. However, as stated before, Shodan has classified the simulated network as a valid ICS and the Siemens S7-300 honeypot was successfully modified to emulate the hardcoded password vulnerability so a longer experiment could have resulted in more interesting activity.
VI. CONCLUSIONS AND FUTURE WORK

This article shows how the IMUNES network simulator can be used to simulate a honeynet. The steps used in this article can be used to emulate any kind of honeynet with IMUNES. Because of the IMUNES GUI it is easy for users to model a network that suits their needs and the addition of the OSSEC email alerts makes supervising the honeynet much easier.

In future work, the tool presented in this article will be improved by adding more templates to Conpot and by adding other honeypot tools to the virtual nodes. That would allow the users to emulate honeynets that better resemble production networks. Additionally, better monitoring capabilities are necessary.

Honeynets emulated by this tool provide owners of ICSs with more options for securing their systems. Along with potentially improving the security of an ICS, this tool could serve as a template to build other kinds of honeynets.

Abstract — Vehicle Ad Hoc Networks (VANETs) in Cooperative Intelligent Transport Systems (C-ITS) are based on the exchanges of messages among ITS-Stations (e.g., vehicles and roadside infrastructure) using the wireless G5 Dedicated Short Rate Communication (DSRC) standard to support safety-critical applications. VANETs require the authentication of ITS-stations and messages but the privacy of the drivers of the vehicles must be supported. In recent years, researchers have proposed solutions to mitigate privacy risks based on the use of pseudonyms. A key design decision is related to the frequency of the change of pseudonyms. The activity of a vehicle under one pseudonym can be linked to another thus providing traceability of the vehicle and a privacy risk for the driver. To prevent link-ability of actions, the vehicle must change pseudonyms over time. In this paper, the authors propose a radio frequency physical layer analysis to determine the frequency of the pseudonym changes. The rationale is that different wireless propagation conditions will impact the capability of the privacy attacker to trace the vehicle, thus reducing the need to frequently change the pseudonyms. The analysis has been performed in different channel fading conditions and for different relative speed values.

Keywords—wireless propagation, privacy, VANET,

I. INTRODUCTION

Cooperative Intelligent Transport Systems (C-ITS) is a set of technologies, which will allow road users, service providers in road transportation and traffic managers to share information and use it to coordinate their actions. One of the main elements is the wireless connectivity among vehicles (V2V) and between vehicles and transport infrastructure (V2I), collectively called V2X. Wireless connectivity is mainly proposed by standardization bodies [1] (e.g., ETSI) with the Dedicated Short Range Communications (DSRC) wireless standard based on the IEEE 802.11p standard, which belongs to the 802.11 family of standards and it is described in the subsequent section of this paper. While other authors have recently proposed the application of different standards like LTE [2], the authors of this paper have focused their study only on the IEEE 802.11p standard. In this context, vehicles and road infrastructures nodes (called ITS-Stations in the ETSI standards [1]) will exchange messages through wireless communications, thus creating dynamic Vehicle Ad Hoc Networks (VANET). The ITS-Stations will broadcast messages like the Cooperative Awareness Messages (CAM) to support the creation of dynamic cooperative awareness in the ITS stations [1]. The broadcast of CAMs from the vehicle can potentially endanger the privacy of drivers, as an eavesdropper could identify the mobility patterns of individual drivers and track the vehicles.

To mitigate these privacy risks, various papers have proposed pseudonymity schemes for VANETs, where the ITS-stations use pseudonyms rather than the real identity when generating and broadcasting the CAMs. A recent and very detailed survey identifies and describes the main pseudonymity schemes for VANETs [3]. As presented in [3] and [4], a static pseudonym may not be sufficient to mitigate privacy risks in VANETs, because a single vehicle could still be identified and tracked based on a time series of eavesdropped messages. In other words, a malicious privacy attacker could be equipped with a RF receiver to eavesdrop messages broadcasted from a vehicle and still correlate specific vehicles or even drivers based on reoccurring travel patterns. As a consequence, there is the need to change the pseudonyms generated by the mobile ITS-station, but it is still an open problem on what could be the frequency of pseudonyms changes [3]. This problem is common to most of the proposed pseudonym schemes, as discussed in [7]. Note that there are trade-offs in the definition of the frequency of the pseudonyms. If the frequency is too high, it can have a significant impact on the storage of the pseudonyms or the computing power, which is needed to generate them. In addition, it increases the frequency of pseudonym refills in the vehicle, which impacts the communication channel used to distribute or activate the pseudonyms [5]. Conversely, if the frequency is too low, privacy attackers can easily track the vehicle. To identify the point of equilibrium in this, the objective is to calculate the required maximum frequency of changes of pseudonyms.

In this paper, we propose an analysis for the definition of the frequency of pseudonym changes based on wireless propagation conditions. The rationale is that there is no need to frequently change pseudonyms if a receiver is not able to collect and process, with an acceptable Bit Error Rate (BER),
targeted values of the CAM messages broadcasted by the mobile ITS-station. If the wireless propagation conditions are not optimal, as in an urban environment, the frequency of change of pseudonyms can be kept to a low value but it should be raised to a higher value in different propagation conditions or depending on the speed of the vehicle. In other words, the frequency of change of the pseudonyms depends on the context where the mobile ITS-station is travelling or even the types of modulation used to transmit the CAM messages. While there can be different contexts which could drive the frequency of changes of the pseudonyms, in this paper, we specifically focus on the radio frequency physical layer context and the capability of the privacy attacker to collect and process the CAM messages based on the 802.11p standard used in the mobile ITS-station.

The structure of this paper is the following: Section II describes the system model with a presentation of the scenario, a brief description of the 802.11p standard and the conditions (attenuation and fading), which can impact the capability of the privacy attacker to collect and process the CAM messages (e.g., if a BER threshold is overcome). Section III provides the simulations results, which gives an indication on the needed change of frequency pseudonyms. Section IV concludes this paper.

II. RELATED WORK

The issue of privacy in VANET is directly linked to the broadcasting of messages as described in the introduction section. The periodic broadcasting of messages from a vehicle can be used to track the vehicle and the driver/passenger and it can be used to attack his/her privacy. In literature, the privacy risk related to the tracking of the position of an individual are part of computational location privacy, meaning computation-based privacy mechanisms that treat location data as geometric information [6]. While the authors in [6] have investigated computation-based privacy in general, recent papers have investigate the risks and related mitigation techniques for privacy in VANET. In VANETS, security is of paramount importance because the integrity of the exchanged messages (e.g., CAM) must be ensured to avoid malicious attacks tampering with the messages and then creating safety hazards. The authors in [7] have proposed digital signatures to ensure the integrity of the messages, which is the approach based on [1]. On the other side, the certificates used for the digital signatures can be uniquely linked to the owner of the vehicle, does creating a privacy threat. Then, pseudonyms were proposed in VANETs to break this linkability [8]. A pseudonym allows authentication of a specific entity without knowing the holder’s real identity. On the other side, an eavesdropper collecting signed messages, could still track a vehicle because it will use the same certificate. To prevent this privacy threats, authors have investigated the possibility to change pseudonyms [3]. The issue is how frequently the pseudonyms should be changed.

The authors in [4] have used a Multi Hypothesis Tracker (MHT), which relies on Kalman filters to calculate the frequency of changes of pseudonyms. The evaluation was based on the definition of a discrete event simulator and a vehicular mobility model to generate mobility traces. Then, the anonymized position samples are processed by the MHT. The evaluation metric the maximum period of time the tracker was able to correctly reproduce the trace of each vehicle, averaged over all traces in the simulation.

An alternative approach to calculate the frequency of pseudonyms changes was proposed in [9], where the authors use the context information (such as the number of neighbors, their direction and speed) for initiating a pseudonym change. For example, vehicles can cooperatively identify good opportunities to blend in a number of vehicles and hence increase their anonymity. Then, the simulations were executed using the vehicular mobility model provided with STRAW.

Both [4] and [9] do not address the aspect that the CAM messages transmitted through wireless communications are subject to wireless propagation errors due to the distance of the vehicle from the eavesdropper and the surrounding environment. This paper addresses this gap in literature, which can be a significant factor to evaluate the practical feasibility to implement the privacy threat.

III. SYSTEM MODEL

A. Scenario

The privacy threat scenario is shown in figure 1. A Privacy attacker is equipped with an RF receiver to collect the radio frequency signal based on the 802.11p standard. In this scenario, we make the following assumptions:

1. The privacy attacker is located in a fixed position.
2. The pseudonym scheme is not based on “silent” periods, where the vehicle stops transmitting for predefined times to avoid being tracked. While a “silent” period could mitigate privacy risks, it also negates or reduces the benefits of V2X [3].
3. The pseudonym scheme is based on traditional public key cryptography schemes, where the vehicle is equipped with a set of public key certificates and...
corresponding key pairs. This is the most common approach proposed by industry and standardization bodies ([10],[11]). The public key certificates are stripped of any identifying information and used as unlinkable pseudonyms. Vehicles sign messages with the secret key of the currently active pseudonym.

As described before, the privacy attacker can be successful only if the receiver is able to collect and process the CAM messages based on the 802.11p signal standard, which depends on the wireless propagation conditions.

It is considered that a vehicle is moving at constant velocity, with a single eavesdropper present within the communications range $R_{max}$. If the location of the eavesdropper is randomly chosen within a circle defined by the transmission range, the average distance between the vehicle and the eavesdropper is exactly $R_{max}$. Thus, the average time in which the eavesdropper can listen to the transmission from the transmitter is obtained by applying the following relationship $T_{max} = R_{max}/v$, being $v$ the speed of the vehicle. Then, the objective is to calculate the value or the range of values of $T_{max}$, because it is inversely correlated with the maximum frequency of change of pseudonyms.

**B. A description of the 802.11p standard**

IEEE 802.11p is a consolidated standard used for DSRC between vehicles [12]. This standard provides both the physical layer (PHY) specifications for the DSRC and the Medium Access Control (MAC) of vehicular communication operating at the 5.9 GHz band. The physical layer consists of two sublayers, the Physical Medium Dependent (PMD) sublayer and the Physical Layer Convergence Protocol (PLCP) sublayer. The first sublayer defines signal parameters, such as modulation and coding rates, and performs the digital-to-analog conversion. The PLCP sublayer is responsible for communicating with the MAC layer. It is also a convergence process that transforms the PLCP Service Data Unit (PSDU) arriving from the MAC layer into PLCP Protocol Data Unit (PPDU). During this conversion, the PSDU is appended with preamble and header. The PLCP preamble is composed of ten repetitions of a short training sequence and two repetitions of a long training sequences preceded by a guard interval in order to combat inter-symbol interference. The PLCP header contains information regarding the transmission rate, tail and padding bits and, also, how many octets are used in the PSDU.

The 802.11p physical layer is based on an orthogonal frequency division multiplexing (OFDM) technique. The OFDM technique transmits data on spaced orthogonal subcarriers, allowing spectrum efficiency improvement and coping with severe channel conditions. A total number of 64 subcarriers are defined, but only the inner 52 subcarriers are employed. Among the 52 subcarrier, 48 of them contain modulated-coded data and the other 4, called pilot subcarriers, convey a fixed pattern used for channel and synchronisation purposes at the receiver [13]. Each of the 48 subcarriers can be modulated by using BPSK, QPSK, 16-QAM or 64-QAM schemes. In addition, different convolutional coding rates can be used, leading to nominal data rate values of 3 to 27 Mb/s when using a 10 MHz bandwidth. The main parameters that define the IEEE 802.11p standard are defined in Table 1.

The transmitter chain is shown in figure 2, where the first block is the bit source unit, which generates random bits following a uniform distribution. Then, the serial number of bits are going through to an encoder and modulator unit. The raw bits are firstly scrambled in order to randomise the data pattern, which may contain large strings of 0s or 1s. Then, a convolutional encoder is applied to the bit stream in order to introduce redundancy. This redundancy is used for error correcting coding, which allows the receiver to combat the channel propagation effects. Subsequently, an interleaver process is applied to the coded bits in order to mitigate correlation channel noise effects, such as burst errors or fading. After the interleaver, the modulation mapper is applied to convert the bit stream into symbols. The following block is the OFDM symbol assembler, which constructs the OFDM symbols by means of mapping the modulated data into the 48 data subcarriers, the pilot sequence of bits into the 4 designated subcarriers and the 12 resting subcarriers are nulled. Once the OFDM symbols are built, an Inverse Fast Fourier Transform (IFFT) process is applied to obtain the temporal representation of the symbols. Finally, the transmitted data is generated by assembling the preamble, signal field and the IFFT modulated data. Note that the receiver performs the opposite processes with respect to the transmitter (i.e. demodulation, decoding, etc.).

MIPRO 2017/ISS 1487
C. Rician Fading Channel Model

In wireless communications, the Rician distribution is commonly used to describe the statistical variations in time of the envelope of the received signal. This signal can present a unique component or several components as a result of reflections and scattering phenomena, also known as multipath signal. In the situation that there is a dominant stationary signal component, i.e. line-of-sight communications, the small-scale fading envelope follows a Rician distribution. The Rician fading channel is characterised by mainly two parameters, $K$ and $\Omega$, where $K$ represents the ratio between the power amplitude of the strongest received path with respect to the other secondary multipath components. The other parameter, $\Omega$, is the result of the total available power from all the multipath components. Additional details on the Rician distribution and the $K$ factor are available in [14].

Two particular cases can arise from the Rician fading channel definition. The first one is when the ratio between Line-of-Sight (LoS) components and multipath rays is very large ($K \rightarrow \infty$). In that case the amplitude of the received signal is constant and the mobile channel acts like an Additive White Gaussian Noise (AWGN) channel. The other case corresponds to $K=0$. In this situation, the envelope amplitude follows a Rayleigh distribution, which can be modelled as the sum of two quadrature Gaussian signals. In Rayleigh fading, the signal weakening can cause that the main component is not noticed among the multipath components.

In addition, another important factor that needs to be taken into account in vehicular communications is the Doppler effect associated to the relative velocity among transmitter and receiver. The Doppler effect is represented by frequency variations of the received signal. In this context, the frequency of the received signal is given by $f = (1+\Delta v/c)f_0$, where $f_0$ is the carrier frequency of the transmitted signal, $c$ is the speed of light and $\Delta v$ is the relative velocity between transmitter and receiver. The Doppler spectrum used in this work follows the Jakes spectrum model [15].

D. Maximum Communication Distance

The maximum reachable communications distance is calculated based on the $\text{SNR}_{\text{min}}$ values for a targeted BER. Following the Friis transmission equation, which is commonly used in Telecommunications to calculate the received power level at a given distance, and the expression of the thermal noise power [16], the maximum reachable distance between transmitter and receiver is given by

$$R_{\text{max}} = \frac{c}{4\pi f} \sqrt{\frac{P_T G_T G_R}{\text{SNR}_{\text{min}} K_B T W N_F}},$$

where $f$ is the centre frequency of the system, $P_T$ is the transmitted power, $W$ is the noise bandwidth, $\text{SNR}_{\text{min}}$ is the minimum Signal to Noise Ratio, $T$ is the ambient temperature and $K_B$ is the Boltzmann constant. The variables $G_T$ and $G_R$ in (1) are the transmit and receive antenna gains respectively. Also, $N_r$ is the noise figure of the receiver. Note that free-space propagation losses conditions are considered in (1). The values of parameters of (1), which are used to calculate the results of this paper are provided in section IV.B.

IV. RESULTS

A. Bit Error Rate Simulations

The Bit Error Rate (BER) performance of a radio communications systems is a unitless metric used for representing the quality of the system in terms of bit reception. This percentage metric computes the relationship between erroneous received bits and transmitted bits. The BER performance of a wireless system is commonly represented as a function of the received Signal-to-Noise Ratio (SNR).

The first step is to fix the value of the minimum required BER value ($\text{BER}_{\text{min}}$), which allows the receiver to demodulate and obtain the transmitted message with a determined quality of service (QoS). In our situation, the goal is to establish this BER value for which the eavesdropper will be able to properly detect the message. In this context, a $\text{BER}_{\text{min}} = 0.001$ value is specified by the IEEE 802.11p standard [13]. Correspondingly, the threshold established by the $\text{BER}_{\text{min}}$ value will provide the minimum required SNR value for correct detection, $\text{SNR}_{\text{min}}$.

In this analysis, two modulation-coding schemes, QPSK with $R_c = 1/2$ and 16-QAM with $R_c = 1/2$, have been chosen for BER evaluation in different channel conditions. Initially, the BER performances as a function of the received SNR are evaluated by considering four relative speeds between transmitter and receiver. These speed values are $v = 0$ (static), $v = 30$ km/h, $v = 70$ km/h and $v = 120$ km/h. Note that a perfect Channel State Information (CSI) and no Doppler estimation mechanism are applied for these Monte Carlo simulations. BER curves as a function of the received SNR are plotted in Figures 3 and 4 for both modulation schemes. Results show the performance degradation caused by the Doppler effect and the low values of $K$-factor of the Rician channel. It is observed that, in some scenarios, the targeted BER is never reached by increasing the SNR values. In
particular, this situation is more pronounced for larger values of the modulation scheme, lower values of \( K \) and higher relative speed values.

Fig. 3. BER as a function of the received SNR for a QPSK \( R_e=1/2 \) system with different relative speed values. Two K-factor values of the Rician channel are considered, \( K=10 \) (continuous lines) and \( K=1 \) (dashed lines).

Fig. 4. BER as a function of the received SNR for a 16-QAM \( R_e=1/2 \) system with different relative speed values. Two K-factor values of the Rician channel are considered, \( K=10 \) (continuous lines) and \( K=1 \) (dashed lines).

B. Eavesdropper Visibility Time

The time in which an eavesdropper (receiver) has in view the transmitter (vehicle in motion) based on the simulated \( SNR_{min} \) values and the maximum achievable distance in (1), is computed for different channel conditions and modulation schemes. Thus, the frequency rate for changing the pseudonym cryptographic key can be obtained straightforward as the inverse of these eavesdropper visibility times. Initially, the simulation scenario and the hypothesis used in this work are defined as follows. As described in section III.A, it is considered that a vehicle is moving at constant velocity and driving in a straight direction with only a single eavesdropper, which is present within the communications range calculated in equation (1). The straight direction is chosen because it is the worst case scenario for the calculation of the frequency of the pseudonyms. As pointed out before, the average distance between the vehicle and the eavesdropper is exactly \( R_{max} \). Thus, the average time in which the eavesdropper can listen the transmission from the transmitter is obtained by applying the following relationship \( T_{max} = \frac{R_{max}}{v} \).

The average eavesdropper visibility time as a function of the relative speed between vehicle and eavesdropper are plotted in Figures 5, 6, and 7 for the three modulation-coding schemes (QPSK, 16-QAM and 64-QAM) and different \( K \)-factor values of the Rician fading channel. For this simulation analysis, the values of the parameter defined in equation (1) are following: \( G_T=G_R=0 \) dBi, \( P_{Tx} = 20 \) dBm, \( N_0=15 \) dB, \( f=5.9 \) GHz and \( T=290 \) K are used. Simulation results showed that the visibility time is minimised by increasing the relative speed due to the Doppler effect, and/or using a large level of modulation-coding scheme and/or transmitting information in urban environments (low values of the \( K \)-factor of the Rician fading channel). From these results, it is clear that the maximum frequency of the pseudonyms depends on the context where the mobile ITS-station is operating and the transmission parameters used to transmit the CAM messages. Higher modulation schemes like 64-QAM allows a lower frequency of change of pseudonyms because the visibility time of the eavesdropper drops drastically in comparison to the QPSK modulation.

Fig. 5. Eavesdropper visibility time as a function of the relative speed for QPSK \( R_e = 1/2 \) and K-Rician fading channel.
V. CONCLUSIONS

The maximum visibility time available for the eavesdropper to obtain the DSRC transmitted data has been obtained by means of Monte Carlo simulations. This analysis has been performed considering different mobile channel conditions, different relative speeds and three modulation-coding schemes. The pseudonym frequency rate used to decide how many times the pseudonym cryptographic key must be changed is inversely proportional to these eavesdropper visibility times. Simulation results showed that, as expected, that the visibility time is minimised by increasing the relative speed due to the Doppler effect, and/or using a large level of modulation-coding scheme and/or transmitting information in urban environments (low values of the $K$-factor of the Rician fading channel). From the results it can be concluded that using conventional power control mechanism, directional antennas and/or applying dynamic modulation-coding and multiple access coding schemes helps to mitigate the eavesdropping impact. Future developments will focus on more complex distributions of eavesdroppers and mobile ITS-stations.

Resilience of students' passwords against attacks

Boštjan Brumen* and Tadej Makari*
* University of Maribor, Faculty of Electrical Engineering and Computer Science, Smetanova 17, Si-2000 Maribor, Slovenia
bostjan.brumen@uni-mb.si

Abstract - Passwords are still the predominant mode of authentication in contemporary information systems, despite a long list of problems associated with their insecurity. Their primary advantage is the ease of use and the price of implementation, compared to other systems of authentication (e.g. two-factor, biometry, ...). In this paper we present an analysis of passwords used by students of one universities and their resilience against brute force and dictionary attacks. The passwords were obtained from a university’s computing center in plaintext format for a very long period – first passwords were created before 1980. The results show that early passwords are extremely easy to crack: the percentage of cracked passwords is above 95 % for those created before 2006. Surprisingly, more than 40 % of passwords created in 2014 were easily broken within a few hours. The results show that users – in our case students, despite positive trends, still choose easy to break passwords. This work contributes to loud warnings that a shift from traditional password schemes to more elaborate systems is needed.

I. INTRODUCTION

The computers of pioneering era needed no passwords. Their security relied on restricted access to the physical machines. Even if an adversary would have gained access to these machines, the lack of knowledge to manipulate the computers was preventing the attacks. Besides, these early computers barely stored anything interesting and/or valuable.

Today, it has become commonplace to note that computer systems protected by authentication systems are either mathematically robust or user-friendly, but not both [1]. Predominant authentication scheme today is the use of the username:password combination. The implementation of this scheme is straightforward, simple, easy to implement, has low cost of maintenance, and is overall accepted by the users.

However, since passwords are at users’ responsibility, they cause many problems. Interestingly, these problems became evident already with first operating systems that implemented the time sharing functionality, all the way back in 1960s. When a PhD student Allan Scherr became fed up with time restrictions imposed on the system, he found a way to print the password file and use other people’s accounts to use the system [2]. In 1978, Thompson and Morris wrote their seminal paper on password security, identifying numerous issues and proposing several countermeasures, which (still) have not been implemented in modern operating systems decades later [3], but only after a breach has occurred.

Badly enough, passwords are not used only on the operating system security level, but also on the application level, ranging from simple stand-alone desktop few-user applications, to multi-million user web applications.

The password issues should have been taken seriously. Breaches are not sporadic and by chance, they are frequent and systematic. They cause several millions of damage, and even take lives – as was the case of a preacher being listed as one of the ashleymadison.com (adult dating website) users [4].

Sadly, the computer community has not made a very much-needed shift in password management for more than 35 years [5].

The present study aims to shed some light on how a young population, students aged 18-24, manage and create their passwords.

In the next section, we present related studies that deal with the issue of users’ passwords and their properties.

II. RELATED WORK

The related work reviews the works by others about similar researches on passwords.

The authors of study [6] have found that users tend to form their own mental models of security and what makes good passwords and they create insecure but easily recalled password by favoring memorability over security.

To help users select better (stronger and/or easy to remember passwords), several solutions have been proposed, such as mnemonic passwords [7, 8], cognitive passwords [9], associative passwords [10] and password checkers and meters [11-14].

A body of research was conducted on the user-centered approach, such as [15-19]. Here, the authors have identified the end user as the weakest link in the security chain and special attention needs to be given to user-related issues, such as memorability.

The education of users and its influence on the password (and overall system) security was researched in several works, e.g. in [20-23].

The impact of password policies was investigated in works of Summers et al [8], Inglesant & Sasse [24], Komanduri et al [25], Farrell [26] and Duggan [27].

The studies show that the average length of passwords is below 8 characters [11, 28, 29], yet these passwords are not completely random, thus of inadequate length, which should be at least 11 characters (mixed upper and lower, case, digits, symbols) [30].

The analysis of the related research has shown that most researchers collected their data, related to textual passwords, through laboratory experiments and/or
surveys. In these settings the participants were aware of the setting, and this very fact may lead to false, fake, less accurate or biased data. Participants may have created or used different password than those used in their daily life in order to protect the latter.

A. Aims, scope, and organization of the paper

In this paper, our research goal is to analyze the strength of real users’ passwords and their resilience against attacks.

Our research question is as follows: how resilient are real users’ passwords against two most common attacks, a dictionary and a brute force attack?

The paper is organized as follows: in the next section, we present the methods of our research, and in the section IV we present the results. Our contribution is concluded in Section V with final remarks.

III. METHODS

A. Data collection

To answer the research question we obtained and analyzed real students’ passwords. We have obtained 185,643 plaintext passwords of students of one of universities located in the EU. The passwords were used by students to log-in into their university accounts where they accessed to various functionalities. The university’s student account system was developed in the 1980s and all passwords were stored in plaintext ever since; fortunately, with no known security incident.

The passwords were made available for research purposes only based on a strict non-disclosure agreement between the researchers and the university management; this agreement prevents the researchers from disclosing the name of the university and/or its location. The passwords resided on a computer that was locked in a separate room without internet or any other network connection, and access to the room and the computer was restricted and logged. Passwords are encrypted using a contemporary encryption system and only when analyzed they are being decrypted to a sandboxed environment and deleted after the analyses.

B. Ethical and legal considerations

Before the research commenced we considered whether it would break any ethical rules. Since the passwords were in plain text, their leakage could have been misused for attacks on other accounts. However, no personally identifiable information (e.g. username, student’s number, etc.) were stored alongside the passwords. For the purpose of the research, other students’ data were available alongside the password, such as sex, year of entry to university, study field, and few others. The passwords (and the corresponding accounts) are no longer being used by the university computing system as the students’ accounts have been upgraded; each student was assigned a new identity and a new default password. Due to password reuse there is still a possibility that a user re-uses her password in any other application or system. However, we believe the chance of a password being matched to a single user is very low. Additionally, the passwords available and the results of the studies based on these passwords will help the professional community to understand better the patterns and the behavior of users and their passwords. We believe the positive aspects of using passwords overweight the potential perils. Last, but not least, the study is in line with local laws and EU regulations as in Directive 95/46/EC [31]. The Article 11§2 allows the personal data to be used for research purposes.

C. Hardware and software

The passwords were hashed using MD5 algorithm, and the hashes were fed into the Hashcat v3.10. The properties of the hardware used are listed in Table I.

### Table I. Hardware configuration

<table>
<thead>
<tr>
<th>Item</th>

</tr>
<tr>
<td>OS</td>
<td>Windows 10 Pro x64</td>
</tr>
</tbody>
</table>

The upper time limit of running the Hashcat software was set to 72 hours to mimic an attacker that has limited resources; from Table 1 one can note that the cost of hardware used was below 1.000 EUR / US$.  

IV. RESULTS

A. Brute force attack

For the first part of the brute force attack, the software was configured to use lower case English alphabet, plus special characters from Slovenian alphabet (‘ć’, ‘š’, and ‘ž’), and digits (0..9). The search space was set to maximum 9 characters (calculations for 10 characters were estimated to last a bit less than 44 days).

![Command line output of Hashcat](image)

The program ran for 1 day, 3 hours and 45 minutes and was able to crack 168,081 or 90,5 % of all passwords.

In the next part we lowered the number of characters from 9 to 8 and added the following special characters: '!"#$%&/()=?*`+_;:,.<>. With this setting we cracked 4,30 % of all passwords, but they partially overlapped with the previous results. Actually there were only 66 passwords with special characters, or 0,04 % of all. This part took 7 hours and 25 minutes.
The last part was configured to check only special characters and digits, with lengths of up to 9 characters. This way additional 10 passwords were cracked, for the cost of 7 hours and 10 minutes.

B. Dictionary attack

For dictionary attack we used a publicly available word lists from http://hashcrack.blogspot.si/p/wordlist-downloads_29.html. The size of all the dictionaries was 6 GB. The software ran for 2 minutes and 40 seconds and revealed 19,7 % (36,497) of passwords.

Next, we configured the software to add up to 5 digits at the end of each word. In 22 hours and 46 minutes we cracked 89,9 % of passwords.

Figure 2 shows an excerpt from the output file with examples of cracked passwords.

```

256 c45d65201a2163934c89039356e5f412239gse10
```

Figure 2. An example of cracked passwords (white: hash value, yellow: front digits, cyan: dictionary word)

Finally, the software added up to 5 digits in front of each word. In 10 hours and 5 minutes we additionally cracked 4,0 % of passwords.

At the end of combined dictionary attack only 11,853 passwords (6,4 %) remained intact.

C. Combined attacks

After combining the results from both types of attacks we were able to crack 95,3 % of all passwords (see Table II).

<table>
<thead>
<tr>
<th>Item</th>
<th>Count</th>
<th>Percent</th>
<th>Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>Complete list of passwords</td>
<td>185,643</td>
<td>100,0 %</td>
<td></td>
</tr>
<tr>
<td>Brute force attack list</td>
<td>168,157</td>
<td>90,6 %</td>
<td>1d 18h 20m</td>
</tr>
<tr>
<td>Dictionary attack list</td>
<td>173,790</td>
<td>93,6 %</td>
<td>1d 8h 54m</td>
</tr>
<tr>
<td>Combined attack list</td>
<td>176,919</td>
<td>95,3 %</td>
<td>3d 3h 14m</td>
</tr>
</tbody>
</table>

The total time to complete the attacks was 3 days, 3 hours and 14 minutes (Haschcat runtime only), where brute force attack took 1 day and 18 hours and dictionary attack lasted 1 day and 9 hours. Combined time, with necessary preparations, was thus less than four days.

It is interesting to observe the length of the cracked passwords (see Table III). Almost 95 % of passwords are of length 9 characters or less, with majority of passwords of length 6. The average length was 6,7 characters.

<table>
<thead>
<tr>
<th>Password length</th>
<th>Count</th>
<th>%</th>
</tr>
</thead>
<tbody>
<tr>
<td>3 or less</td>
<td>472</td>
<td>0.3</td>
</tr>
<tr>
<td>4</td>
<td>1,631</td>
<td>0.9</td>
</tr>
</tbody>
</table>

This result shows the effect of the hint given to the users that “passwords should be 6 characters or longer”, but this policy was not enforced.

We also checked whether male students have had their passwords’ lengths different than their female colleagues.

The difference is slight, 0,21 characters. Namely, male students have their average password lengths of 6,8, and females 6,6.

We checked if the difference is statistically significant. The independent t-test has indicated that the difference (0,21 characters) is not statistically significant (P=0,079) at $\alpha=0,05$ level.

Another interesting finding is the speed of cracking. It was variable in different parts of attacks, but highest values were obtained with plain brute force attack. The cracking speed was close to 3 billion hashes per second (see Figure 1, parameter “Speed.GPU.#1...”) on a single low-cost machine. One can imagine that a serious brute force attacker would have 1 million equivalent machines available, e.g. by means of a botnet. This means that a password should consist of 15-16 totally random characters from upper and lower case letters, digits and special symbols [30].

Next, we checked how passwords differed by the year when they were generated.

<table>

</thead>
<tbody>
<tr>
<td>3 or less</td>
<td>472</td>
<td>0.3</td>
</tr>
<tr>
<td>4</td>
<td>1,631</td>
<td>0.9</td>
</tr>
</tbody>
</table>
From Figure 4 one can notice that until 2012, the percentage of cracked passwords was in the 95 % range (1990: 99.5 %; 1998: 98.2 %; 2006: 95.4 %), with no statistically significant difference (ANOVA test, P<0,000). In 2013, a new policy was introduced for the default, system-assigned passwords, which changed from “XY9999” template (where X and Y were students’ first and last name initials) to randomly generated 8-character password. For 2013 and 2014, the percentage of successfully cracked passwords fell to 65.2 % and 42.7 %, respectively.

V. DISCUSSION AND CONCLUSION

The work presents an analysis to resilience of real students’ passwords against two most common attacks, brute force and dictionary attacks. The passwords were obtained from a university’s student account software upon its migration to a new system. Ethical and legal considerations were taken into account before the analysis and research was conducted. The passwords were obtained from a single university from a single central European country, from a young body of population. The results are inadvertently influenced by these facts, as localization, culture and level of technology all influence the choice of a password. Hence, the results of this study cannot be freely generalized to other types of users, geographical and cultural areas.

The analysis has shown that students’ passwords are extremely vulnerable against these attacks. Astonishing 95.3 % of passwords were broken in a bit more than three days’ time on a single low-cost machine with very simple, publicly available tools and methods. The cracking speed approached 3 giga-hashes, or passwords, per second.

At the beginning we have asked the following research question: how resilient are real users’ passwords against two most common attacks, a dictionary and a brute force attack? The answer is simple and worrying: they are not resilient at all. The password lengths are inadequate and do not come close to the required “safe” password lengths of 15-16 random characters.

The results, in light of the above statement, may well indicate that the authentication systems using username:password are becoming obsolete and urgently need upgrading to more secure (e.g. two-way authentication) schemes. As Haque et al observe, users reuse high level passwords, such as those for banking applications, with little or no modifications for low level

services, leading to a possibility for attackers to use unsafely shared or leaked passwords to crack higher-level passwords [32].

The passwords already have several alternatives, but they are costly, harder to implement and may require additional hardware. Two or three way authentication requires additional devices and/or services to display the second authentication token; biometrics requires additional scanning equipment and raises privacy issues.

The drawbacks of this study are the limitations posed by the data themselves. Results cannot be freely generalized due to the sample of users from one university, using a specific account for specific purposes. The future work will address the questions if different groups of students, such as technical vs. non-technical, have different password lengths; if the grade of a student correlates to the student’s password length and strength, and alike.

Abstract - This study was based on the validated Users’ Information Security Awareness Questionnaire (UISAQ). Authors gathered information on risky behavior and security awareness among 355 pupils from three secondary schools: General program secondary school (Gymnasium), Business and administrative high school and Trade school. Aim of the study was to test adapted version of UISAQ questionnaire on secondary school student population. Questionnaire was slightly modified and validated to meet new requirements regarding young pupils’ behavior. Analysis outcome represent results of secondary school pupils regarding 6 subareas: Users’ usual behavior (x=4.12), Personal computer maintenance (x=3.33), Borrowing access data (x=4.77), Awareness about security in communications (x=2.67), Belief into securing data (x=2.27) and Importance of backup quality (x=3.86). Also some detailed comparisons regarding demographic variables and correlation with students and employed users were given. Additionally, correlations with revealing password and Internet abuse are given. The percentage of young pupils that have revealed their password for their e-mail system access is much higher than usual (77.7%). This information should alert government institutions and schools teachers. Main results of this study have shown that slightly modified UISAQ can be used on the secondary school population. Additional results have shown that there is a great reason to be concerned about pupils’ risky behavior on the Internet and their low awareness about information security and privacy issues.

I. INTRODUCTION

The importance of knowledge, behavior and awareness about information security and privacy issues among Internet users is firstly recognized among network administrators and security experts. Only later scientists acknowledged that average information system’s user is the weakest link in the information security and privacy chain [1, 2]. Much research was made later on this subject [3-16], but systematic research by using validated questionnaires as the scientific measurement instrument was first made three years ago in Croatia named UISAQ [17, 20] then in the USA named SeBiS [18]. By now only Turkish scientists with their Four Measurements Scales [19] and Australian scientist with HAIS-Q [20] have followed. Main reason for this situation is probably because security experts are mostly technicians or partly managers and are not behavioral scientists. Today research on this subject is usually carried out by a team of scientists covering different scientific areas, both computer science and behavioral science.

The main aim of this study was to adapt existing UISAQ questionnaire for usage among secondary school population and to validate this new version. Secondary school students, teenagers, mainly differ in some basic characteristics like cognitive, social and emotional stage of development from adult population as adults and students. The risky behavior in the teenager population is proven to be on highest level, so existing questionnaire has to be adapted and revalidated on this population.

The secondary aim was to gain some new conclusions based on the preliminary results regarding potentially risky behavior and security awareness among secondary school pupils, by carrying out an empirical study with this new version of UISAQ questionnaire.

II. METHOD

A. Participants

Participants in this study were secondary school pupils (N=355) from three different schools: Trade school, Business and administrative high school and General program secondary school (Gymnasium). In this manner sample is representative and stratified because students were chosen from both high school, three and four year vocational schools.

This work is financed by the Croatian Government Office for Cooperation with NGOs and co-financed by the European Union’s Connecting Europe Facility, under project named “Safer Internet Centre Croatia: Making internet a good and safe place”, Agreement Number: INEA/CEF/ICT/A2015/115320. The sole responsibility of this publication lies with the authors. The European Union is not responsible for any use that may be made of the information contained therein.

Participants in this study were secondary school pupils (N=355) from three different schools: Trade school, Business and administrative high school and General program secondary school (Gymnasium). In this manner sample is representative and stratified because students were chosen from both high school, three and four year vocational schools.
Proportion of male students was 36.3% while proportion of female students was 63.1%. The average age of participants was 16.39 +/- 1.15 (arithmetic mean +/- SD).

B. Procedure

During regular classes students were asked to voluntarily give some general information about themselves (age and gender) and to fill out the UIASAQ. Filling out the questionnaire lasted for approximately 30 minutes. Survey was carried out in all three schools during one week period.

C. Instruments

For the purpose of this research authors used adapted version of UIASAQ [21, 22] for secondary school population. UIASAQ consists of two parts with total of 33 questions. Some questions (k=9) were changed and adjusted for secondary school pupils (i.e. Borrow your personal login data to colleague from work into Borrow your personal login data to friend from your classroom). Adaptation was made with minor changes, as it was important to have a parallel form of UIASAQ questionnaire.

First part of UIASAQ consisted of 17 questions measuring computer users’ potentially risky behavior. Second part of questionnaire consisted of 16 questions measuring the level of user’s information security knowledge and awareness.

III. RESULTS

Using descriptive statistics, factor analysis and reliability analysis authors tested if adjusted version of UIASAQ has good psychometrics characteristics.

For the first part of UIASAQ Confirmatory factor analysis with 3 factors (method principal components, Oblimin rotation) was used. Analyses have shown

</table>
exploration of 37.28% of overall variance. First factor explained 16.07% of overall variance, second factor explained 12.96% of overall variance and third factor explained 8.25% of overall variance. For all 3 factors the saturation (factor loadings) was larger than 0.3 and had exactly the same distribution of questions as the original validated version of UISAQ. The factor structure of the first part of UISAQ is shown in Table 1. Then reliability analysis was done for three subscales (Table 2). All subscales had satisfactory internal consistency (first k=5; Cronbach α=0.63; second k=6; Cronbach α=0.59; third k=6; Cronbach α=0.62), and all questions contributed significantly to good internal consistency which implies that this form of subscale should be kept as final one. Results of sensitivity test of new formed questionnaire are shown in Table 3. All items have full range of response which implies good sensitivity. Distribution of results was not normal (Kolmogorov-Smirnov Statistic was significant for all items), which was expected. For the first and the third subscale means were at lower part of subscale (positive asymmetry) meaning less risky behavior of computer users and for the second subscale means were at higher part of subscale (negative asymmetry) meaning more risky behavior of computer users, e.g. low level of users’ maintenance of personal computer systems.

The Confirmatory factor analysis with 3 factors (method principal components) was also used for the second part of UISAQ, which have shown explanation of 54.02% of overall variance. In Table 4, factor structure of the second part of UISAQ is shown and has exactly the same distribution of questions as the original validated version of UISAQ and a satisfactory factor loadings. First factor explained 19.25% of overall variance, second factor explained 14.07% of overall variance and third factor explained 20.07% of overall variance. Reliability analysis (Table 5) had shown high internal consistency (first k=5; Cronbach α=0.78; second k=6; Cronbach α=0.81; third k=6; Cronbach α=0.80). All items had full range of

* a. p < 0.01
response which implies good sensitivity (Table 6). Distribution of results was not normal (Kolmogorov-Smirnov Statistic was significant for all items), which was expected. Means for level of security in communications and backup importance were at higher part of distribution (negative asymmetry) meaning low level of user’s information security awareness.

Additional results present mean values for each subscale among secondary school pupils on 5-point Likert-type scale where five means excellent from the aspect of information security and privacy (Table 7). In the same table, comparison of tested secondary school pupils with results of adults gathered in the previous study [22] is shown. Statistical significance was found between mean values in all subscales except in the subscale regarding Borrowing Access Data. In comparison to adults, secondary school pupils were worse in subscales regarding Usual behavior, Criticism on security in communications and Importance of backup quality. Examined pupils were better in subscales regarding Personal computer maintenance and Belief into securing data.

Among tested secondary school pupils there were 77.7% of them that had revealed password for currently used e-mail system, which is significantly more than adults. Also only 20.0% of tested pupils had made backup during last month period. While 7.6% said that more than two other persons know their password for currently used e-mail system, 5.7% said the same for their Facebook account. Percentage of pupils that have ever experienced cyber violence is 28.8% while percentage of pupils that behaved cyber violently was 22.9%.

Regarding age there was no statistically significant difference in any of subscales for pupils and regarding gender, there was a statistical difference only in subscale about backup quality (p<0.001; Student T Test). Female pupils are making backup more often than male ones.

Pearson’s correlation coefficients are either “low correlation”, “very low correlation” or even “negligible correlation”, as their value is closer to zero than to positive or negative value one (Table 8). Prominent correlation coefficients, with statistical significance, are found between subscale describing Users’ usual risky behavior and Being violent by doing Internet abuse actions; than between subscale describing Borrowing access data and number of persons that know access data for e-mail or Facebook and being violent or experiencing abuse on the Internet; also between subscale describing Personal computer maintenance and time of making last backup. Subscale describing Importance of backup quality is in low or very low correlation with all five external variables that present controlling questions. Subscale regarding Awareness on security in communications is negative, but very low correlation with external variable measuring being violent on the Internet.

IV. CONCLUSION

Main aim is achieved as results show that modified UISAQ questionnaire has the same structure as version for adults and students, satisfying consistency of subscales and excellent sensitivity. The new adapted parallel form of UISAQ questionnaire can be used to trace development of computer risky behavior and information security knowledge from teenage to adulthood. Also it can be used to compare data about risky behavior and information security knowledge between secondary school pupils and both their teachers and parents who are primarily modeling pupils’ behavior.

Validation results have proven that questionnaire can be used in future research applied on the secondary school

population.

Additional results had shown that percentage of the secondary school pupils that have revealed their password for their e-mail system access is much higher than usual. In comparison to adults, they are worse in subscales regarding Usual behavior, Criticism on security in communications and Importance of backup quality. Secondary school pupils are better in subscales regarding Personal computer maintenance and Belief into securing data. In addition, there is relatively high percentage of young pupils that were cyber victims, and also a certain percentage of young pupils that were cyber violent.

Regarding result on correlation analysis there are some expected conclusions. More risky behavior is in positive correlation with cyber violence, either being violent or being victim. Also, borrowing access data is in positive correlation with higher number of other persons knowing access data for e-mail and Facebook. It is also expected that better PC maintenance is in positive correlation with more often backup making.

It is unexpected positive correlation between high awareness about issues regarding importance of backup quality and all other external variables regarding risky and insecure behavior, measured in number of other persons knowing access data or cyber violence. This finding is similar to some previous findings using UISAQ questionnaire among adults, and may mean that persons who have high level of awareness are acting more careless on the Internet.

Also similar to some previous studies, female users are more careful in their behavior regarding information security and privacy issues.

Results of this study have shown that there is a reason to be concerned about pupils’ risky behavior on the Internet, and this is conclusion regardless of pupils’ gender or age. This information should alert government institutions and school teachers and should result in better education and prevention programs in order to increase safe behavior when online and information security and privacy issues.

Main future work is going to be measurement and definition of norms regarding behavior on the Internet among Croatians by carrying out empirical study using the UISAQ including secondary school population, students and adults. Other future plans are to develop international scientific questionnaire, possibly in collaboration with teams that also have some results on this subject e.g. Australian team and Turkish team.

Abstract - The Semantic Web can be used to enable the interoperability of IoT devices and to annotate their functional and nonfunctional properties, including security and privacy. In this paper, we will show how to use the ontology and JSON-LD to annotate connectivity, security and privacy properties of IoT devices. Out of that, we will present our prototype for a lightweight, secure application level protocol wrapper that ensures communication consistency, secrecy and integrity for low cost IoT devices like the ESP8266 and Photon particle.

Keywords: interoperability, IoT security, Semantic Web, IoT device

I. INTRODUCTION

This paper shows our efforts in creating a method for interoperability for IoT devices and creation of a lightweight communication protocol for cheap MCUs (microcontroller unit), that can be used on almost all devices.

Internet of things potential is still underexploited. One of the main reasons is that there is no interoperability among IoT devices and services, because of many differences among IoT devices and IoT services. Each IoT protocol is suitable for different types of applications, and IoT devices support only a small subset of available IoT protocols. The interoperability problems can be solved or its effects can be reduced by using ontology to semantically annotate things and their services. There are many existing IoT ontologies, but none describes well the connectivity, security and privacy properties of IoT devices, so we have developed and presented here briefly a new ontology. JSON for Linking Data (JSON-LD) is a lightweight Linked Data format that provides a way to help JSON-data interoperate at Web-scale. Ontology and JSON-LD enable us to semantically annotate things and their capabilities, together with the mentioned non-functional properties.

One of the more interesting use-cases for lightweight communication and security is the usage of low cost MCU (Micro Controller Units) like ESP8266 [1] or ESP32. One of the main benefits of those MCUs is their low cost. An ESP8266 board costs about 5 USD at the time this paper is published. With a 32-bit processor, 16 GPIO pins and support for connecting to 802.11 based WiFi networks,

ESP8266 and other MCUs became quickly popular as an important building block in many IoT devices. One of the reasons for their increased popularity is that with classic SDK support for writing applications in C, open source developers started enabling support and started porting languages like MicroPython [2], Lua [3] or Javascript to the ESP8266 and similar cheap MCU’s.

One of the benefits of using high level languages such as MicroPython to develop applications for MCUs is the same reason why high level languages are used in modern software development: rapid prototyping and the use of high level abstractions and libraries enables faster and easier development. Coupled with the advancements in the design and availability of various embedded components like sensors and corresponding libraries that drastically simplify development to the point that a developer needs to correctly connect the sensor and write some glue code to collect data from the sensor, enables software developers to venture into the embedded systems domain, for better or for worse.

The background for development of this protocol is one specific professional implementation we needed to develop. The project required a system that would have the following features:

1. Rapidly prototype a system on ESP8266 platform and MicroPython
2. System contains multiple nodes collecting sensor data and/or communicating with other nodes (mesh network scenario)
3. System must enable data exchange and communication with enhanced security
4. Only some nodes have access to a broker / internet, and the network needs to communicate in a best effort scenario.
5. System should support light and deep sleep states for the MCU
6. Develop security in userspace and don’t rely on any specifics like crypto acceleration from the MCU

Since languages like MicroPython, Lua and others when implemented on MCUs lack some features (like raw packet crafting or support for various low level protocols), we wanted to develop a scheme that we could use on all of our preferred development platforms which would not be restricted to a specific C language only SDK like [4]. Therefore, an application level scheme and approach that
doesn't need low level packet access needed to be devised to fulfill the requirements.

Another of our requirements was to avoid the usage of various protocols such as XBee, ZigBee or LoRA, since those protocols solve the problem of scalable mesh communication, but their price is restrictive if we want to explore the possibilities of using sub 5$ MCUs that have basic 802.11 WiFi networking capability.

II. RELATED WORK

Boman et al. [5] used several sensors to demonstrate sensor networks interconnected with systems like GSN and Firebase. They conclude that having XML to define sensor node and its capabilities, is complicated and they suggest researching for different solutions. Cassar et al. propose a new semantic service for IoT device matchmaking method that is based on probabilistic service matchmaking. They state that their hybrid method can overcome most cases of semantic synonymy in semantic service description [6]. Souza et al. propose vocabulary for IoT service discovery. To identify thing in IoT they propose use of URI (Uniform Resource Identifier) the same way it is used in Web and Semantic web. Syntax of this URI is according to XML standard [7]. They also define WSDL (Web Services Description Language) for IoT device that is accessible using provided URI. URI is used in Event driven SOA (Service Oriented Architecture) [8], a concept defined by Zhang et al. In their work, they focus on IoT as a service (publish and subscribe model), however to achieve that level, IOT device must be identified. To achieve that they use custom XML service description.

Hur et al. identify interoperability as an issue between things and platforms and it is one of major challenges in achieving the vision of the Internet of Things (IoT). They propose concept of SSD (Semantic Service Description) ontology that semantically represent heterogeneous things across various platforms [9]. They use JSON-LD to store semantic metadata. To retrieve such data, they propose use of Web Linking [10] and POWDER describedby property. SSD ontology contains three main concepts: Property, Capability and Server Profile. Each of those is designed to support interoperability between platforms and physical objects. Server Profile defines connectivity for device configuration, for example: HTTP methods, server URI, API keys, etc. It is notable that they assume that IoT device is equipped with full ISO/OSI stack, and Internet connection. All of services rely on TCP/IP protocol.

In their next paper, same authors emphasize use of existing, conventional Web technologies to enable interaction between things. They recognize that each IoT platform may have different data structure, data representation format and APIs. Furthermore, this diversity may cause problems caused by challenging interoperability and data inconsistency. They investigated Automated Deployment, more specific TOSCA (Topology and Orchestration Specification for Cloud Applications) that is designed for describing IT services. TOSCA might be used for service deployment in IoT environments [11]. After that they conducted an experiment with five IoT devices that used their SSD processor that automatically publishes semantic metadata to the Internet. Experiment results showed that their approach can be applied to many IoT devices on various platforms without significant effort.

Nordahl and Magnusson present PON (PalCom Object Notation). It is a lightweight format for data interchange that they developed to be used in IoT applications. PalCom is a middleware JAVA framework that simplifies creation of dynamic networks between devices in IoT environments. PON defines a format for structured data that combines the structure and compactness of JSON with efficient data handling defined by FORTRAN’s string format: <Length><Type><Data> for example; 5sIOTIF. PON is purely textual data format and authors present translation scheme between PON and JSON. They demonstrated successful implementation in healthcare environment where PON is used to communicate with HTTP server that marshals all the devices that communicate with managing Database also using PON. In evaluation phase, they compared PON scheme with JSON, conclusion is that PON is 33% shorter than JSON and 70% faster than Gson (Java implementation) [12]. Ngu et al. have classified different architecture types of IoT middleware, they also analyzed composition, adaptability and security of IoT middleware. They emphasize that IoT service discovery is an issue, and propose non-ontological approach: search engine for heterogeneous IoT device and services: ServiceXplorer [13]. Their engine uses WSDL as service descriptor and searches for similarities in descriptions. They also suggest another non-ontological approach that is based on data analytics of IoT device usage log. After analysis, they try to reconstruct relationships between devices and services. This relationship map help with load balancing between similar IoT devices. Ngu et al. have also analyzed security and privacy issues, and they propose lightweight device authentication that uses low bandwidth and low CPU and other resources. It is based on public key cryptographic techniques like NTRU, ECC and AE. They conclude that IoT middleware needs to be designed with security, privacy and trust in the first place. Those concerns should be propagated throughout all of IoT layers. Also, they state that existing approach: using existing high level concepts is not good and that IoT ecosystem needs a dedicated and from-the-scratch approach.

III. DEVELOPING AN IOT ONTOLOGY

We have developed the open IoT ontology using Ontology Development 101 methodology [14] that answers to the following questions: What are the concepts to describe IoT devices and things as a service? How to support mappings of data types among the heterogeneous things and existing cloud services? There are many IoT ontologies in the current literature, but no one was suitable for our case and our implementation, so we have developed a new open IoT ontology. The existing IoT ontologies are shown in Table 1. The ontology is publicly available at:
As a basis for sensor descriptions in our ontology, we have used concepts defined in the W3C defined Semantic Sensor Network (SSN) ontology [15]. We have also used the actuator concepts from Semantic Actuator Network Ontology developed by Spalazzi et al. [16]. A total of 173 classes were defined that are organized in 20 top level classes (Figure 1). The developed ontology will be used to annotate things. The ontology is richer than any existing IoT ontology, because it contains concepts to annotate privacy, security and supported protocols as non-functional properties of things and their services. Main IoT security problems are listed as subclasses of IoTSecurityProblems OWL class and are derived from OWAPS IoT security guidelines [17]. IoT acceptance factors and service privacy factors are also listed in the ontology, as subclasses of the OWL classes IoTAcceptanceFactors and ServicePrivacyFactors. IoT protocols are defined as subclasses of the following OWL classes: IoTDataProtocols, IoTDiscoveryProtocols, IoTInfrastructureProtocols, and IoTTransportProtocols.

### Table 1: Existing IoT ontologies

**Figure 1**: The main hierarchy of the IoT ontology
IV. SEMANTIC ANNOTATION OF THINGS

Thing will be annotated using concepts from the ontology by means of JSON-LD. JSON-LD [22] is a simple method to add semantics to existing JSON documents. Semantic data is serialized in a way that is often indistinguishable from traditional JSON [18]. “The basic idea of JSON-LD is to create a description of the data in the form of a so-called context. It links objects and their properties in a JSON document to concepts in an ontology. A context can either be directly embedded in a JSON-LD document or put into a separate file and referenced from different documents” [22]. We list one JSON-LD example below:

```json
{
  "@context": "http://www.foi.unizg.hr/ontologies/ThingAsAServiceOntology.owl",
  "@type": "Sensor",
  "name": "TMP36",
  "type": "Analog Temperature Sensor",
}
```

Other interesting related work related to our use case is W3C Member Submission: Web Thing Model [23]. The mentioned document describes a model and API for things (physical objects) that will be connected to the Web of Things. They also recommend use of JSON-LD to support semantic extensions and to semantically describe things. Sample extract of one possible Web Thing model [23]:

```json
{
  "id": "pi",
  "name": "My WoT Raspberry PI",
  "description": "A simple WoT-connected Raspberry PI",
  ...
  "properties": {
    "link": "/properties",
    "title": "List of Properties",
    "resources": {
      "temperature": {
        "name": "Temperature Sensor",
        "description": "An ambient temperature sensor",
        "values": {
          "temp": {
            "name": "Temperature sensor",
            "description": "The temperature in celsius",
            "unit": "celsius",
            "customFields": {
              "gpio": 21
            }
          }
        }
      }
    }
  }
}
```

V. DEVELOPING A PROTOCOL

After developing the possible concept for the interoperability part for our use case, we wanted to develop a protocol that enabled simple and secure communication between multiple MCUs. We started our research by analyzing the lowest set of common features that we have available on popular ESP8266 [1] based MCUs. One of the problems we encountered is that a lot of MCUs and their firmware, where we mean the development scaffolding - bootloader and SDK or the bootloader and the high-level language base implementation on the MCU, don't support ad-hoc or infrastructure mode for 802.11 wireless communication. The only two modes that are usually available are station mode (STA) and Access point mode (AP). Other limitations that we found include:

1. No specific support for multithreading or multiprocessing. The lack of support for multiprocessing or multithreading makes any parallel tasks difficult. There are attempts to implement MT for the last 4 years into Micropython [2], but unfortunately such attempts are mostly unsuccessful and result in very buggy implementations [24]. Where there is one implementation from March 2017 which looks promising [25], [26]. One possible approach was to write a MCU specific task scheduler, like [27] which was scrapped because we wanted a minimal, portable solution that could work without any specific bootloader/language combination or any other low level modifications. There is an available Micropython support for uasyncio [28] but it’s not available on ESP8266 [29]. This was our biggest issue which mostly guided our design. One interesting case is that the 802.11 radio of the device can be in both STA and AP mode at the same time, but can’t parallelize the operation of both modes. The MCU will send 802.11 AP regardless if any other code is running on the device. This is because the 802.11 subsystem has one dedicated MCU core that will handle such low-level communication operations but any other code like userspace code that isn’t in the 802.11 PHY layer must be run on the second core.

2. There is no specific supported implementation for services like multicast DNS, LLDP (Link level discovery protocol), SSDP (Simple Service Discovery Protocol), UPnP or any other. Usually such implementations are way too heavy since most MCUs have limited storage space.

3. Multicast support and reliability depends on the firmware image used. In mixed mode environments, this can be a limitation, but we created a simple bypass to avoid implementing a DHCP like protocol, and still be able to use the default TCP/IP stack. If the desired MCU/Firmware combination supports reliable multicast, multicast is the preferred and simplest way to solve the addressing problem on such point to point connection with least hassle. If not, the WiFi interface on the MCU has an interface MAC address, which is broadcast with the SSID name and other information in AP beacon frames and can be seen by every other STA node in range. The first 3 octets of the MAC address are the organizationally unique identifier, while the last 3 octets are network interface controller (NIC) specific part. Each NIC suffix octet has the decimal value between 0 and 255,
same as an IP octet. This means we can easily map the NIC part to a RFC1918 24 bit private IP address by mapping (10.(NIC0),(NIC1),(NIC2)) and thus creating a set of addresses in the range of 10.0.0.0 to 10.255.255.255 with a /8 (255.0.0.0) netmask, which enables us to calculate and both IP addresses at the time the STA is connecting to the AP without resorting to DHCP. If two nodes have the same NIC suffix, both nodes can identify such a collision by comparing the NIC suffixes of both nodes at the time of connection. The resolution method for this problem is by adding +1 mod 255 to the last octet of the NIC suffix. This eliminates the need to use DHCP in an already constrained environment that only focuses on a point to point configuration at a single time.

To facilitate the protocol each node (N) needs to be pre-programmed with some information. One interesting piece of research is from [30] called “Flashing displays: user-friendly solution for bootstrapping secure associations between multiple constrained wireless devices.” which shows we can use a cell phone or other device to securely program and key a device with only an added photodiode to the device. Each node has to contain the following information:

1. MeshID - A random 16 character Base58 string. MeshID is used to identify the mesh network. All nodes that want to communicate need to share the same MeshID. The AP interface SSID of the MCU is set to the value of MeshID and the network is set to Hidden. The reason of hiding the SSID name is not for security reasons, but just to remove the network name from a casual observer (like someone connecting to a normal wifi network).

2. MeshPW - A WPA2 pre-shared key, all nodes need to share the same key in order to connect to each other, ideally at least a 24 to 63 character random Base58 string.

3. ListenInterval - A pair of two values [LiMin, LiMax] defining the lowest and highest time a node will spend serving data.

4. TransmitInterval - A pair of two values [TiMin, TiMax] defining the lowest and highest time a node will spend trying to receive data.

5. Any cryptographic material used for secure communication phases.

Both values ListenInterval and TransmitInterval need to be chosen to account for several characteristics. Depending on the needed communication and data transfer frequency between nodes. For instance, one sensor network needs to send the measurement data to the broker twice daily, while a requirement for another network might be that the data is transmitted approximately every 30 minutes.

It depends on the system and sleep states (modem, low clock, light or deep sleep). In the case that light sleep or deep sleep states are used, all phases of the protocol need to be synchronized in all nodes of the network. Usually by selecting a time interval when the communication will occur. This requires an RTC + battery and code for timekeeping. The needed time for the data exchange which usually needs to account for:

- The time needed for the MCU to discover and for the STA to connect to the AP (other MCU)
- The time needed for the data transfer to be initiated
- The amount of data that needs to be transferred over a low bandwidth channel.

When using the ListenInterval or TransmitInterval, each node stays in the listen or transmit state for a random time that won’t be lower than the minimum bound or greater than the maximum bound. The reason for this choice is trying to remove possible overlaps where two nodes are in the same state at the same time and never exchange data. Our scheme tries to create a simple mesh based communication protocol with the following three main phases:

1. Node discovery and communication:
   a. Each node tries to discover other nodes sharing the same MeshID (SSID).
   b. For each discovered node with the same MeshID add the BSSID values of the node to a table (SeenIDs) sorted by RSSI.
   c. Each node also keeps the track of all seen nodes in a LastSeen table.

2. Data transfer between nodes:
   a. Data is exchanged with the help of an embedded web server running on the MCU. Communication is done with the help of a RESTful service since json encoding/decoding, HTTP requests and a simple HTTP server is available in the standard library for most implementations of alternate firmware on MCUs.

3. Processing phase:
   a. Arbitrary data processing phase like collecting data from sensors, processing data or running any other arbitrary code.

Protocol description:
The protocol can be described with the following pseudocode. Each node in the network runs the following algorithm:

Run the network discovery phase
Randomly pick if the node will be an AP or STA
if STA mode:
   Stay in STA mode for a random time between TransmitInterval if there is an available AP in SeenIDs:
      Try to connect to AP, if connected, access the webserver on the other node
      Remove AP from SeenIDs table
      Update the LastSeen table
else:
   Run network discovery phase
   Try to connect to any other device
if AP mode:
   Stay in AP mode for a random value inside ReceiveInterval
   Enable the local webserver and accept connections

The core logic behind this method is that in a long enough timeframe every pair of nodes will stay in both AP and STA mode and at some time. The random intervals are
used to make sure that each two nodes can't overlap enough to miss connecting to each other. This enables the system to converge on a long enough timeframe.

**Protocol security**

The network security part of the system is reduced down to the security of the WPA2 protocol implemented in the MCUs and the strength of the WPA2 passphrase. The problem with WPA2 connections is that each MCU and firmware stack is implementing the WiFi security protocols on its specific way and isn't reusing a common security library like wpa_supplicant, so an audit of security protocol implementations for common MCU/firmware pairings might be interesting future research path for a professional paper. The current state of SSL/TLS implementations in MCUs is not in a stable phase and since getting TLS right is hard even in standard systems as we can see with the numerous problems of vulnerabilities in standard, wide use libraries like OpenSSL [31], the whole security of the TLS stacks in embedded MCUs is questionable. The integrity and security of communications in reduced to the security of WPA2, and we can't guarantee reliable communications in such lightweight system. One problem is always present in IoT components: what if an attacker obtains physical access to a device, for example if an attacker steals one sensor node or one device? Such an option opens a large attack surface for an attacker to exploit and enables a large number of attacks that can lead to full compromise of the device [32]. In our approach, we tried to set a tradeoff between known security, and ease of implementation. If additional amount of communications security is needed, approaches such as [13], [33] and others can be used on top of our implementation.

VI. CONCLUSION

In this paper, we have explored some possibilities for interoperability and communication between cheap IoT devices. We have developed an open IoT ontology richer than any existing IoT ontology, because it contains concepts to annotate privacy, security and supported protocols as non-functional properties of things and their services. To semantically annotate things using concepts from defined ontology, we propose usage of JSON-LD to extend the Web Thing model [19]. In this way, we can semantically annotate things, their services, and their functional and non-functional properties. Next, we have presented a use-case for lightweight communication and security of low cost MCUs (MicroController Units). Additionally, the lightweight communication protocol for cheap MCUs that can be used on almost all devices, was developed in this work. We plan to further work on IoT security and interoperability problems. Specifically, we plan to use and extend our ontology, semantic annotations approach, and lightweight communication protocol in a number of use cases and on different devices (things).

Abstract—Internet of Things (IoT) can support numerous applications and services in various domains, such as smart cities and smart homes. IoT smart objects interact with other components e.g., proxies, mobile devices, and data collectors, for management, data sharing and other activities in the context of the provided service. Though such components contribute to address various societal challenges and provide new advanced services for users, their limited processing capabilities make them vulnerable to well-known security and privacy threats. Until now various research works have studied security and privacy in IoT, validating this claim. However, to the best of our knowledge literature lacks research focusing on security and privacy flaws introduced in IoT through interactions among different devices supporting a smart home architecture. In particular, we set up the scene for a security and privacy threat analysis for a typical smart home architecture using off the shelf components. To do so, we employ a smart home IoT architecture that enables users to interact with it through various devices that support smart house management, and we analyze different scenarios to identify possible security and privacy issues for users.

I. INTRODUCTION

The development of new type of sensors and actuators combined with the deployment of increasingly powerful and pervasive network connectivities is shaping the concept of the Internet of Things (IoT). Several factors are contributing to the evolution of the current Internet into IoT including the lower market price of IoT devices and the higher demand of customers for new services.

Manufactures are now able to provide mobile, wearable or embedded devices with more memory, processing power, and more diverse sensing technology. As a consequence, this increased capability of IoT devices also increases the amount of data available to services and their value to end users. However, even if IoT is capable of supporting new business models, increasing the efficiency of many applications, and enriching the life of citizens with new services, the risks are also significantly higher. The collection of even larger amount of data and merging of the cyber and physical world implies a higher number of privacy and safety issues than the cyber-only Internet.

More specifically our focus in this paper is on a Smart Home scenario. In this scenario, the potential for privacy breaches is limited if we consider the direct and explicit collection of data regarding the individuals living in the house. However, the activities of these individuals can be indirectly tracked through the observation of the cyber and physical activities of their connected domestic devices, assisted living systems, or smart meters. The protection of privacy in these complex scenarios where different entities and IoT technologies coexist and work together requires new approaches and solutions. Even if various Privacy Enabling Technologies (PET) have been proposed in literature, their market adoption is still relatively weak and many concrete threats still persist.

In this paper we set up the scene for a security and privacy threat analysis for a typical smart home architecture that relies on existing and readily available market IoT devices and platforms. In contrast to existing security and threat analysis of IoT scenarios, we target a real IoT smart home environment deployed in our testbed focusing on the interactions among the different IoT components. In this architecture, we identify points of interest that an adversary might manipulate either to gain access to unauthorized information or to cause a denial of service. Our contribution, in addition to a concrete threat analysis, is a practical feasibility evaluation of the identified vulnerabilities showing how exploits can be implemented in practice.

The rest of the paper is structured as follows. In Section II we overview a smart home’s architecture and in Section III we analyse its threat model. In Section IV we study the realization of the threat model in a test-bed architecture, and analyze possible consequences to end-users in terms of security and privacy. In Section V we provide guidelines and protection measures for eliminating the threats presence, while in Section VI we overview the related work. Finally, in Section VII we conclude this paper and present some pointers for future work.

II. IoT BASED SMART HOME ARCHITECTURE

Smart home can be defined as the symbiosis of different elements i.e., sensors, connections, and applications that build a dynamic heterogeneous architecture with the aim of efficiently managing home devices, and providing to users advanced services.

Due to a still missing generic interoperability standard among IoT devices, in this architecture, without loss of generality, the IoT devices organised in islands are connected to a corresponding hub and are not directly accessed by other devices. Moreover, the majority of commercial sensors do not provide direct Internet connectivity; instead the intermediate
hub is the component responsible of providing such connectivity.

The communication between the IoT devices and the hub is usually wireless, based on different protocols depending on the device’s manufacturer. The most popular are:

- Zigbee\(^1\); 
- Z-wave\(^2\).

The hub is then connected to the smart home’s router either via an Ethernet or a Wi-Fi interface, depending on its capabilities in order to connect the IoT devices with the outside world.

Users can interact with IoT devices and manage their smart home through different platforms such as PCs, smart phones, and tablets. The interaction modalities are in general two:

1) directly interacting with them using the connectivity and services provided by the hub; 
2) accessing Internet cloud services which interact with the IoT hub and the connected IoT devices.

These two scenarios are quite often present at the same time and mixed together to support local and remote interactions with IoT objects. In case of remote management all the information is forwarded to the smart hub through the cloud service, while if the user is acting from the same network where the smart hub is installed the traffic is routed directly to it and thus no Internet access is needed.

However, in order for users to enable IoT devices management, regardless of their location, they must first follow a procedure for correlating their devices with the corresponding hub. In most cases, for an off the shelf based solution to successfully complete this procedure user’s physical action is involved, e.g., pressing a button on the smart hub.

Furthermore, IoT manufacturers support protocols such as the Simple Service Discovery Protocol (SSDP) [1] to enable the transparent configuration of the smart home devices in a plug and play mode that requires minimum user interactions. In this case, the smart hub generates a presence announcement to the multicast channel, i.e. the default IoT devices’ gateway. Any device that searches for available services sends to the multicast channel a discovery request and receives as a response the available requested services. Then the device can communicate directly with the newly discovered services. This procedure is illustrated in Figure 2.

So consider an example in which a user would like to control the smart home’s lights status using his mobile phone, while he is outside the home. To do so, firstly he must have already successfully completed the correlation procedure, otherwise it is not possible to have remote access to the smart home’s devices. Once setup, he can launch the mobile application and request the lights’ status. This request reaches the cloud service which forwards it on behalf of the user to the hub that is responsible for controlling the lights, using a reverse communication channel kept open, through the house router, by the hub itself. As soon as the hub receives such a request, it sends the corresponding command, i.e., status, to the lights in order to receive back their response, and forwards it to the user via the cloud service. All the interactions between the different components of a smart home are illustrated in Figure 1.

III. SMART HOME THREAT MODEL

The formulation of a smart home’s cyber threat model should consider two types of adversaries; internal and external entities that can act maliciously on a passive or an active way depending on their goal. On one hand, the former category consists of malicious entities that are located close or inside the smart home’s premises. On the other hand, external adversaries can interact only through an Internet connection. In both cases adversaries target either the smart home’s infrastructure, or the information stored in the related cloud services. Note that in this work we do not consider adversaries having physical access to IoT components. This is because, cybersphere entities have only virtual access to the components of a provided service.

In this context, similar to any other IP based service, adversaries acting passively will try to eavesdrop available communications in order to acquire information that can either be used to monitor users’ behaviour or can be accumulated and exploited in a later step of an active attack. Adversaries, to access this type of information, will try to capture the traffic in different points of the smart home architecture depending on their capabilities and goals. In this way, adversaries could impact users’ confidentiality and privacy as they can collect information related to the smart home’s status. For instance,

\(^1\)http://www.zigbee.org/
\(^2\)http://www.z-wave.com/
taking as example the architecture shown in Figure 1, if the adversary monitors the communication link (1) between the smart hub and the router in the smart house premises, he could identify which entities the smart hub communicates with, while if he monitors the communication link (4) he can deduce the users daily habits e.g., when the lights turn on and off that might correspond to user’s absence from home.

On the other side, an active adversary will interact actively with the IoT components, instead of only eavesdropping the underlying communication. He could identify the existence of components by generating the appropriate probes through different network devices. Moreover, the adversary could try to impersonate a legitimate user in order to gain access to the smart home devices. Then he could be able to control them, use them or even extract sensitive information from them. An active adversary could impact not only users privacy and the provided service’s confidentiality but also affect data integrity, gain unauthorized access and ultimately disrupt the proper function of provided services.

Obviously in more complex scenarios an adversary could combine a passive and active attack. Consider, for instance the case where a smart socket provides electricity to a health device. If the adversary knows its unique identifiers by eavesdropping the communication traffic, he could cause a denial of service to the IoT that could have an immediate impact on the users safety. For that reason this type of information should be considered of high importance.

Besides the passive and active network layer threats, software exploitation is another aspect that an active adversary will capitalize in order to gain access to otherwise private domains. This is because, IoT relies on light weight versions of well known operating systems that adversaries look to exploit with very few resources. Moreover, most of the largely used IoT devices have a corresponding mobile application that acts as a controller. The mobile application’s execution environment could be used as an attack vector for an adversary as he could be in position to exploit well-known software vulnerabilities of the underlying operating system.

Table I overviews the threats and the possible consequences that they can have to a smart home’s infrastructure.

### IV. IOT BASED SMART HOME CYBER-FLAWS

To study the feasibility of the generic threats reported in Section III we deployed a test-bed architecture similar to the one illustrated in Figure 1. This architecture is based on commercial products that provide connectivity to IoT sensors through a smart hub that is connected to a network and to the Internet via a traditional wireless router. Specifically, a computer (A) supported with a WiFi network card and Internet connection is configured as the access point to which the mobile device with the IoT management apps is connected to. In a second computer (B), which is connected to computer’s A WiFi for having Internet, the IoT device or Hub (depending on the device type) is attached. This way, computer A monitors the traffic shown in point 3 and 4 of Figure 1, while computer B monitors the traffic of point 2. By running wireshark on both computers we are able to capture all packets passing through the specific points.

As our goal is to illustrate the security and privacy issues of IoT in general, and not to criticize a specific product, we do not provide any related information for it. Note that, as we are interested in studying the interaction between the different components, we assume that a powerful adversary [2] can get access to the underlying communication e.g., by exploiting a specific device or protocol vulnerability, using default or common WiFi and router passwords, cracking insecure passwords, social engineering, etc., however, such an analysis is out of scope of this work.

In the following subsections we discuss the implementation of the threats described in Section III considering information that we gather from our test-bed architecture as well as other related research reports.

#### A. Eavesdropping

An adversary might use different tools and techniques for capturing the traffic among the different components of an IoT based smart home infrastructure, considering its heterogeneous architecture. These techniques are highly related with the attacker’s location and capabilities.

If the attacker manages to connect to smart home network components, e.g., adsl router, he is able to capture all the traffic between the smart hub and the local or the remote users; that corresponds to reference points 2, 3 and 4 of Figure 1. In that case the adversary relies on well known tools such as tcpdump3, wireshark4, etc., to gain access to the data. In case the communication is wireless, the adversary might use specific hardware equipment, for instance the WiFi Pineapple5, that can spoof access points and intercept the underlying communication; this corresponds to reference points 1, 2, 4 of Figure 1.

So taking into consideration an adversary that intercepts the traffic among the reference points 1,2 and 3, he can identify:

1) whether or not the smart hub communicates with a cloud supported service e.g., (cloud.iot.com:80)
2) the user device’s type (e.g., Linux, Android 7.1.1; Nexus 5X Build/NMF26F)
3) unique identifiers for user’s access to the smart hub services
4) the device’s status through traffic analysis
5) the smart hub’s operating system (e.g., unix like OS)
6) methods that can be used to send commands to the smart hub (e.g., POST, GET, DELETE, etc.)

Listing 1 illustrates the example of an eavesdropped message during a smart hub service announcement in the local network. In this case the adversary can deduce the operating system that the smart hub runs, its IP address, and its unique ID. In this point it should be mentioned that this information might be slightly changed depending on the IoT manufacturer.

B. Impersonation

An adversary could try to impersonate and act on behalf of a legitimate user. To do so, he requires either access to users’ credentials or to any other information that provide access to the IoT resources. The former case is used in IoT architectures requiring access to the IoT devices remotely, while the latter is normally used to access the IoT resources from the local network (an example of key information needed in this case is for instance the unique identifier that the smart hub generates during device registration for enabling local access). Note that the smart hub often recognizes the location of the user based on his IP address. So if the adversary captures such a message, he can impersonate the user and can consequently interact with the smart hub on behalf of the user. This can be achieved by simply crafting the appropriate request towards the smart hub’s resources with the appropriate parameters, e.g.,

\[\text{http://ip-address/api/unique-id/rsrc}\]

Recall that the adversary can intercept the unique identifier during an eavesdropping attack. In this category we also classify replay attacks as the adversary reuses previous requests either towards the hub or the cloud based service so that the user does not have the proper information about the status of his devices. Though this type of attack assumes that the adversary acts on the same network that the smart hub belongs to, it introduces a vulnerability in the smart home architecture in case that the adversary can reach the smart home router from outside world.

C. DoS

Similarly, to other IP based services, the adversary using different techniques might try to cause a Denial of Service (DoS) either to the hub or to the sensors themselves. As the adversary knows the smart hub’s IP through eavesdropping, he can easily launch a single DoS or a Distributed DoS (DDoS) attack against it by simply sending numerous requests to it. Note that as IoT devices rely on low capabilities processing hardware they are susceptible to low rate DoS [3] as well.

Alternatively, the adversary might try to craft specific messages e.g., malformed messages, so that the provided service cannot process them properly and cause either a DoS or provide unauthorized access.

DoS can also take place directly at the IoT devices, without passing through the smart hub. An adversary having the appropriate hardware that enables him to use the IoT devices’ protocols can send directly messages to them and attempt to interfere with their proper functioning.

Finally, a DoS attack can also take place at the router or the cloud service. This may be a general attack, not linked to IoT, but the consequences for the end user would be the same. Without a working router or a could service, he will not be able to access his smart home’s IoT devices through the Internet.

D. Software exploitation

Malicious software (malware) can affect the IoT services and devices. As IoT devices run autonomously light weight versions of well known operating systems adversaries will search for software vulnerabilities and exploit them to gain access to otherwise private information.

However, currently IoT is becoming an attack target for executing DoS in order to increase the amplification factor of the generated traffic to break down a target. For instance, IoT devices have been exploited for launching a DoS attack [4] against DNS servers in order to paralyze Internet access. In such cases the adversaries exploit the fact that these devices are running over the Internet with default configurations, e.g., default passwords, while most of these devices are not patched in most of the cases against security flaws.

The malware can reach the IoT devices through different channels:

1) Device Acquisition: When the device is bought by an end user there is a risk of buying malware infected devices. For instance, an adversary could purchase many new devices, infect them, and sell them to users through online auction sites (e.g., eBay)\(^6\).

2) Firmware Upgrade and Trusted Boot: Orthogonal to device infection during acquisition, adversaries might be able to upgrade IoT firmware with a malicious acting version. For instance, this was a channel that adversaries exploited in the case of Mirai malware [5].

3) Apps and services: Users control their IoT devices through corresponding applications and online services. Lately, the most common way to manage one’s devices is to use a mobile application on the user’s mobile device. Almost all manufacturers provide such applications that can be downloaded directly from the mobile operating system’s application market. Since these applications are executed on the user’s personal device, they can be infected by malware that is already present on the device, or exploited directly by an adversary that takes advantage of either the mobile application’s or the operating system’s vulnerabilities.

Moreover, several IoT manufacturers assume that they can delegate security on the smart home’s underlying architecture, such as the router’s firewall. However, this assumption should not be taken for granted. As Sivaraman et al. demonstrate with their work [6], the security measures deployed at one’s

\(^6\)http://www.ebay.com/
smart home could easily be bypassed with a malware mobile application.

Similarly to mobile applications, online services that interact directly with the smart hub could pose a weak point in the IoT architecture chain. If one manages to access them through standard web services attack methods, he could then easily manipulate all connected IoT devices.

V. Discussion

Considering the above mentioned discussion in current smart home architectures, adversaries can gain access to underlying infrastructure and exploit it. As a result, smart homes should deal with security “flaws” in the same manner other IP based services with advanced resources do.

So in the case of smart home, adversaries can eavesdrop the underlying communication and extract different information due to the lack of an end-to-end encryption between the different components of IoT. This is also a flaw for the existing protocols that IoT builds on; for instance, the SSDP protocol does not use any encryption and thus the adversary could exploit this fact and identify available smart hubs and their capabilities.

Furthermore, the current access control approaches that smart home deployments follow, e.g., generating unique identifiers during correlation of user’s device with the smart hub, expose IoT services to impersonation attacks as the adversary can eavesdrop the unique identifier, and use it for future attack attempts. However, these types of attacks can be mitigated if the appropriate integrity and authentication mechanisms are deployed.

Protection against DoS and their distributed counterpart (DDoS) is a challenging task especially for IoT architecture considering its limited capabilities, while currently we even lack effective solutions for IP based services that are supported by high power security infrastructures. To the best of our knowledge, only research related solutions such as [7] have been proposed for the protection of IoT against DoS attacks. However, such approaches do not focus on the application layer, but are mainly dealing with network layer protection.

As the majority of low cost IoT manufacturers do not usually consider mechanisms for validating firmware integrity during installations, upgrades and on execution, for instance using a trusted boot, IoT devices are exposed to possible software flaws. To eliminate software exploitation users should also use applications and services provided through well known channels, as unknown third party applications can manipulate the existing infrastructure introducing backdoors for future attacks.

One major issue is the possibility to deploy IoT installations using the default configurations. As explained in the previous section this is what made the DNS attack [4] possible. A recommendation in this could be to force users to properly configure the devices, otherwise the services cannot be started (i.e., routers cannot have ports open by default, remote login can be enabled only if you set a strong password, IoT services can be started and accessed only if a good password was set.) Next to this, for what concerns wireless communications, open connections should not come as default configuration, the router can be started only if the default password was changed, vulnerable protocols should be deprecated and removed from configuration options.

VI. Related Work

Jacobsson et al. in [8], [9] presents the results of a risk analysis of a smart home automation system developed in a research project involving leading industrial actors. Their architecture was identical to the one discussed in this paper including sensors/devices, in-house gateway, cloud server, mobile devices and apps. The risk analysis was performed during collaborative workshop sessions with nine persons including security experts, domain experts, and smart home system developers. The discussion was organized using an open information security risk assessment questionnaire used to reason, identify, analyze, and evaluate threats. The identified threats were linked to the respective system vulnerabilities and the corresponding probability, likeliness of occurrence, and potential impact associated with each threat was estimated by each participant using a five level scale (1-5) from unlikely/negligible to likely/disastrous. The risk analysis results were organized in five categories relating to: software, hardware, information, communication, and human-related risks. The higher ranking risks in each category were related respectively to the software security in apps and APIs, inadequate physical security, inadequate access control policy/mechanisms, inadequate authentication and confidentiality, and poor password management. The results of their risk analysis are presented in a high-level and are in-line with our findings in this paper. Furthermore, in their work the a main observation was the need of empirically based methods that support the evaluation of risks in smart home environments, which is precisely the focus of this paper.

Kozlov et al. in [10] describe a threat analysis for an overall IoT architecture including security, privacy, and trust issues. Their threat analysis is mostly a high-level selection of threats discussed in the literature considering many scenarios and application domains (e.g., smart home, road transportation, smart energy meters, and mobile apps). The scenarios discussed illustrate threats to personal data privacy, availability, and also safety, for example, when an exploited vulnerability in a road traffic system could cause an accident. In contrast to their work, the analysis performed in this paper is more concrete with respect to the threats and vulnerabilities identified, and is also focused specifically on a deployed smart home scenario. We show not only the high-level issues but also demonstrate how they can be realized by attackers in real IoT devices.

Perera et al. propose in [11] a privacy-by-design framework for assessing IoT applications and platforms, which is proposed as a systematic method to guide privacy analysis and design in IoT based on a set of 30 guidelines. Each guideline should be applied during different phases of the data lifecycle including consent and data acquisition, data pre-processing, data processing and analysis, data storage, and data redistribution. The major privacy risks addressed by the guidelines are unauthorized access and secondary usage of information, meaning the use of already collected data for purposes not initially allowed by the data owners. The authors show the application of their framework in two open source IoT middleware platforms: OpenIoT and Eclipse SmartHome. For each
middleware a table was constructed showing if the guideline is supported, extendible, or not supported considering each of the phases in the data lifecycle. An extendible support means the middleware provides a plug-in mechanism that could make it straightforward to implement the functionality. By comparing the support for each guideline it is possible to compare the middleware with respect to their privacy-by-design features and gaps; in a sense more compliance to the guidelines implies a lower privacy risk. In contrast to the technical contributions in this paper the proposed guidelines are more abstract (e.g., data anonymization, encryption, etc.) and can be mapped to the threats and vulnerabilities detailed in this paper.

Ziegeldorf et al. in [12] classify and examine RFID privacy threats in a broad sense with the goal of presenting relevant challenges that should be overcome in future deployments. In their reference model, they consider the collection of information by devices in the user environment, the processing and dissemination of the information by services that exploit the RFID technology. In their analysis they list the main threats to privacy, namely: identification, localization, tracking, profiling, privacy-violating interaction and presentation, decommissioning of devices, inventory attacks, and linkage of RFID related components. As a result of their analysis profiling is considered the most severe threat. In contrast to our approach this work focuses on RFID based IoT systems, while we concentrate on smart home components threat analysis.

VII. CONCLUSIONS & FUTURE WORK

IoT architectures will be an important component of future Internet as it closes the gap between physical and virtual objects. Among others, smart home is one of the main developments of IoT environments as it enhances the user’s experience when using home devices.

Albeit the advantages that IoT offers to smart home users do not only expose homes to well known attacks but also the (IoT) sensors should deal with flaws that have not been previously considered. This is due to the fact that such devices are of limited processing power, and rely on heterogeneous network architectures that increase the attack surface of the provided service.

In this paper, we introduced a smart home threat model, and analysed it in our test bed architecture considering off the shelf components. Our initial analysis demonstrates that existing smart home IoT infrastructure could be vulnerable to eavesdropping, impersonation, DoS and software exploitation attack vectors under specific conditions e.g., considering an attacker that manages to get access to the underlying network.

Currently, we are planning to extend our analysis demonstrating in detail the consequences and the impact of the different threats on users and the IoT infrastructure, as well as introduce the appropriate countermeasures for enhancing smart home security. In this direction, we envisage a framework that is able to automatically identify vulnerable points in a smart home architecture.

Abstract - Although the importance of information security in everyday’s business and private life is obvious, there is a constant increase in number of security breaches. A wide array of all kinds of issues have either direct or indirect impact on the overall information security and privacy level.

The aim of this work is to collect and describe these issues in a standard manner. For this purpose, a taxonomy modeling was used, since it is a commonly used technique for classification.

Building taxonomy scheme means classifying elements on some subject with parent-child relations between entities. After defining main parent node as the Overall Information Security and Privacy, its main child nodes are defined to represent main subareas in the scheme: Network Protection, Software Protection, Physical Protection, Security Procedures, Web Site, System's Paper Elements, Security Legislations and Users' Influence. Each subarea is further divided into smaller information security and privacy subareas, and further into even smaller subareas, until it was no longer possible to divide.

This taxonomy can be used as a basis for security ontology and various analytical and decision support systems used for security evaluation and risk assessment.

I. INTRODUCTION

Today, there is no special need to highlight the importance of information security in everyday’s business processes and private life. Value of the information in today’s world is becoming higher than the value of time and even money, since the important piece of information can save time and bring profit. Generally, a wide range of all kinds of issues have either direct or indirect impact on the overall level of information security and privacy (IS&P) and cause constant increase of number of security breaches.

Most of the actual information security and privacy projects do not include all possible segments of information security, but are focused on one or several security segments, e.g. only privacy, or only password quality [1]. Conceptually, they are more often organizationally than technically oriented. So, there is a need for integration of separate security areas in the overall security solutions and new information security and privacy tools. Those new solutions should combine risk management, infrastructure safety, hardware solutions, security protocols and especially users' education and control [2].

Taxonomies of security concepts and security ontologies are common methods for modeling and sharing knowledge on information security and privacy. Although OWL (W3C Web Ontology Language) based ontology is more often used to describe information security concepts and protocols than taxonomy, former is simpler, has wider range of usage, is more flexible in modeling and is easier for humans to read [3].

Existing security ontologies and security taxonomies found in literature lack generalization. Each rare overall taxonomy on information security and privacy have different aim and scope than IS&P Taxonomy or they are rather old [3-5].

Development of overall information security and privacy taxonomy is based on previous work [6, 7] and on cooperation with other security experts. Different security standards like ISO 27000 family; security analysis tools like CORAS method, GIS Tool, EBIOS methodology and COBIT method; and different security recommendations published by international and national security offices like ENISA, ANSI, BSI, CSEC are also included as basis for taxonomy modeling.

The aim of this work was to collect and describe a wide range of security and privacy issues in standard manner, from perspective of both ICT security technicians

This work is financed by the Croatian Government Office for Cooperation with NGOs and co-financed by the European Union’s Connecting Europe Facility, under project named “Safer Internet Centre Croatia: Making internet a good and safe place”, Agreement Number: INEA/CEF/ICT/2015/115520

The sole responsibility of this publication lies with the authors. The European Union is not responsible for any use that may be made of the information contained therein.

1514
and security consultants and managers, by using taxonomy modeling procedure. This work is still at its beginnings and security taxonomy is conceived as ever-changing model. The security taxonomy model should be basis for different security ontologies and various analytical decision support systems.

II. IS&P TAXONOMY

Constructing taxonomic scheme is commonly used technique of classification modeling by classifying elements on some subject of interest. It is not general requirement for taxonomy to have hierarchical structure, but in this work it is defined in order to meet requirements for future work. So taxonomy as knowledge scheme in the area of information technology should be defined with entities and corresponding parent-child relations among them. The hierarchical tree structure starts with main parent node named “Overall Information Security and Privacy”.

In the (current) IS&P Taxonomy main parent node has eight child nodes presenting main information security and privacy elements in the scheme. They define eight main subareas on the first level of structure complexity (Fig.1). Further steps in modeling taxonomy are defining child nodes of those eight parent nodes at the second level of complexity. Eight child nodes of first level of complexity are now parent nodes for the second level of complexity. This modeling steps were applied until the smallest elements in the scheme were defined as ending child nodes in the hierarchical tree structure. Current version of the IS&P Taxonomy has four levels of complexity in depth.
Four of eight main subareas that have most of the constructing elements are presented in the separate and more detailed schemes. They can be used as a sort of sub-taxonomies and are named as follows: “Network Protection” (Fig.2), “Security Procedures” (Fig.3) “Physical Protection” (Fig.4), and “Web Site Protection” (Fig.5).

The “Network Protection” sub-taxonomy describes all the hardware elements with belonging software that can be used to build network infrastructure. It encompasses administration with previous configuration of network hardware; functionality and optimization regarding business needs; and usage of network infrastructure with compliance towards system requirements (Fig.2).

Second main sub-taxonomy named “Security Procedures” covers all the security procedures and protocols that should be defined in every company’s IS&P documents (Fig.3).

The “Physical Protection” sub-taxonomy covers all kind of possible methods of physical protection regarding data and ICT system’s elements, both hardware and software. Physical protection encompasses hardware equipment that is not necessary computational, software
As it was more important to cover all considered security issues and ICT system’s elements there are partial overlaps between sub-taxonomies, but it is not considered as problem in the proposed solution. When using this taxonomy for e.g. security evaluation, it is probably better to double-check than to omit some important security and privacy issue.

### III. Conclusion

The proposed information security and privacy taxonomy is the first proposal and should be considered as a live construct. It will be further developed in the future, along with new issues that may, and surely will, arise.

Main information security and privacy areas that are covered with this taxonomy are: network protection, software protection, overall backup quality, physical protection, security protocols including employees’ influence, system’s paper elements protection, legislative and legal regulations and web site protection.

Presented IS&P Taxonomy can be used as basis for security ontology and all kinds of analytical and decision support systems used for security evaluation and risk assessment. Plans for future work are to validate this taxonomy and to develop the decision support system as information security and privacy self-assessment software tool based on taxonomy presented in this work.

### Literature

Trends in IoT Security

Abstract – The incredible rapid development of internet technologies, primarily thanks to omnipresent access of high speed broadband internet access and supporting technologies like Big Data, Cloud Computing, REST/Web services as well as cheap electronic equipment that use new wireless communications standards, lead to equal rapid growth of number of smart devices – “things” - connected to the internet. Increased number of connected smart devices results with huge daily data traffic on the internet and data volume stored and available on the internet. IoT becomes part of our homes and our companies, and security in these systems is very important. What does that outlook hold for the next 5, 10 or 20 years, will mostly depend on the development of security standards, user behavior and education in a next few years. This paper is trying to summary and analyze trends in IoT standards regarding security.

Keywords - Internet of Things (IoT); Cybersecurity; SCADA;

I. INTRODUCTION

Each new technology potentially involves some risks. The worst of which are security threats. This is especially the case with a fast-growing technology where it is difficult to predict all possible risks involved. On the other hand, the number of skilled malignant hackers, highly motivated to abuse new technology inadequacies is rising.

Quoting Kevin Ashton, the probable author of the term “Internet of Things” [1], from 1999, the size of the Internet in 1999 was about 50 petabytes of data, and the prediction for 2020 is that the size of the Internet will be about 40 zettabytes of data.

Although the industrial giants are for security reasons very conservative with beginning to utilize new things, IoT is already there. Smart devices are everywhere around – smart wearable, smart medical devices, smart homes, smart buildings, smart cars, smart cities, smart grids, smart agriculture and many other aspects of life [2] (see Fig. 1). The challenge grows further as IoT devices have the option to control important industry infrastructure. This will certainly increase society exposure to cyberthreats. In today's approximations, the damage from cybercrime is assessed at about 400 billion dollars per year.

The smart future has already arrived. Are we ready for it? Do we behave responsibly in order to have all around us “smart”? Is it smart to be surrounded with smart things, can we be sure that our privacy is not compromised? These smart devices are smarter and smaller, but are they reliable and secure enough? Especially when we know that parts of IoT have not been well defined and designed, or still use parts of old architecture from “wired” era.

The main aim of this paper is to summarize the current state of security trends in IoT technologies and to analyze what needs to be considered to shape the security standards for the new generation of connected systems.

This paper is organized as follows: Section II gives a short timeline of IoT, the present state and predictions for the future. Section III shows security and privacy trends in the development of IoT and new protocols which cover these trends, and Section IV impact of IoT to industrial security. Section V gives a conclusion of the paper.

II. HISTORY, PRESENT AND FUTURE OF IoT

At the beginning of computer era (1950’s until late 1970’s), there were dominant mainframe computers with terminal-server architecture. During 1980’s, the computer market takes over minicomputers and personal computers. 1990’s comes internet era, first with analog modems (2400, 9600, 14400, 28800 bps) through analog telephone wire, then from 2000’s with a digital connection (ISDN, DSL, VDSL) and finally with the broadband and wireless internet connectivity. Late 1990’s comes mobile era, and a few years later, in the third millennium, the mobile device meets computer – first in shape of PDA’s, and later as tablets and smart phones. Although the internet for commercial use was available

Figure 1. IoT fields of use
first in the late 1980’s, the first internet appliance was a Coke machine at Carnegie Melon University in 1982. The commercial internet began to exist in late 1980’s as the “Internet of Computers” [3], providing global services such the World Wide Web. Broadband internet connectivity is becoming fast, cheap and omnipresent. Last 10 years Internet has changed to the Internet of People. This “network of humans” covers more than 1 billion people. According to the statistics portal Statista (https://www.statista.com), in 4th quarter 2016, just Facebook had 1.86 billion active users. A number of active e-mail accounts worldwide in 2016 was 4.626 billion, and prediction for 2019 is about 5.6 billion (see Fig. 2).

Just 25 years ago, in 1992 was less than 100.000 devices connected to the internet. In 2012 number of connected devices exceeded human population in the world. Predictions of Cisco [5] for 2020 is about 50 billion devices [6] (See Fig. 3).

Fast broadband internet, Web services architecture, Big Data and Cloud Computing technologies, together with small and cheap microprocessors, led to “Internet of Things”. In this case, “things” are any beings (humans, animals, plants) or items (cars, buildings, cities, factories, devices) with unique ID, internet connection and set of sensors or actuators. At any moment in time this unique items carry its status and position and provide remote access to read data from its sensors or control its actuators. It was initially proposed to use RFID to uniquely identify, track and monitor any object with RFID tag [3]. RFID is a foundational technology for IoT, while it allows microchips to transmit the ID information to a reader through wireless communication [4], widely used in industry since 1980’s. Another foundational technology for IoT is wireless sensor network (WSNs), from 1990’s – set of a wirelessly interconnected smart sensor attached to devices.

The newest trends in IT have established a way to Big Data era – everything goes to the Cloud. All data will be stored somewhere on the internet, or will be transferred to the storage destination through the internet. This trend can easily be seen by observing the internet size since 2000. The amount of all data published on the internet in 2000 was about 50 PB. In 2012, this size was 4 ZB, today is about 8 ZB, and expected size in 2020 is about 40 ZB (see Table 1.).

Table 1.: Orders of magnitude of data

The numbers in the timeline – number of people connected to the internet, number of active e-mail accounts, number of connected devices, amount of published or transferred data – are just presenters of development of technology in last years, and show how fast this development is. Such a rapid development of technology enables a range of new opportunities, but also demands a development of new communications and security standards.

### III. SECURITY TRENDS IN IoT

Security in IT includes availability, integrity and confidentiality. Availability means that the remote system in online and can offer the service to the customer. In the moment when system is not available, either system is down or communication is broken, the security is compromised. Integrity means that all data are the same on the source as on the destination, in communication process between client and server, or between two or more nodes in the network, and can be accessed or modified just by those authorized to do that. If during the communication process there is an unauthorized data modification the security is compromised. Confidentiality refers to the data protection on both sides in communication (client/server, sender/recipient) as well as on the network side, during data transportation. The data must be encrypted and protected, so that just sender and recipient can read it.

One of IoT technology main security challenges is in its fast growth in development of electronic devices. Security standards are often not implemented, not proven enough, or even do not exist. This is particularly the case with
cheaper devices intended for home use made by no name producers. IoT technology is today still based on the standard communication architecture, which was defined for stationary clients or mobile clients under owner’s control. These clients are usually located in some protected environment, and under security standards set to protect this environment from malicious interventions in every way. IoT architecture has three basic parts: Perception, Network and Application [7] (see Fig. 4).

![Architecture of IoT](image)

Perception layer contains hardware – sensors, actuators, RFID, programmable control unit with processor and memory. These are all necessary to collect and send data or receive data. These devices are connected to the Network layer – whether standalone with independent wireless connection to ISP, or wireless grouped by hub or internet access point and through it connected to ISP. They are placed everywhere, and not always protected enough from unauthorized access, so they can easily be damaged or stolen. In this case, by unauthorized access to data or just by breaking connection between devices and the cloud, the security system will be compromised. Also, these devices are often powered by batteries or solar cells, which raises another important issue – autonomy time.

Network layer serves for the communication between sensing devices and data storage in cloud. There is a wide spectrum of technologies and standards used to exchange data. New standards are in continuous development, based on existing LAN, WLAN and WAN standards. They differ from each other by radio frequency spectrum, data exchange rate, range and power consumption. Being easily exposed target to malicious attempts security is especially important on this layer.

Highest layer is Application layer – Cloud architecture and data management systems as well as analytic and presentation software. At this point data must be protected from unauthorized access and anonymized when used for public purpose.

Together with good known WiFi, 2G/3G/4G Cellular, NFC and Bluetooth communication technologies, for industrial and commercial use are developed some new low-power and wide-range protocols: Bluetooth Low-Energy (BLE), ZigBee, Z-Wave, 6LowPAN, Sigfox, Thread, LoRaWAN.

NFC (Near Field Communication - [http://nearfieldcommunication.org/](http://nearfieldcommunication.org/)) is RFID based technology for contactless data exchange using electromagnetic induction in range of 10 cm at a rates of 106, 212 or 424 kbps [7].

BLE is Bluetooth 4.2 version designed for small chunks of data. Works at 2.4 GHz, has 50-150m range by 1Mbps speed [8].

Zigbee with last version 3.0, is based on the IEEE802.15.4 industry protocol at 2.4 GHz that require low data rates of 250 kbps within 100m range. This protocol is robust, scalable and highly secure.

Z-Wave is a low-power RF simple protocol made by Sigma Designs for home use products. Works at 900 MHz frequency within 30 m range at rates of 9.6/40/100 kbps.

6LowPAN is an acronym Ipv6 Low-Power Wireless Personal Area Networks, formed by Internet Engineering Task Force (IETF). The standard can use number of frequency band across multiple communications platforms. Its specialty is using IPv6, which offers 5*10^38 addresses – practically each connected device can have its own unique IP address [9].

Sigfox is technology designed to handle low rate up to 1 kbps, but consumes only 50 μW. for communication at range of 30-50 km in rural and 3-10 km in urban environment. For example, the solution COPERNIC ([https://partners.sigfox.com/products/copernic](https://partners.sigfox.com/products/copernic)) for monitoring of thousands of fire hydrants sending status and timestamp by an email or SMS, runs on lithium battery with estimated lifetime of 10 years. Startup Sigfox was developed in 2009. Today covers 31 countries with more than 7 million registered devices.

Thread is newer protocol based on 6LowPAN, primarily designed as a complement to WiFi on existing IEEE802.15.4. wireless chips as Freescale or Silicon Labs.

1 Bluetooth Special Interest Group (SIG) – Ericsson, IBM, Intel, Nokia, Toshiba Alliance, [https://www.bluetooth.com/](https://www.bluetooth.com/)
4 Sigfox, [www.sigfox.com](http://www.sigfox.com)
5 Thread Group, [http://www.threadgroup.org/](http://www.threadgroup.org/)
6 LoRa Alliance, [https://www.lora-alliance.org/](https://www.lora-alliance.org/)
7 Internet Engineering Task Forces, [www.ietf.org](http://www.ietf.org)
LoRaWAN is another concept similar to Sigfox. It works over WAN area and is designed for low-power bi-directional communication for industrial purpose and smart city solutions. It uses unlicensed public spectrum called the ISM s (Industrial Scientific and Medical) frequency band. Its range is 2-5 km in urban and 15 km in suburban environment, at rates of up to 50 kbps. As well as Sigfox, LoRaWan is world-wide present, with more than 150 on-going trials and city deployments and more than 400 members in the Alliance. Korea’s ICT giant Samsung, together with Korea’s Telecom is building nationwide LoRaWAN IoT network, covering 99% of the population in South Korea.

Proposed IoT strategy to operators is to offer hybrid technologies (See Table 2). For applications that need long range and high data rates, there are existing networks such a cellular, LTE or WiFi (15% of IoT market). Short range technologies as ZigBee, NFC, Z-Wave, BLE should be used for short range systems such a smart meter systems, buildings, parking systems etc., and in this cases, it is possible to use hubs to aggregate metering devices and send data to the cloud (40% of IoT market). Nevertheless, to meet long range coverage it is necessary to use low-power WAN devices with low data rate and low cost (45% of IoT market).

Table 2: Technology usage

Here listed technologies are all based on the RF communication, and hacking a radio connection can be performed without physical access to the device. The attacker has unlimited time to try to perform malicious operation. A good protected radio communication would be a first line of defense against hackers. Second line of defense is to keep data signed with encrypted fingerprint, using hashing mechanisms as well as asymmetric mechanisms for encryption. Asymmetric mechanisms can also be used for authorization and authentication. Firmware and internal programs should be stored in the internal memory rather than to external memory and also protected with some locking mechanisms, similar to hard drive encryption software. In this way, the attacker has limited access to the communication interface through hardware using for example oscilloscope or logic analyzer. This keeps the data stored in internal memory safe and protected from unauthorized access.

IV. IMPACT OF IOT TO THE INDUSTRIAL SECURITY

Traditionally, cyber security for Information Technology (IT) focuses on the protection required to ensure the confidentiality, integrity, and availability of the electronic information communication systems. IoT imposes that cyber security must include a balance of both cyber system technologies and processes in IT and industrial system operations and governance.

For example, in the power industry, the focus has been on the implementation of equipment that could improve power system reliability [9]. Until recently, communications and IT equipment were typically seen only as supporting service. However, the distinction is getting less and less visible (OT – Operational Technology and IT Network Integration). For example, electricity transmission system operators face the challenges of adopting large amounts of energy coming from renewable sources. Many of renewables are inherently volatile and thus difficult to predict and plan. New methods and algorithms of planning had to be adopted to maintain the grid reliability. All this could not be done without the support of evolving IT technologies.

Supervisory control and data acquisition (SCADA) is an information system architecture that uses computers, networked data communications and graphical user interfaces for high-level industrial, infrastructure or facility processes supervisory management.

SCADA systems are used to control and monitor physical processes, examples of which are a transmission of electricity, transportation of gas and oil in pipelines, water distribution, traffic lights etc. The security of these SCADA systems is important because compromise or destruction of these systems can have an impact on multiple areas of society. Other systems for automatic meter reading or planning usually extend basic SCADA functionalities.

We can roughly speak of three phases of SCADA system evolution. At the beginning, SCADA systems were standalone with proprietary protocols and completely isolated thus making everything intrinsically secure.

The next phase included increased number of connections between SCADA systems, office networks and the Internet which made them more vulnerable to types of network attacks that are relatively common in IT world.

Today with the increasing availability of cloud computing, SCADA systems have adopted Internet of things technology to significantly reduce infrastructure costs and improve ease of maintenance and integration. As a result, SCADA systems can now report state in near real-time and use the horizontal scale available in cloud environments to implement more complex control algorithms than are practically feasible to implement on traditional programmable logic controllers. All these changes imply many new threat vectors to a modern SCADA system.

SCADA systems may differ. But from a security point of view, they can be broken down into the components that are present in every system in some form. A typical SCADA system consists of four elements.

Data acquisition includes sensors, meters and field devices, such as photo sensors, pressure sensors, temperature sensors and flow sensors. For example, in sensor accepting modifications without sufficient checks may cause the system to default to a failsafe condition. Another example could be unsecure energy meter reading devices allowing the unauthorized users to change the internal data.

Conversion and control include devices like remote terminal units (RTU), intelligent electronic devices (IEDs) and programmable logic controllers (PLC). Remote terminal units connect to sensors and actuators in the process, and are networked to the supervisory computer system. Programmable logic controllers are connected to sensors and actuators in the process, and are networked to the supervisory system in the same way as remote terminal units but have more sophisticated embedded control capabilities. Unauthenticated ports could allow modification of memory and logging. This can allow attackers to change system configuration and furthermore remove log records that indicate system change to hide malicious activity.

Communication infrastructure connects the supervisory computer system to the remote terminal units and programmable logic controllers, and may use industry standard or manufacturer proprietary protocols. Failure of the communications network does not necessarily stop the process controls, and on the resumption of communications, the operator can continue with monitoring and control. Some critical systems will have dual redundant data highways, often cabled via diverse routes. A theoretical attacker could (if gained access to the unencrypted network) retrieve sensible industry data.

The supervisory computer is the core system component responsible for gathering process data and sending control commands to the connected devices. To increase the integrity of the system the multiple servers it can usually be configured in dual configurations.

The interface is linked to the SCADA supervisory computer to provide live data to drive the mimic diagrams, alarm displays and trending graphs. Typically, it also includes a drawing program that the operators or system maintenance personnel use to change the way these points are represented in the interface as well as historian database which accumulates time series, events, and alarms data which can then be used to populate graphic trends etc.

Majority of all SCADA vulnerabilities fall in this category. Most SCADA vendors are shifting to web based HMIs. As a result, a lot of web related vulnerabilities could affect this component. Also, traditionally IT system administrators have unrestricted access to all the system databases allowing them the possibility to change or share the data outside the organizational security perimeter.

Table 3: SCADA evolution

Traditional isolated SCADA system have security implicitly applied to it by keeping the very tight border between who has access to what particular SCADA function or data together with the dedicated secure communication channels (see Table 3.). The focus was on keeping thing tightly coupled and locked as much as possible. On the other hand, in modern systems number of different types of connections within and across network boundaries continue to grow at an accelerating rate, opening new points of exposure. The introduction of IP-based technology and general-purpose computing devices into operational environments is introducing new vulnerabilities along with their benefits. The focus is now on large scale IoT data integration and sharing information as much as possible. Now it is not only the protection of the core SCADA functionalities which has to be secured from cyber-attacks we also have to deal with security at the data layer. For example, settlement data is the pillar of modern energy market structure and can be affected with targeted subtle security attacks affecting metered data [11].

The human-machine interface presents process information to the operating personnel graphically in the form of mimic diagrams, which are a schematic representation of the process being controlled, and alarm and event logging pages (See Fig. 5).
Technologies (tools, strategies) available to protect the control system:

- Access controls – authentication and authorizations at functional and data level, including industry topology segmentations
- Bidirectional gap (e.g., firewall) between control systems and rest of network
- Application whitelisting - to control which applications are permitted to install or execute on a specific host
- Anomaly detection tools
- Patch management / upgrade services
- Vulnerability scanning
- Security awareness training for staff, contractors and vendors
- Asset identification - visibility of components within the control system equipment and network activity
- Antimalware/Antivirus
- Assessment and audit
- Continuous Monitoring and log analysis
- Data forensics

The energy sector benefits from a head start. From the very beginning, cybersecurity was a key requirement of the Smart Grid initiative and significant efforts have been invested in defining requirements that have been formalized in reports such as the NIST 7628 Guidelines for Smart Grid Security. While these guidelines do not address the IoT per se, they do define the cybersecurity requirement for applications in the energy sector, from generation plants to customer premises. Furthermore, many utilities are required to meet the NERC CIP cybersecurity standards and have thus acquired valuable experience in protecting their assets.

The most common vision of IoT is thus for a loosely coupled network of devices and sensors that publish their data through a messaging architecture using web services and messaging protocols such as Message Queuing Telemetry Transport (MQTT), Constrained Application Protocol (CoAP), Data Distribution Service (DDS), and Advanced Message Queuing Protocol (AMQP). Besides AMQP, most of these protocols are not yet widely used. The AMQP protocol is used in the financial industry and supports a transactional model, making it more complex and not appropriate for edge devices. To our knowledge, none of these protocols are used in energy sector automation systems and devices.

IoT evolution will certainly force the industrial system architectures to change significantly. The idea is to abandon the monolithic and monolithic like designs and replace it with the more natural and simpler design paradigms which can more easily be formally checked for security deficiencies. We can think of sensors and actuators as a primary service providers in a networked environment. By using the data which those primary services provide we can add additional services to the network (secondary services) which can then be further combined or exploited by adding new services. Formally we designed a graph of interconnected nodes. Nodes represent services and edges represent the data flows between them (service dependencies). If we further exploit that idea we can easily connect the IoT with the newest information system architectural patterns of today. First major pattern is using microservices as an architectural model for the deployment of lightweight and loosely-coupled services and the second is the adoption of containers instead of virtual machines for certain types of workloads and thus benefit from the more efficient resources usage as well as easier deployment operations. Both introduce more visibility into the services topology, versions tracking, logging errors etc. This implicitly improves security model by increasing visibility, resiliency and elasticity of the system. What we described is implementation of a more agile design for failure concept where the system is structured in a way that in case of service failure the effect of the compromised service is minimized.

Another benefit of that kind of approach is the side effect of reducing the dependency on the network itself. The service nodes take on a greater role in terms of processing and behavior without hard-coding it in the communication layer (as was the case in Enterprise Service Bus component of the Service Oriented Architecture).

V. CONCLUSION

As IoT brings numerous new possibilities it is expected to be widely applied to industry and home solutions. As it integrates various internet technologies – powerful devices capable of sensing, processing and exchanging data, new low-energy communication protocols, big data and cloud systems it is obviously very important to use existing security technologies for dealing with security issues. But in the future, we will have to address this problem further by moving to a more systematic approach to IoT security. More work will have to be done in the area of communication standards of consumer IoT products as well as enforcing them. Also, new methods for testing the formal security in communication protocols will probably emerge as well. Data forensics as a tool to pinpoint and understand the subtle changes (potentially unauthorized) in the sensor data received from the smart devices is already widely used through the industry.

Systems today are reusing and repurposing existing technology in conjunction with newer, more IoT aware solutions. This is obviously only the first step towards fully interconnected IoT network.

Summary - The opportunities provided by the information and communications technology, with a special emphasis on the Internet, have become an integral part of life. However, are we sufficiently aware and prepared as individuals, nations or the international community for the threats coming from cyberspace or for the denial of the use of that dimension of communication, commerce and even warfare? Namely, despite the growing number of users, the Internet is still beyond or below minimum regulation. Those are precisely the conditions for the organization and realization of hostile action in cyberspace. There are security issues within the cyberspace that represent a security risk and challenge of modern times.

The development and application of the information and communications technology has created a new battleground. As a special challenge to international security, cyber terrorism arises. Cyber security will significantly affect international relations in the 21st century. This paper gives an overview of the concepts and principles of cyber threats that affect the safety and security in an international context.

Keywords: cyberspace, cyber-attack, cyber terrorism and crime, international security.

I. INTRODUCTION

Cyber warfare and terrorism do not know borders. Action in cyberspace requires the rejection of the common assumptions related to time and space because such attacks, by means of modern information and communications networks, can be performed from anywhere in a very short time. The processes of globalization did not have the impact only on the achievements of civilization, but also on the development of new threats to the civilization. It is a fact that terrorism and national threats changed under the influence of the globalization process and the Internet information revolution. Strategic advantage no longer lies in the fighting power or geographical location, but in the information and knowledge. International cooperation and intelligence sharing are essential for an effective prevention of cyber threats. Even though cyber threats have in the recent years been specifically emphasized in the modern military doctrines of great powers and NATO, they are still shrouded in secrecy.

The purpose of this paper is to draw attention to cyber threats, which endanger the safety of modern states, organizations and international relations. By combining the principles of a review and professional research paper, this paper aims to show cyberspace, in terms of security challenges, as a dimension in which international relations unfold. It is necessary to distinguish the main subjects of the international cyber security environment, analyze their intentions and set a paradigm of the multipolarity of cyberspace and analyze its uniqueness and principles.

NATO's Strategic Concept, adopted at the end of 2010 at the Lisbon summit, determines that cyber-attacks have become more frequent, more organized and more expensive, causing damage to the government administration, the business sector, economies, and potentially to the transport and supply. It also states that cyber-attacks can reach the level that threatens the national and Euro-Atlantic prosperity, security, and stability. Foreign military and intelligence services, organized criminals, terrorists and extremist groups are the potential sources of such attacks. What is also emphasized in the conclusions of the Lisbon summit is the need to further develop the skills of prevention, recognition, defense and recovery from cyber-attacks, including the use of the NATO planning process for the advancement and coordination of the national abilities of cyber protection, assembling all NATO bodies under a centralized cyber protection, and a better integration of the NATO cyber awareness, warnings and common response of the member states [1].

It should be borne in mind that the rapid development and adoption of technologies through their use in everyday life opens up many opportunities for the attackers, whether they are in the form of states, terrorists or criminals, because they are always at an advantage in cyberspace. We can therefore conclude that a new concept of cyber security in which prevention represents a significant portion is being created.

The initial hypothesis is that cyberspace is a growing security risk and challenge of modern times. Moreover, cyber security will significantly affect international relations in the 21st century, while the threats and challenges will exponentially increase.

The goal of this paper is the synthesis and analysis of knowledge based on a review of recent literature and professional and scientific articles that problematize the challenges of international security in cyberspace. The scientific work seeks to show cyberspace as an operational dimension of international relations in terms of the cyber security challenges. With the systematization of the cyber warfare strategy and the very methods of attack, links with
the planned action will be set up through the application of technical, computing and network systems.

II. INTERNATIONAL CYBER SECURITY

The cyber domain has a great influence on the transformation of the international security and the very concept of security. Many authors highlight the necessity of the duty understanding and setting up of cyber doctrines.

The new, cyber dimension of international relations is a major challenge for the theories of the preservation of power and intimidation. Cyber threats are serious, destabilizing and on the increase. The theories and strategies of intimidation designed and implemented during the Cold War cannot be implemented in the cyber domain. Many scientists are working on the understanding of the cyber revolution in international relations. Authorities have also taken certain steps in cooperation, especially in the area of crime and the establishment of CERTs (Computer Emergency Response Teams) [2]. Tataločić, Grizol and Cvrtila write that the processes of internationalization and globalization have brought a greater cohesion and efforts for a unified regulation of the world order, more than it was in the system of sovereign states during the Cold War. This is reflected in the core of the states' security policies. In that context, a new concept – human security concept – emerged in theory and political practice. In contrast to the traditional concept of national security, it primarily emphasizes the security of an individual, not the state [3]. Lin theorizes [4] about cyber security. The concept of intimidation was the basic idea of the nuclear strategy. However, the question is whether the dissemination of the principles of intimidation on cyberspace is a viable strategy. Even though nuclear and cyber weapons share a key feature – the superiority of the attack in comparison with the defense – they differ in many ways. Only a few countries possess nuclear weapons and the number of possible enemies is limited, as is then the application of intimidation. The situation is completely different when it comes to cyberspace. Unlike nuclear weapons, each state has access to cyber "weapons", and such attacks cannot be firmly linked to state action. The protection of national infrastructure against attack could become another common interest of states. Experts and analysts estimate that the efforts of Russia and China to dominate cyberspace have over the past few years intensified so much that any delay in this area could present a big problem for the modern West.

Cyber-attack, whether it happens as a conflict between states, a terrorist or a criminal act, is an attack in cyberspace with the aim of compromising a computer system or network, but also of compromising physical systems as it was the case with the Stuxnet worm. In layman's, popular terms, most often mentioned in the media, it is called a hacker attack. Identical methods of a hacker attack are applied for both military and terrorist purposes.

Janczewski and Colarik [5] divided cyber-attacks into phases, which they consider to be basically the same as the phases of conventional criminal offenses:

- the first phase of the attack is the scouting of potential victims. By observing the implementation of the normal operations of targets, useful information that are accumulated and determined through the used applications and hardware;
- the second phase of the attack is intrusion. Until the attacker gets into the system, there is not much that can be done against the target apart from disrupting the availability or access to certain services provided by the target;
- the next phase is the identification and dissemination of internal opportunities by examining the resources and the right to access the restricted and important parts of the system;
- in the fourth phase the intruder does damage to the system or steals certain data;

Furthermore, they indicate that today cyber-attacks consist primarily of:
- malware via attachments in the Internet browser, e-mail or other system vulnerabilities;
- denial of service (DoS) to prevent the use of computer systems and networks;
- deletion or transformation (leaving a message) to government and commercial websites for propaganda purposes or in order to disrupt the informing;
- unauthorized intrusion into systems for the theft of confidential and/or proprietary information, compromising of data or using the system in order to launch attacks against other systems.

In such circumstances of transformation and different views and understandings of security in general and international security, cyber threats certainly redefine those terms. In line with the efforts to ensure security on one hand and specificities of cyber threats and motives of the actors who initiate them on the other, it will be necessary to set up a new international security paradigm of the cyber age.

III. MULTIPOLARITY OF CYBERSPACE

The USA, Russia and China are nations known for their skilled military cyber units. In addition to the aforementioned states, France and Israel are working on the development of cyber capabilities. American intelligence officers believe that there are 20 to 30 armies with respectful capabilities for cyber-war, including Taiwan, Iran, Australia, South Korea, India, Pakistan and several NATO countries. The United States Cyber Command, along with the agencies they work with, has some of the most intelligent, patriotic-minded civil servants, both military and civilian, who create plans and capabilities for the domination in cyberspace with the goal of preserving the national security and peace [9].

Strategic domination in cyberspace has not yet been achieved by any of the entities of international relations. That is undoubtedly the goal of many nations such as the
USA, China and Russia. However, as much as they might invest in their defense system and offensive capabilities, the system of power has not been set up. As opposed to the bloc division of the world into two centers of power during the Cold War, intimidation based on offensive capabilities is not crucial in cyberspace and there are many centers of power. The strength of those nations will mostly depend on the possibility of establishing an adequate defense system which is also influenced by their dependence on the information infrastructure. The dependence on information infrastructure is in correlation with the level of vulnerability of the economically and militarily developed digitized countries.

Due to the specificity of cyberspace, especially the asymmetry with the actual time and space and the geostrategic factors, a new security challenge that requires new military concepts is put before states and organizations. Namely, it is necessary to develop specific defense doctrines, but also offensive plans for action in cyberspace.

The dependence on networked computers and computer communication leaves the USA vulnerable to possible attacks, which made the cyber world a major source of uncertainty [6]. The vulnerability to attacks and the possibility of action is defined by Clarke and Knake [8] as the national cyber power. They state that the national cyber power is the net estimate of the ability of a nation to wage a cyber-war. National cyber power takes into account three factors: offensive cyber capabilities, national dependency on cyber networks and the nation's ability to control and defend its own cyberspace by implementing measures such as stopping the traffic outside the state. Based on these three factors, the authors provide an assessment of the overall cyber power of the United States, Russia, China, Iran and North Korea. To facilitate the comparison and analysis, the results of the assessment are systematized in the following table. The measurement scale goes from 1 to 10, with the smaller value representing a worse assessment and the higher value representing a better assessment.

</tbody>
</table>

Table 1. Assessment of the national cyber power

They further explain why the USA, according to the assessment, is not the dominant power of cyberspace. If the total national cyber power was observed only on the basis of the offensive capabilities, the USA would occupy the first place. However, the outcome of a cyber-war does not depend only on the offensive capabilities. The important part is the dependence of a nation on the systems in cyberspace. Unlike the USA, China is developing its offensive cyber capabilities, but it is also oriented on the defense. Cyber warriors of the Chinese military have both offensive and defensive tasks in cyberspace and in contrast to the military of the USA, when talking about the defense, they also refer to the defense of the nation, i.e. the civil networks, not just the military networks. In China, the networks that make up their Internet infrastructure are under the control of the government. The Chinese government has the power and means to shut down the Chinese portion of the Internet from the rest of the world, which it would very likely do in case of a conflict with the USA. On the other hand, the USA has no plans or the capacity to do so, because their cyber connections are largely privately owned. China may limit the use of cyberspace in a crisis, refusing access to certain users. The USA cannot do it. North Korea has high scores when it comes to the defense and low dependence on the network infrastructure. Namely, that country may terminate its limited connections with cyberspace in an easier and more effective way than China. North Korea has few systems that are dependent on cyberspace that a large cyber-attack on its systems would have a minimal effect. The authors warn that one should bear in mind that cyber dependency is not the percentage of households with a broadband connection or the number of people who have smartphones, but the degree to which the critical infrastructure (electricity, railways, supply chains) depend on the network systems. Thus, a state which is largely dependent on the systems in cyberspace has greater challenges in the creation of a national cyber defense. This is why the USA is more vulnerable to cyber-war than Russia or China. It is certainly more risky for the USA to engage in cyber-war than it is for a small country such as the North Korea. With three large entities of international relations (the USA, China and Russia) and the balance of power in cyberspace, the overall cyber power of two states that pose a threat to the world because of their totalitarianism and nuclear problems has been analyzed. Clarke and Knake estimate that they do not have great offensive capabilities, but have participated in the abuse of cyberspace.

The Iranian presidential election of 2009 sparked a huge public protest against election fraud. Social media platforms, mostly the two most popular, Twitter and Facebook, served for the organization, rebellion and spreading of anti-regime news. The Iranian government responded by introducing harsh police actions against the demonstrators, by shutting down media channels, and disabling Internet access within the country. Some members of the
opposition launched DDoS attacks (distributed denial of service) against the websites of the Iranian government. Due to the speed and ease of communication, they used Twitter to organize and recruit cyber activists. They also used it to exchange links on an software that facilitated the inclusion of participants in the DDoS attack [7]. It is clear from the available data that this is not an international, but intrastate conflict. This is by no means a cybercrime because the attackers were politically motivated.

Because of its nuclear program, Iran was a target of an attack by the computer worm Stuxnet in June 2010. The worm was created to infect the industrial systems, and it proved its danger by sabotaging the Iran's nuclear program. In addition to the Iran's nuclear program, it also infected thousands of computers and industrial facilities worldwide. The Stuxnet worm can hide in cyberspace for a longer period. Analysts disclosed that the complex worm was written specifically for the breaching and taking control of the computer systems of Natanz nuclear facility in Iran. The worm takes very good care of itself for a longer period in cyberspace. Experts describe Stuxnet as a sophisticated piece of software with half a million program lines of code. For such a complex malware, it is necessary to have knowledge of the certain types of industrial control systems that are being attacked, and it seems that the code was written by an expert team, and not just one person [11]. Therefore, there was a suspicion that it was done by American or Israeli programmers. In an article published in the New York Times, Sanger [12] writes that the American President Obama ordered the cyber-attack on Iran, i.e. on the centrifuges used for the uranium enrichment.

North Korea, due to its poor technological development, is not very dependent on the systems in cyberspace. That is also the reason behind the very good assessment of their defense capabilities. Even though it has no developed offensive capabilities, it is obvious that it has recognized the importance of playing an active role in cyberspace. In fact, in July 2009, a few dozen American websites, including the website of the White House, were under a DDoS attack (denial of service). The main suspect was North Korea. That status was confirmed after the attacks spread to South Korea. The South Korean media and government officials publicly accused its northern neighbor, and the officials of the USA advocated a cyber-counterattack “in order to send a strong message” [7]. In November 2014. a group which calls itself GOP or The Guardians Of Peace, hacked its way into Sony Pictures and stole the data that included personal information about the Sony Pictures employees and their families, e-mails between the employees, information about the executive salaries at the company, copies of the then-unreleased Sony films, and other information [9]. The purpose of the attack, attributed to North Korea, was to deter Sony Pictures from releasing a movie which was (correctly) understood as ridiculing that country’s dictator and portraying the North Korean regime and its leader, Kim Jong-Un, with sarcasm and mockery [10].

IV. CONCLUSION

The topic of the paper, cyber threats to international security, stands out merely by its title as an interesting and challenging area of research. The explanation for it is first and foremost that the area has not yet been sufficiently explored, especially not in the Croatian context. Due to the intensive development of international relations in cyberspace, conditioned and supported by the speed of the development of technologies and their implementation in the relations of states, organizations and individuals, this area will always be interesting and challenging. That conclusion arises from the constant change of attitudes and technology. It is precisely that instability which indicates that from that specific, interdisciplinary field of research, in 5 or 10 years, it will be possible to draw some new conclusions, and according to them, set some new paradigms and doctrines. Curr [7] states that cyber-warfare has been present for about a decade, but that it is still not well defined. There is no valid international agreement which would establish a legal definition of an act of cyber aggression. In fact, the entire area of international cyber law is still unclear.

The development and availability of information and communications technologies and the ever-present tensions between politically and ideologically different states have conditioned the international relations in cyberspace. Strategic domination in cyberspace has not yet been achieved by any of the entities of international relations. A large number of international entities demonstrated their presence and willingness to act in cyberspace. That demonstrates a multipolar dimension of cyberspace in which it is very unlikely that domination or bloc division will occur. The reasons lie in the mutual mistrust and fear of espionage in the case of linking the defense systems. However, the nations that are the most influential are the ones that are the most powerful, economically and militarily, and at the same time are the most dependent of the cyber-infrastructure – the USA, Russia and China. NATO also plays an active role. We can conclude that in the recent years, a new concept of cyber security that can be defined as a paradigm of the multipolarity of cyberspace is being created.

Most authors predict an escalation of conflicts and intelligence activities in cyberspace, which supports the confirmation of the initial hypothesis of this paper. They state that cyber-attacks are among the biggest threats to the international security. Unlike conventional conflicts, such attacks will become increasingly common, and they could, as a conventional attack, cause large-scale destruction, even with fatal consequences. It is therefore essential to establish an effective defense in which the key role is that of prevention, international cooperation
and the adoption of the internationally recognized, legally binding norms.

Due to the increase in cyber-terrorism and crime, it is necessary to organize systematic education and to strengthen operational military, intelligence, police and civil centers for the defense from cyber-attacks.

If we take into consideration all that has been stated in the elaboration, and the confirmation of the initial hypothesis, we can conclude that cyber security has become one of the prerequisites of the democratic concept of life in the modern society.

Abstract – Cloud computing became very popular in past few years, and most of the business and home users rely on its services. Because of its wide usage, cloud computing services became a common target of different cyber-attacks executed by insiders and outsiders. Therefore, cloud computing vendors and providers need to implement strong information security protection mechanisms on their cloud infrastructures. One approach that has been taken for successful threat detection that will lead to the successful attack prevention in cloud computing infrastructures is the application of machine learning algorithms. To understand how machine learning algorithms can be applied for cloud computing threat detection, we propose the cloud computing threat classification model based on the feasibility of machine learning algorithms to detect them. In this paper, we addressed three different criteria types, where we considered three types of classification: a) type of learning algorithm, b) input features and c) cloud computing level. Results proposed in this paper can contribute to further studies in the field of cloud threat detection with machine learning algorithms. More specifically, it will help in selecting appropriate input features, or machine learning algorithms, to obtain higher classification accuracy.

I. INTRODUCTION

Cloud computing is a technology that delivers IT resources and applications as a service, over the Internet, with pay-as-you-go pricing. It consists of number of individual computing nodes with corresponding networking and storage subsystems [1]. Cloud technologies and services have been used by individuals or companies daily, from storage services using Google drive to chatting services using Skype. Skype, which was known as peer to peer architecture (P2P), has been transitioning from P2P to cloud based architecture, with improved existing features and the new ones that are launched, such as mobile group video calling, Skype Translator, etc. [2].

Most of the services such as emails, search engines, social networks are hosted in the cloud [3]. Adopting cloud computing over traditional data center shows several benefits, and National Institute of Standards and Technology (NIST) defined it in following way [4]:

“Cloud computing is a model for enabling ubiquitous, convenient, on-demand network access to a shared pool of configurable computing resources (e.g., networks, servers, storage, applications, and services) that can be rapidly provisioned and released with minimal management effort or service provider interaction.”

A. Cloud Computing Security Overview

However, the biggest concerns of cloud users and main hurdles to move their in-house business to a public cloud is security. The issue might be that cloud vendors do not provide security of the data while being transported to the cloud [1]. Moreover, remote access is under the client’s responsibility and clients need to have a strong knowledge of security aspects related to the networking and Internet, before obtaining access to a cloud. Nothing connected to the Internet is perfectly secured. Therefore, many data breaches happen [1, 5].

Stealing information is the biggest concern when it comes to a cloud computing. According to the Breach Level Index website [6], totally 3 989 114 5677 records were lost since 2013. In 2016, around 554 million records were stolen, with highest peak in October (around 472 million stolen records). Even the technology giants were not left out, namely Microsoft, with the 8 recorded data breaches in period 2013 – 2015 [6].

Other popular companies in the field of technology attacked by data breach are shown in Table 1.

1530 MIPRO 2017/ISS
Source of the breach for each of them was malicious outsider, and all of them are with severe and catastrophic risk score [6].

Many cloud attacks such as phishing and fraud, unauthorized access, malicious insider, insecure interfaces, etc., lead to the data breach [7, 8].

This paper presents the model for classification of cloud security threats based on the feasibility of machine learning algorithms to detect them.

Machine learning algorithms are powerful tools, being used in financial services, government, health care, transportation, information security, etc. for different prediction problems. These algorithms get computers to act without being explicitly told or programmed how to do something. Moreover, they make computers learn from the past experiences and solve some future problems. Considering their wide usage, we decided to see whether we can apply machine learning algorithms for cloud computing threat detection. Therefore, this paper provides general overview of the detection model with machine learning algorithms, in the field of cloud computing security.

The work presented in this paper is the part of the larger study and PhD work of the first author who recognized, in the process of the literature review research in cloud computing security, that there is no such available classification model. Therefore, decision was made to contribute by making this classification model.

This paper is organized as follows: Section II outlines the review of the literature on cloud security threats. Section III introduces our proposed model for threat classification based on the feasibility of machine learning methods to detect them. Section IV concludes and ends the paper.

II. RELATED WORK

Cloud computing security threats and their classification is the subject of research in many articles [9, 10, 11, 12, 13, 14].

A. Overview of Cloud Computing Threats Classifications

Ahmed, Litchfield and Ahmed [9] provided the generalized threat taxonomy in a cloud computing environment. In their taxonomy, they involved human and technological factors as root categories, from which security challenges in cloud computing emerge. Chraib, Harroud and Maach [14] provided taxonomy for cloud computing security issues according to the level to which they belong. They identified security issues on hardware level, virtual machine manager (VMM) level, guest operating system level, application level, network level and governance level. Jouini, Rabai and Aissa [10] proposed the model for threat classification, based on the following threat classification criteria: source, agent, motivation, intention; and their potential impacts: destruction of information, corruption of information, theft or loss of information, disclosure of information, denial of use, elevation of privilege and illegal usage.

However, it is important to know what are the most important cloud computing threats in recent years. Therefore, Cloud Security Alliance [15], a not-for-profit organization that promotes the use of best practices to provide security assurance within cloud computing, identified twelve cloud computing threats specifically related to the shared, on-demand nature of cloud computing, and ranked them by the severity of each threat. These threats are: a) data breach, b) insufficient identity, credential and access management, c) insecure interfaces and APIs d) system vulnerabilities, e) account hijacking, f) malicious insiders, g) advanced persistent threats, h) data loss, i) insufficient due diligence, j) abuse and nefarious use of cloud services, k) denial of service, l) shared technology issues [16].

B. Threat Classification Principles

The most important thing when it comes to the cloud computing security and cloud computing threats is to successfully detect those threats, and efficiently protect the system from attacks.

One of the approaches that has been taken for threat detection and classification is the application of machine learning algorithms. Many research articles focused on cloud computing threat classification, based on the system performance information, or based on the information within the packet that has been exchanged over the network, when some attack occurs. They are summarized in the Table 2.

Classification results which are shown in the Table 2 show high classification accuracy of the machine learning algorithms that have been used in previous work. Furthermore, sensitivity or true positive rate (TPR) which shows the rate of correctly classified attack cases, and false positive rate (FPR) which shows the rate of non-attack cases, incorrectly classified as attack cases, are included in the table.

Therefore, it would be beneficial to identify what cloud computing security threat types could be detected using machine learning algorithms. The aim of this paper is to make cloud computing threats classification model, which will help in identification and organization of security threats into the classes, finding out the best possible way
to detect them and protect system and data from the attacks.

Based on the previous research works in the field of cloud threat detection with machine learning algorithms, we have identified criteria to our threat classification:

- type of machine learning algorithm
- input data features
- cloud computing level

**TABLE 2. PREVIOUS STUDIES ON APPLICATION OF MACHINE LEARNING ALGORITHMS ON CLOUD COMPUTING THREAT DETECTION**

**III. THE PROPOSED CLASSIFICATION MODEL**

In our paper, we propose threats classification based on three criteria:

- Criterion 1: Machine Learning Algorithm Type
- Criterion 2: Input Data Features
- Criterion 3: Cloud Computing Level

**A. Criterion 1: Machine Learning Algorithm Type**

We classified cloud computing security threats firstly by machine learning algorithm, or categories of learning, these algorithms belong to: supervised and unsupervised learning. Supervised learning is the classification learning where the actual outcome for each training example is provided, whereas in unsupervised learning, training example outcome is not specified. Classification learning success can be judged by trying out what has been learned on the independent set, with known, true classification outcomes. When there is no specified outcomes/class, items are grouped based on the features that denote similar items [31]. Popular supervised learning algorithms are support vector machine (SVM), random forest (RF), artificial neural networks (ANN), decision tree (DT), Naive Bayes (NB), etc., and clustering (k-means, expectation-maximization) belongs to unsupervised learning algorithms [32]. Selecting appropriate machine learning algorithm is a critical step. Algorithm is selected based on different criteria, but usually it is the prediction accuracy (or percentage of correctly predicted items over the total number of items). Furthermore, computational time, handling high dimensional values or overfitting are also important factors to consider, when selecting machine learning algorithm [33].

**B. Criterion 2: Input Data Features**

Each instance that provides an input to machine learning algorithms is described by the number of attributes where each attribute can have number of values. Therefore, cloud attacks have attributes that describe them and are input to machine learning algorithms. It is important to determine appropriate input data to the machine learning algorithms, as classification performance depends much on it. However, determining input features is not easy and it requires considerable effort, as it is hard to determine what features are important and what not, and in most cases, it contains noise and missing data, which affects the classification performance and its classification accuracy. In our research, we analyzed two categories of input data: system performance data [16, 17, 23, 24, 25], such as: CPU,
network, memory, disk, hypervisor, guest OS performance when the attack starts and during its execution, and network traffic features, or packet data being exchanged over the network while executing an attack [18, 19, 20, 21, 22, 26, 27, 28, 29]: source and destination IP address, protocol, packet length, port numbers, flags, etc. While considering system performance data, it is important to detect activity pattern by looking at the change of parameters in the computer. For network packet data, packet sniffer is used to catch all packets being sent during the attack execution. This step also involves features selection process, where irrelevant and redundant features are removed. This enables machine learning algorithms to operate faster and more efficiently.

C. Criterion 3: Cloud Computing Level

Finally, attack categories to which cloud security attacks belong are added to the whole schema. We classified cloud security threats into two broad categories, considering the level of cloud on which attack might happen: network specific threats and cloud computing specific threats. When developing cloud solutions, important factor to consider is network security, as network is a vulnerable spot for different attacks. The purpose of network attacks is one of the following: to monitor the network and obtain useful information, to change the content with the intent to destroy or corrupt the data, or to consume network’s resources. Popular network attacks in the cloud are account or service hijacking that happens when the attacker cavedrops on the user’s activities and transactions, or denial of service (DoS) attacks that prevent user from a normal use of resources. Cloud computing specific threats are major threats in cloud computing too. Cloud computing specific threats include insecure interfaces and APIs, which are offered to clients for the interaction with cloud services, shared technology vulnerabilities, or malicious insiders who has an authorized access to organization’s network, system or other resources and intentionally misuse it for some malicious activities [16].

Fig. 1 represents the diagram of the cloud threat classification, considering all three criteria that we proposed above.

![Diagram of the cloud computing threats classification model based on the detection on feasibility of machine learning algorithms.](image)

Fig. 1 shows that network specific threats and cloud computing specific threats can be described by both, system performance and network traffic data. The choice depends on the aim of the research, tools that will be used in the experimentation phase, interest of the researcher and what a researcher is trying to find out or prove.

Furthermore, system performance data and network traffic data are input to both types of learning, supervised and unsupervised. The researcher decides on the machine learning algorithm by considering different criteria, such as complexity of the algorithm, computational time, handling missing values, overfitting, etc.

IV. CONCLUSIONS

Popularity of the cloud computing has been increasing over the years, which made the cloud computing services a target for many cloud specific attacks. Security of the cloud computing is a critical factor for both, cloud providers and cloud users. Therefore, cloud providers need to implement strong protection system on their cloud infrastructure. In this paper, we have developed a threat classification model that uses machine learning algorithms as tools for threats detection. In our model, we considered three criteria: a) type of machine learning algorithm, b) input data features, and c) cloud computing level. First criterion considers two types of learning: supervised and unsupervised. Second criterion considers system performance data and network traffic data, which are input to both types of learning. Finally, last criterion considers network specific and cloud environment specific threats, which are described by system performance and network traffic data. Results proposed in this paper can contribute in further studies in the field of cloud computing threat detection with machine learning algorithms in a way that it can help researchers to select the appropriate learning algorithm for their research, or appropriate input features to the selected algorithm. Proposed model can be optimized, by extending it with additional criteria, such as: threat motivation (malicious, or non-malicious), or threat intention (accidental, or intentional).

Legal Framework Issues Managing Confidential Business Information in the Republic of Croatia

Goran Vojković, Ph.D.
Melita Milenković, LL.M.

University of Zagreb
Faculty of Transport and Traffic Sciences
Vukelićeva 4, Zagreb, Croatia
E-mail: goran.vojkovic@fpz.hr
melita.milenkovic@fpz.hr

Abstract – Confidential business information in the Republic of Croatia is regulated in an insufficient mode - the Data Confidentiality Act provisions are still on force for more than 20 years, and entirely inadequate for today's time. Considering that information is now greatly kept in electronic form, it is necessary by the internal documents, and in accordance with the existing outdated legislation, to regulate in detail the issues of confidential business information. In case of exchange of business information which are confidential - it is necessary to sign the appropriate contract between the parties. This paper is about existing of legal shortcomings and how to overcome them in practice.

I. INTRODUCTION

On 13 of July 2007, that is nearly 10 years ago, Croatian Parliament passed the Data Confidentiality Act [in Croatian: Zakon o tajnosti podataka, further: ZTP] [1] which was in the matter of data confidentiality arranged on a fundamentally different level than the old Act on Protection of Data Confidentiality [in Croatian: Zakon o zaštićenj tajnosti podataka, further: ZZTP] [2], back from the 1996.

The scope of the ZTP is defined significantly narrower than the scope of the old Act because the purpose of the ZTP is something essentially different. In fact, in the old Act from 1996 it has been stated that it "stipulates the concept, types and degrees of confidentiality and the measures and the procedures for determining, use and protection of confidential business information", and it regulates the state, military, official, business and professional confidentiality.

Unlike the above, Art. 1, para. 2 of the ZTP, which determines: "This Act shall apply to the state authorities, local and regional government, legal persons with public authorities and legal and natural persons, who in accordance with this Act, gain access or handle classified and unclassified information." [3]

The definition of classified and unclassified business information, in the art. 2 of ZTP, according to which, classified information is the one that the competent authority, (in the prescribed procedure), marked and determined by the degree of confidentiality. As well as the fact that the Republic of Croatia was handed by data from another state, an international organization or institution that the Republic of Croatia cooperates with. Furthermore, unclassified data is data without the determined level of classification, which is used for official purposes, as well as the fact that the Republic of Croatia was also handed by data from another state, an international organization or institution that the Republic of Croatia cooperates with. ZTP harmonized categories of data confidentiality, in accordance with international safety standards (top secret, secret, confidential or restricted). [4]

For our presentation, it is important to emphasize the fact that the scope of the ZTP is limited on the information whose confidentiality is of public interest and the information without an established level of classification, used for official purposes. ZTP does not regulate the question of confidential business information.

In the ZTP’s Final Proposal [5] it states: "This Act does not prescribe the terms of business and professional confidentiality, unlike the ZZTP (Croatian Official Gazette 108/96), since it is not common in the legislation of the most EU and NATO’s member states. Therefore, the provisions from the Head 8 and the Head 9 will remain in force until this matter is not regulated by the other relevant laws."

ZTP’s First Proposal had an interesting observation: "The confidentiality of data of legal and natural persons outside the state system (including private companies) is regulated by their own internal rules, especially within those companies which have their headquarters in the other countries and had already established a proper system of confidentiality of their data". [6]

However, except for certain adjustments of the Croatian Criminal Act [7], the new regulations have not been enacted. Therefore, the question of confidential business information in the Republic of Croatia is solved by the transitional provisions of ZTP and by the two heads of the old ZZTP’s, from 1996.

In more than 20 years, there has been a remarkable development of the high-speed Internet, as well as completely new business models, which include engagement of many business subjects, on one or several projects. Also, the business innovation and the ‘know-how’ is becoming increasingly important in today's modern business practice.

In short, questions of regulation and storage of confidential business information are getting more important regardless the fact that Croatian legal framework is based on several out-dated legal provisions. This deficiency is partly possible to be solved in practice – by the
quality agreements between business partners but it is necessary to be aware of this deficiency. Foreign business partners can come across this problem, during the fact that they are not familiar with the Croatian legal practice.

II. CONFIDENTIAL BUSINESS INFORMATION BY THE CURRENT REGULATIONS

ZZTP regulates confidential business information in the head VIII, in the articles 19 - 26.

According to this Act, the confidential business information is represented by the information which is defined by the Act of law, also other regulation or by the general company Act, or by the other legal entities, which represent confidential business information, results of research or construction work and other information whose disclosure to an unauthorized person could have harmful effects on its economic interests (ZZTP Art. 19, para. 1). Further, it states that the general Act cannot determine that all the information relating to the business of legal persons is considered for confidential business information nor can such information be in the contrary to the legal person’s interests. (ZZTP Art. 19, para. 2).

In the Article 19, para 1, the legislator wanted to restrict confidential business information to the information that makes sense for declaring it confidential, and not for confidential business information to become a way of introducing police state for the economic subjects. [8]

Here we come to the first important provision related to the confidential business information – which must be stipulated. At the same time, the legislation adopted by the state is an exception - usually, confidential business information should be stipulated by the internal act of the organization (institution, company or association). If the organization fails to adopt such an act and if it is not systematic and appropriate to business organizations – then the whole concept of confidential business information cannot be applied.

By doing so, we must avoid the general rulebooks where the only guidance for confidential business information is: "everything that a responsible person declares as a confidential business information", because there is a high probability that at some changes of the extent and the type of business of the organization, part of the data remains unprotected.

The legal person is obliged to keep as a secret the information, which has been learned from the other legal entities (ZZTP’s Art. 20, p. 1). The provision is obviously ambiguous: what’s happening with the natural persons - sole traders and natural persons who are self-employed or who are employed by the service contracts? [8]

The question is: how can a legal entity know if the information that it received from other entities is indeed confidential. The simplest answer is - "it says on the paper" which would hardly be enough in the era before computers. If the relationship between the two parties includes access, processing of data which is confidential business information, it is necessary to sign an appropriate non-disclosure agreement (NDA). (see below)

ZZTP does not speak a lot about NDA, but because confidential business information is extensively described; it is giving a wrong message that this issue is resolved through legislation. As we have said, this is referred only to the legal persons, but contemporary business often includes external teams of experts, freelancers and similar categories of non-classical legal persons. It is a failure of the legislator, however, originated in another time, because the complex forms of work from today were not common.

The ZZTP in its provisions if there is a proper general act, in which any legal person; (the Act forgot to add craftsmen and freelancers!); but more closely it regulates the issue of confidential business information in accordance with its business and needs.

General Act elaborates questions of confidential business information and in the Art. 21 of ZZTP it states, where it provides a framework for handling with classified information. The information that is considered confidential business information under The General Act can be transmitted to the other persons by the persons authorized and determined by The General Act (Art. 21, para. 1). Also, The General Act describes in detail the cases and the manner of protection when the above information may be disclosed to the other persons (Art. 21 para. 2).

The general "guidelines" are given on the information which is supposed to be described by the regulations of the legal person. The legal person will be determined by the authorized person or by the special body that has access to confidential business information, the task of their storage, and deciding which of the persons employed in that legal person could be authorized to keep those confidential business information, and to which persons’ confidential business information could be told (Art. 21, para. 3).

The data that are considered as confidential business information should not be disclosed or made accessible to unauthorized persons, unless a special act provides differently (Art. 22, para. 1). The employees are obliged to keep the confidential business information if they find out an information that is the confidential business information (Art. 22, para. 2). That limits the ability for disclosure of the confidential business information by an informal communication.

The 24th Article of the ZZTP’s consists of exceptions to the provisions which provide obligation of keeping the confidential business information. It is not considered a violation of the disclosure of the confidential business information to the natural or legal persons, to which, such information can or should be disclosed: 1) under the basis of this Act and other regulations, 2) under the authority which is resulting from the duties they perform, the position or the workplace where they are employed (Art. 24, para. 1).

Also, it is not considered as a violation of confidential business information the disclosure of information that are considered as confidential business information in the sessions, if for example, the communication as such is necessary to perform the work (Art. 24 para. 2). The authorized person (at the meeting), who discloses confidential business information should inform those present at the meeting that the information is considered confidential, and that they are obliged to keep the information confidential (Art. 24, para. 3).

The 25th Article of the ZZTP’s stipulates that as a violation of confidential business information, it won’t be considered as a statement that a person familiar with the confidencial business information gives while reporting the crime, (also an economic offense or misdemeanour), to the competent body for the exercise of their labour rights.

1536 MIPRO 2017/ISS
The 26th Article of ZZTP’s contains a general provision according to which a general act of a legal person specifies the method of administration and storage of information that is considered confidential business information, measures, procedures and other circumstances of keeping the confidential business information.

III. MARKING OF THE CONFIDENTIAL BUSINESS INFORMATION IN THE CROATIAN LEGISLATION

As already stated, ZTP’s Article 34 has determined that by its coming into force, provisions of the ZZTP ceased to be valid, except of the provisions stated in the Head 8 and 9, provisions about business confidential information.

However, the manner of marking the business confidential information is not stated in the Head 8 or 9! How to mark that some information is confidential? In our opinion, it is necessary to apply the ZZTP’s provisions which ceased to be valid, but the ones that are writing about marking the business confidential information.

According to the ZZTP’s business confidential information has its own type and level. The 3rd Article of the ZZTP has determined, to the type of confidentiality, the confidential business information can be state, military, official, business or professional, and according to the level of confidentiality – state’s confidentiality, top-secret, secret and confidential.

In accordance with the ZZTP’s Article 5, para. 2, information representing the confidential business information can have level of business confidential information as ‘top-secret’, ‘secret’ and ‘confidential’ and they are marked by the appropriate mark, type or level of confidentiality. Therefore, to the ZZTP, the proper way of marking was: ‘business confidential information – as top secret’, ‘business confidential information – as secret’ or ‘business confidential information – as confidential’. [8]

We can certainly recommend that such marking could be used today – for, it is simple and understandable, even if that part of the ZTP is not in force. What can prove to be a problem - is that this is the authors’ opinion, and as such the court in the case of a dispute, does not have to accept it.

IV. THE CONFIDENTIAL BUSINESS INFORMATION IN THE CRIMINAL LEGISLATION

The Republic of Croatia regulates the protection of confidential business information in the criminal legislation by very strict (long) prison sentences. In the Article 262 of the Criminal Act, it states that whoever, without an authorization, delivers or otherwise makes available any information that is confidential business information, or whoever collects such information with the aim of delivering it to an unauthorized person, will be punished by the imprisonment of up to three years. There is also much worse form of this criminal act - if the offender acquired considerable material gain for himself or for another, or caused a considerable damage, will be punished by imprisonment from six months to five years. [7]

In the same article, there is one exception – there is no criminal offense of disclosure and unauthorized acquisition of the confidential business information, if the offense is committed, predominantly in the public interest.

The stated criminal offense is prosecuted by the proposal. This means that the State’s Attorney will not initiate proceedings ex officio, but in concern with the proposal of the injured party.

Naturally, the Criminal Act does not define what the confidential business information is - it only states that it should be defined by the other already mentioned acts, (by the separate act or the general act of the legal person’s).

V. COMPARATIVE VIEW

Among other things, the ZTP’s Final Proposal [5] states: “According to the criteria of comparative legislation, business confidential information isn’t regulated together with the secrets of the state bodies sphere, but separately, and mostly within the framework of regulations on market operations. If we consider the practice of several relevant countries, it is only partially true. Austria has a dual model of protection of business confidential information: ‘The Austrian Law provides for the protection of trade secrets prevalently in the Act against Unfair Competition, specifically in sections 11 to 13 but also in the Penal Code. These provisions are supported by the general clause according to section 1 of the Austrian Unfair Competition Act. Also, Sections 11 and 12 are provisions of criminal law. The general nature of these provisions is the disclosure or exploitation of trade or business secrets, that have been entrusted to the offender during a professional occupation, or which have been obtained by espionage. The penalties in question are imprisonment or fines. The legal values protected under this framework are the legitimate interest in the confidentiality of trade and business secrets and to punish infringements of such legitimate interests.’” [9]

A similar solution is offered by the United States: “In contrast to other types of intellectual property (trademarks, patents, and copyrights) that are governed primarily by federal law, trade secret protection is primarily a matter of state law. Thus, trade secret owners have more limited legal recourse when their rights are violated. State law provides trade secret owners with the power to file civil lawsuits against misappropriations. A federal criminal statute, the Economic Espionage Act (EEA), allows U.S. Attorneys to prosecute anyone who engages in “economic espionage” or the “theft of trade secrets.” The EEA’s “economic espionage” provision punishes those who misappropriate trade secrets with the intent or knowledge that the offense will benefit a foreign government, instrumentality, or agent.” [10]

The Federal Republic of Germany has solved this issue through several regulations, primarily through the Unfair Competition Regulations but also through the labour regulations, which does not exclude criminal liability. It is interesting that there is a special obligation of keeping the information of the other side, in case of business negotiations. [11]

It is obvious that also in the other countries there is a considerable disagreement over the legal protection of business confidential information. It is regulated by the Regulations of Competition’s Protection, by the Civil Code, but also by the system of Criminal law. Considering that numerous business ventures are supranational, it represents pre-regulation. It should be taken into
consideration that the perpetrators (especially those for the first time) were condemned on parole or short prison sentences, which in practice is proven to be troublesome. [12] De lege ferenda, it should be advocated that the business confidential information issue remains within the civil liability for damage.

VI. A NON-DISCLOSURE AGREEMENT

A non-disclosure agreement (further: NDA), also known as a confidentiality agreement is a private contract, which is used for keeping and saving valuable information. It can be of a great benefit for researchers and organizations that are involved in research and development projects. NDAs’ are legally binding, for determining the conditions under which one party is (the ‘discloser’ of information), the one who reveals confidential business information to another person (the ‘recipient’ of the information). In doing so, one party provides information, and the other party receives the information. Depending on the number of parties who share information, NDA can be unilateral, bilateral or multilateral.

For an NDA to become valid, in Croatian legal system, it is not required to be verified by a notary public, but the signature of the contracting parties is sufficient, (in case of organizations, the agreement should be concluded by the authorized representative/s). Other than mentioned, the ZZTP (in the Head 8), is familiar with the protection of confidential business information, but there is no NDAs’ in Croatian legislation.

Any information which may not be in public domain, or generally known, may be protected by a non-disclosure agreement. It can protect any sort of confidential information like: a concept for a new restaurant, a new business venture, or any sort of confidential business information that could be of value to others if it was disclosed. [13] Additionally, confidentiality agreements should contain a provision stating that no implied license to the technology or information is to be granted to the recipient and that all tangible embodiments of the information (e.g., models, data, and drawings) should be returned upon request and in no event later than the end of the agreement term, and that no copies shall be retained by the recipient. [14]

In conclusion, there are several situations where a confidentiality agreement is appropriate and may be proposed. Knowing a few basic points concerning confidentiality agreements can ensure that the important purposes they serve will not be defeated by ambiguities or ignorance of the meaning of terms used in the agreement. [14]

VII. CONCLUSION

The confidential business information in The Republic of Croatia is, therefore, defined by the 1996 ZTTP’s, and by the provisions of the Criminal Act. At first glance, one might conclude that it is extensively regulated by the acts of public authorities.

However, after a review we have given in this paper, it can be concluded that the entire state regulation concerning the confidential business information in Croatia is deficient. It is based on the over 20 years old provisions of the ZZTP, which are applied based on the transitional provisions of the ZTP from 2007, and partly by an outdated criminal legal liability (the issue of confidential business information in the developed countries, mainly lays within the scope of civil liability for damage).

This regulation gives only an illusion of protection of the confidential business information - so it could easily be said that it is even harmful, in practice. Therefore, for all, that are doing business in Croatia and want to protect their information, we recommend that they primarily do:

a) their own quality act on the protection of business information;
b) the signing of an appropriate NDA agreement with their partners (standardized, or if necessary, custom),
c) Signing NDA agreements with external partners (individuals, craftsmen, freelancers).

Also, it is necessary to inform its own staff about confidentiality and ask them confirmation and familiarity with the same.

Only, if the organization does its own measures then it can partly rely on the national system of protection of business information.

In the end, we emphasize that this legal system of protection of confidential business information, literally represents a rarity in the world, so it is important to familiarize foreign business partners in businesses which include confidential business information.

Abstract—The known attacks on different cryptosystems lead to a number of criteria that the implemented cryptographic algorithms (ciphers) must satisfy. The design of cryptographic systems needs to consider various characteristics simultaneously, which can be regarded as a multi-objective combinatorial optimization problem. Evolutionary computation present a range of problem-solving techniques based on the principles of biological evolution. Evolutionary algorithms can quickly offer satisfactory solution to combinatorial optimization problems. Evolutionary computation can be also used in evolving pseudorandom number generators which play important role as a countermeasure against side channel attacks. The purpose of this paper is to give a state-of-the-art overview of the evolutionary computation area in symmetric and asymmetric cryptography, as well as for the evolving pseudorandom number generators. In symmetric cryptosystem, one of the important components is the substitution box which can be successfully built by evolutionary algorithm. In asymmetric cryptosystem, evolutionary algorithms can be used to speed-up some discrete mathematic operations, like modular exponentiation.

I. INTRODUCTION

Combinatorial optimization is a topic that consists of finding an optimal object from a finite set of objects. In many such problems, exhaustive search is not feasible. It operates on the domain of those optimization problems, in which the set of feasible solutions is discrete or can be reduced to discrete, and in which the goal is to find the best solution.

Cryptography is the study of mathematical techniques for all aspects of information security. The security of information encompasses the fundamental aspects: confidentiality, data integrity, authentication, and non-repudiation. To ensure all the previous aspects, cryptographic algorithms and modes should satisfy a number of criteria, which can be regarded as a multi-objective combinatorial optimization problem.

Evolutionary computation algorithms represent a range of problem-solving techniques based on principles of biological evolution. Such algorithms can be used to solve a variety of difficult problems, among which are those from area of cryptography and which can be represented as combinatorial optimization problem. It is justified to mention several other methods like cellular automata or addition chains, which in cooperation with evolutionary algorithms can result with better cooperation with evolutionary algorithms can result with better results than conventional algorithms.

This paper is not intended as a detailed survey of possible applications of evolutionary algorithms in cryptography nor detailed explanation of mathematical background in cryptography. Rather, the purpose of this paper is to give a state-of-the-art overview of evolutionary computation methods applied to cryptographic systems design.

The paper begins by discussing evolutionary computation algorithms in Section II. Section III describes relevant theory in cryptography and the criteria that cryptographic algorithms should satisfy. In Section IV the state-of-the-art of different cryptographic problems and the applications of evolutionary computation methods used in cryptography is given. Finally, Section V draws a conclusion.

II. EVOLUTIONARY COMPUTATION

Evolutionary computation is a family of algorithms inspired by biological evolution, and the subfield of artificial intelligence and soft computing. It can be roughly divided to three groups: evolutionary algorithms, swarm algorithms, and other algorithms. Evolutionary computation uses iterative progress, like growth or development in population. This population is then selected in a guided random search to achieve the desired goal. In following paragraphs, briefly is explained each of these three groups of evolutionary computation.

A. Evolutionary Algorithms

Evolutionary algorithms could be broadly divided into 4 different approaches: genetic algorithms [1], genetic programming [2], evolutionary strategies [3], and evolutionary programming [4]. All of these algorithms have been successfully applied to the variety of problems in the field of combinatorial optimization [5]. Evolutionary algorithms are based on the Darwinian theory of evolution.

The population of individuals which represent possible solutions to an optimization problem evolve toward a better solution. To measure the quality of a solution, the fitness function is defined, which is always problem dependent. The evolution usually starts from a pool of randomly selected individuals and then, by utilizing evolutionary operators, new and better population is generated. Main evolutionary operators are selection and recombination. Selection is a process of selecting individuals that will produce a new generation. Recombination consists of two operators: crossover and mutation. Crossover combines two or more parent individuals to form one or more child individuals, that inherit parents’ good characteristics. Mutation is a random change of individual alleles in an individual [6].

Main difference between all evolutionary algorithms is the way of individual encoding and evolutionary operators implementation. The genotype in genetic algorithm is usually represented as a string of bits, array of floating point numbers or a permutation vector. In genetic programming, the genotype
is encoded as a tree structure. That tree structure is built by functional nodes and terminal nodes. The result of genetic programming is called a program. One of possible problems in genetic programming is bloat and there are numerous methods to avoid it. After some generations, the search for better programs halts as the programs become too large. Bloat can be caused by inefficient code, e.g. two times programs halt as the programs become too large. Bloat can be caused by inefficient code, e.g. two times programs halt as the programs become too large. Bloat can be caused by inefficient code, e.g. two times programs halt as the programs become too large. Bloat can be caused by inefficient code, e.g. two times programs halt as the programs become too large.

Cartesian genetic programming [7] is a type of genetic programming where a genotype is encoded as a graph structure. It is called Cartesian because functional nodes are organized in rows and columns, which reminds to a Cartesian system. This type of genetic programming solves bloat problem as well as the number of individuals in population. The genotype length is constant size and because of that the bloat problem is inherently solved. Typically, evolution strategy ES-(1+4) is used in Cartesian genetic programming. For more details on evolutionary algorithms, we refer readers to [6].

B. Swarm Algorithms

Swarm algorithms consist of ant algorithms [8], particle swarm algorithm [9], bee algorithms [10], and others. Some swarm algorithms are inspired by experiments made by biologists or by software imitation of swarms in computer graphics. Common to all algorithms is a swarm population consisting of individuals of different characteristics. For more details on ant algorithms refer to [11] and bee algorithms refer to [12]. In the next paragraphs the particle swarm algorithm will be described.

Particle swarm optimization algorithm is created to simulate a flock of flying birds. Flock of birds is represented as a set of particles and each particle must satisfy several rules according to the neighbor particles: avoiding collision, speed harmonization, and low distance. Those rules determine social aspect of particles. Each particle is described by velocity and position. Position is a possible solution of a problem, a velocity vector changes the particle position according to the previous rules. For more information on particle swarm optimization algorithm refer to [13].

C. Other Algorithms

Other algorithms relevant for this paper are artificial immune system algorithms and cellular evolutionary algorithm. Each of these algorithms are specific and have different individual encoding or solution finding method.

Artificial immune system algorithms is a family of algorithms inspired by human immune system. Clonal Selection Algorithm (CLONALG) is the most used algorithm from this family. The algorithm begins by creating initial population of antibodies. The antibodies are made by some random mechanism. Then, affinity of each antibody is measured. By selection operator, according to affinity, antibodies are selected for cloning. The operator of hyper-mutation is applied to clones in order to improve fitness between antibody and antigen. This procedure is repeated until termination condition is reached. To read more about CLONALG, we refer interested readers to [14].

A cellular evolutionary algorithm is a type of evolutionary algorithm in which individuals cannot mate arbitrarily, but every one interacts with its close neighbors on which a basic evolutionary algorithm is applied. A cellular evolutionary algorithm usually evolves a structured bi-dimensional grid of individuals, although other topologies are also possible. In this grid, cluster of similar individuals are naturally created during evolution, promoting exploration in their boundaries, while exploitation is mainly performed by direct competition and merging inside them. This reproductive cycle is executed inside the neighborhood of each individual and consists in selecting two parents among its neighbors according to a certain criterion, applying the variation of evolutionary operators. For further information about cellular evolutionary algorithm, we refer readers to [15].

III. MODERN CRYPTOGRAPHY

Modern cryptography designs cryptographic algorithms that are assumed to be hard to break by an adversary. It is divided into symmetric key cryptography, asymmetric key cryptography, and hash functions [16]. Pseudo-random number generators can be singled out as separate algorithm that have relevance to this paper.

A. Asymmetric Key Cryptography

This type cryptography is also known as public key cryptography. In public key cryptography two keys are used, one for encryption and other for decryption. The encryption key is a public key and the decryption key is private. Public key cryptography can be divided into three groups: cryptosystems based on factorization problem, cryptosystems based on discrete logarithm problem and others.

The most famous public key cryptosystem is RSA, called after its creators [17]. The security of the RSA cryptosystem is based on the difficulty of the integer factorization problem. In the process of encryption, modular exponentiation is used. Let \( p \) and \( q \) be prime numbers. Then \( n = pq \), where \( p, q \in \mathbb{Z} \), \( d \in \mathbb{Z} \), and \( \phi(n) \) is Euler function. Public key is then defined as \((n, e)\) and private key as \((p, q, d)\). The RSA algorithm is believed to be secured as long as large \( p \) and \( q \) are used.

Famous cryptosystems or protocols based on discrete logarithm problem are Diffie-Hellman [18] or ElGamal [19]. Another large family cryptosystems are elliptic curve discrete logarithm problems (ECDLP). One representative of that family is Menzes-Vanstone cryptosystem [20]. Other public key cryptosystems are Merkle-Hellman, McEliece and NTRU.

B. Symmetric Key Cryptography

Symmetric key cryptography uses the same key for encryption and decryption, therefore some mechanism to keep those keys secret is needed. This type of cryptography is called symmetric because communication participants have the same secret key. Symmetric key cryptography’s main advantage over
asymmetric key cryptography is the fact that it is much faster. Symmetric key cryptography can be divided into block and stream ciphers.

Block ciphers take as an input block of plaintext and a key, and the output is a block of the ciphertext of the same size as the plaintext. Stream ciphers create an arbitrary long stream of key material, which is combined with the plaintext bit by bit. In a stream cipher, the output is created based on a hidden internal state which changes as the cipher changes.

The design of block ciphers relies on two fundamental principles: confusion and diffusion. Confusion means that each digit of ciphertext should depend on several parts of the key. Diffusion means that if a single bit of a plaintext is changed, then, statistically, half of the bits in the ciphertext should change and vice versa.

An S-box or a substitution box is a basic component of symmetric key algorithms. The main purpose of using an S-box is to introduce a confusion. The nonlinearity property of S-boxes is one of the most important cryptographic criteria because cryptographic algorithm should be resistant to linear cryptanalysis [21]. S-box \((n,m)\) consists of \(n\) input variables and \(m\) output variables. These \(m\) outputs can be viewed like \(m\) Boolean functions. If nonlinearity of a Boolean function is equal to maximum then it is called bent function. The nonlinearity bound, show in 1, is called the covering radius bound and is strict for bent Boolean functions.

\[
N_f \leq 2^{n-1} - 2^{\frac{n}{2}-1}. \tag{1}
\]

Other criteria which is considered in Boolean or vectorial functions are algebraic degree, balancedness, resiliency, algebraic immunity, and others [21]. If all criteria are used simultaneously then the problem of finding the best Boolean function or an S-box is a multi-objective problem. To inform more about definitions or mathematics background see [22], [23].

C. Pseudo-random Number Generator

A pseudorandom number generator (PRNG) is a deterministic algorithm for generating a sequence of numbers that have the properties of random numbers. The sequence obtained by the pseudorandom number generator is not truly random because it is determined by small set of initial values, called the state. Pseudorandom number generators play important role in the area of cryptography. General security requirements of PRNGs are listed in below [24]:

- the random numbers should not show any statistical weaknesses,
- the knowledge of subsequences of random numbers shall not allow to compute predecessors or successors practically or to guess them with non-negligibly larger probability than without knowledge of these subsequences,
- it shall not be practically feasible to compute preceding random numbers from the internal state or to guess them with non-negligibly larger probability than without knowledge of the internal state and
- it shall not be practically feasible to compute future random numbers from the internal state or to guess them with non-negligibly larger probability than without knowledge of the internal state.

The most famous and the simplest PRNG is the linear congruential generator (LCPRNG) given in equation 2. The \(s_0\) is called seed. Another PRNGs are RSA PRNG and Blum-Blum-Shub PRNG.

\[
s_{i+1} = (as_i + b) \mod M, a, b \in \{1, \ldots, M - 1\}. \tag{2}
\]

IV. EVOLUTIONARY COMPUTATION IN CRYPTOGRAPHY

In next subsections the state-of-the-art overview of the evolutionary computation algorithms will be given.

A. Evolutionary Computation in Asymmetric Key Cryptography

Two problems in asymmetric key cryptography chosen to be described are finding short addition chains and cracking of the Merkle-Hellman cryptosystem using genetic algorithm.

1) Addition Chain: Field of the modular exponentiation has several important applications in cryptography. Well-known public key cryptosystem such as RSA adopt modular exponentiation. Modular exponentiation is defined as follows:

\[
B = A^c \mod p. \tag{3}
\]

where \(A\) is an integer in the range \([1, \ldots, p - 1]\) and \(c\) and \(p\) are arbitrary positive integers. In cryptosystems, \(p\) is a large positive prime number defined in III-A. One possible way of reducing the computational load of Eq. (3) is to minimize the total number of multiplications required to compute the exponentiation. Since the exponent in Eq. (3) is additive, the problem of computing powers of the base \(A\) can be formulated as an addition calculation, for which so-called addition chains are used. For example, if \(A^{2^{20}}\) wants to be calculated, the traditional procedure would require 50 multiplications. If the addition chain is used, then only 7 multiplications are required: \([1 \rightarrow 2 \rightarrow 4 \rightarrow 8 \rightarrow 16 \rightarrow 32 \rightarrow 48 \rightarrow 50]\).

Usual deterministic algorithm is the binary method. The exponent is written in binary representation (of length \(d\) and then each occurrence of digit 1 is replaced with the letters "SM" and each digit 0 with letter "M", where "S" stands for squaring and "M" stands for multiplication. After all digits are replaced, the first "SM" occurrence on the left is crossed. This method is deterministic but it does not give the optimal solution. There are two version of binary method: left-to-right and right-to-left. Both methods have same number of operations: \(d\) times squaring and multiplications as much as there is number of digit 1.

In [25] experiment with the Particle Swarm Optimization algorithm in order to find optimal short addition chains. Authors in [26] implement the Ant Colony Optimization algorithm on a System on s Chip (SoC) in order to speed up the modular exponentiation in cryptographic applications. In [27] use a GA to find minimal Brauer chains where a Brauer chain is an addition chain in which each member uses the previous member as a summand. In [28] authors investigate the usage
of evolutionary programming for minimizing the length of addition chains.

In [29] authors proposed a genetic algorithm to find short addition chains for a given exponent. The main paper contributions were a new representation of solutions, design several mutation and crossover operators designed to improve convergence and design a special part of algorithm called repair heuristics that is believed to be an integral part of the algorithm.

Internally the alleles were pair of positions \((i_1, i_2)\) that hold values \((u_1, u_2)\) which form value on given position. That type of encoding is called encoding with summation positions. Repair heuristics is strategy needed to recreate invalid individual. The genetic algorithm in that paper is described as follows. First, set zeroth element to \(1\) and the first element to \(2\). Then uniformly at random select between all minimal subchains consisting of three elements and a random choice of the second element. With a probability equal to \(3/5\) double the elements until they reach half of the exponent size. Check weather the current element and any previous element sum up to the exponent value. Uniformly at random choose mechanisms given in paper to obtain the next value in the chain, under the constraint that it needs to be smaller than the exponent value. The used fitness function was the number of elements in the chain.

Authors showed that with proposed genetic algorithm is possible to find better solution than with the binary method.

2) Merkle-Hellman Cryptosystem: Merkle-Hellman cryptosystem is a public key cryptosystem based on a concrete case of the knapsack problem [30]. The knapsack problem is defined as follows: for a given set \(\{v_1, v_2, ..., v_n\}\) of \(n\) integers and an integer \(V\), find an array \(m = (\epsilon_1, \epsilon_2, ..., \epsilon_n)\), where \(\epsilon_i \in \{0, 1\}\), so that \(\epsilon_1 v_1 + ... + \epsilon_n v_n = V\), if such \(m\) exists. This problem is NP-complete, which means that there is no polynomial algorithm to solve that problem. However, the special case of the knapsack problem is the super-increasing sequence, which can be solved in polynomial time. Super-increasing sequence is satisfied if \(v_j > v_1 + v_2 + ... + v_{j-1}\) for \(j = 2, 3, ..., n\). One example of the super-increasing sequence is \(v_i = 2^{i-1}\). The main idea of the Merkle-Hellman cryptosystem is to mask the super-increasing sequence to look like a random sequence. The message receiver should know how to remove the mask, and than solve the super-increasing problem. Masking is done by modular multiplication.

Shamir [31] showed existence of polynomial algorithm for breaking Merkle-Hellman cryptosystem. However, there is a genetic algorithm twice faster. In [32] authors proposed a genetic algorithm as a method to crack the cryptosystem. The authors proposed a new selection and crossover method.

The selection function chooses the selection candidates, which the most satisfy the fitness function, i.e., their fitness values are higher than those of others. In case the population size is \(L\) only \(L/5\) solution candidates is chosen. Exactly these solution candidates form new generations.

The crossover function receives the population of the solution candidates. From this population solution candidates with \(t1\) and \(t2\) numbers are chosen in pairs by means of a random generator taking into account that \(t1\) and \(t2\) do not coincide with each other and the used pair is not repeated. Each solution candidate is divided in two parts (at the mid point). To explore more about given algorithm refer to [32].

B. Evolutionary Computation in Symmetric Key Cryptography

In next subsections the state-of-the-art overview of the evolutionary computation algorithms applied to Boolean and vectorial functions construction will be shown.

1) Cryptographic Boolean Functions: Boolean functions represent an important primitive in the design of various cryptographic algorithms. Three main approaches for generating Boolean functions for cryptographic usages are distinguished: algebraic constructions, random generation, and heuristic constructions.

There exists a number of works that examine Boolean functions in cryptography and their generation with evolutionary computation techniques. Here will be enumerated only relevant papers.

[33] compare the effectiveness of Cartesian genetic programming and genetic programming approach when looking for highly nonlinear balanced Boolean functions of eight inputs. Boolean function is balanced if there is same number of ones and zeros. Nonlinearity is minimal Hamming distance between Boolean function and its all affine functions. [34] investigate several evolutionary algorithms in order to evolve Boolean functions with different values of the correlation immunity property. In the same paper, the authors also discuss the problem of finding correlation immune functions with minimal Hamming weight, but they experiment with only one size of Boolean functions. More extensive investigation on finding correlation immune Boolean functions with minimal Hamming weight and different sizes is conducted by [35].

[36] use Particle Swarm Optimization to find Boolean functions with good trade-offs of cryptographic properties for dimensions up to 12. The same authors use genetic algorithms where the genotype consists of the Walsh-Hadamard values in order to evolve semibent (plateaued) Boolean functions [37]. Semibent Boolean function has all values in Walsh-Hadamard spectrum in \(\{0, 2^{n/2}, -2^{n/2}\}\), where \(n\) is input space dimensionality.

[38] conduct a detailed analysis of the efficiency of a number of evolutionary algorithms and fitness functions for Boolean functions with 8 inputs.

In [39] authors used several evolutionary algorithms to evolve Boolean functions with several cryptographic criteria. Authors used genetic algorithm, evolutionary strategy, genetic programming and Cartesian genetic programming. Individuals were, according to the algorithm, encoded by string of bits whose values define a truth table of th Boolean function, trees of Boolean primitives which are then evaluated according to the truth table they produce or directed graphs that are also evaluated in accordance to the truth table they produce.

Authors used two objective functions. First function was the nonlinearity where the goal is maximization. In the work, truth table was transformed by using Walsh-Hadamard transformation as follows:

\[\text{MIPRO 2017/ISS}\] 
1543
where $\vec{a} \cdot \vec{x}$ is the inner product of two vectors. With that objective function the goal was to find the bent function. Although bent functions are not appropriate as parts of filter and combiner generators, there is nevertheless motivation in their generation. Filter and combiner generators are generators of random sequence which uses linear feedback shift registers (LFSR). The first reason is that this problem can be used as a benchmark to test various evolutionary algorithms. The second reason lies in the fact that using bent functions it is possible to build highly nonlinear functions that are balanced [22]. The second objective was combination of balancedness and nonlinearity. The goal was to find highly nonlinear function that is balanced.

In that paper authors showed that genetic programming and Cartesian genetic programming performed the best, which indicates that the truth table representation in not the most appropriate one when evolving cryptographically suitable Boolean functions.

In [40] authors investigate the efficiency of two immunological algorithms: CLONALG and optimization immune algorithm with elitism. For all algorithms is experimented with two different representations for encoding a Boolean function: string of bits and floating point representation. Same objective functions were used as in [40].

By using those algorithms and individual encodings, it is impossible to conclude whether the string of bits or floating point encoding should be used. Furthermore, the results show that the optimization immune algorithm performs better than the CLOANLG, but both perform slightly worse than the genetic algorithm and evolutionary strategy.

2) Evolution of S-boxes: Substitution boxes (S-boxes) play an important role in many modern-day cryptographic algorithms, more commonly known as ciphers. Without carefully chosen S-boxes, such ciphers would be easier to break. In the process of the design of S-boxes (similarly as in the design of Boolean functions), one can roughly follow three directions, namely, algebraic constructions, random search, and heuristics.

There are several unique S-box representations. An $(n,m)$-function $F$ can be represented as a list of values (lookup table - LUT), with each value ranging from 0 to $2^n - 1$. Alternatively said, an $(n,m)$-function can be implemented as a lookup table with $2^n$ words of $m$ bits each. When $n = m$ it is usual that the S-box is bijective, i.e., that each value in the output appears exactly once.

A Boolean function $f$ on $\mathbb{F}_2^n$ is represented by a truth table (TT), which is a vector $(f(\vec{0}), \ldots, f(\vec{1}))$ that contains the function values of $f$, ordered lexicographically, i.e., $\vec{a} \leq \vec{b}$, where $\vec{a}$ and $\vec{b}$ are two input entries for the truth table [22]. An S-box can be represented in the truth table form as a matrix of dimension $2^n \times m$ where each column $m$ represents one Boolean function (i.e., one coordinate function).

The Walsh-Hadamard transform of an $(n,m)$-function $F$ equals [23]:

$$W_F(\vec{a}, \vec{b}) = \sum_{\vec{x} \in \mathbb{F}_2^n} (-1)^{F(\vec{x}) \cdot \vec{a} \cdot \vec{b}}$$

where $\vec{a} \in \mathbb{F}_2^n$ and $\vec{b} \in \mathbb{F}_2^m$.

An $(n,m)$-function $F$ is called balanced if it takes every value of $\mathbb{F}_2^m$ the same number $2^{n-m}$ of times. Balanced $(n,m)$-functions are permutations on $\mathbb{F}_2^n$ [23].

[41] experiment with a GA that works in a reverse way in order to generate bijective S-boxes of dimensions from 8 × 8 to 16 × 16. They seed the initial S-boxes population with solutions based on the finite field inversion method and then evolve them to find new solutions. The same authors use a modified immune algorithm to generate 8 × 8 S-boxes that are balanced, with high nonlinearity, and low δ-uniformity [42].

[43] explore how to generate S-boxes of size 8 × 8 with a better resistance against side-channel attacks (SCA) as measured with the transparency order property. Next, [44], [45] investigate side-channel resilience of 4 × 4 S-boxes as well as when considering the confusion coefficient property. [46] use genetic algorithms to evolve S-boxes with better SCA resilience and they implement such S-boxes in both software and hardware settings in order to properly evaluate them. Finally, [47] experiment with the modified transparency order property in order to achieve S-boxes with better SCA resistivity.

[48] use Cartesian genetic programming (CGP) and genetic programming (GP) to evolve S-boxes where they discuss how to obtain permutation-based encoding with those algorithms.

In [49] authors experimented with three different S-box representations: truth table, Walsh-Hadamard transform coefficients and the lookup table representation where in the case that $n = m$ an S-box can be represented as a permutation.

The goal was to evolve highly nonlinear S-box with different dimensions. The authors proposed a new cost function that is faster than those in given related work. This cost function is defined as a two-component vector with the nonlinearity as the first component and a cost associated with a part of the Walsh-Hadamard spectrum as the second component; when using in a single criterion optimizer, to determine better solutions, a hierarchical comparison should be performed.

C. Evolving Cryptographic Pseudorandom Number Generators

Random number generators are used in a range of applications spanning from producing simple values and adding randomness to programs, over online betting to various cryptographic applications. One real-world application of pseudorandom number generators in cryptography is to use them for masking as a countermeasure against side channel attacks [50]. When used for such a purpose, those generators need to be extremely fast and small when implemented in hardware. To obtain a generator with such characteristics, “expensive” operations like multiplication or addition should be avoided as much as possible.

John Koza used genetic programming (GP) to evolve programs that output random numbers [51]. As a fitness function...
he used the notion of information entropy as defined by Shannon and the end result was a program that was able to accept a sequence of consecutive integer values and transform it into random binary digits.

Hernandez, Szecne, and Isasi used GP to evolve random number generators where they used the strict avalanche criterion (SAC) as a fitness function [52]. Martinez et al. designed a pseudorandom number generator suitable for cryptographic usage by means of GP. The obtained generator, Lamar was tested with a number of tests where the input values were obtained via a counter function.

In [50] authors used Cartesian genetic programming to evolve a pseudorandom number generator. Functional nodes consisted of logical functions like AND, NOT, XOR, operations RR/RL (rotate right or rotate left) and SR/SL (shift right or shift left), and a function P which is shuffle function. The test for randomness was the bias of the output sequence, which is defined as a ratio of zeros and ones in the sequence.

As the fitness function the entropy is used, where the goal is to maximize entropy in order to achieve randomness. With that fitness function and by using Cartesian genetic programming authors evolved pseudorandom number generators that are extremely small and fast in hardware implementation because they don’t rely on expensive operations like multiplication or addition.

V. CONCLUSION

In this paper, we showed how evolutionary computation can be successfully used in cryptography. We present different approaches in asymmetric key cryptography, symmetric key cryptography and pseudo-random number generator. In asymmetric key cryptography, evolutionary computation can speed-up exponentiation calculation or be used for breaking Merkle-Hellman cryptosystem. In symmetric key cryptography, evolutionary computation can build Boolean functions or S-boxes which satisfy various characteristics simultaneously. Finally, evolutionary computation can be successfully used in evolving pseudorandom number generator.

Abstract - DDoS attacks are attacks that use multiple compromised systems to attack target in order to make service they provide unavailable for legitimate user. Those kind of attacks are popular and one of the hardest problems of computer security today. The reason this is happening is that the traffic sent to the victim usually looks like a regular traffic. Along with hard detection, these attacks are relatively easy to execute because of existing tools that can help the attacker to launch them with almost no knowledge of how the attack exactly works. Because of that DDoS attacks can make huge and permanent damage to the victim. This paper presents the problem of DDoS attacks and gives a taxonomy for classifying attacks, with the intention of educating and raising overall awareness. Also given is an overview of tools that can be used to launch DDoS attacks and some real world examples of DDoS attacks to show that no one is safe from them.

I. INTRODUCTION

Modern Internet gives us possibility to access a wide range of information and people are increasingly relying on that, but information only has value if the right people can access it at the right time. DoS attacks are attacks that try to deny access to information by making computer or network resources unavailable to its intended users, most often by interrupting or suspending services connected to the Internet [1]. These attacks are one of the hardest security problems in today's Internet because of their impact and how easy they can be executed.

DDoS attacks are a subset of DoS attacks where traffic to the target is arriving from many different sources. A set of these sources is called a botnet. A botnet is a number of Internet-connected devices (usually called zombies) used by a botnet master [2]. Botnet master usually recruits zombies through the use of Trojan horses, worms or backdoors [3]. Botnets can be classified according to the way of communication between master and zombies.

There exist Agent-Handler model, Internet Relay Chat (IRC) model, Web-based model [4][5] and Peer-to-peer (P2P) based model [4]. Difference between DoS and DDoS attack is depicted in Figure 1.

Launching a DDoS attack consist of three steps [6][7]:

1. Creating botnet: The attacker is discovering vulnerable hosts and exploits vulnerabilities and security holes to install the attack code.
2. Communication: The attacker communicates with hosts to determine which ones are active to perform tasks like scheduling of attack or upgrade agents.
3. Launching: The attacker specifies victim and command the start of the attack.

The reason DDoS attacks are possible is that the current Internet design focuses on effectiveness in moving packets from the source to destination and not on security. The intermediate network provides the bare-minimum, best-effort packet forwarding service, leaving to the sender and the receiver the deployment of advanced protocols to achieve desired service guarantees such as quality of service, reliable and robust transport and security. This design pushes much of complexity to end hosts leaving them with one unfortunate implication. If one party in two-way communication is malicious it can do damage to its peer. No one in the intermediate network will step in and stop traffic. One security issue with this Internet design regarding opportunities for DDoS attacks is that every Internet entity has limited amount of resources that can be exhausted by too many users. The second issue is that even if the victim is secured its susceptibility to DDoS attacks depends on the state of security in the rest of Internet [8].

There are many motives why would attacker perform the DDoS attack. Most usual reasons for the attacks are personal (revenge), financial gain (preventing the work of competition), ideological belief (Anonymous), cyberwarfare (military or terrorist), intellectual challenge.

Following this introduction, Section 2 presents a taxonomy of DDoS attacks according to different attributes. In Section 3 overview of the tools is given. Section 4 contains biggest and most famous DDoS attacks to show how dangerous they can be. The conclusion is given in Section 5.
II. TAXONOMY OF DDoS ATTACKS

The DDoS field is evolving quickly and it is becoming increasingly hard to grasp a global view of the problem. This section strives to introduce some structure to the DDoS field by proposing a classification of DDoS attacks. In Figure 2 is given taxonomy that is described in detail in this chapter.

Before describing classification it is important to mention that various classifications of DDoS attacks were proposed in literature. Classification based on network protocol stack. Two types of DDoS attacks exist under this classification: network/transport and application layer DDoS attacks. Determinant factor for classification is type of packets send to victim [4]. A different classification is by impact on the victim where exist disruptive and degrading DDoS attacks. The goal of disruptive attacks is to completely deny the victim's services to its clients. Disruptive attacks can be further classified as self-recoverable where the victim recovers without human interaction, human-recoverable where victim requires human intervention (e.g reconfiguration or reboot) for recovery and non-recoverable where attacks inflict permanent damage to victim's hardware. The goal of degrading attacks is to consume some (but not all) of a victim's resources, seriously degrading service to legitimate clients [8].

Also, classification based on rate dynamics exists. Those attacks are divided in high rate, low rate, varied rate, continuous rate and variable rate attacks [4][8]. Another classification based on source address validity exist where source addresses can be spoofed or valid [8].

A. DDoS classification based on attack methods

One of the main ways of classifying DDoS attacks can be based on attack method. These DDoS attacks exploit different weaknesses to cause denial of service of the victim to its clients [8]. There are two types of DDoS attacks under this classification:

- Flooding attacks, also known as brute force attacks are attacks in which an attacker is trying to exhaust bandwidth, network resources, router processing capacity, CPU, memory, disk or I/O bandwidth. Exhaustion of resources is caused because the attacker is sending a vast amount of seemingly legitimate traffic.

- Logical attacks, also known as "Low and Slow" attacks are attacks that take advantage of a specific feature or implementation bug of some protocol, operating system or application installed on the target victim to consume an excess amount of its resources [4]. Both flooding and "Low and Slow" attacks are sending seemingly legitimate traffic, it should be noted that flooding attacks need to generate much more traffic to cause denial of service of the victim.

Examples of flooding and "Low and Slow" attacks are given below in classification of DDoS attacks based on which resources they target.

B. DDoS classification based on target resources

Different types of DDoS attacks are attacking different target resources to cause denial of service of victim. There are three main types of DDoS attacks under this classification [9]:

- Attacks targeting network resources
- Attacks targeting server resources
- Attacks targeting application resources

Every category of these attacks will be explained and some of the most famous attacks in each category will be explained as well.

a) Attacks targeting network resources

DDoS attacks that target network resources with intention to deplete all network bandwidth of victim by using huge amount of illegitimate traffic. These kind of attacks, which are called Network floods, are very simple but effective. In typical flooding attack, the attack is distributed (botnet) and huge amount of traffic is sent towards to the victim what results with network saturation. Although, in minor amounts, this kind of traffic may seem legitimate, in larger amounts it can cause quite a damage. A legitimate user, who tries to access the attacked victim, will experience very slow response or there will be no response at all. There are several types of flood attacks [5][9]:

UDP flood: UDP flood attack exploits only normal behavior but on level heigh enough to result with network saturation. The attacker (computer) sends large number of UDP datagrams (usually from fake IP address) to random ports. The victim can not handle all that traffic or process every single request so all the victims' remaining permeability is used for sending ICMP "destination unreachable" packages in response. UDP flood is measured in permeability (Mbps) or packages per second (PPS).

ICMP flood: ICMP flood works on same principle as UDP flood but ICMP "echo request" packages were beeing sent until network is saturated. It is also measured in Mbps and PPS.

IGMP flood: Similarly to the first two, large number of IGMP packages is sent towards the victim so network
DDoS attacks mentioned above belong to connectionless attacks because they do not need connection between attacker and server to be successful. Result of this type of attacks is congestion of network resources, creating DDoS state even before packets can arrive to victim. In opposition to connectioless attack there are attacks that relay on connection between two parties, but this type of attack most often target server and application resources.

DDoS attack can also be described as reflective if attacker uses potentially legitmet third party for sending attack and by doing this attacker is hiding his real identity [10].

b) Attacks targeting server resources

DDoS attacks that target server resources have intention to deplete CPU power or memory and potentially cause unavailability of services that victim offers. Idea is that attacker uses vulnerabilities on server (most often in communication protocols) with intention that server is busy resolving nonlegitimate requests so it can no longer resolve legitimate requests. Server in this context is most often Web server, but this type of attacks can also attack firewalls or Intrusion prevention systems (IPS).

Most famous examples of attacks targeting server resources are one that target weaknesses in desing of TCP/IP protocol. Those attacks use six control bits in TCP/IP protocol - SYN, ACK, RST, PSH, FIN and URG - to disrupt normal work of TCP protocol [10]. TCP/IP is connection oriented protocol and that means that before any packets could be send between two parties, first connection need to be established. TCP/IP protocol is based on a three-way handshake. First user send SYN packet, server respond with SYN-ACK packet and lastly user send ACK packet. Majoriti of attacks described in this section will abuse this handshake to produce DDoS attack by sending this three packets in different orders, resulting in depletion of server resources while server is trying determine this abnormal traffic.

TCP SYN flood: When user sends SYN packet, server opens new thread and reserve part of his memory for that connection. The server is than responding with SYN-ACK packet and waits for ACK packet to arrive to successfully establish connection. In case when the user is also the attacker, he sends SYN packet and recives SYN-ACK packet but never responds with ACK packet. This cause server to reserve memory for malformed connection. After not recieving ACK packet, server is retransmitting SYN-ACK few times and then removes connection leaving space for new one. Problem is if attacker can send requests for new connections faster than server is removing malformed, it will cause connection table to completely fill and leaving no space for connections from legitmet users [11].

TCP RST attack: TCP RST flag indicates to server that it needs to immediately restart that TCP connection. In TCP RST DDoS attack attacker is trying to interfere with connection between legitmet user and server by guessing sequential number. By doing that attacker can use IP address of legitmet user to send packet with TCP RST flag set to server. In this instance botnet is used for guessing sequential number. Once the server accepts packet with TCP RST flag set it send RST packet to user and breaks connection [11].

TCP PSH+ACK flood: This DDoS attack exploits vulnerabilitie in TCP stack by overfliming it with TCP packets that have set PSH flag. By doing that it disables server to process requests or even respond with ACK packets [9].

Unlike network resources which are vulnerable exclusively to flood DDoS attacks, server resources are also vulnerable to "Low and Slow" DDoS attacks [9]. Although these types of attacks most often target application resources, some DDoS attacks of this type that attack server resources also exist. The main advantage of these attacks is that they are very hard to detect because they do not look different than legitmate traffic.

Sockstress: This type of DDoS attack can be produced in two ways. First way is that attacker sends ACK packet with TCP window size of zero. TCP window is buffer that enables receiving data and when is set to zero it means that user is not able to accept data. Server will repeatedly check if size of TCP window did grow and because the attacker will not change size, the server will continue to check and connection will stay open. Opening huge amount of that kind of TCP connection the attacker will fill connection table and server will not be able to accept connections from legitmet users. The second way is that attacker can set TCP window size on very small number (like 2 bytes), and with that attacker force server to split data on many small pieces of 2 bytes. Huge number of connections like that will use all memory and disrupt normal work of server.

Another type of DDoS attack that target server resources are SSL-base attacks. These attacks are targeting various parts of SSL protocol: SSL handshake, sends malformed data to SSL server or using some functionalities in negotion of encrypted key. SSL-based attacks can even mean that attack is executed over SSL connection, making that attack very hard to detect. That kind of attacks are also sometimes called asymmetric attacks because they demand much more server resources for dealing with them then launging it.

Encrypted-based HTTP attack (HTTPS flood): HTTPS flood is DDoS attack that uses encrypted HTTP traffic (HTTPS flood is explained in next section).

THC-SSL-DOS attack: After establishing connection with legitmet SSL handshake, attacker immediately demands new negotion of encrypted key. Negotion continues until the attacker deplet all server resources. Attack is very effective because of earlier mentioned asymmetric property of attack. Every SSL session demands approximately 15 times more time on server side than on attacker side. Because of that property small amount of packets are enough to cause unavailability of server (this attack also falls in "Low and Slow" category) [9].

MIPRO 2017/ISS 1549
c) Attacks targeting application resources

DDoS attacks that target application resources are getting more popular in recent years. They do not use only HTTP protocol, but also HTTPS, DNS, SMTP, FTP, VoIP and many other application layer protocols that are known for having vulnerabilities which can be used for conducting DDoS attacks. Like attacks that target network and server resources they are separate in two groups: flooding attacks and "Low and Slow" attacks. "Low and Slow" attacks are much more popular and use HTTP protocol because of his wide use [9].

HTTP flood attack: Attacker uses botnet to constantly repeat request for downloading web page (HTTP GET flood). With that attacker deplete all application resources, resulting in unavaiable condition of service that victim offers [5].

DNS flood attack: The attacker sends huge amount of DNS packets using botnet. It works like all other flood attacks but attacks DNS protocol. It is very easy to execute this type of attack, but it is hard to detect it [5].

In previous section "Low and Slow" DDoS attacks where directed to attack server resources. In this section will be described attacks that work on same principal, but difference is that they attack application layer. They attack specific application vulnerabilities, allowing attacker to execute them with small probability of detection. Because this attacks are work on application layer, TCP connection is already successelly established and malicious traffic looks like legitimet over legimet connection [9].

Slow HTTP GET request: The attacker generates and sends incomplete HTTP GET requests to server, server is creating new threat for every connection and waits for rest of data to arrive. Attacker continues sending HTTP GET requests very slowly and in intervals just small enough that server would not dismiss connections. With that attacker occupies all entries in connection table and server can not accept connections from legitimet users [5].

Slow HTTP POST request: Attack similar to HTTP GET attack, but sends data thorugh forms on web pages. The attacker sends thorugh form byte at a time, preventing server to close connection and leaving server to wait for rest of the data. If attacker opens enough parallel connections at the same time, it can fill entire connection table of server, preventing server to accept connection from legitimet users.

Regular expression (RegEx) attack: It is very specifical attack because it targets library for regular expression installed on server. Attacker sends specifically crafted packets (Evil RegExes) which then demand huge amount of resoources on the server for evaluating that regular expression.

Hash Collision attack: Another very specific attack that targets hash tables that are used for indexing parameters of POST session. When multiple values are return for one hash value it is said that collision is occurd. Evaluating request that produces collision is very time consuming. In hash collision DDoS attack, attacker sends specifically crafted POST requests with intention to cause collision, thereby occupies resources on server and drastically slows down server response.

C. DDoS classification based on communication

As described in Chapter 1, in order to execute DDoS attacks, an attacker uses intermediate agents that are called bots or zombies. Zombies are just compromised computers, which are remotely controlled by the attacker. The attacker gives commands to zombies through master computer. In response to commands from the master computer, zombies performe the actual DDoS attack. There are four types of communication between master and zombies [12]:

- Agent-handler model of DDoS attacks consist of masters (attacker), handlers and agents (zombies). The attacker is giving commands through master. Then these master systems are used to communicate with agents with the help of some software packages called handlers. It is important to say that agents are also programs that are installed on compromised systems using some exploitation technique. At the end agents will carry out DDoS attacks on the target system, while real attacker remains safe [4].
- IRC-based model is very similar to Agent-handler model, but instead of using some arbitrary handler program, it uses IRC communication channels to connect master systems and agent. Using IRC channels makes tracking DDoS command packets more difficult and attacker can more easily hide his presence because IRC server tends to have large volumes of traffic [13].
- Web-based model is another centralized model similar to Agent-handler, but it uses HTTP protocol as a communication protocol. The Web agents downloads the instructions using web requests periodically. The main advantage is that this approach is stealthier since this traffic can be easily hidden inside legitimate HTTP traffic [3].
- P2P-based (Peer-to-Peer) model is the most sophisticated communication technique. This model uses Peer to Peer technologies that make use of application layer Peer To Peer protocol. Unlike previous models, this model is not centralized, but distributed and that is main advantage of this approach. The model is distributed which makes it harder to shut down [4].

D. DDoS classification based on degree of automation

Each phase of recruit, exploit, infect and attack can be performed either manually or automated. There are three types of DDoS attacks based on automation:

- Manual: The attacker performs all steps manually. It scans a remote machine for
vulnerabilities, exploit them, install attack payload and commands the attack.

- Semi-automatic: First three steps are automated (recruit, exploit and infect). The last step is manually executed via some kind of communication described in the previous section [6].

- Automatic: All four steps are executed automatically. Information like start time of attack, attack type, duration and victim are preprogrammed in the attack payload, and thus it is avoided the need for communication between the attacker and zombies [8].

III. TOOLS FOR DDoS ATTACKS

Launching DDoS attacks manually requires some skill to execute properly but there are a plenty of available tools that can help make that process very easy. They are free and easy to access and that is one of the reasons why DDoS attacks are very popular. In this section some of the most popular tools are described.

- Stacheldrath is DDoS attack tool that can generate ICMP, SYN and UDP flood attacks. It has the capability to congest the link and spoof the IP address. It can run on the Linux and the Solaris 2.1 and has a command line interface [6].

- Tribe flood network (TFN) is DDoS attack tool that can generate a number of different attacks that has the capability to deplete both resource and bandwidth of the target. It can run on all major operating systems (Windows, Linux, etc.) and has a command line interface [4][6].

- Low Orbit Ion Cannon (LOIC) is DoS attack tool that utilizes the UDP, TCP or HTTP packets to execute flooding attacks with the goal to deplete the resources of the victim server like network bandwidth or CPU and memory capacity. It can run on all major operating systems and have a graphical user interface [14].

- High Orbit Ion Cannon (HOIC) is a high speed, multi-threaded DDoS attack tool that uses HTTP GET flood and POST requests that are sent to the victim. It can run on all major operating systems and has a graphical user interface [15].

- Slowloris is DDoS attack tool that creates an unavailable condition for a server by using a very slow HTTP request. By sending HTTP headers to the target site in tiny chunks as slowly as possible, the server is forced to continue to wait for the headers to arrive. If enough connections are opened to the server in this way, the server becomes unable to handle legitimate requests. It is implemented in Perl language and has both graphical user and command line interface [1][15].

- R U Dead Yet? (R.U.D.Y.) is a slow rate DDoS attack tool that uses long-form field HTTP POST submissions. By injecting one byte of information into an application POST field at a time, it causes application threads to await the end of the never-ending request in order to perform processing. This will ultimately exhaust the server connection table [1][15].

- #Ref is a DDoS attack tool that targets vulnerabilities in SQL database software that allow for injection attacks. Using SQL injection, it forces a target server to use a special function that consumes a large portion of victim resources. It is written in Perl, making it platform independent and has a graphical user interface [15].

While the attacker can manually launch attacks using their own scripts or use the tools mentioned above, there is a third option and that is buying DDoS attack. Today on the Internet exists many websites that offer attacks for a reasonably small amount of money (compared to damage they can cause). Providers of these services have already prepared existing botnets to attack targets that their customer wants.

IV. REAL WORLD DDoS ATTACKS

The popularity of DDoS attacks is increasing and new threats emerging very quickly. In this section some of the biggest and most famous DDoS attacks will be enumerated to show that no one is secure from them.

The first documented DDoS attack was reported in August 1999 against a university [16] which lasted for 2 days. On Monday, 7 February 2000 a high-profile DDoS attacks hit Yahoo, the most popular site on the Web which leads to high revenue losses to Yahoo. In October 2002, 9 of the 13 root servers that provide the Domain Name System (DNS) service to Internet users around the world shut down for an hour because of a DDoS flooding attack [4]. In 2008, an attack against Scientologist church was executed by hacktivist group Anonymous. The attack was meant to be a protest against churches philosophy and practice [17]. In 2014, attack on Chinese government was executed because of political reasons (famously known as a Hong Kong DDoS attack) [17]. In 2016, DDoS attack with peaks of over 1 Tbps traffic was launched against France-based hosting provider OVH [18].

V. CONCLUSION

DDoS attacks are attacks that target availability of resources potentially causing huge and permanent damage to victim. Because of their nature, they are one of the hardest problems of computer security. New attack and tools for producing attacks are constantly emerging and evolving, but countermeasures against DDoS attacks is not on appropriate level because it is hard to effectively apply defence mechanisms to completely prevent the attack. In this paper is given taxonomy of attacks that can help victims and security experts to better understand types of DDoS attacks so they can build their defense properly against them. It is also important to educate people about DDoS attacks and how to react properly in situations when they occur.

Uvođenje novih sadržaja u nastavu digitalne forenzike i kibernetičke sigurnosti upotrebom studentskih radova

Damir Delija, Antonio Zekić
Visoka škola za informacijske tehnologije
Klaićeva 7, 10000 Zagreb
damir.delija@vsite.hr
Antoni.zekic@vsite.hr

Sažetak - U ovom radu razmatramo načine kontinuiranog uvođenja novih sadržaja u predmete s područja kibernetičke sigurnosti. Kao primjer navodimo „Osnove računalne forenzike“ u kojima se novi sadržaji uvode korištenjem studentskih praktičnih i teoretskih radova, ideje za radove predlažu studenti i predavači. Predloženi postupak se sastoji iz testiranja kroz studentski rad, te ugradnje rezultata u nastavne materijale. Da bi se studentski rad uspješno koristio mora zadovoljiti niz zahtjeva: prilagođenost stupnju znanja studenta i raspoloživo opremi, raspoloživost alata i sustava, jednostavna implementacija i prenosivost, upotreba alata otvorenog koda i slobodnih alata, te minimalna cijena.

Ključne riječi: nastava kibernetičke sigurnosti, osnovne računalne forenzi, nastava računalne forenzi, studentski rad

I. UVOD

Kibernetička sigurnost i digitalna forenzička sve više se pojavljuju u stvarnom životu, izvan čisto tehničkog svijeta ili filma, zbog toga je važno da se za ta područja sustavno obučavaju studenti računarstva. Nastava i obučavanje studenata za ta vrlo brzo razvijajuća široka područja zahtijevan je zadataka koji traži stalno uvođenje novih sadržaja i unapređenje postojećih. Da bi održala kvalitetu i prihvatljivost nastave potrebno surađivati sa studentima i njihov interes i profesionalno znanje iskorištiti za uvođenje i proširenje sadržaja.

Na Internetu postoji velika količina dostupnih slobodnih materijala iz kojih se mogu izgraditi kvalitetne vježbe i nastavni materijali. Ipak, vrlo često ti materijali su i dosta stari ili zahtijevaju određene specifične alate ili uređaje za koje su inicijalni pripremani, pa sadržaji nisu pogodni za direktnu primjenu. Dobar primer su Nacional Institute of technology [10] forenzičke web stranice, forenzički blog SANS institute [7], Volatility blog [8] forenzičkog alata za analizu radne memorije i mnogi drugi koji daju odlične materijale za učenje, samoučenje ili primjenu u nastavi.

U korištenju tih materijala potrebno je uzeti u obzir i specifičnosti vezane na lokalno okruženje, pravne aspekte naročito resurse koje ti materijali traže a koji često nisu dostupni u hrvatskoj.

Količina novih relevantnih ideja i alata je tolika da ju je teško pratiti i evaluirati u smislu primjene u nastavi. Uz takve uvjete i polazne pretpostavke vrlo je korisno surađivati sa studentima tako da studenti putem svog praktičnog rada i istraživanja isprobaju neku od predloženih metoda ili ideja, te da je kroz jedan ili više radova prezentiraju i ugrade nastavne materijale i prenesu ostalim sudionicima nastave. Takav način rada prisutan je i tradicionalnim dobro uhodanim institucijama koje se bave kibernetičkom sigurnošću i digitalnom forenzičkom, SANS reading room [17] predstavlja kako dobar primjer rezultata takvog načina rada.

Sličan pristup suradnje sa studentima korišten je i ranije, u sklopu nastave računalnih mreža. Kao primjer može se uzeti studentski rad, koji je evoluirao kroz niz iteracija, preko seminarског rada, u diplomski rad, pa u osnovnu skriptu za laboratorijske vježbe. Rad je baziran na korištenju mrežnog simulato dione i IMUNES [6]. Seminarски rad je primarno ispitao primjenjivost alata IMUNES u
nastavi, da bi ga kroz kasniju razvoj u potpunosti implementirao. Mrežni simulator IMUNES je i dalje u kontinuiranom razvoju, pa se nastavni materijali periodički osjećavaju s novim modulima iz novih verzija alata IMUNES. Nedavno proširenje primjera IMUNES alata za sigurnost mogu se koristiti kao dio vježbi mrežne digitalne forenzihe.

U ovakvo zamišljenoj pristupu može se uočiti ciklus koji olakšava održavanje predmeta i potiče predavače i studente na suradnju. Taj ciklus može biti tako koristan i efikasan, ako je uočen i podržan organizacijom fakulteta te ako ima uspostavljenu pravu nastavnu informatičku infrastrukturu za suradnju nastavnika i studenta. Ciklus možemo prikazati nizom od 4 koraka koji se periodički ponavljaju sa svakim novim semestrom i nastavnim ciklom kao što je prikazano u tablici I.

Nažalost to često nije slučaj, najčešće postoje samo sustavi za praćenje tj. ekvidenciju nastave, ali ne i za području nastavi koji bi dozvolili jednostavnu distribuiranu suradnju studenata i nastavnika kroz raspoložive dijeljene računalne resurse.

II. KIBERNETIČKA SIGURNOST I DIGITALNA FORENZIKA

Kibernetička sigurnost je relativno novi krovni pojam računalne sigurnosti koji obuhvaća sve elemente računalne i fizičke sigurnosti računalne opreme i podataka. Digitalna forenziha se pozicionira kao jedno od područja koje obuhvaća kibernetičku sigurnost.

U kontekstu nastave kibernetičke sigurnosti i digitalne forenzihe važno je uočiti međuzavisnost područja i kako digitalna forenziha čini važan temelj u razumijevanju pojava računalnim sustavima a time i osnovu za razumijevanje i primjenu kibernetičke sigurnosti. Da bi nastava kibernetičke sigurnosti bila razumijeva potrebno je prvo uvesti forenzički pristup, te tako kod studenata sistematičariti način rada u analizi složenih situacija mogućih incidenata koji se javljaju u velikim heterogenim IT sustavima. Primjeri i materijali koji se koriste u nastavi posebno oni iz praktičnih vježbi digitalne forenzihe, mogu se direktno koristiti u demonstraciji kibernetičke sigurnosti.

Bez poznavanja digitalne forenzihe je nemoguće razumjeti i pravilno opisati pojave i procese kibernetičke sigurnosti. Kad studenti ispravno usvoje digitalnu forenzihu kao dogradnju svojih osnovnih računalnih vještina i znanja lako će usvojiti i razumjeti kibernetičku sigurnost.

Koristeći ciklus iz tablice I može se i s ograničenim resursima kakvima tipično raspolagu škole i fakulteti u hrvatskoj održati stalni priljev novih ideja i sadržaja. Manjak sredstava nažalost usporava proces.

Sadržaji računalne forenzihe su se počeli uvoditi u nastavu 2013 kroz predmete USI (Upravljanje sigurnosnim incidentima) i ORF (Osnova računalne forenzihe) [1]. Glavni cilj je bio upoznavanje studenata s područjem i stvaranjem osnova za kasnije proširenje prema kibernetičkoj sigurnosti. ORF se sastoji iz niza cjelina: osnove digitalne forenzihe, digitalni dokazi i artefakti, alati digitalne forenzihe, antiforenzički postupci, te razvoj i budući izazovi digitalne forenzihe. Cjelina osnove digitalne forenzihe obuhvaća uvod u digitalnu forenzihu, osnovne pojmove i definicije, te osnovne postupke digitalne forenzihe. Cjelina digitalni dokazi i artefakti u digitalnoj forenzičkoj obuhvaćaju definiciju digitalnih dokaza, veze s ostalim područjima računalne sigurnosti te pravno značenje digitalnih dokaza i artefakata. Cjelina alati digitalne forenzihe obuhvaća karakteristike i primjene alata digitalne forenzihe, te verifikacije i odabir alata. Cjelina antiforenzički postupci definira metode i alate antiforenzihe, te isto tako i pravne aspekte antiforenzihe.

Cjelina razvoj i budući izazovi digitalne forenzihe obuhvaća mobilnu i mrežnu forenzihu, preventivne forenzičke postupke, te tekuće stanje računalne sigurnosti i digitalne forenzihe. Sadržaji su uvedeni i održavani za prošječne grupe do 15 polaznika, laboratorijske vježbe su izvođene u jednostavnom računalnom laboratoriju opće nastavne namjene. Jedan od problema koji se odmah pojavio je prikladnost praktičnog rada tj. da laboratorijske i auditorne vježbe budu suvremene, instruktivne i da se mogu provesti na raspoloživoj opremi.

Tijekom vježbi studenti moraju usvojiti praktične osnove digitalne forenzihe U skladu s tablicom II, zadaci u vježbabama i alati koji se koriste moraju biti tako riješeni da budu u skladu s tekutim stanjem digitalne forenzihe i općenito kibernetičke sigurnosti. Nenamjenski laboratoriji i nedostatak komercijalnih alata su tu glavni problem. Relativno loša opremljenost za računalne zahtjevne sadržaje digitalne forenzihe ograničila je puni samostalni rad. Da bi se taj problem izbjegao prilagođen je izbor alata i sadržaja koji se mogu praktično odraditi u raspoloživom vremenu na postojećoj opremi.

U daljnjem održavanju nastave poboljšavala se oprema i alati pa su se tako uočeni početni problemi počeli
rješavali. Isto tako se kontinuirano proširivao i usavršavao sadržaj koji se prezentira na vježbama i u nastavi. Ideje za proširenje i poboljšanje usvajane su u skladu s ciklusom opisanim u tablici I. Odabir koje će poboljšanje biti primijenjeno je obavljeno prema nizu praktičnih kriterija (tablica IV):

- prilagođenosti stupnju znanja studenta i raspoloživoj opremi,
- raspoloživosti alata i sustava za vježbe,
- jednostavnosti implementacija i prenosivosti,
- upotrebi alata otvorenog koda i slobodnih alata.

Korištenje navedenih kriterija je omogućilo jednostavno i prihvatljivo brzo poboljšanje nastave. Neujednačenost osnovnog računalnog znanja studenata te neprikladna računalna oprema u višenamjenskim laboratorijima su važni ograničavajući čimbenici u uvođenju novih sadržaja koji se moraju uzeti u obzir u razmatranju uvođenja promjena i poboljšanja. Važno je da studentski rad uzme u obzir te kriterije tako da bi rezultati rada bili lako primjenjivi.

### III. CIKLUS U NASTAVI RAČUNALNE FORENZEKE

U planovima za nastavu računalne forenzeki [1], [2] [3] vidljiva je važnost samostalog rada studenta i uvođenja novih sadržaja, odnos vježbi i predavanja je 15 : 30 sati, s naglaskom na praktičnom načinu radu studenata. Tijekom predavanja ključno je uvesti osnovne ideje i pojmove koje studenti mogu usvojiti te im odmah dati praktičnu primjenu kroz uvježavanje. Taj dio može se odraditi putem provjerjenih udžbenika i priručnika, [4], [5]. Praktični dijelovi nastave moraju obuhvaćati postupno uvođenje u koncepte i alate, a praktični zahvati se moraju objediniti s višeslovnim upotrebljem raznih alata. Idealna je upotreba i komercijalnih alata te alata otvorenog koda da bi se demonstrirale opcije i računi rada te prednosti jednih i drugih alata. U tom slučaju nastava se sastoji iz predavanja, auditorijnih vježbi i laboratorijskih vježbi, nove sadržaje treba efikasno ugraditi u sva tri područja, tako da se nadograđuju, uz zahtjev da studenti mogu sami uočiti prednosti pojedinih postupaka i tipova alata.

Kao upotrebivij primjer možemo opisati kako se u obaveznom dijelu vježbi prolazi izrada i analiza forenzičke slike digitalnog uređaja, koraci su navedeni u tablici II. U tom procesu studenti se upoznaju sa svim elementima forenzičkog postupka i raznim alatima i njihovim mogućnostima, a njihov rad se nadograđuje. U prvom koraku upoznaju se s idejom digitalnih dokaza i medijima na kojima se tok dokaze dolaze. Slijedeći korak je akvizicija tij. izrada forenzičke slike uz upoznavanje s potrebnim alatima i procedurama. U koraku nakon akvizicije, u analizi forenzičke slike medija, studenti ponovo koriste alat kojim je obavljena akvizicija, za analizu forenzičke slike. U koraku analize moguća je upotreba dodatnih alata koji ne moraju biti forenzički, na primjer dodatna analiza podataka u tabličnom, kalkulatoru. Cijeli postupak završava u koraku 4, u izradi izvještaja, gdje se rezultati i nalazi integriraju u završni izvještaj. Rezultati analize forenzičke slike mogu biti dobiveni iz raznih forenzičkih alata kao i još nekim od dopunskih ili opcionih alata. Takav pristup daje mogućnost variranja alata i uspoređivanja njihovih prednosti tijekom vježbi, a ujedno naglašava važnost planiranja i discipliniranog samostalnog rada studenata. Vrlo često kao posljedica samostalne analize vježbe studenti dolaze s idejom moguće poboljšanja.

Svaki od medija navedenih u koraku 1, tablice II. zahtjeva posebne alate i proceduru za ispravan rad, što
definira različite varijante jedne te iste osnovne vježbe. Alati i procedure ali i sami mediji se mijenjaju, pa ih je

potrebno redovito održavati i osvježavati.

Da bi proširili postojeće teme, koristimo se rezultatima studentskih radova, posebno onih studenata koji imaju potrebna praktična iskustva i znanja stečena studiranjem uz rad.

Diplomski rad „Forenzička analiza maliciognih programa“ [4] sastoji se iz teoretskog i praktičkog djela. Praktični dio rada se uklapa u niz praktičnih labortorijskih vježbi za studente, a teoretski dio rada koristi se kao osnova za unapređenje postojećih uputa i vježbi. Teoretski dio sastoji se iz poglavlja „Uvođ“, „Priprema i prikupljanje podataka, ispitivanje i analiza podataka.“. Praktični dio rada sastoji se iz poglavlja „Forenzička analiza računala zaraženog maliciognim programom“, te „Zaključak“. Odnos poglavlja rada i redoslijeda forenzičkih koraka dan je u tablici III.

Za proširenje sadržaja ključna su poglavlja vezana uz praktični rad „Forenzička analiza računala zaraženog maliciognim programom“, te „Ispitivanje i analiza podataka“. Iz njih se grade nove praktične vježbe, te potrebna teoretska proširenja predavanjima.

Alati i postupci koje diplomant opisuje i koristi u svom radu su iz tekuće prakse, novije verzije od onih koje su korištene u postojećim vježbama pa se tako na osnovi njegovog praktičkog iskustva poboljšava i osuvremenjuje sadržaj predmeta. Primjer analize maliciognog koda koji je korišten u diplomskom radu također je poboljšanje u odnosu na postojeće vježbe pošto se radi o primjeru maliciognog koda iz stvarne prakse a isto tako i u analizi stvarno korištenim dodatnim alatima otvorenog koda. Prema tablici III se ti sadržaji iz rada uklapaju kao nove vježbe, te nova ili proširena poglavlja u predavanjima.

U radu korištene forenzičke slike s digitalnim dokazima se mogu odmah izrazno koristiti, jednako kao i drugi dijelovi rada. U osnovi je potrebno izraditi upute za rad studenata, upute za instalaciju alata te pitanja tj. zadatke koje student treba obaviti kroz vježbe. U nastavi teorije potrebno je formalno uvesti alate koji se koriste u novim vježbama, objasniti potrebne teoretske pretpostavke uz razradu primjera i literaturu za dodatno učenje. Svi ti podaci su već sadržani i provjereni u diplomskom radu.

Iako postoji zadaća struktura diplomskoga, svaki rad je drugačiji, time je i proces izrade materijala za nastavu i vježbe je isto tako postaje specifičan i zahtjeva dodatni zajednički rad studenta i predavača. Kao rezultat tog dodatnog zajedničkog rada, nakon diplomiranja, uz materijale za nastavu napravljen je i ovaj članak.

Može se rezimirati da ovakav kvalitetan diplomski rad može značajno osuvereniti sadržaj predmeta. Sam rad i njegovo prihvaćanje od strane ispitne komisije garantira kvalitetu i izvedljivost sadržaja opisanih u radu.

Uz ovaj diplomski rad koji je obranjen i koji je u fazi ugradnje u nastavne materijale, odvija se još nekoliko novih studentskih aktivnosti. Namjera je da se razradi korištenje alata Foreman za upravljanje digitalnim forenzičkim laboratorijem [16], te da se uvedu vježbe iz mrežne forenzičke aktivnih sustava putem Google GRR alata [15]. U toku su pripreme za dva diplomska rada za navedene alate. Ugradnja novih sadržaja iz tih radova će se evaluirati i obaviti u skladu s kriterijima iz tablice IV, ti kriteriji opisuju potrebne promjene u postojećoj nastavi, njihov opseg i cijenu a time i definiraju primjenjivost elemenata rada. Proces vrednovanja i primjene bit će duži i kompliciraniji nego za rad [4] zbog složenijih alata i specifičnih zahtjeva u izgradnji praktičkih implementacija alata.

**IV. ZAKLJUČAK**

Diplomski i završni radovi predstavljaju kvalitetne izvore za proširivanje i usavršavanje sadržaja nastave, posebno ako su kao u primjeru [4] studenti sami duboko uključeni u praktični rad na zadanom području. U ovom slučaju se ekspertiza koju je student posjeduje kroz svoj svakodnevni rad u IT kompaniji ugrađila u realističnim primjerima maliciognog koda, stvarnih alata koji se u realnom okruženju IT kompanija u hrvatskoj koristi. Svi drugi oblici samostalog ili mentoriranog studentskog rada također su korisni za unapređenje nastave. Studentski rad i inicijativa se mora iskoristiti i poticati zbog kvalificiranosti studenata i njihovog otvorenog načina razmišljanja o problemima. Na područja kao što su digitalna forenzika i kibernetička sigurnost studenti bi trebali dolaziti sa
solidnim računalnim predzanjima, što u pravilu nije slučaj. Kad takva znanja postoje ona omogućuju korisne doprinose i ideje koja treba evaluirati i upotrijebiti.

Zamke u sigurnosti web aplikacija i njihovog izvornog koda

Lucijan Carčić, Leon Juranić i Neven Biruški
DefenseCode L.L.C., Konjščina, Hrvatska
defensecode@defensecode.com

Danas na svijetu gotovo i ne postoji poznata institucija čiji informatički sustavi nisu bili kompromitirani, najčešće upravo napadom na web aplikacije koje se nalaze izložene na internetu. Moderni informatički kriminalci iznimno su motivirani, raspoložu značajnim resursima, stručnim i specijalističkim znanjima, te visokom tehnologijom. Iako imena "provaljenih" institucija postaju udarne vijesti, i dalje se sigurnosti web aplikacija i njihovog izvornog koda pristupa, u najmanju ruku, prilično nonšalantno i paušalno. Podaci kažu da je čak 64% svih web stranica nesigurno, jer se na njima nalazi bar jedna kritična sigurnosna ranjivost [1]. Naše iskustvo na području automatizirane sigurnosne analize web aplikacija i njihovog izvornog koda govori da su ovi podaci možda i previše optimistični. Mnoge institucije, nakon što postanu svjesne kritičnih ranjivosti u svojim web aplikacijama, često ih mjesecima, pa i godinama, ne uklanjuju. Snučene s očitim i brojnim problemima sigurnosti izvornog koda radije biraju pometanje pod tepih infrastrukture korištenjem resursa napadnutih korisnika. Suočene s očitim i brojnim problemima mjerenje sigurnosti web aplikacija i njihovog izvornog koda, pokazati kako ih hakeri vješto iskorištavaju, te kako izbjeći zamke u pristupu sigurnosti i uporabiti moderne tehnologije u svoju korist, a ne na svoju štetu.

I. UVOD

Područje sigurnosti web (a u novije vrijeme i mobilnih) aplikacija iznimno je izazovno. Zlonamjerno visokotehnološki kriminalci iskorištavaju sigurnosne probleme (ranjivosti) ugrađene u aplikacije kako bi preuzeli kontrolu nad korisničkim informatičkim sustavima, mijenjali i krali podatke, novac, činili zamke u sigurnosti web aplikacija i njihovog izvornog koda, pakati kako ih hakeri vješto iskorištavaju, te kako izbjeći zamke u pristupu sigurnosti i uporabiti moderne tehnologije u svoju korist, a ne na svoju štetu.

1558

MIPRO 2017/ISS
voljni pomoći i dati privolu za ispitivanje svojih aktivnih web instalacija.

Statično sigurnosno ispitivanje moguće je provesti samo u situacijama kada je dostupan izvorni kod aplikacije. Izzumemo li aplikacije otvorenog koda (open source), izvorni kod dostupan je jedino proizvođaču i naručitelju (korisniku) koji je zatražio isporuku ili pristup izvornom kodu.

No, čak i u situacijama kada izvorni kod nije dostupan i dalje je moguće provesti dinamično sigurnosno ispitivanje aktivne aplikacije, pod uvjetom da je ona instalirana na sustavima koji se nalaze pod kontrolom korisnika, te da ne postoje nikakva ograđenja koja bi proizlazila iz općih propisa ili pristup izvornom kodu.

A. Otkrivanje sigurnosnih ranjivosti

Tijekom protekle dvije godine ispitali smo sigurnost više od stotinu web i mobilnih aplikacija i u oko 80% njih pronašli kritične sigurnosne ranjivosti, dakle ranjivosti koje omogućuju relativno jednostavno, direktno i verificirano kompromitiranje aplikacije.

Proveli smo više desetaka ispitivanja sigurnosti informatičke infrastrukture i pripadajućih aplikacija, te u njima imali gotovo stopotstotnu učinkovitost u pronalaženju kritičnih sigurnosnih ranjivosti, često i metoda za potpuno kompromitiranje ispitivanih sustava. Potpuna kompromitacija znači mogućnost stjecanja nadzora ili kontrole nad ključnim elementima, a ponekad i nad cjelokupnom infrastrukturom korisnika. Ova ispitivanja provođena su našim automatiziranim alatima, kao i individualnim ("ručnim") tehnikama. Kombinacija tehnika znači i veću učinkovitost – automatizirani alati imaju svoje prednosti, prvenstveno brzinu, točnost i uniformnost, dok je specijalistički ljudski rad supštini i kreativniji.

U okviru naše javno-korisne djelatnosti, upotrebom našeg alata za statičnu sigurnosnu analizu izvornog koda ispitali smo popularne javne i besplatne CMS (Content Management System) aplikacije otvorenog koda napisane u Javi i C#, te smo u oko 70% njih pronašli kritične sigurnosne ranjivosti.

Nakon toga, proveli smo sigurnosno ispitivanje popularnih modula (plug-in) za WordPress (njapopularniji besplatni javni CMS otvorenog koda), te smo tijekom mjesece dana u njih trideset pronašli kritične sigurnosne ranjivosti.

Sve navedene ranjivosti su novootkrivene (zero-day), što znači da nisu otprije poznate, niti su podaci o njima do sada objavljeni. Nadalje, sve pronađene ranjivosti su verificirane, što znači da je pružena mogućnost njihovog iskorištavanja u praksi. Za javne aplikacije pripremili smo odgovarajuće dokumente (advisory), koji će biti objavljeni prema našim mogućnostima.

Nakon nešto više od tri mjeseca ponovo smo testirali ranjivosti otkrivene u WordPress modulima kako bismo provjerili da li su još uvijek prisutne ili su u međuvremenu uklonjene. Utvrdili smo da su u tom periodu eliminirane samo tri ranjivosti (10%).

Većina drugih kritičnih ranjivosti koje smo otkrili nisu uklonjene ni nakon šest mjeseci. Imamo i par slučajeva gdje kritične ranjivosti koje smo otkrili na web instalacijama nisu uklonjene ni nakon godinu dana, čak i više – bez obzira na to što je korisnik upoznat s njihovim postojanjem.

Prema našem iskustvu može proći od par tjedana do nekoliko godina dok informacije o dotad nepoznatim (ali postojećim) ranjivostima budu objavljene, a one uklonjene. No samo otkrivanje i izrada ispravaka malo znače, sve dok velika većina korisnika ne preuzme potrebne ispravke i nove, ispravljene, verzije takvih aplikacija. U pravilu, ovaj drugi dio ciklusa nikad u potpunosti ne završi i postoje korisnici koji godinama i godinama nakon što su ispravke postale dostupne i dalje koriste sada poznato ranjive i nesigurne aplikacije.

B. Najčešće pronađene ranjivosti

Najčešće otkrivenе ranjivosti su SQL Injection (SQLi) i Cross Site Scripting (XSS), koje su i sada ne samo vrlo prevalentine, nego i opasne.

SQL Injection je jedna od deset najčešćih kritičnih sigurnosnih ranjivosti [4]. To je oblik napada na sigurnost, odnosno iskorištavanja ranjivosti, koji spada u zlonamjernje tehnike injektiranja programskog koda. U većini aplikacija koje koriste korisnički unos podataka zlonamerni napadač umjesto legitimnog i očekivane podatka podmeće programski kod (u ovom slučaju SQL naredbe). Ukoliko aplikacija spremna je za dovoljan napad, zlonamjerni napadač može napraviti stranu web-a ili podaci korisnika direktno, kao i pomoću daljgradnja. Ukoliko aplikacija spremna je za dovoljan napad, zlonamjerni napadač može napraviti stranu web-a ili podaci korisnika direktno, kao i pomoću daljgradnja.
C. Osnove zlopotrebe

Moderni informatički kriminalci nisu romantični genijalci željni istraživanja, samodokazivanja i priznanja okolnih što većinu ekipe prikazane u filmu Hakeri. Oni jesu iznimno motivirani, ali njihov glavni motiv je novac. Raspoložu značajnim financijskim resursima, stručnim i specijalističkim znanjima, te visokom tehnologijom. Djeluju u organiziranim grupama koje provode kriminalne aktivnosti velikog opsega i složenosti. Posljedično, štete takvih napada su ogromne i procjenjuju se na nevjerojatnih 445 milijardi američkih dolara [7]. Uspoređbe radi, tržišna kapitalizacija Microsofta tada je iznosila 411 [8], a bruto domaći proizvod Hrvatske 48,7 milijardi američkih dolara [9].

Nažalost, u stvarnosti, kompromitacije kompjuterskih sustava uopće ne moraju biti tehnološki previše zahtjevne. Korištenjem javno dostupnih i poznatih informacija, poput objave o otkrivenim sigurnosnim ranjivostima, već uz minimum tehnološkog znanja moguće je relativno jednostavno pretraživati internet kako bi se pronašli ranjivi sustavi, na primjer traženjem ranjivih verzija operativnih sustava i često korištene aplikacije. Također, primjenom jednostavnih automatiziranih skripti moguće je masovno i relativno neprimjetno ciljano ispitati ranjivost velikog broja sustava.

Nažalost, u stvarnosti, kompromitacije kompjuterskih sustava uopće ne moraju biti tehnološki previše zahtjevne. Korištenjem javno dostupnih i poznatih informacija, poput objave o otkrivenim sigurnosnim ranjivostima, već uz minimum tehnološkog znanja moguće je relativno jednostavno pretraživati internet kako bi se pronašli ranjivi sustavi, na primjer traženjem ranjivih verzija operativnih sustava i često korištene aplikacije. Također, primjenom jednostavnih automatiziranih skripti moguće je masovno i relativno neprimjetno ciljano ispitati ranjivost velikog broja sustava.

Nažalost, u stvarnosti, kompromitacije kompjuterskih sustava uopće ne moraju biti tehnološki previše zahtjevne. Korištenjem javno dostupnih i poznatih informacija, poput objave o otkrivenim sigurnosnim ranjivostima, već uz minimum tehnološkog znanja moguće je relativno jednostavno pretraživati internet kako bi se pronašli ranjivi sustavi, na primjer traženjem ranjivih verzija operativnih sustava i često korištene aplikacije. Također, primjenom jednostavnih automatiziranih skripti moguće je masovno i relativno neprimjetno ciljano ispitati ranjivost velikog broja sustava.

Na kraju, stručne i tehnološke metode zaštite su korištenje alata za statičnu analizu. Na neki način ovo je i logično, jer je ispitivanje sigurnosti izvornog koda moguće je provođenjem penetracijskog testiranja. Najboljom praksom smatramo provođenje ovih mjera točno navedenim redoslijedom. Automatizirane mjere dolaze prve, sigurnosnu provjeru izvornog koda slijedi sigurnosna provjera aktivne aplikacije (jer se tako testira i okruženje u koje je aplikacija postavljena). Na kraju, izvodi se i ispitivanje sigurnosti provođenjem penetracijskog testiranja.

Ispitivanje sigurnosti izvornog koda moguće je provoditi i individualnim pristupom ("ručno"), ali kvalitetni alati umnogome nadmašuju sposobnost i efikasnost čovjeka u analizi velike količine izvornog koda. Zato ovu mjeru predlažemo kao komplementarnu automatiziranoj analizi, pogotovo što se tiče potvrđivanja otkrivenih sigurnosnih ranjivosti, eliminacije lažno pozitivnih detekcija, te nadopunu strojne analize ljudskim znanjem, iskustvom i domišljatošću.

E. Moguće zamke

Nažalost, broj korisnika koji provode automatizirane metode dinamičnog i statičkog testiranja aplikacija još uvijek nije velik. Nešto više institucija primjenjuju dinamične metode testiranja, koje su u pravilu i financijski dostupnije. Jedan dio korisnika, pogotovo u financijskom sektoru, redovito provodi mjere ispitivanja sigurnosti putem penetracijskog testiranja. Najmanje je rašireno ispitivanje sigurnosti izvornog koda prijenom alata za statičku analizu. Na neki način ovo je i logično, jer je kvalitetnih alata malo, u pravilu su skupljii i time manje dostupni, pogotovo srednjim i malim poduzećima (ne samo u Hrvatskoj).

Međutim, kako su štete od visokotehnološkog kriminala sve veće, broj institucija koje koriste automatizirane metode će se povećati. Velike institucije, pogotovo one koje proizvode ili naručuju aplikacije sigurno će se prilagođavati ne samo situaciji, već i regulativi poput spomenute EU 2016/679, ali i drugih, npr. PCI DSS.

Samim rezultatima, ma koliko točni bili, mnogima u tom trenutku predstavljaju više problem, a manje rješenje istog. Osim toga, postoje alati koji imaju relativno velik broj lažno pozitivnih rezultata, dakle ukazuju na probleme koji u stvarnosti ne postoje. U nekim slučajevima vidjeli smo čak i do 40% lažnih uzbuđa, no može ih biti i više. Takvi alati ne samo da izazivaju nepovjerenje korisnika u metodu statičnog testiranja, već i čine medved ju uslugu cijelom segmentu te djelatnosti. I dalje, svaku pojedinu otkrivenu ranjivost potrebno je "ručno" provjeriti. Različiti alati mogu različito tretirati (označiti) stupanj otkrivenih ranjivosti. Korisnik će sam morati odlučiti koliko su te ranjivosti zaista rizične.

Ako se institucija s ovim izazovima suočava postupno i tijekom razvoja, prilagoditi će svoje tehnike izrade koda i steći će iskustvo u prepoznavanju, eliminaciji i procjeni pojedinih ranjivosti. Korisnik će sam morati odlučiti koji u stvari ne postoje, a ne protiv njega, nešto od čega se ne smijemo skrivati ili stidjeti, već nešto što možemo ponosno pokazivati kao svoje djelo.

III. ZAKLJUČAK

Kako bi se obranile i spriječile napade na sigurnost svojih web aplikacija i posljedično napade na sigurnost svojih informatičkih sustava institucije na raspolaganju imaju samo jedno zaista kvalitetno rješenje – temeljito i redovito testiranje sigurnosti instaliranih aplikacija i njihovog izvornog koda. Automatizirane metode dinamičkog i statičkog testiranja sigurnosti mogu biti od velike pomoći u pronalaženju skrivenih kritičnih sigurnosnih ranjivosti. Ove metode se međusobne ne isključuju niti nadomještaju, već su komplementarne i nadopunjavaju se. Osim što proširuju i produbljuju doseg analize, ovi alati donose ogromnu uštedu u vremenu, to veću što je aplikacija veća ili što je više koda za analizu. Posebno smatramo da će se povećati važnost i primjena statičke metode testiranja sigurnosti, uzevši u obzir velik broj prisutnih sigurnosnih ranjivosti, velike štete od sigurnosnih incidenata, te razvoj legislativne, ali i standarda struke.

Pozornost je svakako potrebno posvetiti i izboru razvojnih alata, okruženja, kao i metodama rada i razvoja programskog koda. Ističemo važnost edukacije i praćenja trendova, kao i postojećih opasnosti i rizika.

INVITED PAPERS
Multidimensional Mining of Big Social Data for Supporting Advanced Big Data Analytics

Alfredo Cuzzocrea
University of Trieste and ICAR-CNR, Trieste, Italy
alfredo.cuzzocrea@dia.units.it

Abstract - Big social data are now everywhere. They constitute a rich source of knowledge that is prone to be explored and mined in order to support advanced big data analytics. Multidimensional mining identifies a promising collection of tools to this end. Following this recent trend, in this paper, we provide an overview on two state-of-the-art proposals that show how big data analytics over big social data work in practice.

I. INTRODUCTION

Big data (e.g., [2,30]) and big data analytics (e.g., [13,14,15,16,17,18]) are now top keywords in actual database and data mining research. Among the plethora of possible big data settings, big social data (e.g., [31,32,40]) play a leading role. Twitter is a typical case of big social data. Indeed, tweets are a rich source of knowledge that is prone to be explored and mined in order to support advanced big data analytics.

Multidimensional mining identifies a promising collection of tools to this end. These tools allow us to extract interesting knowledge from big social data via fortunate multidimensional metaphors, among which OLAP (e.g., [7]) plays the leading role. Indeed, the majority of tweets already identifies multidimensional spaces, mining that Twitter contents usually incorporate multiple variables. For instance, consider the case of political elections. Here, tweets related to this topic are used to contain, for instance, the following dimensions: (i) region, which models the place where the election will take place (including the respective hierarchy); (ii) time, which models the time when the election will occur (including the respective hierarchy); (iii) elector, which models the electors that will express their vote during the elections (including the respective hierarchy). This rich multidimensional knowledge base is prone to support a variety of big data analytics tools, thanks to which decision makers can perform effective decision-making processes.

Figure 1 shows a reference architecture for supporting big data analytics from tweet data, which is multi-layer in nature. As shown in Figure 1, the layers of the reference architecture are the following:

- **Big Data Analytics Layer**, where multidimensional analytics tools extract interesting knowledge from tweet data – here, technologies like Hive [35] and Pentaho [36] are adopted;
- **Big Data Knowledge Layer**, where the final knowledge from tweet data is delivered to knowledge makers.

Following this recent trend, in this paper we provide an overview on two state-of-the-art proposals that show how big data analytics over big social data work in practice. In particular, the first one is represented by a framework for supporting OLAP analysis over multidimensional tweet streams [1]. The second one is represented by a framework for supporting advanced big data analytics over geo-tagged tweets via intelligent multidimensional clustering methodologies [19].

II. OLAP ANALYSIS OVER MULTIDIMENSIONAL TWEET STREAMS

[1] introduces a framework for supporting OLAP analysis over multidimensional tweet streams. Nowadays, people extensively use social networks (e.g., Facebook, Twitter, etc.) and multimedia aggregators (e.g., YouTube, Wikipedia, etc.) to share with their friends across the world: tastes, opinions, ideas, and so on. Millions of tweets about brands, news and so forth, hundreds of thousands of Facebook “likes” and check-ins on Foursquare, happen every day. So, we are heading into a social media data explosion. Collecting these data and performing analytics on social media data streams is one of the main challenges of big data because very interesting business goals could be achieved, such as: addressing marketing strategies, profiling people tastes, targeting advertisements, and so forth (e.g., [2]).

Specifically, [1] is focused on the metadata available in Twitter and we point out that there is a need to
investigate and define suitable knowledge mining approaches to go beyond explicitly available metadata analyzing unstructured data in order to provide intelligent analytics services to support decision-making.

Twitter is the most popular microblogging service with more than half a billion of users. Recent statistics pointed out that the average number of tweets per day is more than 100 million, and thousands of them happen every minute. So, tweets exchanged over the Internet represent an important source of information. Tweets are associated with meta-information that cannot be included in messages (e.g., date, location, etc.) or included in the message in the form of tags having a special meaning. Tweets can be represented in a multidimensional way by taking into account all this meta-information as well as associated temporal relations. Twitter’s API enables us to acquire public tweet metadata (e.g., Twitter’s Search API and Streaming API).

[1] focuses on the definition of a multidimensional data model for the storage of tweet data streams for enabling OLAP analysis. Furthermore, we exploit the implicit information that could be derived or discovered in the tweets by investigating beyond explicit metadata. In particular, we propose an aggregation operator for the text embedded in the tweets’ content based on the Formal Concept Analysis (FCA) theory [3,8].

The data warehouse model enables us to manipulate a set of indicators (measures) according to different dimensions that may be provided with one or more hierarchies. Associated operators (e.g., roll-up, drill-down, etc.) allow an intuitive navigation on different levels of the hierarchy. Indeed, the collected tweets will be represented by means of fuzzy mathematical model in order to extract timed fuzzy lattice through fuzzy extension of FCA [4]. Taking into account the resulting lattice of tweets, a microblog summarization algorithm is introduced to provide subset of the tweets that best represents the values of the chosen dimensions in a specific region of the OLAP cube.

In order to prove the benefits of our proposed innovative multidimensional tweet stream OLAP aggregation and analysis model, we provide a real-life case study focusing on tweets associated to the 2015 Italian election campaign.

In our model [1], the main research result consists in the definition of the so-called OLAP Tweet Cube, along with its multidimensional modeling. A data cube can model an analysis subject called fact F defined on the schema $D = \{T_1, T_2, \ldots, T_n, M\}$ where $T_i \ (i = 1, \ldots, n)$ are several dimensions and $M$ stands for a measure. Every dimension defined on a domain $D$ includes attributes $A = \{a_1, a_2, \ldots, a_n\}$ that can be organized in several hierarchical levels $(l_1, l_2, \ldots, l_n)$. In the proposed cube of tweets, the tweet represents the fact and some of its metadata explicit or implicit will be selected as hierarchical or flat dimensions.

OLAP dimensions can be classified in the following two types.

Semantic Dimension. In our model, this dimension is extracted from Wikipedia knowledge base and it makes use of the titles of Wikipedia articles and of the Wikipedia category graph. Wikipedia provides a knowledge base for computing word relatedness in a more structured fashion than a search engine and with more coverage than WordNet. Obviously, semantic dimension could be extracted from other domain ontologies or vocabularies related to the dimension area as external knowledge source (e.g., GeoNames, WordNet, etc.). Each level $l_i = \{c_{i1}, c_{i2}, \ldots, c_{in}\}$ includes a set of concepts $c_j \ (j \in [1; n])$ extracted from Wikipedia category graph.

Metadata Dimension. Metadata refers to the information about the tweet that can be derived from its metadata, such as: timestamp, user, hashtag, location, etc. So, we have to create a metadata dimension to represent each metadata information that we want consider. In this case we focus on time and location that are both hierarchical dimensions.

OLAP measures definition starts from considering that tweets are significant source of evidence when extracting information related to the reputation of a particular entity (e.g., a particular politician, singer or company) or, more general, a topic. In order to analyze the textual content of tweets, there is a need of an automated methods to disambiguate tweets with respect to entity or topic names in their content. To address this issue we propose a measure which exploit wikification service, wikiify, that is the practice of representing a sentence with a set of Wikipedia concepts [5,6]. Wikification enables us to recognize sense of main concepts and named entity mentioned in the tweet associating a Wikipedia link and a corresponding weight representing uncertainty degree of the disambiguation results.

Specifically, the tweet content is wikiified to extract a set of $(\text{topic}, \text{rd})$ pairs corresponding to Wikipedia articles that are related to the tweet content itself with a specific relevance degree $(\text{rd})$ [5]. Let us report an example by considering the following $i$-th tweet in the tweet stream:

\[ \text{tweet} = \text{“Hillary Clinton is running for president to be a champion for everyday Americans. Join Hillary for America today.”} \]

The wikiification process extracts from the above text a set of $(\text{topic}, \text{relevance})$ pairs. These pairs are features characterizing meaning of the input text. Taking into account the example above, the extracted topic are:

\[ \{\text{Hillary Rodham Clinton}, 0.94\}, \{\text{Bill Clinton}, 0.24\} \]

Hence, let $S$ be the vector space defined by the set of topics:

\[ S\{\text{topic}_1, \text{topic}_2, \ldots, \text{topic}_n\} \]

A tweet, in a multidimensional space is represented by a weights vector as follows:
tweet_{i} = \{(topic_{i}^{1}, rd_{i}^{1}), (topic_{i}^{2}, rd_{i}^{2}), (topic_{i}^{n}, rd_{i}^{n})\}

where topic_{i}^{k} is one of the topic associated to tweet_{i},
rd_{i}^{k} is the relevance degree associated to topic_{i}^{k}, n is
the number of topics detected by sentence wikification of
the tweet_{i}.

Our innovative aggregation model for tweet data lies
along classical aggregation mechanisms [7] with
the novelty of being target to such kind of data that are
inherently textual in nature, hence achieving the proposed
methodology for microblog summarization. This
methodology essentially makes use of a fuzzy extension
of Fuzzy Formal Concept Analysis (FFCA) [3,8] as
fundamental theoretical tool. In more detail, based on
the lattice theory, the FCA deals with concepts (objects and
their attributes) and their hierarchical relationships. It
supplies a basis for conceptual data analysis, knowledge
processing and extraction. To this end, [4] combines fuzzy
logic into FCA representing the uncertainty through
membership values in the range [0, 1].

Aggregation is the fundamental step for computing the
target OLAP cube over tweet data. Before that, microblog
summarization is applied. Our summarization algorithm
over multidimensional tweet streams has been defined
walking across concepts of the timed fuzzy lattice
structure resulting from temporal extention of FFCA.
The general idea behind is to explore fuzzy formal concepts
according to the chronological order of the peak areas.
The algorithm incrementally selects the best tweet, that is
the tweet with highest degree of membership belonging to
the most representative concept C, at each exploration
stage. The most representative concept is one that has
highest weight w(C). Formally, the weight w(C) of fuzzy
formal concept C will be evaluated as follows:

\[ w(C) = \frac{\sum_{\mu_{m}}}{|M'|} \]

where |M'| is the number of attributes in C and the
membership \( \mu_{m} \) is defined as follows:

\[ \mu_{m} = \max_{g \in I_{C}} \mu(g, m) \]

where \( \mu(g, m) \) is the membership value between object
\( g \) and attribute \( m \).

In the following, we describe our case study that
follows on the 2015 Italian election campaign. Nowadays,
Twitter plays an important role in the political agenda at
national and international level. So, the definition of
advanced analytics services on Twitter is assuming much
interest. Therefore, a motivating example of application of
the methodology proposed in this work is about political
elections. For the sake of clarity, here we illustrate a case
study of OLAP and timed FFCA integration applied to
tweet streams collected during Italian regional election
campaign held in May 2015, thus showing how our
microblog summarization works. A large round of

regional elections were held in Italy in seven of the twenty
regions composing the country, including four of the ten
largest ones: Campania, Veneto, Apulia and Tuscany. The
other three regions holding elections were Liguria, Marche,
Umbria, along with more than 700 of Italy’s
municipalities went to the polls. An estimated 23 million
Italians are eligible to vote.

The target case study clearly demonstrates how OLAP
analysis methodologies are perfectly suitable of
supporting advanced analytics over tweet data, similarly
to other recent and correlated research experience (e.g.,
[9,10]). In fact, summarizing the information content of
massive amounts of data like streaming tweet data plays a
leading role with respect to the goal of extracting useful
knowledge from so abundant data. Indeed, even semantics
issues must be considered, as summarization is not only
data reduction but, better, knowledge synthesis (e.g.,
[11,12]), which is now becoming more and more relevant
in the emerging context of big data analytics.

Figure 2 shows the three-dimensional OLAP data cube
defined on a set of collected tweets, having as measure the
set of tweets belonging to the dimension candidate (e.g.,
Beppe Grillo), location (e.g., Rome) and Political Party
(e.g., Democratic Party). The detail of a data cube cell
(i.e., the lattice computed via microblog summarization) is
also shown.

III. CLUSTERING-BASED BIG DATA ANALYTICS OVER
GEO-TAGGED TWEETS

[19] proposes a framework for supporting advanced
big data analytics over geo-tagged tweets via intelligent
multidimensional clustering methodologies. Nowadays,
we are entering the so called big geo-data era (e.g.,
[20,21]), i.e. we are in the condition of having a huge
amount of information that could be exploited to answer
the above question, whenever appropriately filtered and
analyzed. This aspect plays a critical role, especially when
dealing with big data analytics (e.g., [22,23,24]). In this
respect, the widespread diffusion of smart devices has
favored a new way of sharing impressions about places
visited by travelers on social networks; people can post
geo-tagged (i.e., geo-localized) and time-stamped (i.e.,
with a date) messages and pictures; these meta-data give a
ready to use key to know where and when the messages
were sent. Also, adaptive metaphors (e.g., [39]) could be integrated in this respect.

Among all social networks, Twitter (as well as other social networks that adopt the same approach) is particularly attractive to the purpose of searching messages that have something to do with travels: in fact, the limitation on the length of tweets makes them a suitable means to exchange impressions in a couple of words when people are moving around and are not keen to write long posts. Furthermore, they represent a kind of voluntary contribution, because users voluntarily install the (Twitter) app and voluntarily post messages (tweets) so that every user can see messages by other users without limitations. Even if only 20% of the tweets are geo-tagged, this posts' information, are hardly acquirable with traditional survey methods.

The above considerations motivate the research that we describe in this paper. It is necessary to design an architecture of tools that: 1) are able to continuously gather geo-localized posts from social networks; 2) provide novel methods to analyze travelers' trips, on the basis of gathered posts; 3) enable to visualize results in an integrated fashion, i.e., exploiting open geo-data sources in an integrated way; 4) make results available to other geographic services. This objective is very relevant for emerging big data analytics tools (e.g., [25,26,27,28]).

In order to be compliant with modern standards and to enable interoperability with open data sources and other services, we defined a web service architecture, in which standard components and external sources are integrated with services and tools specifically developed for this research. One suite (called the FollowMe Suite has been described in a previous work (see [29]), queries social networks to discover posts sent by travelers from specific geographic areas, identifies the possible tourists and follow their tweets to reconstruct their time lines, i.e., the history of posted messages. A new suite (called the Trip Analysis Suite) proposes and implements an original method for knowledge-based trip clustering. Finally, a geo-portal (named Tourists Tracker Geo-portal) enables to analyze most popular tours (i.e., clustered trips) contextualizing them with the characteristics of the territory.

A main characteristic of the approach is that it is a knowledge-based approach. In facts, our goal is to semantically analyze the tracked tourist trips, by correlating them with information regarding POIs such as commercial, social and natural attractions of a specific territory of interest. The final and ambitious goal is to be able to guess which are the most plausible resources the tourists have visited.

Different knowledge of the territorial resources can be exploited, in order to perform distinct analysis of the tourists’ trip. For example, in our experiments we represented tours as sequences of zip areas they crossed; however, it could be possible to represent trips as sequences of the closest POIs they came across. This is the knowledge-based geo-clustering method, developed as part of the Trip Analysis Suite.

Furthermore, by publishing the popular tours by an interoperable Web GIS enables their mapping and analysis contextually to other multi-source open geo-spatial data themes relative to the territory resources such as historical and world heritage, naturalistic places, shopping centers. This is provided by the Tourist Tracking Geo-portal.

The interoperable framework we devised for tracking and analyzing trips is depicted in Figure 3. It is constituted by two main suites of tools: the FollowMe Suite [29] for trips identification and the Trips Analysis Suite for its geographic analysis.

A third component of the architecture is the GeoServer open source Web GIS, that is used to publish on the Web the analyzed trips in order to share them as open data, so that any OGC compliant geo-portal client, such as QGIS, can visualize them and spatially analyze trips with respect to other geo-spatial data.

A forth component of the framework is the Tourists Tracker Portal, which provides users with specific functionality to analyze popular tours, getting them from GeoServer.

The communication is based on the web service paradigm and related protocols and formats. The joint adoption of the web service architecture and of the OGC standard for open geographic data enables the easy extension with new dedicated services; this choice guarantees flexibility in the future development of the project. This way, the framework is actually interoperable, both internally (new services and components can be easily added) and externally (easy bidirectional exchange of data with external source and services).

In the rest of this Section, we describe the tasks performed by each service.

The FollowMe Suite implements the first service developed during the project. The interested reader can find details in [29]. Here, we briefly describe its three main functionalities.

1. The FollowMe Suite queries Twitter API to find hang tweet, i.e., tweets posted in the area of the monitored airports.

2. For each user identified by means of hang tweets, the FollowMe Suite queries (through Twitter API) his/her Timeline, i.e., the history of tweets posted by the user, to get tracked tweets. These are geo-localized tweets posted in the next 8 days after the date of the hang tweet. Both hang tweets and tracked tweets are stored in a local storage area.
3. Given an area of interest, trips that occur in that area are reconstructed and extracted, by querying hang tweets and tracked tweets previously stored in the local storage area. Reconstructed trips are exposed and exported through the web service interface.

The Trip Analysis Suite performs the geographical analysis and tour discovery on trips tracked by the FollowMe Suite. These are the main functionalities in our framework.

Basically, the Trip Analysis Suite performs the activities of knowledge discovery on trips collected by the FollowMe Suite. To this end, we propose a knowledge-based clustering method, where semantics is given by geo-slots in which punctual coordinates of tweets fall. Different geo-slots partitions give different results. Analysts can import geographic description of geo-slots from external interoperable sources. For example, it is possible to analyze tours with respect to municipalities, regions, countries, neighborhoods, etc.

This means that row trips must be pre-processed before discovering tours. The tasks hereafter described constitute the knowledge discovery process performed by the Trip Analysis Suite:

1. fetching of the Geographic Slots descriptions;
2. fetching the gathered trips w.r.t. an area of interest;
3. geo-partitioning of tweets in trips, in order to semantically labeling tweets with geographic slots;
4. clustering trips in order to identity tours, i.e., groups of trips that mostly visited the same geographic slots.

Results of the tour discovery tasks are deployed to Geoserver.

To illustrate the rationale behind the clustering technique, in Figure 4 we report five sample trips, labeled from A to E (left upper corner). Matrices in the right side of Figure 4 reports the similarity measures at each step, and the dendogram in the bottom left corner shows the hierarchy of generated clusters.

Finally, the Tourists Tracker Geo-Portal is the last service in our architecture. It is an OGC compliant geo-portal that provides the end-user interface to visualize tours, by getting them from Geoserver.

Mainly, trips belonging to the same tour are depicted with the same color, while each tour is visualized with a different color; this way, for users it is easier to analyze different tours.

IV. CONCLUSIONS AND FUTURE WORK

In this paper, we have provided an overview on two state-of-the-art proposals focusing on big data analytics over big social data. Future work comprises advanced topics such as privacy of big social data management (e.g., [37]) and performance of big social data processing (e.g., [38]).

ACKNOWLEDGMENT

The author is grateful to colleagues who contributed to early versions of referred state-of-the-art works: C. De Maio, G. Fenza, V. Loia, M. Parente, G. Bordogna, L. Frigerio, G. Psaila.

REFERENCES

PAPERS
Abstract—The paper presents a parallel implementation of a Dynamic Itemset Counting (DIC) algorithm for many-core systems, where DIC is a variation of the classical Apriori algorithm. We propose a bit-based internal layout for transactions and itemsets with the assumption that such a representation of the transaction database fits in main memory. This technique reduces the memory space for storing the transaction database and also simplifies support counting and candidate itemsets generation via logical bitwise operations. Implementation uses OpenMP technology and thread-level parallelism. Experimental evaluation on the platforms of Intel Xeon CPU and Intel Xeon Phi coprocessor with large synthetic database showed good performance and scalability of the proposed algorithm.

Index Terms—frequent itemset mining, dynamic itemset counting, bitmap, OpenMP, many-core, Intel Xeon Phi

I. INTRODUCTION

Association rule mining is one of the important problems in data mining [1]. The task is to discover the strong associations among the items from a transaction database such that the presence of one item in a transaction implies the presence of another. Association rule mining is decomposed into two subtasks [1]. The first one is to find all frequent itemsets that consist of items which often occur together in transactions. The second one is to generate all the association rules from the frequent itemsets found.

In this paper, we address the task of frequent itemset mining which can be formally described as follows. Let \( I = \{i_1, \ldots, i_m\} \) be a set of literals, called items. Let \( D = \{T_1, \ldots, T_n\} \) be a database of transactions, where each transaction \( T_i \subseteq I \) consists of a set of items (itemset). An itemset that contains \( k \) items is called a \( k \)-itemset. The support of an itemset \( I \subseteq I \) denotes the percentage of transactions in \( D \) that contain the itemset \( I \). If support of an itemset \( I \subseteq I \) satisfies the user-specified minimum support threshold (called \( \text{minsup} \)) then \( I \) is frequent itemset. Let the set of frequent \( k \)-itemsets be denoted by \( L_k \) and \( L = \bigcup_{k=1}^{k_{\text{max}}} L_k \) denotes a set of all frequent itemsets, where \( k_{\text{max}} \) is number of items in the longest frequent itemset. Given the transaction database \( D \) and minimum support threshold \( \text{minsup} \) the goal of frequent itemset mining is to find the set of all frequent itemsets \( L \).

There is a wide spectrum of algorithms for frequent itemset mining and none of them outperforms all others for all possible transaction databases and values of \( \text{minsup} \) threshold [7]. Apriori [1] is one of the most popular itemset mining algorithms for which many refinements and parallel implementations for various platforms were proposed. Dynamic Itemset Counting (DIC) [2] is a variation of Apriori, which tries to reduce number of passes made over a transaction database while keeping the number of itemsets counted in a pass relatively low. Despite the fact that DIC has good potential of parallelization [2] it still has not been implemented for modern many-core CPU and accelerators, to the best of our knowledge.

In this paper we propose parallel implementation of the DIC algorithm for Intel Xeon and Intel Xeon Phi (Knights Landing) many-core platforms. Intel Xeon Phi device is an x86 many-core coprocessor of 61 cores, connected by a high-performance on-die bidirectional interconnect where each core supports 4× hyperthreading and contains 512-bit wide vector processor unit. Knights Landing [13] is a second generation MIC (Many Integrated Core) architecture product from Intel. As opposed to predecessor it is an independent (bootable) device, which runs applications only in native mode.

We suggest a bit-based internal layout for transactions and itemsets assuming that such a representation of a transaction database fits in main memory. This technique has a few major merits. It reduces memory space of storing the transaction database and simplifies support counting and generation of candidate (potentially frequent) itemsets via logical bitwise operations. We parallelize the algorithm through OpenMP technology and thread-level parallelism. We conduct experiments on large synthetic database to evaluate performance and scalability of our algorithm.

The rest of the paper is organized as follows. Section I provides a brief description of an original DIC algorithm. The proposed parallel algorithm is presented in section II. In section III related work is discussed. The results of experimental evaluation of the algorithm are described in section IV. The conclusion contains summarizing remarks and directions for future research.

I. SERIAL DIC ALGORITHM

Dynamic Itemset Counting (DIC) [2] is a variation of the most well-known Apriori algorithm [1]. Apriori is an iterative, level-wise algorithm, which uses a bottom-up search. At the
first pass over transaction database it processes 1-itemsets and finds \( L_1 \) set. A subsequent pass \( k \) consists of two steps, namely candidate generation and pruning. At the candidate generation step Apriori combines elements of \( L_{k-1} \) set to form candidate (potentially frequent) \( k \)-itemsets. At the pruning step it gets rid of infrequent candidates using the \textit{a priori} principle, which states that any infrequent \((k-1)\)-itemset cannot be a subset of a frequent \( k \)-itemset. Apriori counts support of candidates which have not been pruned and proceeds with such passes so forth until no candidates remain after pruning.

**Algorithm 1.** DIC(in \( D \), in \( \text{minsup} \), in \( M \), out \( L \))

\begin{algorithmic}
\STATE \texttt{Initialize sets of itemsets}
\STATE \texttt{DashedBox} \leftarrow \emptyset; \texttt{SolidCircle} \leftarrow \emptyset; \texttt{DashedBox} \leftarrow \emptyset
\STATE \texttt{DashedCircle} \leftarrow \mathcal{I}
\WHILE {\texttt{DashedCircle} \cup \texttt{DashedBox} \neq \emptyset}
\STATE \texttt{Scan database and rewind if necessary}
\STATE \texttt{Read}(\( D \), \( M \), \( Chunk \))
\IF {\texttt{EOF}(\( D \))}
\STATE \texttt{Rewind}(\( D \))
\ENDIF
\FORALL {\( T \in \text{Chunk} \)}
\STATE \texttt{Count support of itemsets}
\FORALL {\( I \in \texttt{DashedCircle} \cup \texttt{DashedBox} \)}
\IF {\( I \subseteq T \)}
\STATE \( \text{support}(I) \leftarrow \text{support}(I) + 1 \)
\ENDIF
\ENDFOR
\FORALL {\( I \in \texttt{DashedCircle} \)}
\IF {\( \text{support}(I) \geq \text{\text{minsup}} \)}
\STATE \texttt{MoveItemset}(\( I \), \texttt{DashedBox})
\ENDIF
\ENDFOR
\FORALL {\( I \in \mathcal{I} \)}
\STATE \( C \leftarrow I \)
\IF {\( \forall s \subseteq C \, s \not\in \texttt{SolidBox} \cup \texttt{DashedBox} \)}
\STATE \texttt{MoveItemset}(\( C \), \texttt{DashedCircle})
\ENDIF
\ENDFOR
\STATE \texttt{Check full pass completion for itemsets}
\IF {\texttt{IsPassCompleted}(\( I \))}
\STATE \texttt{MoveItemset}(\( I \), \texttt{DashedBox})
\ENDIF
\ENDFOR
\FORALL {\( I \in \texttt{DashedBox} \)}
\IF {\texttt{IsPassCompleted}(\( I \))}
\STATE \texttt{MoveItemset}(\( I \), \texttt{SolidBox})
\ENDIF
\ENDFOR
\STATE \( L \leftarrow \texttt{SolidBox} \)
\ENDWHILE
\end{algorithmic}

The DIC algorithm tries to reduce the number of passes made over the transaction database while keeping the number of itemsets counted in a pass relatively low. Alg. 1 depicts pseudo-code of the DIC algorithm. DIC processes database with stops at equal-length intervals between transactions (parameter \( M \) of the algorithm). At the end of the transaction database it is necessary to rewind to its beginning.

DIC maintains four sets of itemsets, namely Dashed Circle, Dashed Box, Solid Circle and Solid Box. Itemsets in the “dashed” sets are subjects for support counting while itemsets in the “solid” sets do not need to be counted. “Circles” contain infrequent itemsets while “boxes” contain frequent itemsets.

Thus, Dashed Circle and Dashed Box contain itemsets that are suspected infrequent and are suspected frequent respectively while Solid Circle and Solid Box contain itemsets that are confirmed infrequent and are confirmed frequent respectively. At start Dashed Box, Solid Circle and Solid Box are assumed to be empty and Dashed Circle contains all the 1-itemsets.

Before the stop, DIC counts support of itemsets from “dashed” sets for each transaction. At any stop DIC performs as follows. Itemsets whose support exceeds \text{\text{minsup}} are moved from Dashed Circle to Dashed Box. New itemsets are added into Dashed Circle, they are immediate supersets of those itemsets from Dashed Box with all of its subsets from “box” lists. Itemsets that have completed one full pass over the transaction database are moved from the “dashed” set to “solid” set. DIC proceeds if any itemset in “dashed” sets remains.

II. PARALLEL DIC ALGORITHM

A. Internal Data Layout

In this work we suggest \textit{direct bit representation} for both transactions and itemsets. For a transaction \( T \subseteq D \) (for an itemset \( I \subseteq \mathcal{I} \), respectively) this means that it is represented by a word where each \( p \)-th bit is set to one if an item \( i_p \in T \) (\( i_p \in I \), respectively) and all other bits are set to zero. The word’s length \( W \) in bytes depends on system environment and it is calculated as \( W = \lceil \frac{m \cdot \text{\text{sizeof}}(\text{byte})}{P} \rceil \). In our implementation we use C++ and unsigned \text{\text{long long int}} data type, so we have \( W = 8 \) and \( m = 64 \). This could be extended through an open-source library for arbitrary precision arithmetic, for instance, GNU Bignum Library[1].

Let us denote by \textit{BitMask} a function that returns direct bit representation of a given itemset or transaction as a word, i.e. \( \text{BitMask} : \mathcal{I} \rightarrow \mathbb{Z}_4 \). Then direct bit representation of transaction database \( D \) is an \( n \)-element array \( \mathcal{B} \), where \( \forall j, 1 \leq j \leq n \), \( \mathcal{B}[j] = \text{BitMask}[T_j] \).

Direct bit representation has several major merits. It often requires less space than byte-based representation for dense transaction database with long transactions. In fact, \( \mathcal{B} \) requires \( n \cdot W \) bytes to store and allows \( \mathcal{B} \) to fit in main memory. For instance, \text{\text{netflix}}[1] one of the most referenced datasets, contains \( n = 17,771 \) transactions consisting of \( m = 480,189 \) distinct items. Hence, direct bit representation of the \text{\text{netflix}} dataset takes about 1 Gb. Thus, in what follows we assume that \( \mathcal{B} \) has been preliminary produced from \( D \) and it is available in main memory.

Direct bit representation simplifies support counting as well. The fact of \( I \subseteq T \) can be checked by the predicate with one logical bitwise operation, that is \( \text{BitMask}(I) \land \text{BitMask}(T) = \text{BitMask}(I) \).

Thereby, we implement an itemset as a record structure with the following basic fields, namely \textit{mask} to provide direct bit representation, \( k \) as number of items in the itemset, \textit{stop} as counter to determine when full pass for the given itemset is completed, and \textit{supp} to store support count.

The GNU Multiple Precision Arithmetic Library

http://www.netflixisprize.com
To implement a set of itemsets, we use vector, which represents an array of elements belonging to the same type and provides random access to its elements with an ability to automatically resize when appending elements. Such a data structure is implemented in C++ Standard Template Library as a class with iterator and methods for inserting an element and removing an element with complexity of $O(1)$ and $O(s)$ respectively, where $s$ is the current size of a vector.

To reduce costs of moving elements across vectors, we establish a \textit{DASHED} vector for "dashed box" and "dashed circle" itemsets and a \textit{SOLID} vector for "solid box" and "solid circle" itemsets and provide the itemset’s record structure with \textit{fig} field to indicate an appropriate set the given itemset belongs to.

B. Parallelization of the Algorithm

The proposed parallel version of DIC algorithm is presented in Alg. 2 and basic sub-algorithms are depicted in Alg. 3–5

\textbf{Algorithm 2.} \textsc{ParalDIC}(in \textbf{B}, in minsup, in \textbf{M}, out \textbf{L})

\begin{itemize}
  \item 2: SOLID.init(); DASHED.init()
  \item 3: $k \leftarrow 1$
  \item 4: \textbf{for all} $i \in 0..m - 1$ do
  \item 5: \hspace{1em} \textit{I}.\textit{fig} $\leftarrow$ \textsc{NIL}; \textit{I}.\textit{bitmap} $\leftarrow 0$
  \item 6: \hspace{1em} \textit{I}.\textit{mask} $\leftarrow$ \textsc{SelBit}(\textit{I}.\textit{mask}, \textit{i})
  \item 7: \hspace{1em} \textit{I}.\textit{stop} $\leftarrow 0$; \textit{I}.\textit{supp} $\leftarrow 0$; \textit{i}.\textit{k} $\leftarrow k$
  \item 8: SOLID.push_back(\textit{I})
  \item 9: \textbf{stop}$_{\text{max}}$ $\leftarrow \lceil \frac{n}{k} \rceil$; \textbf{stop} $\leftarrow 0$
  \item 10: \textbf{while not} DASHED.empty() do
  \item 11: \hspace{1em} $\triangleright$ Scan database and rewind if necessary
  \item 12: \hspace{2em} \textbf{stop} $\leftarrow$ \textbf{stop} + 1
  \item 13: \hspace{2em} \textbf{if} \textbf{stop} $> \textbf{stop}$_{\text{max}}$ then
  \item 14: \hspace{3em} \textbf{stop} $\leftarrow 1$
  \item 15: \hspace{2em} \textbf{first} $\leftarrow (\textbf{stop} - 1) \cdot \textit{M}$; \textbf{last} $\leftarrow \textbf{stop} \cdot \textit{M} - 1$
  \item 16: \hspace{2em} \textbf{k} $\leftarrow k + 1$
  \item 17: \hspace{1em} \textbf{CountSupport}([\textsc{DASHED}])
  \item 18: \hspace{1em} \textbf{CutDashedCircle}([\textsc{DASHED}])
  \item 19: \hspace{1em} \textbf{GenCandidates}([\textsc{DASHED}])
  \item 20: \hspace{1em} \textbf{CheckFullPass}([\textsc{DASHED}])
  \item 21: \textbf{L} $\leftarrow \{ $\textbf{I}\in \textsc{SOLID}, \textbf{I}.\textit{fig}=\textsc{BOX}$ \}
\end{itemize}

We enhance the classical DIC algorithm by adding two more stages, namely \textbf{FirstPass} and \textbf{CutDashedCircle} where each of them is aimed to reduce the number of itemsets to perform support counting of.

We parallelize the following stages of the algorithm, namely support counting (cf. Alg. 3), reduction of Dashed Circle set (cf. Alg. 4) and checking full pass completion for itemsets (cf. Alg. 5) through OpenMP technology and thread-level parallelism.

In the classical DIC algorithm, the Dashed Circle set is initialized by all the 1-itemsets (cf. Alg. 1, line 3). In contrast with classical DIC, we use the technique of full first pass [4]. This means that we initially perform one full pass over \textbf{D} to find \textbf{L}$_1$, the set of frequent 1-itemsets (this done similarly to Alg. 3). Then candidate 2-itemsets are computed from \textbf{L}$_1$ through the Apriori join procedure [1]. This done via logical bitwise \textbf{OR} operation on each pair of frequent 1-itemsets and candidates are inserted in the Dashed Circle set. This technique helps to reduce cardinality of the Dashed Circle set in further computations because infrequent 1-itemsets and their supersets have been pruned according to the a priori principle.

\textbf{Algorithm 3.} \textsc{CountSupport}(in out DASHED)

\begin{itemize}
  \item if DASHED.size() $\geq$ num_of_threads then
    \item \#pragma omp parallel for
    \item \hspace{1em} \textbf{for all} \textit{I} $\in$ DASHED do
      \item \hspace{2em} \textit{I}.\textit{stop} $\leftarrow$ \textit{I}.stop + 1
      \item \hspace{2em} \textbf{for all} \textit{T} $\in$ \textit{B}[\textit{first}] .. \textit{B}[\textit{last}] do
        \item \hspace{3em} if \textit{I}.\textit{mask} AND \textit{T} = \textit{I}.\textit{mask} then
          \item \hspace{4em} \textit{I}.\textit{supp} $\leftarrow$ \textit{I}.\textit{supp} + 1
    \item \#pragma omp parallel for reduction(+:\textit{I}.\textit{supp})
    \item \hspace{1em} num_threads(DASHED.size())
    \item \textbf{for all} \textit{I} $\in$ DASHED do
      \item \hspace{2em} \textit{I}.\textit{stop} $\leftarrow$ \textit{I}.stop + 1
      \item \hspace{2em} \textbf{num_threads}([DASHED.size()])
      \item \hspace{2em} \textbf{for all} \textit{T} $\in$ \textit{B}[\textit{first}] .. \textit{B}[\textit{last}] do
        \item \hspace{3em} if \textit{I}.\textit{mask} AND \textit{T} = \textit{I}.\textit{mask} then
          \item \hspace{4em} \textit{I}.\textit{supp} $\leftarrow$ \textit{I}.\textit{supp} + 1
  \end{itemize}

In the original algorithm support counting is performed through two nested loops (cf. Alg. 1 lines 9–13) where the outer loop takes transactions and the inner loop takes the “dashed” itemsets. As opposed to the classical DIC algorithm we change the order of these loops to parallelize outer loop through \textsc{omp parallel} for pragma (cf. Alg. 3). This shuffle avoids data races when threads process different transactions but need to change support count of the same itemsets simultaneously.

Additionally, our algorithm balances the load of threads depending on the current total number of elements in both Dashed Circle and Dashed Box sets. If the number of available threads does not exceed current total number of “dashed” itemsets, we parallelize the outer loop (along itemsets) using all the threads. Otherwise, we enable nested parallelism and parallelize the outer loop using a number of threads equal to the current total number of “dashed” itemsets. Then we parallelize the inner loop (along transactions) so that each outer thread forks an equal-sized set of descendant threads where descendants perform counting through reduction of summing operation. This balancing technique allows to processing data effectively in the final stage of counting when the number of candidate itemsets tends to zero and increases overall performance of the algorithm.

After the support counting, in addition to moving appropriate itemsets from Dashed Circle set to Dashed Box set as in classical DIC (cf. Alg. 1 line 17), we reduce Dashed Circle set pruning clearly infrequent itemsets as follows [9]. We compute an itemset’s highest possible support by adding
its current support to the number of transactions have not been processed yet (cf. Alg. 1). If the value of the itemset’s highest possible support is less than minsup threshold, then the itemset is pruned and after that we prune all its supersets according to the \textit{a priori} principle.

After the reduction of \textit{Dashed Circle} set we generate fresh itemsets to be inserted in that set performing Apriori join procedure \cite{1} via logical bitwise OR operation between all the itemsets marked as “boxes”.

\textbf{Algorithm 4. CutDashedCircle(in out DASHED)}

\begin{verbatim}
#pragma omp parallel for
2: for all \( I \in \text{DASHED} \) and \( I.fig = \text{CIRCLE} \) do
4:   \textbf{if} \( I.supp \geq \text{minsup} \) then
6:     \textbf{else}
8:       \textbf{if} \( \text{supp}_{\max} < \text{minsup} \) then
10:        \textbf{else}
12:          \textbf{if} \( I.fig = \text{CIRCLE} \) do
14:            \text{DASHED}.erase(\( \forall I, I.fig = \text{NIL} \))
\end{verbatim}

Finally, for all itemsets in the \textit{Dashed Circle} set we check if an itemset has been counted through all the transactions and if yes, we make the itemset “solid” and stop counting it (cf. Alg. 2). This activity is also parallelized along itemsets through \texttt{omp parallel} for pragma.

In the end \textit{DASHED} vector contains “box” itemsets as a result of the algorithm.

\textbf{Algorithm 5. CheckFullPass(in out DASHED)}

\begin{verbatim}
#pragma omp parallel for
2: for all \( I \in \text{DASHED} \) do
4:   \textbf{if} \( I.stop = \text{stop}_{\max} \) then
6:     \textbf{if} \( I.supp \geq \text{minsup} \) then
8:       \text{DASHED}.erase(\( \forall I, I.fig = \text{NIL} \))
\end{verbatim}

\section{Related Work}

The Original DIC algorithm was presented by Brin et al. in \cite{2}, where the authors briefly discuss a way to parallelize DIC using the distribution of the transaction database among the nodes so that each node counts all the itemsets for its own data segment. The authors noticed that it is unnecessary to perform synchronization and load balancing in parallel version of DIC.

Paranjape-Voditel et al. proposed \textit{DIC-OPT} \cite{10}, a parallel version of DIC for distributed memory systems. The key idea is that each node sends messages to other nodes after every \( M \) transactions have been read regarding the counts of potentially frequent itemsets. This initiates the early counting of the itemsets on other nodes without waiting for synchronization with other nodes. Authors carried out experiments on up to 12 nodes where their implementation showed sub-linear speedup.

Cheung et al. suggested \textit{APM} \cite{4}, a DIC-based parallel algorithm for SMP systems. APM is an adaptive parallel mining algorithm, where all CPUs generate candidates dynamically and count itemset supports independently without synchronization. The transaction database is partitioned across CPUs with a highly homogeneous itemset distributions. This technique addresses the problem of a large number of candidates because of the low homogeneous itemset distribution in most cases. The experiments on the Sun Enterprise 4000 server with up to 12 nodes showed that APM outperforms Apriori-like parallel algorithms. However, APM’s speedup gradually drops down to 4 when the number of nodes is greater than 4. This is because APM suffers from the SMP’s inherent problem of I/O contention when the number of nodes is large.

Schlegel et al. proposed \textit{mcEclat} \cite{12}, a parallel version of the well-known mining algorithm Eclat \cite{14} for the Intel Xeon Phi coprocessor. mcEclat converts a dataset being mined into a set of tid-bitmaps, which are repeatedly intersected to obtain the frequent itemsets. \textit{Tid-bitmap} maps the IDs of transactions in which an itemset occurs to bits in a bitmap at certain positions. For instance, if the itemset \( i \) exists in 4-th and 7-th transactions then the respective bits of \( i \)’s tid-bitmap are set to one while all its other bits are set to zero. Tid-bitmaps are intersected via logical bitwise AND operation and then support of an itemset is obtained by counting the one bits in its respective tid-bitmap. Experiments showed up to 100× speedup of mcEclat on the Intel Xeon Phi. However, the algorithm’s performance on the Intel Xeon Phi coprocessor is similar or slightly worse (for smaller values of \textit{minsup}) than on system with two Intel Xeon CPUs when the maximum number of threads is employed on both systems. The reason is that mcEclat does not fully exploit the Intel Xeon Phi’s powerful vector processing capabilities.

Kumar et al. presented \textit{Bitwise DIC} \cite{9}, a serial version of the DIC algorithm based upon tid-bitmap technique mentioned above. Bitwise DIC outperforms the original DIC. Unfortunately, the authors poorly supported their study by experiments and discussion of the results (only five runs of the algorithms on one dataset with 5,000 transactions for fixed value of \textit{minsup} were conducted and only runtime was presented).

In serial algorithms \textit{MAFIA} \cite{3} and \textit{BitTableFI} \cite{6} Burdick et al. and Dong et al., respectively, used vertical bitmap to compress the transaction database for quick candidate itemsets generation and support count. \textit{Vertical bitmap} is a set of integer in which every bit represents an item. If an item \( i \) appears in a transaction \( j \), then bit \( j \) of the bitmap for item \( i \) is set to one; otherwise, the bit is set to zero. This idea is applied to transactions and itemsets. In cases where itemsets appear in a significant number of transactions, the vertical bitmap is the smallest representation of the information. However, the
weakness of a vertical representation is the sparseness of the
bitmaps, especially at the lower support levels.

In this paper we suggested a parallel version of the DIC
algorithm for Intel Xeon and Xeon Phi many-core systems
(which was done for the first time, to the best of our
knowledge) where we use direct bit representation of both
transaction database and itemsets.

IV. EXPERIMENTAL EVALUATION

To evaluate the developed algorithm, we performed exper-
iments on the Tornado SUSU [8] supercomputer’s node (cf.
Tab. I for its specifications).

In the experiments, we studied the following aspects of
the developed algorithm. We compared the performance of
parallel DIC with serial implementations of DIC and Apriori
algorithms. We also evaluated the scalability of our algorithm
depending on the value of M (the number of transactions that
should be processed before stop) and on minsup threshold.

Fig. 1 illustrates the results of the first set of experiments
where we compare the performance of parallel DIC with
serial DIC and Apriori on CPU. As was seen, serial DIC
performs the worst for all the datasets we have tested and
this is in accordance with testing results of B. Goethals. For
datasets with relatively small number of short transactions,
serial Apriori performs best whereas parallel DIC demonstrates
degradation of the performance. However, in case of a large
dataset, parallel DIC outperforms serial Apriori. Hence,
our algorithm behaves the best way when the transaction database
provides sufficient amount of work in support counting, which

is the heaviest part of the algorithm. This is why we use 20M
dataset in the next set of experiments.

Fig. 2 depicts the results of the second set of experiments
where we studied the scalability of parallel DIC w.r.t. M
parameter on both platforms using 20M dataset. Experimental
results show that parallel DIC outperforms serial Apriori much
more often than not. A greater value of M results in less
runtime and greater speedup. On both platforms at greater
value of M our algorithm shows speedup closer to linear when
the number of threads matches the number of physical cores
the algorithm is running on and speedup becomes sub-linear
when the algorithm uses more than one thread per physical
core. Parallel DIC achieves up to 12× and 90× speedup on
CPU and Xeon Phi, respectively.

(a) Intel Xeon CPU

(b) Intel Xeon Phi coprocessor

Fig. 2: Scalability w.r.t. M (20M dataset, minsup = 0.1)

---

3 We use IBM Quest Synthetic Data Generator similar to original paper [2].
4 Frequent Pattern Mining Implementations by Bart Goethals
5 Apriori – Frequent Item Set Mining by Christian Borgelt
6 For 20M dataset Serial DIC was stopped after 30 hours without output.
In this paper we presented a parallel implementation of Dynamic Itemset Counting (DIC) algorithm for Intel many-core systems, where DIC is a variation of classical Apriori algorithm for frequent itemset mining.

We enhance the DIC algorithm by adding two more stages, which are devoted to reducing the number of itemsets to perform support counting of. We also propose direct bit representation for transactions and itemsets with the assumption that such a representation of the transaction database fits in main memory. This technique reduces memory space for storing the transaction database and also simplifies support counting and candidate itemsets generation via logical bitwise operations. We parallelize the DIC algorithm through of OpenMP technology and thread-level parallelism. Our algorithm balances support counting between threads depending on the current total number of candidate itemsets. We performed experimental evaluation on the platforms of the Intel Xeon CPU and the Intel Xeon Phi coprocessor with large synthetic database, showing the good performance and scalability of the proposed algorithm.

In continuation of the presented research, we plan to implement the developed parallel algorithm for the case of cluster systems based on nodes with the Intel Xeon Phi many-core coprocessor on-board.

**References**

ETL (Extract Transform Load) process is the industry standard term for data extraction, transformation and loading into the Data Warehouse (DW). ETL process is the most resource demanding process in DW implementation and typically has to be evolved and maintained for the duration of the DW. To facilitate the development and maintenance of ETL processes many ETL tools have been developed featuring Graphical User Interfaces and various built-in functionalities (parallelism, logging, rich transformation libraries, documentation generation, etc.). The downside of such GUI ETL tools is that development is carried out heavily using mouse operations and less by writing programming code, which feels unnatural for some developers, especially with many similar, repetitive tasks. In this paper we present an alternative approach – an ETL framework “ETLator” based on Python scripting language where ETL tasks are defined by writing Python code. ETLator implements various typical ETL transformations and allows the user to simply and efficiently define complex ETL tasks with multiple sources and parallel tasks whilst leveraging full flexibility of Python. ETLator also provides logging and can document ETL tasks by generating data flow images. On a test case we show that ETLator simplifies ETL development and rivals the GUI approach.

1. INTRODUCTION

Data processing is the purpose of most computer programs. For the purposes of storage and manipulation, the data is usually structured and stored in relational databases. However, relational model (normalized to the third normal form) used in relational databases is not the optimal solution for analytical purposes. For that part, data is restructured and stored in a Data Warehouse (DW) - a special database used for storing analytical data. To populate the DW, data is typically transferred from (often multiple) relational databases and potentially additional data sources (text files, Excel files, etc.) by a process known as ETL (Extract Transform Load). ETL process is a complex and most resource intensive part of the DW project. To reduce development and maintenance costs ETL tools have been developed. ETL tools are program solutions intended to transfer and transform data. They gather data from various sources, transform and integrate the data, and, finally, store it in the destination system. Since every ETL process is specific, users need the ability to configure the tool to suite their needs. Most of the ETL tools today (e.g. Informatica, Microsoft SSIS, Talend [3]) feature Graphical User Interface (GUI) which makes them more user-friendly for non-programmers, but can limit their flexibility. In a different approach, ETL frameworks enable defining ETL processes using programming code, but without having to write the whole program from scratch, because they provide most of the code leaving only the specifics of the process to the user. Scripting programming languages are especially suited for this task processes because of their simplicity and efficiency. The question of text based versus GUI based modelling/interface is neither new nor decided (e.g. [1]), in software development in general, and thusly in the ETL domain. For instance, in [2] authors conclude that “that text-based modelling constitutes a noteworthy alternative to graphical modelling because of its simple usage, scalability and easy development and reuse of tool support”. This is very much true in the ETL process definition where GUI approach implies a lot of point and click mouse operations, property settings editing, drawing, etc. which can be tedious and tiresome, especially with many similar tasks, often found in the ETL environment. Text is much more easily reused, or even generated when appropriate. Of course, GUI tools have their advantages, namely when documentation is concerned, and also when introducing new developers in the existing projects. Without going into further debate over this issue, in this paper we present a text based ETL tool named “ETLator”. It is an ETL framework written in Python scripting language that allows the user to simply and efficiently define ETL processes with advanced and automated features while maintaining the flexibility and extensibility of Python. ETLator provides standard ETL tool features like logging, parallelism, batch loading, caching, support for slowly changing dimensions [14], and can even generate documentation featuring images of data flows.

II. RELATED WORK

ETL tools fall under a more generic category of data integration tools, which are heavily used in the industry, not only in the DW domain. There is a number of commercial and a few open-source data integration tools available. Gartner Magic Quadrant brings a yearly overview of these tools [3] where companies like Informatica, IBM, SAP, Oracle, Microsoft and, most notable open-source company – Talend, dominate the market. All of these tools employ a GUI approach to ETL process design, as opposed to the approach presented here. A survey paper [4] brings an overview of academic papers in the ETL domain, most of them using UML or graphs to model an ETL workflow [5]. Scriptella [6] is a Java based scripting ETL framework where XML is used to define tasks. It is also possible to mix Java code and XML. Scriptella provides no support for DW specific constructs, like Slowly Changing Dimensions (SCDs). Also, there is no support for parallelism. Petl [7] is a general purpose Python package for ETL supporting a number of different data sources (relational databases, text files, XML, HTML, JSON, Excel). ETL tasks are designed via ETL pipelines.
representing data flow. Petl does not support SCDs or parallelism. Bubbles [8] is an open-source Python framework for data processing and data quality measurement. ETL tasks are represented as data processing pipeline graphs. Bubbles does not support SCDs or parallelism. Most notably, Pyrametl [9] is an open source ETL framework written in Python first released in 2009 and continually upgraded ever since. Version 2.4 was released in 2015 with extended support for Slowly Changing Dimensions (SCD) and batch-load of data. Pyrametl consists of multiple classes that represent fact tables, dimensions and data sources. Data is accessed by iterating through a data source. Each row is represented by a Python dictionary with keys being the column names. Pyrametl supports parallelism and SCD types 0, 1 and 2. Several concepts from Pyrametl were adopted in ETLLator including table representation with table name and attribute names, representing a row with a dictionary, a class for processing connections with databases and a special class for handling SCD type 2. As an added value, and compared to Pyrametl, ETLLator has more automated advanced features such as logging and documentation generation. Those features require user programming in Pyrametl. Also, while Pyrametl offers parallel execution, it uses threads to achieve it, which makes it run sequentially in CPython, the most common Python interpreter, because of Global Interpreter Lock, so it forces users to use JPython to run parallel ETL tasks. ETLLator takes a different approach (described later), which does not even require programming to achieve parallelism, resulting in simplier development and maintenance.

III. BASIC FEATURES OF ETL TOOLS

ETL tools have to be able to connect to a data source, process the data and store the processed data to the destination. Sources are usually different databases and various files, and destinations are in most cases DWs. The ability to connect to databases of various vendors is a necessary feature of all ETL tools, as is the ability to parse various files (CSV, XLS, JSON, etc.). ETL tools also have to be able to validate and integrate the data from multiple sources and lookup the data on the destination to reference it from new data. For example when adding a row into the fact table it has to reference existing data in the dimension tables.

Most ETL tools (e.g. Informatica, Microsoft SSIS, Oracle Data Integrator [3]) also provide some more advanced features that speed up the ETL process and make maintenance of ETL and the data itself easier. Some of the more advanced features of ETL tools are:
- Batch loading the data to the destination
- Caching the data when reading from source
- Parallelism of ETL jobs within a process
- Reusability of jobs or parts of jobs
- SCD support
- Data transformations libraries
- Support for snowflake schema
- Documentation generation

- Logging

IV. ETLLATOR ETL FRAMEWORK

ETLLator is an open source framework for ETL processes definition in Python programming language. The main goal of ETLLator is simplicity and productivity - to provide means to the user to define an ETL process with the least amount of written code, leveraging Python features to the full extent, in the process. ETLLator can work with various relational databases, CSV files and MongoDB NoSQL database as a source or a destination. Tables are, like in Pyrametl, iterators and rows are represented by dictionaries. Parallel task execution is realized without writing any additional code (addressed later). ETLLator automatically generates logs and documentation in form of flow charts and text files with table information and data changes within the table.

A. Main classes

Fig. 1 shows a partial class diagram of ETLLator, where attributes are omitted for the sake of simplicity.

Figure 1. ETLLator class diagram

ETLLator contains three main classes:
- Connector – used to connect to various relational databases
- Logger – enables logging feature
- Table – represents tables in databases

1) Connector Class

Connector class is an abstract class providing common functionalities for connecting to relational databases. It is extended by concrete classes representing various database systems. Connections are executed using Python modules that comply with PEP 249 specification [5]. All methods of Connector class correspond with PEP 249 methods of the same name.

Subclasses of the Connector class must contain their own implementation of the methods “copy”, “connect” and the constructor. Loading of modules to access various databases is done dynamically in the constructor to allow
the use of ETLator on systems that do not have the modules and database drivers for all of the supported databases, but only the ones that are used. Currently supported databases are: PostgreSQL, SQLite, MySQL and Microsoft SQL Server, but additional connector classes can be easily added. File “connector.py” in the “lib” directory contains all class definitions that extend the Connector class for connecting to supported databases. Users can write their own subclasses of the Connector class to connect to originally unsupported databases.

2) Table Class

Class Table is an abstract class from which classes used to define tables of data are extended. Name and attribute names must be defined for all tables. Location where local logs are stored, master log, operation counters and source table can also be defined. Table class does not have to be based on physical table, it can also be defined via SQL query, e.g. a query that joins and filters multiple tables.

Each class that extends Table class must implement “copy”, “get_next_row”, “insert” and “lookup” methods. Tables can be in a relational database, CSV file or MongoDB database. Subclasses of the Table class are: SQLTable, CSVTable, and MongoDBTable.

3) SQLTable Class

SQLTable class represents tables in relational databases. It can be used as a source or a destination of data, but not as both at the same time. SQLTable class automatically generates SQL queries for all the operations and executes them against the database.

Caching is used to store accessed or previously loaded data for faster lookup. It allows lookup without sending a query to the database. Cache size is by default set to 1000 records, but it is recommended to change this parameter depending on the table size and the system specifications. Caching is very useful in the DW ETL context, because, in accordance with best design practices, production tables’ keys are replaced with surrogate keys in the dimensional model typically used in the DW. This implies looking up dimension members when loading fact tables to replace production foreign keys with corresponding dimension table surrogate keys. Issuing lookup SQL statement for every fact table row is expensive in terms of performance, hence leveraging ETLator’s client computer RAM by caching dimension table’s production key, surrogate key pairs can greatly improve performance. Another performance booster is batch loading. Batch loading is not enabled by default, but enabling it can substantially improve performance because, again, the number of queries sent to the database is greatly reduced. Batch loading by default can be confusing for novice developers since one erroneous row in the batch (e.g. violated referential integrity) can cancel the entire batch, which can be hard to spot in the development phase.

In dimensional modelling, type 2 slowly changing dimensions are a classic technique for tracking historical changes to the dimension tables. With SCD’s a change in the tracked attribute causes a new record in the dimension table, consequently a SCD can have multiple records with the same production key. SCDDTable class is defined to simplify SCD type 2 operations. SCDDTable class extends SQLTable class and contains new implementations of abstract methods and defines new methods: “scd_update” and “lookup_all”.

The “scd_update” method adds a new record into the table, sets it as active and sets the old record as inactive and changes the timestamp indicating the end of its activity. The “lookup_all” method returns all versions of the record, not only the active one as the “lookup” method does.

4) Other Subclasses of the Table Class

CSVTable class is used to define tables stored as CSV files. It can be used both as data source and as a destination. CSVTable’s constructor accepts a number of parameters used to define CSV format (delimiter, quote char, header definition, etc.). There is also a concept of “dialect” where well-known CSV formats are represented with a dialect (e.g. Microsoft Excel dialect) so that one can easily define a CSV format via dialect.

MongoDB class is used to define tables stored as single-depth JSON objects in MongoDB NoSQL database.

5) Logger Class

Every instance of the Logger class generates its own text file where log messages are stored. In accordance with most major logging frameworks, messages are ranked in five levels:

1. “DEBUG” – Notifications for user who is tasked with ETL process development
2. “INFO” – General notifications for the user
3. “WARNING” – Alerts that show anomalies in execution
4. “ERROR” – Errors in execution
5. “CRITICAL” – Critical error that prevents ETLator from proceeding with work

It is also possible to define a Master logger – a parent instance of Logger class to which all local logger messages are forwarded (“bubble up”).

Each log message entry comprises of log level, timestamp and message text. By default, ETLator generates master logger object and logger objects for all tables defined in the “flow” directory, but developers can also define their own, additional logger objects. ETLator automatically generates messages of “INFO” and “ERROR” levels. By default, master logger dismisses all messages below “ERROR” level.

**B. Project structure**

File and directory structure of ETLator is predetermined and is shown in Fig. 2.
With these two simple rules it is possible to define arbitrary data flows in terms of ordering and parallelism by leveraging the well-known paradigm – file system. For instance, Fig. 3 shows data flow as it would look like in a typical GUI ETL tool corresponding to the example in the Fig 2.

![Data flow diagram](image)

Figure 3. Data flow corresponding to the project in Fig 2.

We argue that it is even easier to define flows using file system operations (make directory, rename, copy, move) than it is to draw them, especially since these file system actions can be easily scripted, e.g. if we want to generate a flow for each table in the database.

Within each subdirectory of the directory “flow” ETLator automatically generates directory “logs” where logs and documentation files are stored.

Directory “finalization” contains user-defined scripts that will be executed at the end of the run.

Root directory “logs” is automatically generated by ETLator and is used to store summary logs.

Script “main.py” is used to run ETLator and should not be changed by the users unless there is need to change the behaviour or add functionality. All the parameters that are set by default in “main.py” can be overridden on the global level using scripts in the “setup” directory or locally in the scripts within subdirectories of the “flow” directory, without changing “main.py”.

Note that this project setup makes it portable even between different OS platforms, provided of course, that Python interpreter is installed. A simple zip file is all it takes to deploy a project.

C. Parallelism

Parallel execution of scripts within subdirectories of the “flow” directory can significantly speed up the execution on multiprocessor systems, especially when multiple data sources and destinations are involved.

For each script in the directory a process is created that evaluates the script. Maximum number of processes can be set in scripts in the “setup” directory. Processes are
used instead of threads because memory management of Global Interpreter Lock (GIL) in CPython, the most commonly used implementation of Python interpreter, is not thread safe. GIL prevents multiple native threads to execute Python bytecode at once [13]. Consequently, multithreaded Python programs work slower than equivalent single threaded programs because GIL incurs additional costs for thread synchronization are. GIL can also cause starvation of important threads while unimportant threads are using all processor cycles because thread priority cannot be defined. Jython, an implementation of Python interpreter in Java programming language doesn’t have GIL so multithreaded programs can work in parallel, but is rarely used because of lower performance and module incompatibility problems.

By using separate processes we circumvent GIL so that the execution of operations that do not require often synchronization is faster than a multithreaded program, despite the slower initial operation of starting a new processes.

D. Running example

A well-known Northwind database is taken as a running example. Due to space considerations, we consider only a subset of Northwind database shown in Fig. 4:

![Source database schema](image)

**Figure 4. Source database schema.**

1) Directory “setup”

Setup directory contains the definitions of Connector objects that will be used multiple times and definitions of destination tables that will be the target of lookup operations from other tables. These scripts can set ETLator parameters such as turning off documentation generation and set the maximum number of processes used. In this example the “setup” directory contains files “connSrc.py” and “connDest” that contain the definition of connections to the source database and the DW, and files “dCity.py”, “dCustomers.py”, “dDate.py”, “dEmployees.py” and “dShippers.py” that contain definitions of the tables that have to be accessible from every process, as can be seen in Fig 5. Order of execution is usually not important in the setup directory, which holds true also for this example, otherwise file names would be prefixed with a number.

2) Directory “flow”

Three directories are added into the “flow” directory: “1”, “2” and “3” with scripts for populating dimension tables (directories 1 and 2), and the fact table (directory 3), as shown in Fig 5. Scripts in directories 1 and 2 will be evaluated in parallel.

![Project structure subset for the running example](image)

**Figure 5. Project structure subset for the running example**

City source table is actually not a physical table, but is defined via SQL query that is extracting attributes used in dCity dimension in the DW. The following snippet is used in loadDCity.py to populate dCity dimension:

```python
columns = ['PostalCode', 'CityName', 'Region', 'Country']

connectorSrc = connectorSrc.getConnection()

tabCity = lib.table.SQLTable(
    connector=connectorSrc,
    name='dCity',
    column_names=columns,
    default_args=default_args)

connectorDest = connectorSrc.copy()

tabDCity = lib.table.SQLTable(
    connector=connectorDest,
    name='dCity',
    column_names=columns,
    src_table=tabCity,
    default_args=default_args)

tabDCity.auto_transfer()
```

To fetch the connection getConnection() method is used which returns a clone of the Connector objects as to avoid potential collisions during parallel execution. Primary key definition is omitted above since dCity uses autogenerated surrogate key. “default_args” argument is generated by “main.py” and is typically reused (as above) to confirm default documentation generation, logging and automatic table finalization settings.

The following snippet shows the script for populating SCD dimension dEmployees:

```python

tabDCustomers = lib.table.SCDTable(
    connector=connectorDest,
    name='dCustomers',
    column_names=['CustomerID',
                  'CustomerIDDB', 'CompanyName',
                  'ContactTitle', 'Address', 'CityID', 'CityIDDB',
                  'CityPostalCode', 'CityName', 'CityRegion',
```
Finally, the following snippet shows part of the script used to populate the `fOrders` fact table:

```python
for row in tabdOrders:
    row['OrderIDDB'] = row['OrderID']
    custLkp = tabdCustomers.lookup(row, {'CustomerIDDB'})
    if custLkp is not None:
        row['CustomerID'] = custLkp['CustomerID']
    else:
        row['CustomerID'] = 0
    # other lookups, and field transformations
    tabfOrders.insert(row)
```

Data transfer is achieved by iterating over rows of source table, calculating each row of the destination table and executing “insert” method of the destination table (actual insert to the database occurs depends on the batch load settings). To fetch data from other tables (e.g. to fetch dimension keys in the fact table), lookup method of the target table is used. Lookup method takes a row that contains attributes it will try to match and, optionally, a list of attribute names to match. The return value of “lookup” method is either the found row or a “None” value if a matching row is not found.

3) Directory “finalization”

Simple ETL processes usually do not need any finalization operations. In this example the “finalization” directory is left empty, and is not shown in the Fig 5, as well as log folder, lib, etc.

4) Running

Upon starting “main.py”, all scripts in “setup”, “flow” and “finalization” directories are executed in described order, and logs and documentation is generated. Fig. 6 shows data flow diagram generated as a part of the documentation process.

**Figure 6. Data flow diagram generated for the running example**

E. Future development

Future development of ETLator will include support for additional connections, from relational databases to various NoSQL systems (e.g. Hadoop). Also, our plan is to develop rich data transformation and data quality library.

V. Conclusion

In this paper we present ETLator - a scripting ETL framework. ETLator is an open-source, platform independent ETL framework written in Python programming language, with support for various data sources, parallel task execution, slowly changing dimensions, etc. ETLator prescribes the project’s file and folder structure, and enables users to define data task’s ordering and parallel execution simply by using conventions for file and directory naming and nesting. In comparison with other frameworks ETLator is simpler to use, while retaining typical ETL features. Also, unlike similar tools, ETLator features built-in logging and documentation generation features (data flow charts included) which are traditionally features found only in GUI based ETL tools.

Definition of ETL process in ETLator consists of writing short scripts in Python, with the ETLator library and all other Python libraries at one’s disposal, which results in terse and expressive code, and overall an easier and faster experience of developing and maintaining ETL projects.

Abstract - Business intelligence (BI) allows companies to analyze business information in order to support successful decision making. Currently, the research on the level of BI maturity in Croatian and Slovenian companies is limited. In addition, several BI maturity models have been developed, but most of them are not comprehensive. In order to shed some light to this issue, this paper is focused on two goals: (1) to investigate the impact of BI maturity on business process performance and (2) to explore the requirements for the alignment of two concepts, BI and business process management (BPM) within the organization. Paper presents the following: (i) investigation of BI and BI systems in general, (ii) adaption of the BI maturity model (called biMM) for the purpose of this research, (iii) results of the primary research on the sample of Croatian and Slovenian companies which has been conducted as one of the activities of the project financed by the Croatian Science Foundation: IP-2014-09-3729 Process and Business Intelligence for Business Excellence, (iv) level of BI maturity and the role of BI and business process alignment for the impact of BI maturity on business process performance in investigated companies.

I. INTRODUCTION

The vast amount of daily generated data in organization is a result of a growing number of business transactions. It becomes crucial for organizations to transform collected transaction data into valuable information using information technology (IT). According to Dinter [6] and Forrester [38] business intelligence (BI) has the essential role in this part since it encompasses all processes and systems that transform raw data into meaningful and useful information and enable effective, systematic and purposeful analysis of an organization and its competitive environment. BI can be defined as the acquisition of skills and abilities to adapt the organization to different business conditions ([23]; [24]; [16]; [22]). Agile, real-time BI becomes a prerequisite in the environments of constant change in which organizations operate [39]. In general, the role of BI in improving business process performance has gained a lot of attention because of its ability to provide a detailed insight into business operations and to enhance operational intelligence ([13]; [7]; [8]; [20]).

However, the empirical evidence of how BI impact organizational processes with improving business processes is still lacking. Accordingly, the aim of this paper is to explore if and how the higher BI maturity increases process performance.

This paper presents following sections: a theoretical background about BI and BI maturity model introduction, a discussion about BI and BPM alignment, the detailed empirical research methodology, the results analysis and a discussion on the results and, finally, the conclusions and implications for further research.

II. BI AND ORGANIZATIONAL PERFORMANCE

BI uses different tools and applications for collecting and analyzing business data. Business intelligence systems (BISs) can be defined as software platforms that provide users of the system with relevant information, which enable them to make better decisions. Today, BISs combine methodology, applications, technologies and platforms for storing information such as data warehouses, data marts, analytical tools such as reporting tools, ad hoc analytics (OLAP), in-memory analytics, planning, alerts, forecasts, scorecards, data mining and online analytical mining (OLAM) ([7]). The results of the researches claim that BI became the driver of organizational success and process performance, so business practitioners and academicians search for strengths and weaknesses of existing BI structures in order to make these more effective [18]. For this purpose, BI maturity models are applied.

In general, maturity models usually consist of several (4-6) dimensions of maturity and enable organizational assessment and organizational development [21]. Though a large number of BI maturity models exist, the majority of these models still indicate certain shortcoming such as the lack of transparency, comprehensiveness, systematization, appropriate assessment tools and the lack of empirical data ([6]; [26]). Dinter [6] developed a BI maturity model (called biMM) that was structured in 3
dimensions (functionality, technology and organizational dimension), within each dimension several categories were introduced and the design objects for each category were defined. According to Dinter [6] functionality dimension includes aspects of the use and impact of BI within the organization, as well as other content-related issues. Technology dimension highlights the system and the architecture of the data and the BI tools along with their associated functionality while organizational dimension refers to separate organizational structures, processes, profitability and the strategy of BI in an organization [6]. For the purpose of this research an aggregated BI maturity model based on Dinter’s biMM is designed. This model distinguishes ten categories comprising the most important elements of Dinter’s biMM.

III. BI AND BPM ALIGNMENT FOR PROCESS PERFORMANCE MEASUREMENT

The emergence of a large number of activities in the process, possible automation and a large number of errors result in the need for business process management (BPM). One of the most widely used definitions of BPM is Harmon’s [11]: “BPM is a management discipline focused on improving corporate performance by managing a company's business processes”. BPM enables the alignment of business processes and the organization’s strategic goals [4] and comprises different phases, from analysis and design, through implementation and automation, to process monitoring and measurement phase [2]. Both of these concepts, BI and BPM, are considered key drivers for process and organizational performance improvement.

Business process performance is measured by the business data on the costs and time required to perform the activities so as by the costs and resource capacities involved in the activities, keeping in mind that the focus should be on the quality of products or services [3]. For this purpose, business process management systems (BPMSs), whose functionalities support the documentation, automation and tracking of business processes, real-time monitoring and collecting historical data on the business processes performance and optimization of processes, are used [19]. In terms of internal processes, an organization is directed towards measuring product quality and production costs, while the focus of external processes is aimed at measuring customers’ satisfaction. According to empirical data by Huang [12] collaboration of process performance measurement together with the reduction of costs and increased speed of the internal processes, as well as an improved quality of the external processes, result in the improvement of the organizational performance.

Kuang [17] defines process performance measurement systems (PPMSs) as information systems that integrate relevant information of the performance of one or more business processes, compare historical and desired future values with achieved business process value and report the results to participants of the process. Also, data on business processes can be collected from ISs systems, which are focused on the collection and storage of financial and time-oriented data [17]. Similarly, Hammer [9] emphasizes the need for “match between organization’s information and management systems and the process’s needs, and the quality of the metrics that the company uses to measure process performance”. Since the BISs also serve to collect data relevant to the assessment of process performance this study discusses the effects of connecting BISs and BPMss.

The results of the researches from business practice show that the full potential of BISs and BPMs integration and information exchange is still not recognized [3]. According to the authors the major obstacles are systemized as follows: “(1) the main goal of BPM initiatives is to improve business processes, while BI initiatives are usually focused on achieving marketing, customers and sales objectives; and (2) although management starts both initiatives, the results evidence lack of the strong commitment towards coordinated usage of BISs and BPMs as tools for supporting performance management” [3].

Hammer et al. [10] specify seven obstacles of performance measurement success in organizations. Some of these imply the need for BPM and BI alignment. According to Hammer et al. [10] “Provincialism” refers to the existence of conflicting goals among departments that result in defining process metrics and KPIs within the functional boundaries. Besides, “Pettiness” or “the policy to measure only a small component of what matters” must be discussed [10]. “Inanity” is concerned with the organization’s approach “to implement metrics without giving any thought to the consequences of these metrics on the performance on organizational level” [10]. Such situations could be avoided by setting up and measuring the organizational KPIs on the end-to-end process level and by implementation of performance management systems in line with cross functional processes ([15]; [1]). This approach could help organizations to increase the relevance and usefulness of their performance measurement systems. The authors suggest to coordinate BPM and BI initiatives in a company and to provide very intensive communication between BPM and BI experts and mangers ([27]; [3]). According to Nenadal [34] the main goal of process performance system is to identify if processes meet strategic goals and this goal is achieved through “the monitoring of agreed performance indicators”. For this reason, it is very important to establish the role of the process owner and to ensure that process owners monitor business process execution and KPIs achievement through BISs and BPMs [25]. It’s very important to achieve a common understanding of business process terminology on the level of entire organization ([43]; [9]). Customer focus, collaboration, teamwork, and a willingness to reach process KPIs must be shared and accepted by employees across the organization.

Some authors emphasize the need to apply BI techniques in BPM, so the new term “business process intelligence” is introduced in literature [41]. According to van der Aalst [42] the combination of BPM and data mining, called “process mining” is applied in business practice with the aim to extract and discover knowledge from process events (log) data. Schifer, Jeng and Chowdhary [40] present a solution for merging business data with typical workflow data by adding process metrics
(such as throughput time, utilization and cost of resources, process volume and frequency) to existing data warehouse technologies. Bucher and Gericke [43] specify several reasons for the integration of BI and BPM platforms, such as: “(1) a lot of operational processes require “data analytics” in real-time or near-real time; (2) operational processes provide the context for data analysis and decision making, hence BI techniques can be used to merge and consolidate raw data about process execution into KPIs; (3) once operational decisions have been made based on KPIs, useful knowledge about KPIs, corresponding decisions and related consequences can be added into a dedicated data store, so developing the rules for future decision making.”

Since the ultimate goal of both, BI and BPM, is to increase process performance, this paper aims to investigate if the need for alignment of these concepts is recognized within the organizations and to evaluate its impact to process performance.

IV. EMPIRICAL RESEARCH METHODOLOGY

Based on the previous theoretical discussion, it is reasonable to expect, that BI and BPM will result in higher process performance improvement when they are implemented as coordinated and aligned initiatives. Thus, we put forward the following hypotheses:

H3: Business intelligence maturity positively influences BPM/BI alignment.

H4: The impact of Business intelligence maturity on Process performance is mediated by BI/BPM alignment.

Our questionnaire is presented in appendix, and was developed based on the previous theoretical knowledge, as presented in parts II and III of this paper, in order to assure content validity. We used a structured questionnaire with five-point Likert scales, with anchors ranging from totally disagree (1) to totally agree (5), for all items used in our study. The data were collected through a survey of medium- and large-sized business organizations in Croatia and Slovenia. Questionnaires were addressed to top management in the contacted organizations. The two rounds of call-up were conducted yielding altogether a sample of 65 completed surveys in Croatia and 118 in Slovenia.

V. RESEARCH RESULTS: ANALYSIS AND DISCUSSION

To conduct the data analysis, partial least squares (PLS), a component-based structural equation modeling (SEM) technique, was used. This is a widely used methodology in the IT and IS field as it is suitable for predicting and theory-building because it examines the significance of the relationships between the research constructs and the predictive power of the dependent variables ([28]; [32]). The estimation and data manipulation were performed using SmartPLS [36] and SPSS.

We have examined the reliability and validity measures for our reflective measurement model. In the model, all Cronbach’s alphas by far exceeded the 0.7 threshold [35]. Without exception, the latent variables composite reliabilities were higher than 0.8 and in all cases even higher than 0.9, showing the high internal consistency of indicators measuring each construct and thus confirming construct reliability ([35]; [32]). The Average Variance Extracted (AVE) was generally around 0.7 or higher, thus exceeding the threshold of 0.5, demonstrating the convergent validity of the constructs [29]. The reliability and convergent validity of the measurement model were also confirmed by computing standardized loadings for the indicators and Bootstrap t-statistics for their significance. All standardized loadings of the indicators in the model exceeded the 0.7 threshold and they were found without exception to be significant at the 0.001 significance level, thus confirming the high indicator reliability and convergent validity ([33]; [32]). Based on the discriminant validity tests, that “two conceptually different concepts should exhibit sufficient difference” [32], BI3 and BI9 indicators were excluded due to too high cross loadings with BUBPM ALIGNMENT indicators. Discarding the mentioned items substantially and sufficiently improved the discriminant difference between the items of the two constructs.

The assessment of the indicator loadings on their corresponding constructs indicated that manifest variable correlations with their theoretically assigned latent variables are an order of magnitude larger than other loadings to other constructs [30]. Therefore, all the item loadings met the criteria. The square roots of AVE for constructs were significantly higher (and also substantially larger than the threshold of 0.5) than the correlations between the constructs, thus confirming that they are sufficiently discriminable ([28]; [29]).

We further estimated the inner path model. We tested the significance of the hypothesized relationships between the constructs by bootstrapping with 1,000 replicates. The structural model was then assessed (see Figure 1) by examining the coefficient of determination (R2) of the endogenous latent variable, the estimates for the path coefficients of relationships in the structural model and their significance levels (via bootstrapping) [28].

The path and indicator loadings are shown in Figure 1. The influence of BI MAT and BUBPM ALIGN explain 20.3 % of the variance in PP. Further the influence of BI MAT on BUBPM ALIGN explains 48.3% of the variance in BUBPM ALIGN. Since the exogenous variables explain a moderate to high proportion of the variance of the endogenous variable, we may conclude that the model holds sufficient explanatory power and is capable of explaining the constructed endogenous latent variable [32]. The direct impact of BI MAT on PP is not statistically significant ($\hat{\beta} = 0.200; p=1.660$) rejecting H1. The direct impact of BUBPM ALIGN on PP is statistically significant ($\hat{\beta} = 0.289; p=2.592$) and positive thus our H2 is supported. The positive impact of BI MAT on BUBPM ALIGN is statistically significant ($\hat{\beta} = 0.694; p=13.189$) and supporting our H3. To test that the impact of BI MAT on PP is mediated by BUBPM alignment we followed the procedures explained in Kenny [14] and Rucker et al. [37].
First, the direct effect of BI MAT on use intentions was tested. The direct impact of BI MAT on PP is not statistically significant, thus our hypothesis H1 is rejected. However, the causal variable (BI MAT) is correlated (0.400) with the outcome (PP), thus there is an effect that may be mediated [14]. In the second step, the mediator (BI/BPM ALIGN) needs to be treated as the outcome variable and BI MAT as the causal variable [14]. The path is statistically significant at 0.001% significance level, where BI MAT have direct positive influence on BI/BPM ALIGN. The causal variable is also correlated with the mediator (0.693). The third step involves showing that the mediator affects the outcome variable [14], which was tested with H2 and proven to be statistically significant. Since, the direct impact of BI MAT on PP is not statistically significant, BI/BPM ALIGN completely mediates the impact of performance perceptions on use intentions [37], proving our H4.

VI. CONCLUSION

In this paper we have presented preliminary results of the comprehensive research conducted in Croatian and Slovenian companies. Structural equation model was developed in order to test hypothesis. First, the impact of BI maturity to business process performance (H1) was not confirmed. Second, the positive impact of BPM/BI alignment to the process performance (H2) was confirmed. Third, positive impact of business intelligence maturity to BPM/BI alignment (H3) was confirmed. Fourth, the mediating effect of BI/BPM alignment to the impact of BI maturity on Process performance (H4) was confirmed, which is an important finding, since the direct impact was not confirmed. The contribution of this model is thus to indicated a path towards the future research on an interrelation of BPM/BI alignment and Process performance. Practical implication of this research stems in the greater need of the synchronized efforts in the implementation and development of BI and BPM.

MapReduce Research on Warehousing of Big Data

M. Piček and B. Vrdoljak
University of Zagreb, Faculty of Electrical Engineering and Computing
Department for Applied Computing, Zagreb, Croatia
{marina.picek, boris.vrdoljak}@fer.hr

Abstract - The growth of social networks and affordability of various sensing devices has lead to a huge increase of both human and non-human entities that are interconnected via various networks, mostly Internet. All of these entities generate large amounts of various data, and BI analysts have realized that such data contain knowledge that can no longer be ignored. However, traditional support for extraction of knowledge from mostly transactional data - data warehouse - can no longer cope with large amounts of fast incoming various, unstructured data - big data - and is facing a paradigm shift. Big data analytics has become a very active research area in the last few years, as well as the research of underlying data organization that would enhance it, which could be addressed as big data warehousing. One research direction is enhancing data warehouse with new paradigms that have proven to be successful at handling big data. Most popular of them is the MapReduce paradigm. This paper provides an overview on research and attempts to incorporate MapReduce with data warehouse in order to empower it for handling of big data.

I. INTRODUCTION

Data-oriented systems have recently been faced with overwhelming amount of various-type data. Data warehouses, core of all traditional decision-support systems, also have to face these challenges. It has become crucial to analyze almost all possible data to keep up with the competition by following the shift in data warehousing trends. Transactional data do not provide sufficient support anymore and other emerging data sources must be embraced. These new data sources are part of big data phenomena. Traditional data warehouses and RDBMSs are not an adequate storage for big data, and that needs to change because the quantity of unstructured data exceeds the quantity of structured data by four to five times [1]. In big data analytics, MapReduce programming framework has gained popularity because of its ability to effectively process large databases, as well as big data. For that reason, researchers have turned to application of MapReduce to overcome the gap between data warehouses and big data.

Research approaches include integration of data storage systems, changing relational paradigm to non-relational, and new algorithms and approaches to creating and storing data cubes. This paper presents an overview of some of the interesting work done in this field. The paper is organized as follows: section II presents the current data trends, features, storages and paradigms; section III presents main issues of data warehouses with big data and unsuitability of Hadoop alone for solving them; section IV presents two research approaches to solving problems described in previous section through describing representative work that has been done; section V discusses the presented approaches; and the section VI concludes this paper.

II. DATA TRENDS

A. Big data

The term big data was invented to describe new types of data that emerged with popularization of social networks and data-generating smart or simple devices. There are quite a few big data issues from analytical point of view: they may be unstructured and/or semi-structured and lack formal model and metadata; they arrive fast and in large quantities; they may be incorrect to a certain level. Most importantly, it is questionable if a certain set of big data holds any value at all, but that can only be known through data exploration. Big data features are usually described by 4Vs – volume, variety, velocity, and veracity – but, three more V features have been identified [2]: variability (in ways to interpret same data), value (actual usefulness of extracted information), and visualization (need for illustrative visualization of big data sets to understand them).

B. Shared-nothing architecture

Shared-nothing architecture is a distributed computing architecture that features a collection of independent and self-sufficient nodes. These nodes may be various (virtual) machines, where each one has a local disc and main memory. The nodes are connected via network and there is no contention point in it. The phrase shared-nothing came from the fact that nodes do not share any kind of memory. The most popular paradigm based on this concept is the MapReduce.

C. MapReduce

MapReduce (MR) has recently become one of the most popular frameworks for processing large amounts of data. It is specially designed for scalability of data processing in the cloud environments. It hides the implementation of its main features from the programmer, e.g. fault tolerance, load balancing, parallelization and data distribution.
D. NoSQL

The term NoSQL is interpreted as "Not Only SQL". In this case, having SQL as a synonym for relational databases, NoSQL does not imply the complete absence of relational. NoSQL databases are usually open-source and their main features are: data and processing distribution, horizontal scalability, fault tolerance, fast data access, simple APIs, relaxed consistency and being schema-free [3]. However, they also have their downsides. The current issue with NoSQL databases is that they do not offer a declarative query language similar to SQL and there is no single, unified model of NoSQL databases.

There are multiple NoSQL database families, which differ significantly in their features. Main NoSQL database families (sometimes referred to as 4 true NoSQL database families) are: column-oriented, document-oriented, key-value stores, and graph. Also, there are less commonly mentioned families that had been present long before NoSQL term was used: object-oriented, XML-native, and other database families like multimodel, multivalue, and multidimensional databases.

In attempts of big data warehousing, mostly used NoSQL systems were based on Hadoop’s implementation of MR, running on top of it or along with it, e.g. HBase, Hive, Pig, Spark, Sqoop, Impala, etc., but attempts have also been made without using a MR-based system. Those that best served for research purposes are briefly described below.

- HBase is a column-oriented distributed database that runs on top of Hadoop. It was modelled after Google BigTable. It features data compression and Bloom filters on column-level. Its tables can be used as input and output for MR. One of the most popular data-driven websites that uses HBase is Facebook, which uses it for its messaging platform.

- Hive [4] is a data warehouse infrastructure running on top of Hadoop. In Hive, data can be stored in various databases and file systems, all interconnected with Hadoop. It supports SQL-like commands in its language, HiveQL, which shifts the focus from low-level programming to a much more declarative level. Given queries are translated into MR jobs that are executed on Hadoop. Hive contains a system catalogue called metastore that stores metadata about tables, and that makes it a data warehouse.

The idea behind Hive was to bring in well-known concepts of structuredness (e.g. tables, columns, partitions and subset of SQL) into unstructured Hadoop environment, but still keeping the flexibility and extensibility Hadoop has. Organization-wise, table is a one logical unit of data and is stored as a directory in HDFS; table partitions are stored as a subdirectory within table’s directory; buckets are stored as files within partition’s or table’s directory, depending on table being partitioned or not.

Hive adopted one of the main changes in approaches to data (warehouse) modelling: schema-on-read approach rather than schema-on-write, meaning that the data are loaded more quickly because there is no validation against a pre-defined schema. The validation is performed during run-time, which impacts the query time to be slower.

One of the main downsides of Hive’s design is its naive simple rule-based optimizer. The authors predicted optimizer improvements as the future research work, as well as exploring other data placement ways, e.g. column-oriented to improve data reading performance.

- Pig is a high-level platform that runs on top of Hadoop and serves for creating programs running on it. Unlike Hive, which is meant for exploring datasets, Pig is more appropriate for processing data flows [4]. Its language Pig Latin is more declarative comparing to MR programming in Java and also supports user-defined functions, written in Python, Java, etc. Pig Hadoop jobs cannot only be run in MR, but also in other frameworks, e.g. Spark.

- Google BigTable [5] is a NoSQL database for unstructured data. It was built on a few Google technologies, including Google File System. In BigTable, data are mapped by triplets <row key, column key, timestamp> and each stored value is an uninterpreted array of bytes, while the timestamps are used for versioning. There is a false perception that BigTable is a column-store database, but its connection to column-oriented approaches lies in usage of column families. Column families are groups of column keys that are grouped into sets, i.e. columns are clustered by key. Usually, a column family contains data of the same type.

- Apache Spark is a cluster-computing framework featuring data parallelism and fault tolerance. It was made to overcome MapReduce’s dataflow limitations and has proved to be faster than MR framework. For that reason it should be considered at the time of choosing the right technologies to deal with big data in general, as well as in OLAP.

III. DATA WAREHOUSE’S BIG DATA ISSUE

There is a misconception that standard data warehouse architecture is not completely compatible with big data. One of the main arguments of this misconception is the notion that data warehouses are primarily focused on “stock” or fixed data supply oriented on the past and not suited for real time streaming analytics [2], but real-time BI, which is supported by real-time data warehouses is its counterargument. The problem lies in the intensity of the data streaming, which has become too high with the emergence of big data. The hype around big data has even caused some vendors and analysts to foretell the death of data warehousing and even relational databases. Most popular BI platforms do not support integration with NoSQL databases, but some provide native access to them (e.g. Hive).

MapReduce is considered “appropriate to serve long running queries in batch mode over raw data”[1], which is exactly what ETL process does. However, integrating or replacing traditional systems with Hadoop is a challenging research topic. Despite Hadoop’s ability to provide instant access to large amounts of high quality data, the implementation of ETL processes in Hadoop is not simple. The users need to manually write custom programs, which are sometimes not effective and cannot compare to ETL tools for data cleaning, transformation and coordination. Authors in [6] suggest that using ETL
tools is still suitable for small amounts of data, while design of custom programs in Hadoop is more feasible for larger amounts. Another important feature Hadoop lacks is adding dynamic indexes to the framework, which is still an open issue.

IV. MapReduce Approaches in Research

Research of MapReduce approaches in data warehousing can be grouped into two categories:

i. system-level research: focused on system-level improvements and/or integration;

ii. data cube research: focused on an OLAP data cube component of data warehouse.

A. System-level research

1) Simple data warehouse augmentation

The simplest way of data warehouse’s coexistence with new big data solutions was presented in [2], where big data are treated as an additional data source for the data warehouse. This idea does not include integration of data warehouse and big data system on any level, but the data sequentially going through processing systems based on their kind, and in the end - ending up in the data warehouse. Before loading, big data are processed (analysed) in a MR framework, while the rest go through standard cleaning and transformation processes. In this case, the resulting data from the MR processing enrich dimension tables by adding more attributes to them and thus enrich the overall analytical power of the data contained in the data warehouse. Authors pointed out that the good approach would be to leave the original data source intact to enable different types of analyses because the same data processed in different ways can yield different results. However, the issue with this solution is that the programmer or analyst needs skills and knowledge to write map and reduce functions, which may have a big span of complexity – from simple counting to using data mining algorithms and machine learning.

2) HadoopDB

HadoopDB [7] is a hybrid of parallel databases and MR. It is an open-source solution made of other open-source technologies like Hive, Hadoop and PostgreSQL, all organized in a shared-nothing architecture. The idea behind such integration was to benefit from scalability advantages of MR, and from performance and efficiency featured in parallel databases. Comparing its used storage systems with those used in Hive, HadoopDB uses relational databases in each of the nodes instead of distributed file systems. MR is used as communication layer; Hive serves as a translation layer (queries expressed in SQL are translated into MR jobs); on the database layer there can be multiple nodes running DBMS. The main research contribution was improving query optimization compared to optimization in Hive by pushing query processing logic maximally down to the databases (because Hive did not consider table data colocation in a single node, while HadoopDB does), and modifying Hive by adding four more components to it – database connector (for connecting to databases, executing queries and returning the result), catalog (for maintaining information about the databases), data loader (for partitioning and re-partitioning of data and data loading), and SQL-to-MapReduce-to-SQL planner (for extending Hive query planner). So far, HadoopDB implemented filter, projection and aggregation operators, while the authors expect that this system will benefit from future Hadoop improvements, despite of parallel databases currently still being faster.

3) Starfish

Starfish [8] is a self-tuning system for Hadoop for big data analytics: it tunes Hadoop parameters, but it does not improve its peak performance. Starfish is placed between Hadoop and MR job-submitting clients like Pig, Hive, command line interface, etc. MR jobs, workflows, or collections of workflows are expressed in language Lastword (Language for Starfish Workloads and Data). The main focus of this system is its adaptation to user’s and system’s needs. Reasoning behind self-tuning approach lies in Hadoop’s suboptimal usage of resources and time. The problem with Hadoop is that there might be around 190 configuration parameters controlling its behaviour, and most of them need to be set manually, e.g. actions like adding and removing a node based on the needs, or rebalance of data. Even for a single MR job, multiple parameters need to be set, e.g. number of mappers and reducers, controls for network usage, memory allocation settings. Higher-level languages for defining MR jobs – like HiveQL and PigLatin – do not consider cost-based optimization during the query compilation into MR jobs, but only rely on naive hard-coded rules or hints specified by the users. The basic endeavour is to move the computation to the data as much as possible to achieve minimal data movement. Starfish provides automatic system tuning throughout the whole data lifecycle: it is able to perform tuning at different levels of granularity – workload, workflow, and job-level – and the interaction of these components provides Starfish’s tuning in whole.

4) Olap4cloud

Olap4cloud is an open-source experimental OLAP engine built on top of Hadoop and HBase, designed to efficiently perform queries containing aggregations and grouping on large data sets, and to be horizontally linearly scalable. Its main features include data defragmentation, indexing, and preaggregations. Olap4cloud stores rows with the same dimensions close to one another. For preaggregations, aggregation cuboids are constructed using classic lattice modes, which help to achieve lower latency during execution of queries that use already calculated aggregations. For now, Olap4cloud is still in an early experimental stage: it is able to manage and query cubes (fact tables containing dimensions and measures), but it does not fully support dimension tables, hierarchies and measures: dimensions can only be Java data type `long`, and measures must be in Java data type `double`.

5) HBase Lattice

HBase Lattice [9] is an open-source solution that attempted to provide BI “OLAP-ish” solution based on HBase. Author argues that, in discussion of “Cassandra is for OLTP, HBase is OLAP mantra”, this system, based on

---

HBase, has limited support for OLAP features: it does not directly support cube models and has no concepts of dimensions, hierarchies, measures and facts, nor has its own query language. It implements incremental OLAP-like cubes: by pre-building cuboids in a cube lattice model, it is able to cope with aggregate queries.

6) HaoLap

HaoLap [10] (Hadoop based OLAP) is an OLAP system designed for big data that has some common features with MOLAP tools. It uses simplified multidimensional model for mapping of dimensions and measures, and most importantly - it supports dimension operators (e.g. roll-up). In this system, optimization and speed-up are not achieved using indexes nor pre-computations, but by sharding (horizontal partitioning) and chunk selection. Instead of storing large multidimensional arrays, calculations are stored and that simplifies the dimension by having low storage cost and makes this system's OLAP efficient.

Dimension and cube metadata are stored in XML format in a metadata server, while measures are stored in HDFS. Data cubes do not have to be instantiated in memory - OLAP algorithm and MR are used for that. MR jobs are consisted of four parts (input-formatter, mapper, reducer and output-formatter) and are specified as such quadruplets. MR job operates on the level of chunks, and at the end of the processing chunk is stored in the created chunk files, which are then logically combined into the result – a cube.

7) Octopus

Octopus [11] is a hybrid data processing engine. It is a middleware engine that integrates various backend systems and serves as a one access point (Figure 1.) between the user and them. The reasoning behind building such integration system is that neither traditional warehousing systems, nor recent big data systems are able to fully leverage the power of the other – neither can fully take over the other’s role.

Data are distributed in multiple locations of the system, while the system itself bases its optimization on minimizing the amount of data movement by making a query push-down, which is based on the data’s residence. Octopus takes a given query task in an SQL-like form from the user and divides it into multiple subqueries. The initial query is processed with system components, parser and optimizer; parser produces a logical operator tree and optimizer produces an optimal set of query plans. Subqueries derived from the initial query are pushed down to the backend systems and processed inside of them. By sending the queries to systems where the data are physically stored and optimally processed, data movement costs are reduced.

Authors have compared Octopus to Spark, because Spark also supports integration of external data sources and implements unnecessary data filtering for reducing data migration. Experiments proved Octopus to be faster than Spark in processing aggregation queries. Possible future development of Octopus lies in adding support for more types of NoSQL databases, as well as integrating more Spark modules, e.g. machine learning.

B. Data cube research

1) Approach by Abello, Ferrarons and Romero

An approach to building data cubes on BigTable was presented in [1]. BigTable is used for storing all the data together temporarily - data are just partially cleaned and integrated before they are stored - without having a concrete schema, so the schema may evolve easily over time. Also, the authors argue that column storage is good enough for data marts because they have well-defined columns, but for the entire data warehouse more flexibility is required because of unclear data structure and continuous schema evolution.

The basic idea is to have a non-formatted chunk of data just stored and associated to the key, which is later, once it is needed, retrieved and used according to the specific needs. That is the opposite from putting a lot of resources and effort into formatting and structuring the data according to the strict star schema, which after data import may not be used for a couple of months, or may even not be used at all. Upon having an analysis to perform, data quality is specified, suitable technology is selected (e.g. ROLAP or MOLAP), and then ETL is used to prepare the data according to needs. On demand, specific and customized data cubes are extracted and stored in a data mart, which may or may not reside in cloud.

For building cubes three typical table access approaches (assuming denormalized data) have been applied in a way they could benefit from MR and BigTable: full scan, index access, and range index scan.

2) MRDataCube

A new cube computation algorithm MRDataCube (MapReduce Data Cube) was presented in [12]. MRDataCube is a large-scale data cube computation algorithm that uses MR framework and uses concepts of cuboids and cells. Cuboid is considered an aggregated result of aggregate operations upon a cube with the goal of extracting each combination of attributes. Cells construct cuboids, and they represent the values stored in them and can be represented as m-membered tuple, where m is aggregation measurement of the cell.

This algorithm computes the cube in two phases, MRSpread and MRAssemble. Its main feature is continuous data reduction through these two phases. The
first phase produces partial cuboids cells, where one cuboid cell values may spread through outputs of several reduce functions. In the second phase, complete cuboids are generated by computing all partial cells, i.e. merging partial cuboids into one cell. Between two phases, result is stored in HDFS. This algorithm showed 2-16 times better performance compared to previous work in that area, algorithms MRNaive, MR2D, MRGBLP and MRPipeSort.

3) CN-CUBE

An operator CN-CUBE (Columnar NoSQL cube) for computing OLAP cube from column-oriented data warehouse was presented in [13], and it proved to be faster than Hive. The main technology they used was HBase engine. By implementing CN-CUBE operator, authors have attempted to solve one of the most common obstacles of column-oriented databases – the lack of OLAP operators. The CN-CUBE reduces disk access by using a result on an extraction query as a view – based on attributed needed for the cube computation requested by analysts - and avoids re-accessing the data warehouse for performing different aggregations. Using this approach, authors have reduced input and output flows substantially.

This operator performs in three phases. During the first phase, attributes are identified and necessary columns (most recent values) are extracted into an intermediate result. In second phase, intermediate relation columns with the values are hashed to produce the lists of values’ positions. These lists allow some columns to be aggregated separately by each dimension. In the final phase, lists of dimensions’ positions of intermediate results are associated through the logical AND operator.

4) MC-CUBE

Similarly to [13], [14] presents an aggregation operator MC-CUBE (MapReduce Cubular cube) that uses HBase as main technology, and introduces a different approach to building OLAP cubes from columnar “big data warehouse”. In this approach, data are taken at a single, least aggregated level, and other aggregates – at other, higher granularity levels – are computed from it. To perform aggregation, this operator performs invisible join, typical in column stores, and extends the aggregation to cover “all possible aggregations at different levels of granularity of the cube”[14].

MC-CUBE operator performs seven MR jobs during four phases. During the first phase, aggregations are produced from the data warehouse at lowest and highest granularity levels – joins between fact and dimension tables are materialized and aggregates are calculated. In the second phase, aggregations are performed of each dimension separately, and in the third, rest of the aggregates composing the cube are computed. The final phase replaces dimensions’ identifiers with dimensions’ attributes, and completes the cube.

V. DISCUSSION

For big data warehousing solution, system integration approaches usually include integration of one or more MR-based technologies like Hive and Hadoop, and combine them with either NoSQL and/or traditional relational storage. Particularly interesting combination is the integration of MapReduce and parallel databases, where the best features are taken from both of them and combined complementarily because one does well what the other does not.

One of the suggested scenarios [3] for big data analysis is to use Hive in Hadoop environment for OLTP, and ROLAP tool for data analysis. However, problems may occur in case when data arrive too quickly and are stored in real-time in Hive, because the existing aggregates in RDBMSs used for OLAP could in a very short time become inaccurate. Other problems are related to the volume of the data; when using partial aggregates, it still may affect the speed OLAP browsing in a negative way. The solution may lie in using MapReduce processing on both OLTP and OLAP side.

In a few works [8], [15], [16] an acronym MAD appeared, denoting features expected from big data analytics systems: magnetism means that system attracts all kinds of data, regardless of possibly unknown structure, schema, or even partial values; agility stands for system's ability to adapt to data evolutions; depth means that the system supports analyses that go to bigger depths than just roll-ups and drill-downs. Authors in [8] even went further and described three more features that would MADDER analytics systems need to have: data-lifecycle-awareness, elasticity, and robustness. In future data warehouse modifications and research, these features may prove to be a good guiding principle. It is noticeable that some of these features are found in NoSQL databases, but never all of them. This shows that NoSQL technologies are a good candidate for a data warehouse asset, but chances are small that a NoSQL database would ever completely replace data warehouse’s relational basis.

Another potential problem that may affect the course of big data analytics and warehousing development is a large portfolio of technologies and implementations, even among open-source products, and even industry has pointed out this as potential problem [17]. The vendors have approached this matter each in their own way, making new products most compatible with their existing ones. Analyzing the general situation from the perspective of data warehousing future, the existing products from which data warehouses may eventually benefit - NoSQL databases and Hadoop implementations and tools - still have many downsides in terms of lacking concepts commonly used in data warehouses and relational databases (e.g. indexing, profound optimizer, ability of having OLAP operators, dimensions and hierarchies, etc.). All of these downsides combined together create obstacles that are being worked on by the current research.

Through the research overview presented in this paper, we can see various system integration approaches [2], [7], [8], [9], [10], [11] to overcoming these issues. System-level integration raises questions of middleware design, data localization, computation locality i.e. amount data movement, etc. Much work has also been done on optimization issues: it included designing special tuning middleware; building better query and MapReduce job plans; preaggregations – most often in forms of cuboids that are stored in a lattice model; using views to access fewer data – but, one of the most applied approaches is the
query push-down technique, i.e., moving the computation to the data, which is guided by the thought that the data should be stored and processed in the system that does suit their nature the best, whether that are RDBMSs, NoSQL databases or MapReduce environment. Possible progress is seen in designing new middleware, either from scratch or by modifying existing systems like Hive.

Presented research overview from the perspective of building data cubes [1], [12], [13], [14], describes representative approaches that have been made with various ways of data storage, especially with column-oriented [13], [14]. Approaches included: storing measures in HDFS while the metadata reside in simple format on server; storing whole data marts in column-oriented storage; collocating data by their type (rows) in column-oriented storage, etc. The diversity is significant, and further research of this matter is expected.

However, one of the most noticeable downsides in some of the presented approaches is considerable simplification – dimensional model is simplified to the extent that the system does not support dimensions and hierarchies, and sometimes even does not differ dimensions from facts. Simplification is an interesting approach, e.g., solving explosive dimension cardinality issue by using some aggregative calculations, but attention should be paid to not over-simplifying the model to the level of its inapplicability for OLAP. To bring big data into the data warehouse, ETL process may need to be loosened to ensure the flexibility for the warehouse and enable the schema to evolve. Still, the main focus remains on creating the much needed OLAP operators.

VI. CONCLUSION

This paper gives an overview of latest research on bringing big data into data warehouses and organization of big data for OLAP analysis using the MapReduce framework. Big data were described by their main features, which are the main reason they cannot be easily let into the strictly structured and highly organized data warehouse environment. However, they are potentially greatly valuable and their share in available data pool is rapidly growing. Thus, they should not be treated as a distinct issue and completely separated from other data, but should be dealt with and made supportive for BI analytics along with traditional transactional data.

NoSQL databases show great potential for handling big data analytics, especially those that implement MapReduce framework. But, there are many issues with these two concepts. The industry has overwhelmed data analytics field with too many implementations that are still not mature enough, mostly in terms of all the underlying supporting features that RDBMSs offer. NoSQL database families differ a lot and may not handle all types of data equally well, and having no unified database model nor a clear data structure leads to great difficulties in design of analytical systems.

The most realistic future scenario is that the data warehouses will not be replaced by some completely different innovative systems. The more likely scenario is that they will continue to coexist in a symbiotic relationship with the new, more suitable solutions for big data, where big data would serve as an additional analytical asset.

Abstract - Credit risk is related to the risk of the borrower that the lender will not be able to return their debt including interest. Numerous researches have been conducted in the area of credit risk, both using classical models such as Altman Z-score and using machine learning methodology. However, the research using the data from Croatian financial institutions is scarce, especially research focused on the selection of the demographic and/or behavior variables. In addition, it is important to develop robust models that estimate credit risk as accurately as possible.

The goal of this research is to develop a data mining model for prediction of credit risk, using the data from Croatian financial institutions on defaulted clients (demographic and behavior). Decision tree models are constructed for the prediction of credit risk. Different algorithms for the variable selection are evaluated based on the classification accuracy of the decision trees developed based on the selected variables.

I. INTRODUCTION

Data mining methods are used for finding undiscovered valuable information from large databases. In other words, the main goal of data mining methodology is to extract knowledge in order to make successful management decisions [1]. Applications of data mining methods are used in almost every industry: banking, marketing, finance, manufacturing, medicine, education, trade, supply [2, 3, 4]. Each industry has its own characteristics, which implies usage of different data mining methodologies. Therefore, in the banking industry, characterized with a high level of fraud and risks, which requires successful prediction of credit default, scoring and applicants, usage of data mining techniques is very common [5].

Data mining usage is one of the most common techniques used in the financial analysis, especially in the banking industry. Prediction of credit risk, mostly prediction of credit default, presents an important activity of the banking industry [6]. There are several different data mining techniques that can be used for financial data analysis because of their high level of success. However, their success also depends on the data available, its cleaning, and transformation. Therefore, decision trees are one of the most commonly used methods [7, 8].

Decision trees are one of the classification methods which group variables into one or more categories of the target variables [9]. When using the decision trees process it is important to follow three main steps: (i) determine the sample, (ii) choose variables, and (iii) select an appropriate algorithm. In this paper we have used the algorithm C4.5, as one of the ten most popular variables.

The goal of the paper is to compare the classification of banking clients according to the credit default, with the C4.5 decision tree algorithm, using different sets of the variables: Entrepreneurial idea; Growth plan; Marketing plan, Personal characteristics of entrepreneurs, Characteristics of SME, Characteristics of credit program, and Relationship between the entrepreneur and a financial institution. The variables are selected by the usage of three different algorithms, provided in the Weka software: Class CfsSubsetEval algorithm, ChiSquaredVariableEval algorithm, and ConsistencySubsetEval algorithm. Previous research that tested the efficiency of algorithms for the selection of variables was mostly conducted on the retail credit risk datasets, e.g. Oreski et al. [10]. The scientific contribution of our paper is that the algorithms for the selection of variables are tested on the real-world dataset of credit risk of Croatian financial institution’s business clients (entrepreneurs from Eastern Croatia).

The paper consists of six sections. After the Introduction, as the first section, there is Literature review. In Literature review, data mining methodology and its usage for predicting credit default are presented. Decision trees, as one of the data mining methods, are described as well as variables and techniques selection approaches used in this research. In the third section named Methodology, data, decision trees techniques and the variable selection process are discussed. Research results are provided in the fourth and the fifth section. The fourth section elaborates on results of the different variable selection strategies, while the fifth section of the paper discusses results regarding classification efficiency measures, classification matrices and falsely predicted good and bad debtors with different variable selection approaches. The last section is Conclusion.

II. LITERATURE REVIEW

A. Data mining methodology

The amount of data has been constantly increasing, which creates difficulties for managers and successful decision making. A high growth of valuable as well as invaluable data in databases has created a need for the use of different methodologies which can help finding, extracting and analyzing data important for decision makers [11].
Data mining technology combines different approaches, e.g. machine learning, statistics and database management, which are used for finding valuable patterns in data for further prediction and decision making. In addition, data mining techniques can also be used for determining relationships among data in order to create knowledge [12]. The main purpose of data mining is to find and analyse disorganized information with the goal of improving business knowledge and activities.

The most commonly used data mining methods are: classification, regression, clustering, visualization, decision trees, association rules, neural networks, support vector machine [5, 13]. In our research we conducted a decision tree analysis, which is mainly used for classification, in order to predict the credit default.

The main purpose of the decision tree analysis is to predict behavior of the target variable using different algorithms to get the best outcome [14]. Some of possible algorithms are: C4.5, ID3, CART, CHAID, and MARS. One of the disadvantages of the decision tree analysis is that, in the process, analysts should pay more attention to a high variance. Other disadvantage of the decision tree is the overfitting, which occurs when model is excessively complex, and it has a poor predictive efficiency. However, the most important advantage of the decision trees is the possibility of interpretation, which together with the simple usage and implementation make the decision tree method appropriate for a wide range of research.

B. Predicting credit default with data mining approach

Countries, especially their economies and financial institutions, have been facing a strong financial crisis in the last years. Therefore, in many countries, governments have brought many saving measures in order to decrease costs and to restart economy development. In addition, credit default has increased and nowadays banks pay much more attention to credit risk assessment and to prediction of credit default with the goal to reduce risk [15].

Financial institutions and banks are using different intelligent techniques, e.g. mathematical models, statistics analysis, data mining methods with the goal to make efficient credit decisions. A detailed analysis of data on the characteristics of current and previous credit users plays an important factor in forecasting the future credit default of new clients [16].

C. Variables and techniques selection approaches

In order to predict credit default, financial institutions and banks mostly use behavioral and demographic variables of previous and current clients, e.g. monthly income, marital status, real-estate owner, employment, age, gender [17].

The main purpose of our research is to classify banking clients regarding credit default with a decision tree analysis, using different variables related to entrepreneurship activity. In addition, financial institutions and banks, when approving credits to clients, strive to select those clients who will be able to repay it in the given period of time [18]. In other words, they are focused on good clients.

There are also studies about methods used in credit scoring. One of the examples is a research which used demographic and behavioral data and three data mining methods: credit scorecard, logistic regression and a decision tree model [9]. The results of the research showed that all three methods are appropriate for use but the scorecards method is the easiest to apply.

There is also a study in which authors have investigated recent researches conducted in the field of credit risk assessment regarding clients and their ability to repay credits [19]. Research results showed that logistic regression is the most commonly used method to group clients into good or bad debtors.

Recent studies showed that intelligence methods used for discovering credit scoring are mostly non-parametric methods and computational intelligence techniques, e.g. decision trees, artificial neural networks, support vector machines and evolutionary algorithms [20, 21, 17].

III. METHODOLOGY

A. Data

Data used in this research were collected from an entrepreneurship credit dataset. Data were collected randomly from the database of clients (entrepreneurs from Eastern Croatia) of the financial institution, that is focused on financing small and medium enterprises, mostly start-ups. There are 200 applicants in the sample.

There are two main reasons for a small dataset: (i) a quite low level of business activity regarding entrepreneurship in Croatia (Total Early State Entrepreneurial Activity (TEA) index for the year 2015 = 7.69; TEA index for the year 2004 = 7.97) which means that a low number of people is taking a credit to start a business, and (ii) financial institutions are rejecting too risky start-ups applications for a credit. Therefore, collecting a larger sample will be possible in the next few years, when the entrepreneurial climate and perception of entrepreneurship activity improves.

The following variables were used for the development of the credit scoring model: Entrepreneurial idea; Growth plan; Marketing plan, Personal characteristics of entrepreneurs, Characteristics of SME, Characteristics of credit program, Relationship between the entrepreneur and a financial institution, and Creditworthiness. Most of the variables are nominal, while two of them are numeric (Entrepreneurs’ age, Number of employees, and Credit amount).

Variables related to the future plans for the SME were estimated by a banking clerk (Table I).

First, it was estimated whether the entrepreneur has a clear vision of the business development (for newly established SMEs), or it is already an established business (Variable Vision).

Second, the variable Better estimated what the main competitive advantage of the SME (better quality, technology, price, or expertise of employees) is.
Third, it was estimated what the main market for SME’s products/services is: local, national, wider region, or narrow targeted customers (Variable Market). Entrepreneurs stated which percentage of the profit is planned to be reinvested in the business operations (Variable Reinvest), and what the plans for the promotion of products/services are (Variable Ad). Also, it was estimated whether the entrepreneur can identify who SME’s main competitors are.

Source: Authors, using Entrepreneurship credit dataset

Table II presents the variables related to the characteristics of the entrepreneur and SME. Entrepreneurs’ occupations are grouped into 5 main groups: 1 - farmer, veterinarian; 2 - trader, restaurateur; 3 - construction worker; 4 - engineer, physician, and pharmacist, 5 - Technologist, chemist. Entrepreneurs’ ages are expressed as a numeric variable. Entrepreneurs’ locations refer to 4 geographic areas in Croatia.

Table III represents the variables related to the credit program and the bank: interest repayment frequency (monthly, quarterly, half-yearly), grace period, principal repayment, repayment period (expressed in months), interest rates, and amount of credit (expressed in local currency). Also, the variable Client measures whether an entrepreneur has applied for a credit before.

Table IV represents the classification variable that was used for the credit scoring (variable Default), and groups clients as “bad” or “good” based on the regularity of their payment.
TABLE IV: GOAL VARIABLE USED FOR THE CREDIT SCORING

C. Variable selection

Three approaches to the variable selection were applied: (1) selection of the variables using the Class CfsSubsetEval algorithm (searching approach BestFirst), (2) selection of the variables using the ChiSquaredVariableEval algorithm (searching approach Ranker), and (3) selection of the variables using the ConsistencySubsetEval (searching approach Greedy Stepwise).

There are differences in definition and usage of the three mentioned approaches to the variable selection which were applied. The Class CfsSubsetEval algorithm is based on the individual estimation of the variables that are highly correlated with the class variables but are not highly mutually correlated. The ChiSquaredVariableEval calculates the value of a variable regarding the value of the chi-squared statistic with respect to the class. The ConsistencySubsetEval calculates the value of a subset of variables by the level of reliability in the class values [22].

Table VI presents the variables used for a different approach to the variable selection. The Class CfsSubsetEval algorithm selected only three variables: Variable Vision – Does the entrepreneur have a clear vision of the business?, Variable Ad - Promotion of products/services, and Variable Reinvest - Projected percentage of the invested profit.

The ChiSquaredVariableEval algorithm selected all of the variables except the Variable Location. The ConsistencySubsetEval selected all of the variables related to the Entrepreneurial idea, Growth plan, and Marketing plan. However, only a few algorithms were selected that were related to the Personal characteristics of entrepreneurs, Characteristics of SME, Characteristics of a credit program, and Relationship between the entrepreneur and a financial institution.

IV. RESULTS

Table VII presents the results of different strategies for variable selection. The largest tree is produced by the ChiSquaredVariableEval (34 leaves and 48 nodes), which could be expected since this algorithm generated the largest number of independent variables. The next is the ConsistencySubsetEval algorithm with 24 leaves and 32 nodes. The smallest tree is produced using the Class CfsSubsetEval algorithm (3 leaves and 4 nodes).

Figure 1 represents the complete decision tree generated with the C4.5 algorithm, using the algorithms selected by the Class CfsSubsetEval algorithm. However, only one variable was selected for the tree development. The first number in the bracket is the total number of cases classified in the leaf. The second number is the number of
those cases that are misclassified. For example, among 153 entrepreneurs that had a vision of established business, 104 were correctly classified as good, while 49 were incorrectly classified as bad.

\[
\begin{align*}
\text{vision} &= \text{established}\_\text{business}: \text{good (153.0/49.0)} \\
\text{vision} &= \text{no clear}\_\text{vision}: \text{bad (14.0/2.0)} \\
\text{vision} &= \text{clear}\_\text{vision}: \text{good (28.0/5.0)} \\
\end{align*}
\]

Figure 1 Decision tree developed using variables selected by the Class CfsSubsetEval algorithm (Source: Authors, using Entrepreneurship credit dataset)

Figure 2 represents a part of the decision tree generated with the C4.5 algorithm, using the algorithms selected by the ChiSquaredVariableEval algorithm.

\[
\begin{align*}
\text{vision} &= \text{established}\_\text{business} \\
\text{vision} &= \text{missing}\_\text{value} \\
\text{vision} &= \text{yes} \\
\text{vision} &= \text{period} = 12\_\text{months} \\
\text{vision} &= \text{period} = 24\_\text{months} \\
\text{vision} &= \text{age} = 38 \\
\text{vision} &= \text{age} = 38 \\
\text{vision} &= \text{amount} \leq 22227.6: \text{bad (2.0)} \\
\text{vision} &= \text{amount} \leq 22227.6: \text{goods (6.0)} \\
\text{vision} &= \text{reinvest} = 30.1.1950: \text{bad (4.0/1.0)} \\
\text{vision} &= \text{reinvest} = 70.01-100: \text{goods (1.0)} \\
\text{vision} &= \text{reinvest} = 0:30: \text{bad (2.0)} \\

V. DISCUSSION

The following section elaborates on research results regarding classification efficiency measures, classification matrices and falsely predicted good and bad debtors with different variable selection approaches.

Table VI presents classification efficiency measures. According to the percentage of correctly classified instances and the root mean squared error the best approach was to use the ConsistencySubsetEval algorithm. However, according to the Kappa statistics, the best approach was to use the Class CfsSubsetEval algorithm.

<table>
<thead>
<tr>
<th>Variable selection</th>

Source: Authors, using Entrepreneurship credit dataset

Table VII presents classification matrices for the decision trees generated by the different sets of variables selected by the three algorithms. The decision tree generated using the variables selected by the Class CfsSubsetEval falsely predicted 27% of good clients as bad clients, but it falsely predicted only 1% of bad clients as good clients. The decision tree generated using the variables selected by the ChiSquaredVariableEval falsely predicted 22% of good clients as bad clients, but it falsely predicted 12% of bad clients as good clients. Finally, the decision tree generated using the variables selected by the ConsistencySubsetEval falsely predicted 27% of good clients as bad clients, but it falsely predicted only 2% of bad clients as good clients, thus producing the similar results as the Class CfsSubsetEval.

Figure 4 presents falsely predicted good and bad debtors with different variable selection approaches.
VI. CONCLUSION

The main purpose of the paper is to compare the classification of banking clients regarding credit default through the analysis of different entrepreneurial variables using decision tree algorithms. Research results showed that variables selected by the algorithm Class CfsSubsetEval have the best results regarding the percentage of correctly classified instances. On the other hand, according to the percentage of bad debtors falsely predicted as the good ones, the decision tree generated using the variables selected by the ChiSquaredVariableEval is the worse. According to the criteria of the minimal percentage of falsely predicted bad debtors as good, the best approach was to use the decision tree generated using the variables selected by the Class CfsSubsetEval or the decision tree generated using the variables selected by the ConsistencySubsetEval. In addition, for financial institutions, especially for banks, the most valuable data are the data on prediction of bad debtors, and in our case two mentioned algorithms should be used. However, since the Class CfsSubsetEval generates a decision tree that is based only on the Variable Vision, it is prone to subjective mistakes, since this variable was estimated by a banking clerk. The ConsistencySubsetEval could be considered as more reliable, since it produces similar results as the Class CfsSubsetEval, and it is based on a larger number of variables. Most of the variables are related to ‘what has been done’ instead of ‘who is doing it’. In other words, variables related to Entrepreneurial idea, Growth plan, and Marketing plan were more relevant than variables related to Personal characteristics of entrepreneurs, Characteristics of SME, Characteristics of credit program, and Relationship between the entrepreneur and a financial institution.

Abstract - Recent scientific and theoretical studies defining brand communication in social media emphasize the significance consumer engagement in brand-related content. Popularity of brand messages and the reach of target audiences depends on consumer engagement in social media. Therefore, many business companies are seeking to increase an impact on consumers using social media analysis and consumer engagement techniques. Usually, consumer actions such as likes, comments and shares in social media channels are used to estimate the popularity of brand posts. One of the factors, which has not widely analyzed before, is the impact of colors for popularity of visual brand-related posts. In this paper, we analyze the effect of colors for popularity of brand-related posts in social media. We analyze our own dataset of images collected from 35 most popular brand Facebook groups. Our results show that black, gray and brown colors were more often used in images of more popular brand-related posts.

I. INTRODUCTION

Social media has become an influential communication channel, where business companies can foster relationships and interact with customers. In 2016, about a half of social media users followed brands on different social media channels such as Facebook, Instagram, Twitter, etc. According to eMarketer [1], 91% of retail brands use two or more social media channels, and by 2017, social network ad spending will reach $36B, representing 16% of all digital ad spending globally.

The importance of visual perception in marketing and advertisement, including shapes, forms, colors, materials, textures, graphical elements and logos has long been acknowledged [2, 3]. One of the main factors of consumer attraction in the modern world is the color [4]. Psychologically, colors may attract attention, carry specific meanings and communicate information [5], evoke certain emotions or motivations [6], and stimulate our memory, thought and experiences [7]. Colors operate via sensory and cognitive mechanisms. In the sensory mechanism, color helps distinguishing an object from its background or a set of other similar objects. In the cognitive mechanism, color helps assign a specific meaning to the object [8].

Colors impact consumer behavior directly by stimulating visual cortex and the effects of colors determine attitude, feelings, affects, emotional reactions and behavioral intentions of consumers of consumers towards colorful items, e.g., packaging, ads, websites [9]. Targeting of user groups by careful deployment of colors can promote attitudes, feelings and moods and thus differentiate products. For similar products and services, their visual images (logos, posters, ads) have become an important factor in a consumer’s shopping decision-making process [10, 11]. The decision is strongly influenced by color components of imagery used [12]. For example, Lindgaard et al. [13] showed that users’ first impressions are constructed in about 50 ms and about 62-90% of the assessment is based on colors alone [14].

One way of enhancing the engagement and popularity of corporate brand pages such as Facebook brand pages is to include images or animation. Previous research has demonstrated that vivid colors have been effective at improving attitudes to web-based ads [15] and increasing popularity of brand fan pages [16]. Images are the most successful in terms of received likes in Facebook [17]. However, there is still a lack of studies evaluating brand post popularity in relationship with colors. Management-oriented studies about brand post popularity are mainly descriptive as they have no theoretical background and do not formally analyze which activities actually may influence brand post popularity [16].

In this paper, we study the effect of colors and their combinations in images attached to brand-related posts on the popularity of posts. The aim is to identify colors that social network users may find appealing and to determine whether some colors favor popularity of social network posts as well as the engagement of users. The contribution of the paper is a method for identifying the association between image colors and image popularity. To support our claims we have carried out an experimental study of color use in images of corporate Facebook posts, and have analyzed whether the frequency of the use of colors in images posted in social media is related to post popularity (i.e., the number of comments, shares and likes).

The structure of the remaining parts of the paper is as follows. The methodological backgrounds of color research are discussed in Section II. The proposed method is presented in Section III. The results of experiments are presented in Section IV and discussed in Section V. Finally, the conclusions are given in Section VI.
II. METHODOLOGICAL BACKGROUND OF COLOR RESEARCH

A. Colors and their psychology

People experience psychological change when they are in contact with different colors [5]. Colors can stimulate, excite, and invoke different emotions. Each color may result in a different psychological reaction. For example, a color with a long wavelength (such as red) has a stimulus effect, and a color with a short wavelength (such as blue) has a comforting effect [9]. Colors also can be mapped to higher social qualities, e.g., orange indicates friendliness, and grey specifies professionalism [18]. Producing desired emotions through the target user oriented use of color is a key challenge in marketing. But first, one needs to understand how the colors transmit specific traits and cause emotional reactions, which have impact on how we judge the environment and take decisions.

In the first color theory, Goethe back in 1808 proposed the concept of a color circle that separates colors into positive and negative parts. Positive colors (yellow, orange, and red) represent activity and ambition, while negative colors (blue and purple) represent passiveness and obedience [18]. The theories of colors has been summarized by Shirley Willett’s color codification [18], which has interpreted the colors in terms of positive traits, emotions and negative traits. Wright and Rainwater [19] categorized 48 color-emotion scales into six factors: happiness, showiness, forcefulness, warmth, elegance, and calmness. The ability of colors to invoke different emotions can be used to create a variety of experiences for consumers, and these can be described as flow, presence, immersion, and fun. People also take advantage of color terms to strengthen their messages and convey emotions in natural interactions [20]. However, little research has been done on the impact of colors in social networking and only a handful of researchers have conducted studies on this topic in recent years (see, e.g., [21]).

B. Consumer engagement and colors in brand communication

There is a theory in design that people will respect and care for surroundings and objects that they find beautiful, and will disdain and neglect, even damage, those that are unappealing [22]. The success of brand post in attracting readers depends in large part on the appeal of its design and colors. Consumers rate color as one of three most important factor in making a decision to purchase [23]. In some cases a good visual design of a website, with respect to colors, resulted in trust, loyalty and satisfaction [24] as well as raised positive attitudes towards products in terms of their perceived efficiency and usability [25]. Colors also contribute to understandability and efficient use of software tools [26].

With expansion of self-service stores, the color of goods and their packaging has become one of the main factors of customer attraction in the modern world [4]. The effects of colors applied in packaging design similarly could be applied to increase brand post popularity as well. Unique icons, distinctive graphics and easily recognizable color palette can be combined to create instantly recognizable brand that subconsciously prompts the “buy” response from consumers. Because of psychological implications of color, companies often deliberately choose colors that are associated with certain domains or qualities to elicit a desirable emotional response. Examples include organic products marketed using green; gold or silver used for luxury goods, children toys having bright primary colors of red, blue and yellow, and high tech products using black color. Some studies claimed that color impresses consumers to recognize corporate brands and, consequently, improve purchase and profit [18].

In a virtual environment, colors may influence the amount of time spent on the site and items memorized and retrieved [24]. The latter is extremely important for business content in social media, which is steadily increasing from year to year, but is facing the decreased engagement of consumers [27]. Therefore, business companies, which use social media to advertise their products and attract customers, face a challenge to engage consumers into interaction with brand message and to receive consumers reaction (likes, comments, shares and other actions), while at the same time compete with other social media channels. According to empirical studies visual content especially images make an impact on consumer engagement as compared to other forms of posts [28], can stimulate the interest and increase purchase intentions, and determine product choices [29].

C. Color representation in images and analysis

In color image processing, various color models are used. RGB is a non-uniform color space that is universally accepted by the image processing community for color representation. RGB uses three additive primary colors, red, green and blue, which are added together to reproduce other colors. RGB color model refers to the biological processing of colors in the human visual system [30].

However, perceptually uniform color spaces, such as HSV, better correspond to the human perception of color similarity as the measured color differences are proportional to the human perception of such differences. In the HSV model, the luminous component (brightness) has been separated from color-only components (hue and saturation). Hue controls the perceived qualitative experience of; saturation is an expression of the relative purity or the degree to which a pure color is diluted by white light, and value is defined as the largest component of a color [29]. Furthermore, HSV color space is better suited for extracting features that can be used both for image segmentation and color histogram generation, which are important in content-based image retrieval, segmentation and clustering.

III. METHOD

To identify the most popular colors in social media post images we propose the following algorithm:

Inputs: let I be a set of images, and \(L_i, i \in I\) be the popularity value of an image (the number of likes, shares or comments), and \(N\) be the number of desired colors.

Outputs: colors \(C_j\), their probabilities \(P_j\), consistency (p-value), and agreement (Jaccard distance).
1) Resize all images to 128x128 resolution.
2) From each image, sample colors of random pixel with probability of \( p \), here
\[
p = \frac{\max(L)}{\sum L_i},
\]
3) Cluster the colors of random pixels in 3D space (representing the red, green and blue channel values) into \( N \) clusters.
4) Calculate the centroids of each cluster as \( C_j, j = 1..N \)
5) Calculate the number of pixels belonging to each cluster as \( n_j \)
6) Let \( p_j \) be the probability of a color \( C_j \) defined as follows:
\[
p_j = \frac{n_j}{\sum C_j n_j}
\]
7) To evaluate the consistency of our result, we perform a random permutation test, where the popularity vector is bootstrapped (randomly permuted) and the results compared. The \( p \)-value of the test is computed by comparing color probabilities of the original probability vectors with color probabilities obtained using the permuted popularity vector. The \( p \)-value > 0.95 indicates the statistical significance of the result.
8) To evaluate the agreement of the results obtained using the like, share and comment data, we have used the Jaccard distance between two color vectors \( C_1 \) and \( C_2 \):
\[
J(C_1, C_2) = \frac{\|C_1 - C_2\|}{\|C_1 + C_2\|}
\]
The Jaccard distance between three color vectors \( C_1, C_2 \) and \( C_3 \) is calculated as the mean of Jaccard distances:
\[
J(C_1, C_2) = \frac{1}{3}(J(C_1, C_2) + J(C_1, C_3) + J(C_2, C_3))
\]

IV. DATA AND RESULTS

A. Data
We have selected 35 most popular globally brands on Facebook (according to statistics provided by website [www.socialbakers.com](http://www.socialbakers.com)). These brands represent different domains such as technologies (BlackBerry, Intel, Microsoft Lumia, Play Station, Samsung Mobile, Samsung Mobile USA, Skype, Huawei Mobile, KitKat, Sony Mobile, Windows), food and drinks (KFC, McDonalds, Nescafe, Pizza Hut, Pringles, Starbucks, Oreo, Subway, Pepsi, Red Bull), clothing and shoes (Zara, adidas, adidas Originals, Converse, H&M, Nike Football, Victoria’s Secret), beauty (L’Oreal Paris, Dove), retail and e-commerce (Amazon, Walmart), entertainment (iTunes, Netflix) and automobiles (Volkswagen).

We have used a custom script written in Perl language, which used Facebook Graph API to collect images from the brand posts and their popularity information (likes, shares, comments) automatically.

In total, we have collected 801 images from posts made from 2010/11/29 to 2017/02/05. To reduce the influence of outliers, we have performed the removal of outliers, i.e., removed images, whose popularity was more than 3 standard deviations off the mean of the corresponding popularity metric. This procedure has resulted in 785 images. To normalize the popularity data, we have divided the number of likes, shares and comments per post by the total number of likes, because the total number of comments and shares per page is not provided by Facebook API. The statistical characteristics of analyzed images and their popularity characteristics are presented in Table I and Table II, respectively.

</table>

The mean values of all images in RGB and HSV are very similar, both representing light blue color. The distribution of values was evaluated using normality based on skewness and kurtosis [31]. Skewness is a measure of the lack of symmetry. Kurtosis is a measure of outlier. Note that skewness and kurtosis is much higher in the HSV space than in the RGB space. For sample sizes greater than 300, an absolute skew value larger than 2 or an absolute kurtosis larger than 7 may be used as reference values for determining substantial non-normality. In our case, the popularity data is not normal, the RGB data of images can be considered as normally distributed, and the HSV data can not be considered as normally distributed. Image representations in the HSV space are very asymmetric and contain many outliers. Therefore, hereinafter we use the RGB color space for color representation and analysis.

B. Procedure
We use MATLAB Version 8.6.0.267246 (R2015b) running on Microsoft Windows 10 Enterprise Version
10.0 with Java 1.7.0_60-b19 64-Bit Server VM. For color clustering, we used the k-means clustering algorithm with 10 replicates. For bootstrapping, we used 1000 repetitions.

C. Results

We have performed the clusterization of image colors into 5 clusters. The number of clusters was established heuristically. A smaller number of clusters leads to mixed colors of cluster centroids, which are not present in the original images. The results are summarized in Table III. Color names are given according to Bang V2 tool (http://www.perbang.dk/). The name of most similar color as well as the values of similarity to the named color are given.

Figure 1 shows the probability that a random pixel, sampled from an image at the normalized frequency of its likes will belong to a cluster. Each cluster is represented by a color-filled bar with the color of its centroid (sorted by decreasing probability value).

The respective probability calculated by sampling pixels with respect to the number of shares and number of comments of a post is given in Figures 3 and 5, respectively.

Figure 2 shows the $p$-value that represents the confidence of our results. The $p$-value was calculated by applying bootstrapping on randomly permuted like values and comparing the obtained probability with the original probability value. The $p$-value evaluates probability that the obtained result has not been obtained by chance, while $p$-value $> 0.95$ is considered as statistically significant. Again, the color of each bar represents the color of the centroid of each respective cluster (sorted by the decreasing $p$-value).

The $p$-values calculated with respect to the number of shares and the number of comments of posts are given in Figures 4 and 6, respectively.
V. Evaluation and Discussion

Our study has identified a set of colors, which are more likely to be used in images posted in social media. After analyzing 785 images from 35 brand Facebook groups, we have identified the statistically significant prevalence of four colors, which are shades of black, brown, gray and blue (navy).

We have evaluated the probability of colors found in the popular (in terms of the number of likes, shares and comments received) posts with images. The results show that more liked post images contain colors that are close to black ($p = 0.25; p\text{-value} = 0.98$), dark gray ($p = 0.20; p\text{-value} = 0.96$), blue ($p = 0.19; p\text{-value} = 0.94$), brown ($p = 0.11; p\text{-value} = 0.98$); most shared images contain colors that are close to black ($p = 0.30; p\text{-value} = 0.93$), light brown ($p = 0.23; p\text{-value} = 0.91$), brown ($p = 0.18; p\text{-value} = 0.93$), and most commented contain colors that are close to black ($p = 0.26; p\text{-value} = 0.95$), dark brown ($p = 0.19; p\text{-value} = 0.95$), light brown ($p = 0.19; p\text{-value} = 0.95$). Note that light gray (or white) in all cases is not statistically supported (has low $p$-value), maybe due to its common use as background color in images.

The results are consistent with several studies, which, e.g., claim that blue and black are among the most preferred colors amongst Generation Y (18-24 years) who are also the most active group of social [32]; blue is also the color most favored by both males and females [33]. Identified colors also have a strong achromatic component (black, gray), which psychologically are associated with style, wealth and elegance [34]. Blue color is associated with trustworthiness [35]. Cooler colors, such as blue or gray, are generally considered to have a calming effect [36]. While brown is not a popular color, it is often used as the color of a popular product (e.g., drinks or clothes).

Nevertheless we do not claim that the intentional use of colors identified by our research in posted images would increase the popularity of social media posts themselves. That hypothesis would require a separate research of its own, including the analysis of context of the use of color, which has not been performed here. Also note the limitations of our study as most of the brands...
analyzed here have their roots in Western countries and also mainly target Western audience, therefore, the results of the study may be biased towards colors preferred in Western (European and North American) culture.

VI. CONCLUSIONS AND FUTURE WORK

In this paper, we have empirically investigated the use of colors in brand post images and identified colors, which are used more often in popular brand posts. The identified colors (black, gray, brown, blue) are consistent with colors, which have been identified by other cultural and marketing studies. We also have demonstrated statistical validity using bootstrapping and good agreement between the results, obtained using like, share and comment data.

Further research may enrich our initial findings about the factors that determine the popularity of brand posts with a wider investigation of image descriptors (including those, which describe the textures and shapes) that may influence the behavior of social media users. We also plan to expand our dataset to include posted images from other cultural environments (such as Asian, African) to study possible cultural differences between brand image popularity. Furthermore, we have gathered data from the brand pages of only one social networking site. It could be interesting to replicate this research for other social networking sites such as Twitter or Instagram.

Recommender System Based on the Analysis of Publicly Available Data

Goran Antolić*, Ljiljana Brkić*
*University of Zagreb, Faculty of Electrical Engineering and Computing, Zagreb, Croatia
goran.antolic@fer.hr
ljiljana.brkic@fer.hr

Abstract - A recommender system is a software system aimed to make recommendations. To be able to do that, recommender system feature several components, such as: data collection and processing, recommender model, recommendation post-processing and a user interface. Recommender systems apply one or the combination of few of the recommendation techniques. In this paper we present recommender system developed to provide users with recommendations in accordance with their interests in different domains. We deduce user interests based on his activities and posts in social network. Social network used as a source of information on user (Facebook) provides Open API allowing access to the information about the user collected on the social network. Thanks to this data we are overcoming the so-called “cold start” problem and building user profile. A recommender system is commonly associated with only one domain, while the recommender system described in this paper is able to generate recommendations from different domains (movies and music). In addition to recommendations related with the specific domain, our system is able to recommend the web articles (unstructured text), relevant to the user that may belong to more than one category of interest.

I. INTRODUCTION

The unrestrainable growth in the amount of available digital data and the increasing number of Internet user hinders timely access to items of interest on the Internet. Information retrieval systems, such as search engines, have somewhat solved this problem but issues such as personalization and item prioritisation are yet to solve. In an attempt to solve these issues recommender systems were developed. Recommender systems are software systems that filter relevant information out of large amount of available information according to user’s preferences and interest. They play important role in business on the World Wide Web. Recommender system’s goal is to provide the particular user with recommendations based on his profile. To be able to make personal recommendations, recommender systems maintain users’ profiles that take into account their preferences. The profile serves to filter items that will be presented as recommendations assuming that they match user’s preferences. Items can be news, movies, music, books, restaurants, scientific publications, webpages, etc. Service providers on the Internet and customers both benefit from recommender system. They are widely used by online shopping sites [1] [2] and internet streaming media services [3] [4] [5]. Social networking services may suggest future connections with people who you may know or would possibly like to become your friend, groups you might like to follow, jobs or companies you might be interested in [6] [7]. There are also interests-based social networking websites that provide users with recommendations of movies, music, restaurants, food, articles and other items based on users’ ratings [8] [9]. When it comes to the problem of a document recommendation in a large digital library like e.g. in research-paper library, recommender system can be of great help. In a higher education and research institutions, students, academic staff and other researchers need to find the papers most relevant to their research topics. Hence, finding the right papers to read becomes a relevant part of their academic lives. A research paper recommender system will benefit these users by recommending newly published papers that may be of interest to them or papers related to their previous research affinities. Despite the great need, only a few recommendation systems exist for scientific papers [10] [11] [12].

Taking all this into consideration the need for effective recommender systems exist in many aspects of our lives. Efficient recommender system have to implement effective and accurate recommender technique. Three main categories of recommender systems techniques are: collaborative filtering (CF), content-based filtering (CBF) and hybrid approach which combines the previous two methods [13].

The collaborative filtering and the content-based filtering essentially differ in their concept. The basic idea of CBF is that users will be interested in items that are similar to items they previously liked. While, the idea of CF is that users might like items that are liked by his peers. Yet, these ideas are rather fuzzy and are implemented using different approaches.

A. Collaborative filtering

A recommender system using collaborative filtering, recommends items by finding other users with similar taste. The fundamental assumption is that similar users (peers) have similar interests on similar items. An active user is recommended with the items that are most liked by his peers. The correlation between users is usually measured on the basis of common items they have rated. Consequently, the accuracy of collaborative filtering-based systems depend on user willingness to rate the items.
Providing ratings requires extra effort and users tend to avoid that, so in many systems many related ratings will not be available for the prediction. This missing user-item ratings cause two types of problems: the data sparsity problem and the cold start problem.

The cold start problem may occur in three situations [14]: a new user, a new item, and a new community or disciplines. A new user has not rated any item, so the system cannot find his peers and hence cannot provide recommendations. A new item has not been rated by a single user, so it cannot be recommended. In a new community, there are no user-item ratings, so no recommendations can be made and consequently, the users are not motivated to rate items. Although cold start problem affects CF more, it is present in the CBF recommender systems too. A possible approach to overcome the cold start problem is proposed and described later in this paper.

An algorithms for collaborative filtering measure the similarity between users (user-based CF) or the similarity between items (items-based CF) or both. To generate recommendations, different methods for calculating similarity between items or users are used. Some of widely used measures are Cosine similarity, Pearson correlation and Jaccard index [15].

The collaborative filtering technique is implemented in many recommender systems developed in academia and industry. Just two examples are the book recommender system from Amazon [2] and the Jester system that recommends jokes [16].

B. Content-based filtering

In the content-based filtering (CBF) the interests of users are deduced from the items that users interacted with in the past. These items are commonly textual like webpages, scientific publications, books etc. User’s preferences are concluded from the items user downloaded, bought or tagged. A system that deals with textual documents, commonly use structured representation of the documents that originated with text search systems [17]. This structured representation includes words contained in text. Instead of a words in their original form, the root forms of words, created through a process called stemming [18], are used. The goal of stemming is to represent all words having the common meaning (e.g. organize, organizes, and organizing) with a single term reflecting that common meaning. The relevance or importance of the term in the text is presented with the real number usually called the tf–idf weight (term-frequency-inverse document frequency) [17]. Some recommender systems implementing the content-based filtering use non-textual characteristics like a writing style [19] or a layout information [20].

While developing the recommender system presented in this paper we were guided by the idea of using data provided by the public services to collect information about: (1) the users of the system and (2) on the possible recommendations. We use these data as a starting point in building our own system of recommendations and evaluation of offered recommendations. As a source of information on users, ubiquitous and extremely popular social networks, have imposed for two reasons: (1) based on users comments, tags, posts, likes and expressions of emotions regarding other people’s publications, a lot about users preferences can be concluded and (2) almost all social networks (Facebook, Twitter, Instagram etc.) provide an application programming interface (API) allowing access to the data about the user collected on that particular social network. From all the data we can get from the social network API we take over only the data approved by the user. Also, we are interested only in the data from those categories for which our system is able to generate recommendations.

Which publicly available data sources, in the context of generating a recommendations, make sense to use, depend on the domain for which the recommender system makes recommendations. For now, we focus on recommendations for a movie and music domain, so that’s why we chose The Movie Database API [21] and Last.Fm API [22] as a starting point for recommendations.

The main contributions of this paper are: a) the model of building user’s profile based on (i) Facebook API data to overcome cold-start issue and on (ii) user’s ratings of recommended items for tweaking and improving the profile; b) the prototype for recommending text-based content based on matching concepts between user profile and unstructured text.

II. RELATED WORK

Using a social media information to feed recommender system with the data is present in some previous papers. In [23] authors calculate similarities between social network users based on data obtained from Facebook API. They used acquired data to recommend a tourist attractions to users they consider to have similar taste. The authors of [24] also used data extracted from a real online social network to overcome the data sparsity and the cold-start issues.

A recommender systems for the movie and music domain are subject of many research papers. Some dealing with a movies recommendation are based on movie genre correlations [25], while others generates recommendations using various types of data - about users, the available items, and previous transactions [26]. Our recommender system leverages the existing publicly available recommendations APIs for the movie and music domain to get initial set of recommendations for the given genre or author. We further enrich that data based on users feedback and thereby improve subsequent recommendations.

III. THE SYSTEM ARCHITECTURE AND TECHNOLOGIES USED

Figure 1 presents the overall architecture of the software system developed. Rectangles represent program modules, ellipses data components and cloud callouts serve to introduce and describe either outer services or input/output data. Using data gathered from social networks, the user profile generator, creates the initial user profile for each category for which the user has expressed interest. We support several types of sources for recommendation: an application programming interfaces (API), a web links
from RSS feeds and a web links found in process called web crawling.

Consulting these sources, a recommendations generator finds potential items for recommendation and calculate score using the expression presented later in the paper. The score is a numeric value that represents the relevance of the individual item for a specific user profile. The higher the score the greater the likelihood that the item will be of interest to the user. The subsystem for items grading enhances the system with the active learning component.

The user profile is updated based on the grade user has given to the recommended item. Updating a user profile affects the future recommendations. If the user rated an item high, the more likely similar items will be recommended to him in the future. For example, if the user has given the high grade to film starring Viggo Mortensen, the bigger will be the probability that the system will, in the future, to the same user recommend content (movies or articles) that includes Viggo Mortensen. And vice-versa.

All data pertaining to system configuration are stored in a relational database, Microsoft SQL Server, while the data on user profiles and recommendations are stored in the NoSQL database RavenDB. The relational database proved to be a good choice for the system’s parametric data because the data occurring is structured, of simple type and the amount of data is not overwhelming. Data about user profiles and recommendations we store in NoSQL system because of the expected large number of users and improper scheme that is hard to describe and manage using the relational data model.

Figure 2 presents the relational data model holding data about: the interest categories (category); the web sources (webSource) which can be of different type (webSourceType) and can have different parameters (endpoint) for a different categories and response types (responseType); the users (user, userRole), the categories they are interested in (userCategory) and their social network accounts (socialAccount) along with permissions to retrieve data associated with their social network account (socialAccountPermission).

The system collects information about the user or the items for a recommendation by sending HTTP requests to a specific URL. The endpoint holds the exact location-url (path) on the data source. The answer to the request can be in various forms eg. json, xml or txt (responseType).

The repository stored in a RavenDB contains several collections: tUser (the basic data about user along with the relationships to category profiles), CategoryProfile (each user have separate profile for each category he is interested in), DbMovies (data about movies), DBArtists, Recommendations (for a specific user), UserRatings (user’s grades for the recommendations).

IV. CREATING USER PROFILE

To create the initial user profile, our recommender system uses data taken from the Facebook API. Upon the analysis of the most popular social networking APIs (Facebook, Twitter, Instagram, LinkedIn) we came to the conclusion that the Facebook offers best quality data for user profile construction. The Instagram and LinkedIn APIs offer only the basic user information such as name, surname and email. As such, they are not sufficient for the construction of a general user profiles that will present user in different domains (categories). The recommender system presented in this paper, out of all the data that can be acquired from Facebook profile, takes over only the data explicitly permitted by the user and relevant to the domains of recommendations. Therefore, we use Facebook Login for authentication. Data about the user is retrieved in form of JSON document gathered as a result to HTTP GET request to a particular endpoint. The most valuable data about the user's preferences are the Facebook pages marked as "Like". Each page belongs to a category designated by the Facebook page administrator who is, also, in charge for definition of the fields (attributes) that describe the particular category. Data from a different categories have different attributes that describe the page. For example, some of the attributes describing movies (page category "Movie") are: title, genre, list of actors, producer, director, brief description and so on.

Example: Suppose that user with id equal to 575480316 marked with “Like” movie having title "Captain Fantastic". The following HTTP request is sent to Facebook API:

```java
/{575480316 }?fields= likes(id, category, name, genre, starring,
directed_by, id)
```
Result will be JSON file containing the following segment:

```json
{
  "category": "Movie",
  "name": "Captain Fantastic",
  "starring": ["Viggo Mortensen, George ..."],
  "directed_by": "Matt Ross",
  "id": "74089565764"
}
```

For each category of interest that the user follows (table `userCategory`), the system generates a separate category profile because different domains/categories are described with different concepts. Each category profile contains a number of lists of classes (representing concepts) describing that specific domain. For the movie domain it may be list of movie titles, actors, genres, directors etc. Each concept in a category profile is described by three attributes: Name, ExternalId and Rank. ExternalId is external unique identifier that serves as a link to the item in outer system. ExternalId for the movie is a unique movie identifier in The Movie Database, where more detailed information about the movie can be found. For music artist, album or song attribute ExternalId is a reference to an item in an open music encyclopedia MusicBrainz. Attribute Rank is a numeric value that represents the relevance of the observed concept for a specific user profile. The initial value for the Rank is set to value 1 for each concept. Later the Rank will be updated as a consequence of user's grading on recommended items. Grading recommendations is described in section VI.

The following is the example of JSON document from the collection CategoryProfile stored in RavenDB. It presents movie profile for the user "Sk8trGal". The meaning of the field Alchemy is discussed in section VI.

```json
{  "Usernames": ["Sk8trGal"],
  "CategoryName": "Movie",
  "Titles": [{  "Name": "Captain Fantastic",
    "ExternalID": null,
    "Rank": 1 }, ...],
  "Actors": [ {  "Name": "Viggo Mortensen",
    "ExternalID": null,
    "Rank": 1 }, ...],
  "Genres": ...
  "Directors": ...
  "Alchemy": { "entities": [] }
}
```

V. GENERATING RECOMMENDATIONS

A. Recommendations for a specific domain

Out of a recommendations related to a particular domain, we have implemented recommendations for the movie and music domain. The methods are essentially the same, except that they use different external data sources, to retrieve additional information (The Movie Database API for the movie and the Last.Fm API for the music domain). We were guided by the idea to connect concepts from the user profiles with items returned by this public APIs, fetch and store additional information about the found items, and then look for similar items that will be recommended to the user. The Movie Database API provides a method that will, for the given movie ID, return a list of IDs of similar movies. Similar movies are good candidates for the recommendation. To rank recommendations according to the user profile, we present the matching between recommendation and profile with numerical value. The expression that calculates matching between the movie item and the user profile, for example, takes into account the actors who appear in the movie, genre, film director and producer. Assuming that the user's profile and the movie description both contain N concepts, they contribute to the total score according to:

$$\sum_{i=1}^{N} Weight(\text{concept}_i) \times \text{Rank}(\text{concept}_i)$$

Different concepts have different importance meaning different weight. In the movie domain eg, it is natural to assign bigger weight to the movie title or genre than to the word that appears in a short summary of the movie. For example, the weight for the movie title can be 20, for the genre 15 and for the actor 12. Weights are parameters in our system and are determined using the method of trial and error by the administrator. In the present implementation the weight of the particular concept is the same for each user, but in the future implementation different weights of concept for different users can be foreseen.

B. Recommendations based on semantic features

The recommender system introduced in this paper additionally supports recommending web articles that are considered to be of interest to the user. The system is guided by the interests of the user stored in users' profile. Recommending web articles, as unstructured text, is suitable for CBF method. Analysis of content-based recommender systems showed that the representation of items (potential recommendations) and user profiles using keywords is efficient when a lot of text documents describing user's interests is available. In that case it is possible to find the matching words in web documents and users profile. However, the approach using keywords exclusively has its limitations. For example, if the user likes the "French impressionism" keyword-based system will find only documents containing the words "French" and "impressionism", but not the documents containing words "Claude Monet", the originator of this style [27]. To be semantically intelligent, the content-based system needs more advanced strategies for the presentation of items and the user profile, than using the list of keywords. The semantic analysis implies including a knowledge base, such as a lexicon or ontology, for labeling items. Keywords need to be connected to external data sources such as Linked Data sources (Semantic Web). The area of an artificial intelligence - natural language processing deals with assigning a semantic meaning to unstructured text. To decide whether the web article is a suitable recommendation for a user, it is necessary to semantically process the article i.e. to find concepts and entities mentioned in the text. To be suitable as a reference, article and user profile must contain matching concepts. For example, if the user shows the interest for movies, and graded with high grades movies starring Viggo Mortensen, concepts "movie" and "actor" and entity "Viggo Mortensen" appear in his profile. It is expected that this
particular user will be interested in web articles that contain same concepts and entity. Since the semantic analysis of the text is outside of the scope of this paper, we therefore use the free version of Alchemy API [28] tool to perform semantic analysis of text in web articles.

Links (URLs) to web articles are periodically programatically fetched from RSS feeds and forwarded to AlchemyAPI for processing. After the AlchemyAPI processes article on a given URL, as a result, among other things, a list of concepts and entities that appear in the text is obtained. For each entity found, AlchemyAPI returns its name, type and relevance in the article. After that, entities are compared with those contained in the user profile to calculate the suitability of the article as a recommendation for a particular category.

The comparison is done by the name of the entity. We try to pair each entity found by AlchemyAPI with entities contained in the user profile. Each matching contributes to the overall result according to the following expression:

\[
\text{Weight(concept) * Rank(concept) * Relevance(\text{concept}, \text{article})}
\]

VI. GRADING RECOMMENDATIONS

Recommender systems usually rely on a users’ grading to assess the effectiveness and the degree of user’s satisfaction. Users are commonly asked to quantify their overall satisfaction with the recommendations. This general principle is implemented in our recommender system too. With regard to the type of recommendation, user grades (movie, music artist, a web article) are used to update the user category profile.

Figure 3 illustrates the process of updating the movie profile upon grading the recommended movie “Captain Fantastic”. On a scale of 1-5 user graded movie with grade 4. This grade is normalized to the value 0.5 on the interval [0.5, 1]. The grade applies to all concepts/entities related to the movie (title, all actors, genres and director) because there is no way to find out what is actually graded. We used this simplified model since we don’t want to burden user with the detailed assessment. Each concept (entity) describing graded movie is either found and updated or added in user’s movie profile. The grade affects the value of attribute Rank. The normalized grade is added to existing Rank or if the concept does not exist in the profile, a new record with an initial value of attribute Rank equal to normalized grade is added. The procedure for updating the music profile after grading musician is the same.

Remark: The concept that was first found in the data retrieved from the social network is added to the user's profile with default value for the Rank equal to 1 (eg, if the user liked page of the actor Viggo Mortensen and if this concept does not exist in the user profile yet, it is added to the user's profile with Rank equals to 1). The reason for this is the belief that if the user liked the page, that is strong evidence of his high opinion on the actor (concept).

Figure 3 Updating the user profile upon grading

Upon assessing web articles different logic is applied. AlchemyAPI, for each entity found in the text, returns relevance of that particular entity (floating point number between 0 and 1). When a user grades web article, attribute Rating in his profile is updated, for each entity AlchemyAPI had found in the article, with a value equal to the normalized grade multiplied by the relevance of the entity. Example: The user graded with grade 2 article in which the Alchemy API found entity Viggo Mortensen with relevance 0.6. Supposing that the entity Viggo Mortensen exists in the movie profile for the user, the value of that attribute will be modified as follows:

\[
\text{Rank(\text{Viggo Mortensen}) += \text{normalizedGrade(article)} * \text{relevance(\text{Viggo Mortensen}, \text{article}) * -0.5 * 0.6}}
\]

In case that concept/entity found in the article does not exist in the user's profile, it is added to the list of "Entities" under the class "Alchemy" (see JSON presenting user's profile). In assessing the film or music items we could not determine the relevance of certain concepts/entities so we applied same grade to all concepts.

VII. EVALUATION

For the evaluation we used user studies [29]. A user study is carried out by recruiting a set of test users, asking them to interact with the recommender system and additionally to give answers to questions aimed to collect data that is not directly observable.

We evaluated only the recommendations from the movie domain with plans to conduct evaluation on other domains in the near future. The evaluation involved 5 users. After taking over data on users from Facebook API, the initial user profiles were created and the first recommendations from the movie domain were generated. The users were asked to state the number of previously watched movies, out of all the recommended. This information we consider relevant because the system recommending movies that user had already watched is in accordance with user’s taste. The columns Reccomm. and watched under the joint column "1st cycle" in Table 1 present results for recommendations users received for the initial profiles. Out of a total of 125 recommended movies users have already watched 30 of them or 24%. Given the size of the movie database, we found this result satisfactory.

The users are then asked to grade each recommendation regardless they already watched the movie or not. These grades reflect their satisfaction with the recommendation, i.e. expresses a willingness of the user to watch the movie he hasn't seen yet. The average score of all users is 3.28. After users graded movies recommended in the first cycle, new recommendations, were generated (2nd cycle). Recommendations from the second cycle take into account the user's feedback from the first cycle. Results show that the percent of already watched movies (41%) increased which implies that the users’ grades embedded in the user profile closer recommendations to users' tastes.
<table>
<thead>
<tr>
<th></th>
<th>1st cycle</th>
<th>2nd cycle</th>
<th>AVG(grade)</th>
</tr>
</thead>
<tbody>
<tr>
<td>user1</td>
<td>25</td>
<td>4</td>
<td>30</td>
</tr>
<tr>
<td>user2</td>
<td>29</td>
<td>9</td>
<td>-</td>
</tr>
<tr>
<td>user3</td>
<td>14</td>
<td>0</td>
<td>23</td>
</tr>
<tr>
<td>user4</td>
<td>27</td>
<td>6</td>
<td>30</td>
</tr>
<tr>
<td>user5</td>
<td>30</td>
<td>11</td>
<td>30</td>
</tr>
</tbody>
</table>

Sometimes this is not a good feature of the recommender system because it is expected that the recommendations bring novelty not obvious, already consumed items. On the other hand, the evaluation showed that the user’s grades improves recommendations.

### VIII. CONCLUSION

Recommender systems are a powerful technology for entertainment industry and social networks. We presented recommender system that exploits existing publicly available services to gather data needed to build user profile and to generate initial recommendations. User’s interests are deduced from his activities and posts in social network. Using this data for building user profile we bridge the cold start problem. Currently, we have implemented recommendations for items related to two domains: movies and music. We connected concepts from user profile with external items obtained through Open API calls. These and similar items are subsequently recommended to the user. In generating content based recommendations of web articles we use AlchemyAPI to perform semantic analysis of the text. To get feedback from users we implemented recommendations grading. That way users affect future recommendations because grades change and tune user profiles.

Recommender system evaluation showed that generated recommendations for the movie domain are in line with user’s taste.

Alternative Business Intelligence Engines

Ivan Kovačević, Igor Mekterović
FER, Zagreb, Croatia
ivan.kovacevic@fer.hr, igor.mekterovic@fer.hr

Business intelligence (BI) engines enable companies and researchers to perform fast and efficient data analysis and extract relevant information from their data. At the present, it involves the usage of reporting tools and OLAP on top of traditional relational database systems. This paper gives an overview of alternative BI systems, based on various NoSQL and NewSQL databases. NoSQL (Not-only SQL) systems were developed to address the scalability issues of traditional relational databases when exposed to huge amounts of data and large read and write capacities. In addition to fulfilling those requirements, NewSQL systems aimed to preserve the useful properties of relational databases as well, such as ACID transactions, SQL and a relational schema. The various systems bear significant differences in terms of architecture, data representation, query capabilities and optimization techniques, and because of that, they offer diverse means of data analysis. The paper comments on key differences, presents an overview of various NoSQL and NewSQL systems that might be considered in the context of BI engine, and brings an overall feature comparison of those systems.

I. INTRODUCTION

At the time of writing, the amounts of available data are larger and produced at greater velocities than in any earlier period in history. For example, as stated in [1], in 2014, 90% of data on Facebook and Twitter has been created within the preceding two years, with new data adding up 7 to 10 terabytes every day. Most of the recently created data is unstructured, coming from sources such as web logs, social networks, radio-frequency identification tags (RFID), sensor networks, etc. As such, it requires solutions capable of managing and analyzing massive amounts of data while maintaining minimal latency and adaptability to previously unpredicted usage scenarios. According to [2], the crucial requirements for big data processing are the following: fast data loading, fast query processing, highly efficient space utilization, and strong adaptability to dynamic workload patterns. In contrast, traditional BI usually involves relational database systems and On-Line Analytical Processing systems (OLAP), which show serious drawbacks when confronted with big data. In this paper, we explore the use of newly emerging database technologies (many of them prompted by the big data movement) in the context of BI. In the following chapters, we comment on key differences of alternative engines and traditional RDBMSs with regards to storage medium, data model and query processing capabilities, present most notable database systems in this context, and bring a detailed feature comparison of those systems.

II. STORAGE SYSTEMS

Both NoSQL and NewSQL systems can be split into two subgroups based on the type of the underlying storage medium. These are Disk-Based Database Management Systems (DBMS) and In-Memory DBMS.

A. Disk-Based DBMS

Disk based DBMSs use disks as the main storage medium, and use the main memory primarily for buffering. Their data structures and algorithms are optimized to minimize the amount of I/O operations required to perform given queries and data management operations. As the latency of the disks is several orders of magnitude larger than the latency of the main memory, these systems can afford fairly complex and lengthy algorithms to optimize disk access and buffering. Data structures, such as indices, are optimized for the physical structure of disks, since each disk I/O operation can only read or write complete blocks of data. An example of a disk optimized data structure is the B+ tree index, which matches its node size to the pages of the disk [3]. Most NoSQL and traditional relational DBMS are disk based.

B. In-Memory DBMS

One of the goals of research in big data systems is to support ultra-low latency and enable real-time data analytics. Existing disk-based systems are limited by the high access latency of the hard disk, so they cannot offer timely response required by real-time services, such as real-time bidding, social gaming, and advertising [4]. During the last decade, multi-core processors and the availability of large amounts of main memory at decreasing costs are creating new breakthroughs, making it possible to build database systems in which a significant part or the whole of the database can be situated inside the main memory. Note that mere relocation of data to RAM (e.g. using Ram disk) would bring limited performance gains, since the disk-based DBMSs are built to optimize disk access, rather than main memory performances. In-Memory DBMS solve these problems by using main memory specific data structures and algorithms. For example, most such systems use T-trees of Trie structures for indexing [5], and instead of optimizing disk access, aim to optimize the utilization of the cache hierarchy, adapting to Non-Uniform Memory Access (NUMA), and providing efficient in-memory data management. Furthermore, in order to leverage the low latency of the CPU caches (L1, L2, and L3), applications must ensure data locality, so as to reduce the amount of cache misses requiring the data to be fetched from the lower and slower memory levels. An additional concept called hardware transactional memory support, which is important to consider in in-memory DBMS design, is explained in [4]. Transactional memory allows for an optimistic approach to concurrency, where concurrent transactions are performed without locking by using L1 cache lines as their local isolated copies of data. If a

MIPRO 2017/miproBIS
transaction fails, e.g. by trying to commit to a cache line already updated by another transaction, its local copy in L1 cache is dropped and the transaction is either rolled back and started anew, or its locking employing variant is started. Ensuring data durability poses an important challenge for in-memory systems. Since the main memory is predominantly volatile, a power loss could result in loss of data. One potential solution is the introduction of the newly-emerging non-volatile main memory (NVRAM), with properties similar to those of solid state drives (SSD). Such memory is still quite expensive, and suffers from a limited number of successful write operations. Various in-memory DBMS take different strategies to ensure durability. Some systems, like e.g. VoltDB, incorporate checkpoints and logs stored in non-volatile storage to reconstruct the data after a power loss. Furthermore, in-memory systems supporting transactions do not have to log all operations, but just the committed transactions, since a power loss would invalidate the need to undo uncommitted operations.

III. DATA MODELS

In relational systems, such as the NewSQL DBMS, data warehouses are usually built with a star schema, which consists of a single fact table containing measures, and several dimension tables in which the aspects of analysis, such as e.g. time and product are stored. NewSQL databases support the same principles of data warehousing employed in traditional relational systems, since they support SQL and relational schema. On the other hand, with regards to data model, NoSQL systems can be classified in four categories [6] [7]: Key-value stores, which store data as key-value pairs and are useful for caching, Column family oriented databases, adept at storing data in sparse tables, Document oriented databases, organized as collections of documents with variable structure and dynamic number of fields, and Graph oriented databases, which store graph data, such as data related to social networks. Most surveyed sources are focused on using column and document oriented DBMS for BI applications.

A. Column Oriented DBMS in BI

Column based DBMS store data column-wise, and support grouping columns in column-families. The authors in [1] and [8] describe a desirable implementation of the star schema in a column based DBMS, in which the fact and dimension tables are organized as column families, with their attributes being stored in individual columns. In case of building an OLAP cube, an additional cube identifier column is required. Hierarchies are implemented using columns inside the hierarchical dimension’s column families.

B. Document Oriented DBMS in BI

Since document stores, such as Mongodb, often have limited join support, the authors in [6] present a method of using embedded array structures for associating dimensions with documents. Each document represents a fact and contains measures and associated dimensions in its attributes. In this manner, documents satisfying a given predicate can be identified and aggregated using simple filtering.

IV. DATA PROCESSING AND STORAGE CAPABILITIES

Most distributed storage systems implement the MapReduce processing framework. MapReduce enables users to run large scale parallel operations based on the “divide and conquer” model. The model consists of two user-defined functions which are sent to all nodes, namely map, which reads data entities and generates key-value pairs, and reduce, which aggregates the key-value pairs and returns results. An additional intermediate shuffle function can be defined to optimize grouping. Several NoSQL systems are based on the Hadoop ecosystem, which offers a complete distributed architecture, including a distributed file system called Hadoop File System (HDFS) and implementations of several management and data processing functionalities, such as the aforementioned MapReduce. Hadoop is usually bundled with two high level languages based on MapReduce, Hive and Pig Latin [1]. Hive provides a SQL dialect called HiveQL, which enables data definition and access in a manner similar to relational systems. MapReduce is useful for fast aggregation operations required for data analysis, since it enables them to run in parallel on all nodes [2]. Some in-memory DBMS support Main Memory MapReduce (M3R), which mimics the concept of MapReduce parallel processing inside the main memory. As column oriented systems are storing data in a column-wise fashion, a significant increase in query performance can be achieved by using bitmap indexes. Distributed systems often support additional operators for data analysis purposes. Examples are the Hive’s cube and rollup operators, which automatically build an OLAP cube based on a given table. An improved version of the cube operator, called cn-cube, has been proposed in [9]. As the authors of [10] point out, another important aspect of aggregation to consider is the materialization strategy, which defines how intermediate aggregation results are processed. In early materialization, which is the classical approach, row-based tuples are materialized by reading all columns, just to be filtered and aggregated. Late materialization avoids materializing the row-based tuples, and employs bitmap indexes to perform column-based aggregation, resulting in much better performance. In order to satisfy the big data analytics requirements, systems must remain constantly available, without a refreshing time window. This requires a new approach to the data warehouse extraction, transformation and loading (ETL) process. Unlike traditional systems, NoSQL and NewSQL based data warehouses can cope with increased loading frequencies, up to near real-time ETL [2].

V. NOQL SYSTEMS

Unlike classical high-consistency RDBMSs, NoSQL systems take on a more relaxed approach, informally called BASE (Basically Available, Soft state and Eventually Consistent) which fits very well with BI requirements, where data is typically more or less stale. By using the BASE paradigm, NoSQL systems can achieve scalability vastly superior to traditional relational systems, which makes them suitable for working with large volumes of data. Furthermore, most NoSQL systems are schema-less, which means that the processed data does not have to conform to a predefined structure. Such systems possess numerous advantages over relational systems when
working with unstructured data or data with frequent schema changes [6]. Most importantly in this context, NoSQL systems fall short in terms of query languages, especially when standards are concerned. A lack of schema or SQL certainly complicates data analysis. For analytical purposes, most authors present solutions based on column and document oriented databases [1] [2] [6] [8] [9] [10], which are also considered in this paper.

1) C-Store

C-Store was a proof of concept pioneering column oriented storage system released by the associated MIT research group in 2005. The system is optimized to support fast reading patterns required for data analysis, such as customer relationship management (CRM) systems, and data warehousing applications [11]. Furthermore, the system demonstrated the previously mentioned improvements in data compression compared to traditional row-oriented storage systems, and introduces heavy usage of bitmap indexing [11]. Bitmap indexes are binary vectors which enable filtering the data one column at a time [12].

2) BigTable

As described by its author Google, BigTable is a high-performance NoSQL database service intended for large analytical and operational workloads [13]. It is a column oriented storage system which, in addition to its native Remote Procedure Call (RPC) based API, provides an interface compatible with Hadoop based technologies, such as HBase.

3) HBase/Hadoop

Apache HBase is a highly specialized CF (Column Family) oriented database focused on operating with huge amounts of data. It is not intended for usage in small deployments, since it requires a minimum of five distributed nodes for normal operation. Queries are supported through a REST API and a query language called Thrift. In addition to those, the database supports a JDBC/ODBC driver. In CF databases, each column family consists of one or more columns (or attributes) which are stored in sequential order on the storage medium. This manner of storage enables fast column-wise access, with a minimal number of I/O operations, and a high data compression ratio, since the data inside a single column is usually more uniform and repetitive than data contained in several columns stored row-wise. Since columns are not mandatory, column based storage systems enable individual rows to possess different attributes, which allows users to store highly variable data together. HBase is built on top of the Hadoop infrastructure. It offers limited transaction support based on row-wise locks, and thus limits availability in order to satisfy consistency and partition tolerance. The system was initially inspired by Google BigTable.

4) Cassandra

Apache Cassandra is a CF database system which bears a lot of similarities to the aforementioned HBase system. In addition to CFs, Cassandra supports another layer of column hierarchy called supercolumns. Supercolumns are groups of columns which can be contained inside column families like individual columns.

5) MongoDB

According to [14], MongoDB is the most commonly used NoSQL database system. It is a highly scalable document oriented database, used in a variety of projects, such as Foursquare, bit.ly, and the CERN Large Hadron Collider. Document oriented storage systems store data in collections of documents. Each document is a data structure consisting of an arbitrary number of key-value pairs, or fields. Fields can contain nested structures. Documents do not possess an explicit schema. They can be identified and accessed using associated unique identifiers or one or more keys. MongoDB stores documents in BSON (Binary JSON) format. In contrast to relational databases, where related data is stored in several tables, in document stores most related data is usually contained within the same document. Since documents bear a significant similarity to classes in object oriented programming languages, integration is usually straightforward and simple. Up until recently, a drawback of document stores was a lack of support for joining operations. In the recent versions of MongoDB and CouchDb, operations similar to joins are supported through special operators. MongoDB supports automatic partitioning and master-slave replication. It supports a query language represented as JSON-like structures, and exposes a CRUD REST API. For more complex operations, it supports an implementation of the Map-Reduce paradigm. With regards to the Brewer’s CAP theorem, the common configuration supports consistency and partition tolerance while offering a limited availability.

6) CouchDb

Like MongoDB, CouchDb is a highly scalable document oriented database system. Unlike MongoDB, the common configuration supports availability and partition tolerance while offering a reduced level of consistency through MVCC. It supports design documents, or views, which are defined through MapReduce queries and similar to views in relational database systems. Design documents show higher performance when compared to ad-hoc MapReduce queries [15]. Apart from views and MapReduce, queries are supported through the exposed CRUD REST API. Data conflicts caused by concurrent write operations on different nodes have to be resolved manually.

7) Apache Spark

Apache Spark is an engine (framework) for large-scale data processing on a cluster. Spark presents a data abstraction for big data analytics, called resilient distributed dataset (RDD). It is a coarse-grained deterministic immutable data structure, on top of which Spark SQL, Spark Streaming, MLlib and GraphX are built to support SQL-based manipulation, stream processing, machine learning and graph processing, respectively [4]. Spark’s data processing performance comes from its in-memory architecture, as well as the useful properties of RDDs and automatic job scheduling using the DAG scheduler. RDDs support coarse-grained operations called trans-formations, such as map, filter, and join, which are applied to the entire dataset and result in new RDDs. The main two features of RDDs are a persistence model, which can persist datasets in memory, disks or both, and a light-weight fault-tolerance mechanism which makes it possible to recreate RDDs from their dependent RDDs by using transformation logs (i.e. lineage). This makes RDDs suitable for iterative data analytics jobs, because data
doesn’t have to be shuffled on disks at each stage like in Hadoop [4]. Calculations over RDDs can be performed using special operations called actions, such as count or reduce. Operations in Spark are run through jobs, where the DAG scheduler captures the complex job dependencies and relieves programmers from managing them for manual scheduling [16].

8) Apache Drill

Apache Drill stands out in this list, as it is not a DBMS per se, but a distributed SQL engine with support for Hadoop and several other storage systems. It fully supports ANSI SQL-2003, which enables users to write queries like in a traditional DBMS [17]. In addition to that, it incorporates support for advanced JSON data operations through SQL extensions. Within Drill, all data is internally represented as a JSON structure, whose schema can be discovered automatically. This flexible data model makes Drill useful in operating unstructured and semi-structured data from several sources, without writing additional middleware. Drill can be used by most existing BI tools, like Tableau, Qlik, Excel, etc., to interface NoSQL engines, supported through its plugins, such as HBase, MongoDB, Hive and Apache Spark. That simplifies integration or even migration in existing systems. Finally, it can be used as a complete SQL shell over various NoSQL storage systems.

VI. NewSQL Systems

Nowadays, and probably for many years to come, most existing systems work with relational databases, and require a complex migration procedure in order to switch to a NoSQL solution. An example of one such migration is presented in [6]. For OLTP applications, a major drawback of NoSQL systems is the lack of strong consistency. NewSQL refers to various recently developed relational systems aiming to achieve high consistency at scale, where the attribute “New” stands for the predominantly new companies developing such systems. Most of them are in-memory DBMS. All support SQL queries and ACID transactions.

1) Vertica

Vertica is a distributed massively parallel relational DMBS, based on the aforementioned C-Store research project. Although it supports SQL data management operations, it is optimized for supporting analytical query workloads, since the data is organized in columns, rather than rows. The data is stored in a hybrid in-memory/on-disk architecture, where frequently used data and buffer are contained within main memory and only passive data is stored on disk. The column structure enables users to define projections, groups similar to column families in column based DBMS. Data is split into two parts, the read-optimized store (ROS), which holds most of the data stored in index-value pairs, and write-optimized store (WOS), which allows fast data editing. Vertica is not appropriate for usage in update-intensive applications.

2) SAP HANA

HANA is the SAP’s approach to BI based on two main components, the SAP HANA database, which is a hybrid in-memory DBMS with row-based, column-based, and object-based technologies, and the SAP HANA appliance, a combination of hardware and software which enables the analysis of large volumes of data without the need for aggregation materialization. Data is stored into two relational databases, one column oriented, and the other row-oriented. Both support SQL and Multidimensional Expressions (MDX). The column oriented database supports real-time analytics, while the row-oriented database is intended for data which is frequently inserted and updated.

3) Oracle Times Ten

Oracle Times Ten is an in-memory DBMS which supports ACID transactions and can be either used as a stand-alone system or a data subset caching provider for traditional DBMS, used by existing applications using an Oracle database to reduce query latency. The database incorporates a data aging scheme, which periodically removes data that are no longer needed. Similar to SAP HANA, Oracle has commercialized a complete appliance based on Times Ten, called Oracle Exalytics In-Memory Machine. Exalytics comes with a complete MOLAP server which contains a high performance MDX query engine.

4) SQL Server Column indexes

Microsoft decided to take a different approach to column-store technology, by keeping SQL Server as the central database product and incorporating the column oriented store as an optional index. These additions significantly improve the performance of analytical query processing, while maintaining a well-known database system for transactional processing. On the other hand, as the column-based query processing is optimized for smaller result sets typical of data warehouses, such as performing star joins and aggregating, queries returning large result sets suffer from low performance, since batch processing cannot be successfully executed in those cases [1]. Also, up until SQL Server 2016, tables for which a column index had been defined could not have been updated. However, as of version 2016, both Clustered Column Store Indexes and Non-Clustered Column Store indexes can be updated [18].

5) VoltDB/H-Store

H-Store, and its commercial counterpart, VoltDB, are distributed in-memory relational DBMSs, which provide automatic and transparent fragmentation and replication support. In VoltDB, queries are performed using stored procedures, which are run sequentially and possess the properties of ACID transactions. Ad-hoc SQL queries are supported as well, but such queries have limited optimization support and should be avoided in production. Consistency of replicas is enforced by running the same stored procedures on all nodes containing target replicas.

6) NuoDb

NuoDb is a highly scalable in-memory distributed relational DBMS, based on a Distributed Durable Cache (DDC) peer-to-peer architecture. DDC allows peers to be assigned to specific tasks, such as managing durability or orchestrating transactions. Transaction requests are received by transaction orchestrating peers, which forward them to durability peers. Once durability peers have stored the transaction’s effects, the updated data is synchronized on all peers containing it.

VII. CONCLUSION

This paper has given an introduction to the key architectural differences between classic DW technologies and emerging alternative DBMS engines, followed by a basic overview of various NoSQL and NewSQL systems. Tables 1 and 2 bring a feature comparison of presented DBMSs. In general, NoSQL and NewSQL engines show superior aggregation performance and much lower latencies than traditional BI engines for large amounts of data. However, they significantly fall behind in terms of query languages and their analytical capabilities, and consequently – data analysis tools. However, as the requirements of data analysis are changing towards larger data volumes and larger numbers of concurrent users, NoSQL and NewSQL systems are gaining popularity in BI applications, and will most likely be more and more included as an accompanying DBMSs to the existing BI platforms, in the spirit of polyglot database architecture. Along those lines, we believe that integration of existing BI systems and alternative engines is a promising area for future research and practice.

Abstract - In recent period, business process management (BPM) has been increasingly a matter of interest for numerous authors as well as numerous organizations, due to the understanding of business processes as the core part of every organization. Significant efforts have been put into researching and implementing BPM within organizations. This paper’s goal is to present the current state of BPM maturity and usage of social BPM within the companies operating in Croatia and Slovenia by analysing data collected by the PROSPER research group through questionnaires. Moreover, organizational culture is included in the analysis as well. Results indicate higher BPM maturity level and higher usage of social BPM within Slovenian companies than within Croatian ones and some other differences regarding dominant organizational cultures have also been found.

I. INTRODUCTION

Business Process Management (BPM) concept has been explored by numerous researchers for about two decades. The academics define BPM as a holistic and a lifecycle approach that covers different phases; from process documentation and modelling towards process execution, monitoring and optimization, and focuses on different issues that range from organizational structures, management positions and roles to strategy alignment and usage of IT for BPM [7][27][8]. Many of the researchers agree that BPM has a significant role in the organizational performance and a lot of effort was put into investigations related to this area. Accordingly, different maturity models are used to evaluate how the higher BPM maturity drives organizations towards higher performance [26].

Through years many definitions of organizational culture are accepted among researchers, but for the purpose of this paper a one developed by [9] and cited by [34] is used. Organizational culture implies “a system of values, beliefs and customs in an organization which produces certain norms of behaviour when interacting with the formal organizational structure” [9][34]. Though many different instruments for measuring organizational culture exist [14], a lack of researches about the importance of organizational culture type for the success of BPM implementation was evident in BPM literature through many years [36]. Nowadays, the academics and business practitioners intensify the efforts to explore this field [25]. Therefore, this study aims to examine the link between the organizational culture type and the level of BPM maturity. Recently, “the social BPM”, a new term related to BPM was coined out. This concept refers to a collaboratively designed process of BPM implementation [18] and “aims to integrate social aspect throughout the different stages of BPM” [24]. The brief literature overview shows that more research needs to be carried out on the role of social BPM in BPM maturity.

The main goal of this paper is to investigate the current state of BPM maturity in Croatian and Slovenian companies. Besides, the focus is put on two factors that impact the implementation of BPM concept in organizations; these are (1) organizational culture and (2) social BPM. The paper is structured in two parts. First, a theoretical framework is given: concepts of BPM, social BPM and organizational culture are presented. Next, the methodology and the results of empirical research about BPM maturity and social BPM through different organizational culture types are depicted and the final conclusions are given.

II. BUSINESS PROCESS MANAGEMENT MATURITY

Numerous models are used by researchers to assess BPM maturity. The origin of the majority of these models is the Capability Maturity Model (CMM) which was developed to measure the maturity of software development processes [35]. In general, BPM maturity models usually consist of 4-6 dimensions that are used to assess the stage of organizational maturity. Besides, maturity models can serve business practitioners as a guidance to reach higher maturity levels, or for a comparison or benchmarking purposes. Röglinger, Pöppelbuß and Becker [26] identified and analysed ten BPM maturity models, among which Process Performance Index (PPI) - originally founded by [28]. According to their findings, PPI is “a descriptive model that defines statements for ten BPM critical success factors” [26]. It refers to different areas linked to BPM implementation in organization: (1) alignment with strategy; (2) holistic
approach; (3) process awareness by management and employees; (4) portfolio of process management initiatives; (5) process improvement methodology; (6) process metrics; (7) customer focus; (8) process management; (9) information systems and (10) change management.

This model distinguishes three levels of maturity: (1) process management initiation; (2) process management evolution; and (3) process management mastery. Each of these levels and its characteristics are described by [29] and interpreted by [3], as it is presented in Table I.

### TABLE I. PPI MODEL MATURITY LEVELS

<tbody>
<tr>
<td>process management initiation</td>
<td>Although organizations are „nephelites“ to BPM, a strong aspiration to learn about it exists; by starting to focus systematically and formally on business processes, significant benefits could be achieved [3][29].</td>
</tr>
<tr>
<td>process management evolution</td>
<td>Although there are formal process improvement programs and organizations are „process-aware“ there is room for BPM improvements; process roles and jobs are identified, process performance indicators and metrics defined and in some cases process measurement systems are implemented [3].</td>
</tr>
<tr>
<td>process management mastery</td>
<td>For the organizations BPM is fully integrated into their functioning and general performance management system; process owners are rewarded on process performance and every employee understands the processes [3].</td>
</tr>
</tbody>
</table>

### III. THE ROLE OF ORGANIZATIONAL CULTURE IN BPM

According to [30] and [12] organizational culture represents “values, beliefs, attitudes and behaviours” of the employees and reflects their behaviour. Typically, 4 types of organizational culture are recognized [6]: clan, adhocracy, market and hierarchy culture. In business practice, different culture types are usually adopted within an organization, thus forming the combination of culture types that is aligned with the specific internal conditions (e.g. size, industry and company ownership) and with the environmental influences (e.g. legal regulations, governmental policy, market conditions). According to [22] and [23], “a classification of organizational culture called the competing values framework is depicted with 4 quadrants that are determined by a horizontal and vertical axis”. The horizontal axis emphasizes the organizational internal or external orientation, while the vertical axis reflects the criteria of flexibility and control [37]. The position of organizational culture types within the classification proposed by [22] and its main characteristics are shown in Table II.

Through the years many organizational culture assessment models have been developed. Among these, Organizational Culture Assessment Instrument (OCAI) is one of the most often used by researchers. OCAI model is developed by [6] to assess the organizational culture type based on the respondent perception of current organizational culture and preferred one. The model defines six groups of statements: (1) dominant characteristics, (2) organizational leadership, (3) management of employees, (4) organizational glue, (5) strategic emphasis and, (6) criteria for success [6]. Further, each group of statements is structured out of four statements, each of these representing one of the four culture types.

### TABLE II. MAIN CHARACTERISTICS OF ORGANIZATIONAL CULTURE TYPES

<table>
<thead>
<tr>
<th>Culture type</th>
<th>Competing values framework [22]</th>
<th>Culture type characteristics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Clan</td>
<td>Internal focus, Flexibility</td>
<td>A workplace is flexible, friendly and people oriented [21]. A loyalty, tradition, collaboration, participation and teamwork are in focus [6][2].</td>
</tr>
<tr>
<td>Adhocracy</td>
<td>External focus, Flexibility</td>
<td>Creativity, agility and innovation are encouraged within a creative working environment and are supported by the employees willing to take risk and to experiment [21][37].</td>
</tr>
<tr>
<td>Market</td>
<td>External focus, Control</td>
<td>The main characteristics are: very competitive environment strongly oriented towards performance, productivity and achievement of business goals [21][37].</td>
</tr>
<tr>
<td>Hierarchy</td>
<td>Internal focus, Control</td>
<td>A workplace is formal, organizational structures are strong, with very deep pyramid of decision-making levels [21]. A control and stability is achieved by formal rules, regulations and policies [2].</td>
</tr>
</tbody>
</table>

Still, a challenging question for the researchers is if the success of BPM implementation and adoption relies on the dominant type of culture within the organization? The results of the different surveys showed that employees will support the implementation of new concept if it is compatible with the culture that prevails in organization, so it can be concluded that organizational culture strongly impacts BPM implementation success [1][2][7]. Several authors share the opinion that “a change in the organizational culture is an important factor to increase a level of business process maturity” [33][11]. These conclusions promote a need to deepen a research on the role of organizational culture in BPM maturity. Moreover, the focus of researches on the impact of organizational characteristics on the success of BPM is notable [27][36][2][32]. According to [5] and [13], clan and adhocracy culture seem to have a positive role in BPM success.

### IV. SOCIAL BPM

BPM is a holistic concept where different disciplines, such as management, organizational theory and IT are linked. Through the years the attempts to integrate social elements in BPM have evolved [24], so the term social BPM has been introduced. Social BPM comprises two areas: (1) communication and collaboration aspects during all stages of BPM lifecycle and (2) implementation of IT platform to support social user behaviour. According to [20] “social BPM is the practice of actively involving all relevant stakeholders into BPM through the use of social software and its underlying principles”. This approach should help to avoid the limitations of traditional BPM, but still little is known how social BPM can contribute to
the enhancement of BPM implementation and governance.

As a result of brief literature overview conducted for the purpose of this research, four main principles of social BPM concept are systemized and presented in Table III. Similarly, [16] developed an a-priory model to identify the appropriate social technology for inclusion within the BPM lifecycle.

**TABLE III. MAIN PRINCIPLES OF SOCIAL BPM**

**V. METHODOLOGY**

A. Research questions

The research presented in this paper is based on the following research questions: (1) What is the current state of BPM maturity and the usage of social BPM within the Croatian and Slovenian companies?; (2) Are there any statistically significant differences between the results obtained in Croatia and those from Slovenia regarding BPM maturity and the usage of social BPM?; (3) Are there any statistically significant differences between organizations with different organizational cultures regarding BPM maturity? and, (4) Are there any statistically significant differences between organizations with different organizational cultures regarding the usage of social BPM?

B. Research instrument

For the purpose of the research conducted under the PROSPER project, a questionnaire has been developed based on the comprehensive literature review. The final version of the questionnaire contained 12 sections, being: BPM, social BPM, business intelligence (BI), corporate performance management (CPM), BPM/CPM alignment, BPM/BI alignment, CPM/BI alignment, process performance, organizational performance, organizational culture, characteristics of organization and demographic characteristics of the respondent. This paper is based on the three sections of that questionnaire: (1) BPM, (2) social BPM and (3) organizational culture.

BPM section of the questionnaire represents the Process performance index (PPI) developed by [29], containing ten statements as described earlier in this paper. For each statement, the respondents state their level of agreement on the scale from 1 to 5, with 1 being “totally disagree” and 5 being “totally agree”. The cumulative score gained through these ten statements represents organization’s PPI. If the PPI score is in the range from 10 to 25 it means the organization is at the lowest level of BPM maturity, PPI from 26 to 40 points puts organization into the second level of BPM maturity while 41 to 50 points are included in the third, highest (mastery) level.

Social BPM section of the questionnaire has been developed by the PROSPER research group based on the state of the art literature review [31][10][4][20][15]. It contains four statements which refer to the principles of social BPM: (1) egalitarianism, (2) collective intelligence, (3) self-organization and (4) social production, as shown in Table III. The respondents state their level of agreement with the each statement on the Likert scale from 1 to 5, with 1 representing total disagreement while 5 represented total agreement. Higher average of the stated grades represents a higher level of usage of social BPM within the observed company.

Organizational culture section of the questionnaire is the Organizational culture assessment instrument (OCAI) developed by [6] and described earlier in the paper. The respondents are supposed to split 100 points for each of the six groups of statements over a total of four descriptions of culture types in each group, according to the state within the organization. For the purpose of this research, OCAI is used to assess only the current dominant organizational culture types.

C. Data collection and sample description

The data collection for the purpose of this research has been carried out in two phases. Firstly, a preliminary research has been conducted with the purpose of testing the clarity and the design of the questionnaire draft. In February 2016, a series of interviews were conducted in order to test the questionnaire, after which slight modifications of the draft were made and the questionnaire was prepared for the main stage of the research.

The main stage of the data collection started in March 2016 and ended in December 2016. During this period, the questionnaires were distributed to the middle-sized and large companies in Slovenia and Croatia through post or e-mails. Besides the paper versions, an online version of the survey has been made in both countries. In Croatia, the questionnaires have been sent to 500 randomly selected organizations out of 1765 active middle-sized and large organizations in the Register of Business Entities. With total of 101 responses received, the response rate for Croatia was 20.2%. In Slovenia, the questionnaires have been sent to 1394 organizations, which is a whole population of registered middle-sized and large organizations. The response rate for the Slovenian data collection was 12.27%, with 171 responses received. In both countries, the questionnaires were addressed to top
management or person in charge of business process management within the organization. After the overall data cleansing based on the survey fulfilment, a total of 211 answers were taken into consideration. Table IV presents the sample characteristics used in this research.

</tr>
</tbody>
</table>

Our final sample consists of 132 answers from Slovenia, being 62.56% of the sample, and 79 answers from Croatia, being 37.44% of the sample. Majority of total surveyed organizations have between 50 and 249 employees (59.79%), while there is 23.22% those which have between 250 and 1000 employees and 17.06% of those employing more than 1000 employees. When looking at the sales revenue for the year 2015, there is 21.80% of the total surveyed organizations with the sales revenue in 2015 being less than 10 million euros. Majority of the surveyed organizations had sales revenue in 2015 between 10 and 50 million euros (38.39%), while 31.28% of them had more than 50 million euros of sales revenue in 2015 (31.28%). 8.53% of the respondents preferred not to give the answer to this question.

D. Statistical methods

In order to check the reliability of the research instrument, a reliability analysis using Cronbach’s alpha coefficients has been conducted. Since all calculated Cronbach’s alpha coefficients were above the cut-off value of 0.70 recommended by [19], we concluded that the scales used in this research have good overall reliability. We based the validity of used research instruments on the fact that both PPI and OCAF were broadly used in previous researches (e.g. [5]). The validity of a social BPM part of the research instrument was tested during the preliminary phase of the survey execution and was based on the opinions of experts from both academic and practice population.

With the purpose of testing the assumption of the normality of distributions, a Kolmogorov-Smirnov (K-S) test has been used. The results indicated the data distribution is normal for both BPM and social BPM in groups with clan, adhocracy and market organizational cultures. However, the results indicate that the data distribution is not normal in either case in the group with hierarchy organizational culture, nor if calculated on overall data. On the other hand, with the purpose of testing the assumption of the homogeneity of variance, a Levene’s test has been used. The results indicated the variances are not significantly different for social BPM, but are significantly different for BPM. Since neither the assumption of normality of the data distribution nor the assumption of the homogeneity of variance were tenable, the nonparametric tests have been used in the further data analysis. In order to test if the differences in BPM maturity levels and the usage of social BPM across the different organizational culture types are statistically significant, a Kruskal-Wallis test has been used. For the purpose of testing if the differences between Slovenia and Croatia in BPM maturity level and the usage of social BPM within the organizations are statistically significant, a Mann-Whitney U Test has been used.

VI. RESULTS AND DISCUSSION

One of the aims and first research question of this study was to examine the current state of BPM maturity and the usage of social BPM within the companies from Croatia and Slovenia. The results of the BPM maturity research were based on the calculated PPI score. PPI showed that majority of surveyed Croatian companies are currently in the middle BPM maturity phase, being process management initiation (58.23%). These results are in line with previous research of BPM maturity in Croatia (e.g. [17]) and indicate some kind of stagnation in the progress of Croatian companies in achieving the highest level of BPM maturity. On the other hand, majority of surveyed Slovenian companies are in the highest BPM maturity phase, with 53.79% of them being in the process management mastery phase. The average PPI for Croatia is 36.16, while the average PPI for Slovenia is 40.14. The results through levels of BPM maturity are presented in Table V. Regarding the social BPM, the results indicate slightly higher usage of social BPM in companies from Slovenia than those from Croatia. In Slovenia, the usage of social BPM score is above 4 (out of maximum 5) in 46.21% cases, while in Croatia there were 41.77% of them.

<table>
<thead>
<tr>
<th>BPM maturity level</th>
<th>Total (N=211)</th>
<th>Slovenia (N=132)</th>
<th>Croatia (N=79)</th>
</tr>

<td>53.79%</td>
<td>32.91%</td>
</tr>
</tbody>
</table>

The second research question concentrates on the existence of statistically significant differences between the PPI and social BPM results regarding the respondents’ country. In order to answer the stated question, a Mann-Whitney U Test has been used and the results indicated there are statistically significant differences between Croatia and Slovenia regarding both PPI results (p=0.01) for the BPM maturity and social BPM results (p<0.05).

With the intention of answering the third research question, a Kruskal-Wallis test has been performed to
investigate whether the differences between BPM maturity results between organizational culture groups are statistically significant in overall sample. With the purpose of testing group differences based on the dominant organizational culture type, the sample size has been taken into consideration. Since there was an unequal ratio of responses between groups, in some groups there would be a very small number of responses if looking the samples from each country. Instead, the combined sample for Slovenia and Croatia has been used in order to mitigate this ratio. Table VI presents the results of the Kruskal-Wallis test for BPM. The results indicate that BPM maturity is significantly different between the organizations with different dominant organizational cultures ($H(3)=15.31, p<0.01$). When looking at the results, it is evident that BPM maturity had higher scores in organizations where dominant organizational culture is adhocracy or clan than in those where hierarchy or market organizational culture is the dominant one. These results are to some extent in line with the similar previous research conducted by [5] in Croatia and Slovenia as well. In her work, [5] reported the highest BPM maturity score in clan organizational culture.

### TABLE VI. BPM MATURITY THROUGH DIFFERENT ORGANIZATIONAL CULTURES

<td>94,0347</td>
</tr>
</tbody>
</table>

Finally, same statistical method has been used in order to answer the fourth research question, examining existence of statistically significant differences between organizations with different dominant organizational cultures regarding the usage of social BPM. The results of the Kruskal-Wallis test for social BPM are shown in Table VII. As in the previous case, the results showed there are statistically significant differences in the levels of social BPM usage in the organizations from different dominant organizational culture groups ($H(3)=22.95, p<0.01$). Surveyed organizations with dominant adhocracy and clan organizational culture had better scores regarding the usage of social BPM than those in the market organizational culture group, while the lowest scores were obtained from the organizations with hierarchy organizational culture as dominant. These results could be explained if looking the organizational culture types’ characteristics as presented in Table II and social BPM principles as presented in Table III. The concept of social BPM is based on the principles of social software, mainly user engagement, collaboration and real-time reaction. These principles are similar to the characteristics of adhocracy and clan culture types, where flexibility, creativity and teamwork are the main factors. Following that, the higher usage of social BPM score within the companies with adhocracy and clan organizational culture does not come as a surprise.

VII. CONCLUSION

This study has presented the results of the BPM maturity and usage of social BPM research conducted in Slovenia and Croatia in 2016. It has been shown that Slovenian companies are at the higher level of BPM maturity and higher level of usage of social BPM than Croatian companies. While majority of Slovenian companies are at the upmost BPM maturity level, majority of Croatian ones are still at the middle level. However, the limitations of this study include unequal ratio of Slovenian and Croatian companies included in the research.

Regarding the organizational culture part of the research, the results indicated there are statistically significant differences between groups of companies with different dominant organizational culture type when investigating BPM maturity and the usage of social BPM. For the future research it is planned to further examine the role that organizational culture type has on the usage of social BPM and on achieving higher level of BPM maturity.

Abstract - Social network analysis (SNA) is the application of graph theory to understand, categorize and quantify relationships in a social network. It can be a great tool to improve analytic capabilities in any field, for example marketing analytics, churn prediction, health care, etc. In terms of SNA, network structure is defined by nodes, edges and metrics which quantify the importance or influence of certain nodes in the network or relationship strength between nodes. Algorithms for network metrics calculation are complex and that makes SNA difficult to implement in big data environments on large datasets with many nodes and edges. In this paper we will elaborate how to efficiently and performance wise perform SNA and visualize results of the analysis on large datasets using increasingly popular GraphX and JavaScript libraries.

I. INTRODUCTION

Although the concept of social network analysis is not new, with the widespread availability of data and the progress made in recent years in computer science, social network analysis was found valuable in many fields. The increasing expansion of Internet and the growing connectivity have brought a higher level of attention to graph analytics. The benefits of analyzing and visualizing the network type data from a different perspective became clearer, which is something specific for SNA. Instead of putting the focus on the entities and their properties, SNA puts the focus on the links between them - the relations and the structure of the graph they form.

The ‘network approach’ means studying individuals as part of a network structure, in terms of the relations to other individuals, not just entities for themselves. This approach brings new insights, but for some time its computational complexity represented an obstacle to applying these algorithms to ubiquitous large networks. However, with the recent development of new data processing tools and techniques, new tools suited to analyzing large graphs were also developed. One of them is Spark GraphX – a library developed for large scale graph analytics.

II. CHALLENGES OF EFFICIENT SNA

A. SNA basic concepts

Social network analysis applies graph theory to study the relationships (edges or links) between entities (nodes or vertices) in order to better understand and evaluate the network and its actors. It includes social media data, but also any kind of social structure where there is information sharing and a system of connections that can be captured in a graph. Such data can be found in various fields and domains beyond social sciences, e.g. in financial industries for transaction analysis, in telecommunication for fraud detection, in any organization for diffusion of information analysis, Internet traffic, or even in health care for analyzing the spread of contagious diseases.

Nodes and edges, which compose a graph, are the main abstractions in SNA. Nodes are entities – persons, organization or items, and the links describe the relationship between them. Both the nodes and the edges can have properties that describe them, but the main focus of the analysis are the relationships and the structure, not the individual properties. SNA focuses on uncovering the patterns in the links, i.e. interactions between nodes, analyzing the communication flow in the network structure, identifying the individuals and groups playing central roles, or identifying isolated individuals. Some of the usually asked questions are: Who are the key players (by some criteria)? Who is isolated? Which connections act as bridges between groups? Are there clusters and how are they formed? Is there a hub? Etc.

To answer those questions, SNA defines a number of metrics that reveal certain characteristics of the network or specific nodes. On the network level there are metrics designed for better understanding of the overall network structure like density – the ratio of the number of existing connections and the number of all possible connections, diameter – the longest geodesic (shortest path between two nodes), and many others. On the node level, most common are centrality measures, which include: degree, strength, closeness, betweenness, eigenvector centrality, and PageRank. Their goal is to identify the most central and most important nodes in the network. There are also clustering algorithms to detect groups of nodes that communicate most frequently, etc.

The analysis includes both a mathematical and a visual component. In the next few chapters we describe the benefits of using GraphX library for the mathematical analysis. Additionally, we show how visualization using JavaScript can be used to effectively present graphs, to allow a user to comprehend the overall network structure, and a detailed view of the analysis results with the ability to filter and more closely examine certain nodes of interest. Fig. 1 describes the proposed architecture.
B. Tools development

Recently there was a lot of advances in developing general-purpose distributed processing tools, i.e. data-parallel systems like Hadoop MapReduce and Spark, developed as a response for many big data problems. Unfortunately, directly applying specific graph algorithms in those environments turned out to be a poor solution. On the other hand, developers turned to graph-parallel systems for specialized graph processing problems. These systems perform a lot better than general-purpose tools, but their big disadvantage remains that they can only be used for graph specific problems. For a larger analytics pipeline, which is often the case, they would have to be integrated with other systems, which would require unnecessary data movement and duplication [1].

In this paper we present a tool that combines the advantages of both approaches - the graph-parallel approach and the general distributed data processing tools, and thus addresses graph analytics problems in an efficient and yet generally applicable way.

C. Graph-parallel approach

Most of the SNA metrics require implementing complex and iterative algorithms, whose execution time is often not satisfying, especially for very large graphs. For example, PageRank, famously developed by Google for calculating the importance of web pages, now also a popular algorithm for analyzing other types of networks, is implemented through an iterative algorithm to calculate an approximation of the node's importance.

PageRank of a node depends on the PageRank value of its incoming nodes. Also, the number of node’s outgoing links affects the PageRank value of the node it connects to: the more outgoing links it has, the lower the value it propagates to the connected node. Thus, important nodes are the ones who are connected to many other nodes, but also the ones who are connected to fewer, but more important nodes. PageRank values are approximated by running an iterative algorithm. In the start the algorithm assigns an initial value to each vertex, and then in each step upgrades the value based on the values propagated from its incoming links [2].

Therefore, the algorithm is based on iterative local changes; vertex properties (in this case PageRank values) are transformed in each step recursively based on the properties of its direct neighbors. Graph-parallel systems are based on executing these changes in parallel and they are optimized for that kind of iterative graph algorithms. However, they are only suited to computation on static graph structure; their ‘vertex-centric model’ does not work well when there is a need to modify the graph structure like graph coarsening [3]. Furthermore, it is not designed for ETL kind of tasks like graph construction or manipulating the computation results.

III. GRAPHX AS A UNIFYING SOLUTION

A. Graph processing inside a larger platform

GraphX is Apache Spark's built-in library for graph analytics and graph-parallel computation. GraphX leverages graph-parallel computation for the best performance in graph-specific algorithms, but also keeps the ability to interoperate with other tools and modules for general data processing inside the Spark framework. That leaves the possibility to make graph computation a part of a larger, more general analytics pipeline, which is often a requirement of an extensive analytics project. For example there can be multiple data sources, the data needs to be joined, cleaned and prepared for the graph computation, afterwards the results need to be analyzed further and joined with other information, etc. Furthermore, GraphX inherits all Spark’s good characteristics [4] like:

- **Scalability**
  GraphX is designed for scalable graph computation. It is suitable for performing complex computation on very large graphs.

- **Fault-tolerance**
  Unlike many specialized graph processing tools, GraphX as part of a general distributed data processing tool – Spark, does not sacrifice fault-tolerance in favor of latency.

- **Integration with the rest of the Spark platform**
  Specialized graph tools are restricted to a limited range of graph-centric tasks, everything else is beyond their scope. For example, they require the data to be in a specified format, whereas with GraphX the user can easily transform, filter and clean the data the way the analysis needs it. It enables flexible graph construction (ETL tasks) and other data processing tasks after the graph computation part.

- **Interactive computation (Spark shell)**
  All Spark modules can be used and tested interactively from the Spark shell for better developer productivity.
B. GraphX data model

Spark GraphX is based on some key data types that are actually extensions of Spark’s main abstraction – RDD but optimized for graphs: VertexRDD, EdgeRDD, and Graph. Like all RDD-s, they are distributed, immutable, and fault-tolerant. VertexRDD is composed of a unique numeric vertex id and the properties related to the vertex. EdgeRDD contains id-s of the source and target vertex, and edge properties. Both the VertexRDD and the EdgeRDD have internal indices for fast joins. Graph class abstracts a property graph and provides methods for graph-oriented calculations. It is created using the VertexRDD and EdgeRDD i.e. it is essentially a pair of a partitioned collection of vertices and a partitioned collection of edges. Consequently, all RDD methods are available. [5] [6]

GraphX allows the Graph to be viewed and operated with in both a table-oriented and graph-oriented way. There are methods for analyzing and modifying nodes and edges properties, and also performing graph specific algorithms or changing the graph structure. Furthermore, since GraphX is a part of the Spark platform, it can be used together with other modules, including SparkSQL and DataFrames API, MLlib, etc, which means that the whole analytics process, with data computation and graph computation steps, can be implemented within a single application, without sacrificing the performance of the graph specific tasks. For example a user can read raw data from various sources, clean and filter the data, extract the nodes and edges to perform graph analytics tasks, analyze the results, and optionally repeat steps for a different piece of data, or a subgraph. The biggest advantage of GraphX is that it allows graph computation to be performed as a part of a bigger analytics workflow inside a single platform.

C. Best of the graph-parallel and data-parallel world

GraphX is an embedded part of a data-parallel framework and works in that environment, but achieves similar performance as specialized graph systems by using multiple distributed join optimizations. Its graph data model implements graph-parallel abstraction as a specific pattern of join stages and group-by stages, with intervening map operations [3]. Specific graph computation patterns are reconstructed as dataflow optimizations to achieve similar performance without sacrificing the computational flexibility.

The optimizations include the way graphs are implemented as a pair of distributed collections – VertexRDD and EdgeRDD, and the way they are processed to recast the graph-parallel model by using common dataflow operators – join, group by, map. To achieve efficient distributed execution, GraphX enables vertex-cut partitioning scheme; graphs are split along vertices, which has been shown to minimize the communication and movement of data [7]. By leveraging these optimizations, GraphX performance does not fall behind specialized graph systems, and still keeps the generality and applicability.

IV. VISUALIZATION USING JAVASCRIPT

JavaScript is very commonly used for various types of visualizations across many web projects. The most common type of visualization is chart visualization which shows many different aspects of data, which can be interactive.

There are several libraries for SNA analysis which support render of edges and nodes as a network which can also be interactive. Most commonly used are SigmaJS, Linkurious and JSNetworkX [8][9][10].

JSON is the most common data format used for loading data in an SNA graph. It is a lightweight data-interchange format. It is easy for humans to read and write and is also easy for machines to parse and generate. GEXF is a language for describing complex networks structures, their associated data and dynamics.

Most of these libraries support parsing JSON or GEXF data format, but there is a limit to how much nodes and edges JavaScript can render before the page script stops being responsive, so JavaScript developers must be careful not to load too many nodes and edges in the graph network.

One way to reduce the number of nodes and edges is to provide filters on the page, which can help the user to pre-filter the data. Interactivity provides users with ability to move nodes and edges, and show only the ones which are interesting for any given business aspect. The whole process of rendering SNA graph is mainly done by the library, and the user’s part is only to provide the data which needs to be loaded in graph. This data is most commonly consisted of two arrays. First array represents nodes with common properties (size, color), but extended properties can also be wrapped in nodes collection.

Other array is the edges array that describes the relations between nodes which can also be extended with additional properties that can later be rendered in network graph. Extended properties can be added to allow better visualization of network with custom icons, and more information in it, but it’s important to remember that JavaScript execution becomes slower over large collections with many attributes, and the code complexity also increases with each new attribute.

SNA graph visualization is preferred to be used with smaller number of nodes and edges, where it is easy to identify crucial information needed to understand the relation between nodes, and render it smoothly in the user’s browser. As new JavaScript libraries are introduced, a trend is noticed that there is a need to construct more complex networks with large number of nodes for big data analysis, so some newer libraries support loading large collections of arrays, but there is still an issue with rendering them in the web browser, as it is not designed to handle large number of DOM elements. WebGL rendering engine is used for that, but it requires users to have a better graphics card, which is then used to render large networks in one canvas element in 3D. However big data SNA analytics is still a concept, while currently big data is separated into sections, filtered
and then loaded into smaller chunks with any given SNA JavaScript library such as SigmaJS or Linkurious. JavaScript events can help introduce better user experience while browsing through graph, since each zoom or mouse click can be handled with JQuery or a similar library. Some SNA libraries already support event handling so the user is not required to write any additional code except extend logic with only specific behavior. Coloring is also commonly used to separate specific graph sectors, and visually distinct them. Colors can be injected in JSON as hex codes or string values and then rendered. For most SNA graph libraries coloring is natively supported for nodes and edges. Searching through SNA network graph is done in JavaScript by iterating nodes or edges array and setting visibility attribute of filtered elements. After each search SNA graph is reduced to size of only the filtered result, which increases performance of whole network render in browser and also provides more detail result to user, which can then focus only on the part of the network which is interesting for business his business case. Also additional properties provided in data can allow the render of graph to support custom icons, images, and additional data which can then be displayed in filtered output with more detail keeping in mind that each of this attributes increases the dataset size. Custom attributes can also be used to provide better filtering features in graph, so user can filter data with more specific information. There is no limitation in type of custom attributes. Custom attributes can be of any type, so it is possible to define icons or images with custom URL string, dimension values as decimal numbers, or even Date or Boolean values. Most of this JavaScript libraries also support zooming into data, which allows user to see specific part of SNA network with more detail. Usually the initial render of the graph is so out of scope that the user must zoom in to a specific part, so this comes naturally to the user and provides better user experience with higher level of data insight. Nodes are usually represented as dots, and edges are represented by lines, which can be straight or curved depending on the library used. Clicking on each node or edge, the user can get more focus to selected data area, and view only nodes connected to the one he selected, but also only edges related to that node. The way this is achieved through JavaScript is similar to searching; first step is to find selected node in provided nodes array, and then all the connecting nodes are easily identified, and all other nodes are just programatically hidden. Usually library redraws the whole graph with simple Draw() or Refresh() method so this must be called after the filtering is done. An important thing to mention here is that this works smoothly with smaller data arrays, but as arrays get bigger, you might get unresponsive behavior. Best practice for rendering SNA graph is to always provide filters which reduce the size of initial render to only a portion of the dataset, which can then be loaded with any provided JavaScript library, and then further drilled in more detail using mouse zoom. By drilling into data with mouse zoom, the user can better focus on a particular segment of graph. JavaScript as a programming language for integration with SNA graph analysis proves to be a good solution if you need fast insight into your data, but for larger data collections it is not recommended since HTML document object model isn’t made to be used for complex graph analysis, so this is a limitation of using JavaScript in social network analysis.

V. CONCLUSION

This article presents a big prototype platform for SNA analysis in Big Data environment, and gives an overview of the architectural integration in combination with multiple technologies, frameworks and techniques through Big Data architecture. It is shown how the Spark GraphX framework in combination with JavaScript provides a platform for efficient social network analysis with different types of powerful and interactive visualizations. Since SNA can find its application in different industries for different use cases, the presented architecture has a great potential in today’s big data world.

REFERENCES

Abstract - The paper presents results of a research on integration of enterprise data warehouse (EDW) and a master data management (MDM) system. The primary goal was solving a schema evolution problem, and the corner stone of our approach was utilization of a data vault modeling of an integrated meta-model of EDW and MDM as an expansion of a traditional relational database system catalog. The main contributions of this paper are: a) common integration architecture, b) new system catalog based on a meta-model for DW and MDM integration, and c) research prototype used for empirical validation of the effectiveness of the proposed solution.

I. INTRODUCTION

A data warehouse is “a subject-oriented, integrated, time-variant and non-volatile collection of data in support of management’s decision making process” [15]. This means that a data warehouse (DW) can be used to analyze a particular subject area (such as sales, marketing, finance, etc.), it integrates data from multiple heterogeneous data sources, it keeps the history of data, and it never alters the data once it enters a DW. A simpler form of a DW is a data mart (DM). DM is focused on a single subject area and it draws its data not from all the DW data sources, but from a limited number of them (such as retail sales applications with daily transactions). For the logical representation of a DW (or DM), we traditionally use a denormalized dimensional model [12][20] in a combination with a 3NF model for modelling a central and integrated enterprise data warehouse (also called operational data store) [12][15][16]. DW environment (namely its data sources) nowadays is in a state of constant structural (schema) change. Master data management (MDM) comprises the processes, governance, policies, standards and tools that consistently define and manage the critical data of an organization to provide a single point of reference [3][23]. Some of the fundamental tasks of MDM system are duplicate removal, data standardization, and rule implementation and incorporation - all with a goal to eliminate incorrect data from entering the system and to create an authoritative source of master data for further distribution. It is a method of enabling a business organization to link all of its critical data to a common point of reference, which is further shared throughout all the departments and relevant employees. This way, a data quality of an organization greatly improves and the organization can better serve its clients, as well as improve their business by running a more accurate and efficient business analysis and reporting (based on a “single version of the truth” data pool [15]). Dimensional model can also be used here - for the logical representation of MDM data (master data are represented as dimensions here). Master data are the key business entities and their descriptive attributes (e.g., the customer has a name, address, etc., the product has a name, color, weight, category, etc.), which are used by multiple systems, applications, and business processes of the organization as a unique source of data. Reference data can be internal or external and are used for the validation of other data. MDM environment is also in a state of constant change – data sources nowadays often change their structure and content. In this work our focus was on an enterprise size data warehouse (DW) and a master data management (MDM) system integration. We approached the problem through a development of a common system catalog meta-model, with the goal of solving a common schema evolution problem. Schema evolution occurs in both of these systems and is traditionally resolved separately. DW integrates current and historical data from many data sources and serves for business reporting and data analysis. MDM is traditionally used (by other business systems, applications, databases and data warehouses) as a physically independent database of master and reference data (also collected from many data sources). Data sources are often the same ones for DW and MDM and they often change their structure. These changes have to be implemented into both systems, so that they could accurately reflect the current (and historical) state of the real world - so that the DW could provide for effective business analysis and the MDM could achieve the optimal data quality throughout all the systems involved. We aim to resolve this problem on a common level - we state that the schema evolution problem can be viewed as a double issue: at a DW level and at the MDM level. From the DW perspective every event (fact) that is monitored and the events (facts) give them context. And in both of these cases schema evolution problem to solve exists. The paper is organized as follows: section II gives a brief overview of a related work, section III describes our DW/MDM integration research (general research idea, our common integration architecture and integration part of a system catalog meta-model), section IV presents our research prototype and some relevant test results, and in section V we conclude our work with a brief summary and some plans and guidelines for the future.
II. RELATED WORK

With respect to the literature, the DW evolution can generally be traced through three approaches - schema evolution [5][10][29], schema versioning [1][9][25] and view maintenance [2][7][14]. The first two approaches are more interesting to our research because they are based on a DW defined as a multidimensional schema, and the third is based on a DW that is defined as a set of materialized views. Our extensive and comprehensive state-of-the-art on this problem can be found in [28], but from analyzing the related work we can generally conclude that the process of schema evolution and versioning is still demanding in terms of invested time and resources. It is necessary to balance the resource requirements and the quality of schema evolution process. Perhaps the biggest problem here is the preservation of schema consistency and data integrity (there is still a lack of an integrated system-of-records), as well as the simultaneous performance of temporal queries against multiple versions of the schema. Also, migration and transformation of data is still slow and expensive, the loss of information during these processes is still present and there is a lack of effective integration, organization and management of metadata. On the other hand, the view maintenance process can cause network saturation, depending on the amount of updated views and the amount of information they contain. The problems of anomalies and inconsistent changes in the views are still unresolved, the proposed approaches for view maintenance are still limited in terms of efficiency and performance, and the ETL processes, which are an integral part of most of today's DWS are completely ignored. Different approaches to solving the DW schema evolution problem are presented in literature (including a variety of techniques, algorithms, algebras, models, prototypes, methodologies and frameworks), but there is still no widely accepted solution and general framework for managing DW schema changes. More importantly, previous research does not emphasize the fact that the DW requirements, in this day and age, are increasing in the data and meta-data scope and structure (the growing number of data sources and more new and different types of data), which additionally requires developing some new approaches and solutions to the schema evolution problem.

III. MDM AND DW INTEGRATION RESEARCH

A. General research idea

As we already mentioned, the DW needs to preserve the history of data and metadata changes, as well as the history of schema and scope changes, for a very long time period [19][26]. On the other hand, the MDM needs to preserve a data quality of an organization by achieving and maintaining a “single version of the truth” data pool as a basis for accurate and efficient business analysis [3][23]. Seeing that the DW and MDM both integrate basically the same data sources and have the same schema evolution problem, we will integrate those two systems into one and address the evolution problem at the common level. Our main research question was: “Can our new system catalog model serve to successfully integrate DW and MDM systems?” In order to answer this question, we developed a new, integrated architecture for these systems, as well as a system catalog model based on a Data Vault modelling methodology [21][22]. The data vault (DV) is a data modeling method designed for supporting the long-term storage of historical data collected from various data sources and tracking the origin of data contained in the database [21][22]. The DV model (due to structural separation, usage of empiric meta-data and addition-only policy, which relation model does not implement) is able to track the data source values and the history of changes, which is a vital function of a DW system-of-records [19][26][27]. Furthermore, we developed and tested a research prototype based on said architecture and system catalog model.

B. Common integration architecture

Fig. 1 shows our common integration architecture. Central and integrated enterprise DW/MDM (purple section in Fig. 1) is in focus of our research and consists of two parts - the raw copy of the source data (SDV) and the synchronized master and business data (PMDV). Both parts are based on the Data Vault (DV) method, in contrast to traditional approaches based on the relational model [12][15][20]. SDV is focused on obtaining and preserving the original and unchanged copy of data sources for the purpose of governance and auditing, and PMDV is focused on obtaining and preserving the data that has been modified according to business and master rules – the data that later feeds DMs and master dimensions (MDMs) and is oriented to user requirements. The integration of SDV and PMDV is carried out over an extended DBMS system catalog (i.e. our new meta-data repository, MDV), based on the DV model. MDV repository serves to integrate the two parts and to monitor history of changes of meta-data and their schemas, of the business rules and transformations and of mappings between the two systems. MDV contains the history of data sources’ meta-data (their domains and schemas), of central DW/MDM integration and schema changes, of DMs and MDMs schema changes and of security schema changes (user access rights). We can say that MDV repository represents the DW on DW and is a key part of our new architecture. In materialized DMs and MDMs (blue section in Fig. 1) master data and business analysis and reporting data is stored. Data is stored according to the user requirements and a dimensional model is used for representation (data are summarized, aggregated and calculated). A traditional DMs are integrated here with the traditional MDMs – the PMDV forwards the data to MDMs so the MDMs could then forward the data to DMs and data sources. The end-user can then access the DM/MDMs and analyze the data through the selected data analysis and reporting tools. Additionally, the master data is returned from enterprise DW/MDM to the data sources in order to harmonize and refine the data within business organization. Master data collected from PMDV is maintained in one central MDM location and all source systems and applications, as well as DMs, are using this data. This directly affects the quality of data, which later re-enters the raw SDV and passes again through the described layers of the architecture. Also, by reducing the amount of data over which was necessary to make "heavy" transformations we thus speed up the process of
data integration [19]. However, these issues are out of the scope of this paper.

C. Meta Data Vault (MDV) model for SDV/PMDV integration

Fig. 2 shows a simplified meta-data-vault (MDV) model for DW/MDM integration. Due to complexity and size of the full MDV system catalog model and the scope of this work, we will show here one small, but relevant part of the MDV model – the one for SDV/PMDV integration. The whole model is much more extensive because it serves for schema evolution purpose - it incorporates data sources, data marts, materialized views and issues of security - but those are out of scope of this paper. The model (as well as other models in this work) is made in IDEF1X method [17] with the use of the CA Erwin Data Modeler 9.5 modelling software [8]. In our MDV model, SDV/PMDV integration is managed through the same-as-links on four main hubs (H_HUB, H_LINK, H_SATELLITE, and H_ATTRIBUTE) which store metadata about three main DV concepts in a data model (hubs, links and satellites respectively – additionally H_ATTRIBUTE stores data about satellite attributes; column meta-data). For example, if we have two different relational data sources which both have the table CUSTOMER, we integrate these sources into a DV based central EDW (EDV). This means that the relational table CUSTOMER from both sources becomes one hub H_CUSTOMER (stores business keys for CUSTOMER) with its satellites S_CUSTOMER1 (stores columns from CUSTOMER in Source1) and S_CUSTOMER2 (stores columns from CUSTOMER in Source2). This is considered as a copy of the original data sources (SDV).
which is then copied into a PMDV where the business and master rules are applied. For this example it means that
hub H_CUSTOMER gets only one satellite S_CUSTOMER – by the rules those two satellites are integrated into common one and the data is cleansed. Also, data in the H_CUSTOMER is integrated and duplicated. The corresponding meta-data is then stored in our MDV system catalog from Fig. 2. In the H_HUB and its satellites S_BUSINESS_KEY and S_HUB_DEF the meta-data about hub H_CUSTOMER (and generally about all the hubs in a enterprise DW/MDM – from both SDV and PMDV) is stored, including the data about names of the hubs, names of their keys, hub types and their general descriptions, as well as their load dates and record sources. Also, in the H_SATELLITE and its satellite S_SAT_DEF the meta-data about satellites S_CUSTOMER1, S_CUSTOMER2 and S_CUSTOMER is stored. The same is true for all other MDV structures (links, attributes, …). However, at this point the DW and MDM (SDV and PMDV) hubs are not yet integrated (list of hubs with their descriptive meta-data is just stored in a corresponding meta-hub and its meta-satellites - H_HUB, S_BUSINESS_KEY, S_HUB_DEF). For the integration we use the same-as link SAL_MASTER_HUB which relates a single hub from a list of hubs in H_HUB to another hub from that list, in a base-master relation (SDV hub is base one, PMDV hub is master). In the example it would mean that the hub H_CUSTOMER form PMDV becomes master hub to hub H_CUSTOMER in SDV. For the satellites, their integration is stored in the SAL_MASTER_SATELLITE link – for example, the S_CUSTOMER1 and S_CUSTOMER2 meta-data records stored in H_SATELLITE can have (separate) base-master relationship with S_CUSTOMER record. This relationship is stored as a record in SAL_MASTER_SATELLITE where S_CUSTOMER is master structure on S_CUSTOMER1 and S_CUSTOMER2. Additionally, SAL_MASTER_HUB (as well as other master links) relates to H_RULE and H_TRANSFORMATION, the two hub meta-concepts that store the data about business rules that can be applied to data and (ETL) transformations needed to apply those rules, respectively. This way, we get the complete history of SDV/PMDV integration – we can keep track of all the business rules and transformations applied to the specific integration, with SAL_MASTER_HUB storing the load date and record source data about that specific integration. In that way we can create and manage master hubs and store the history of their changes. SAL_MASTER_HUB has its satellite S_BDV_CODE_HUB, with descriptive data about the code (ETL or other) used for that specific integration. This satellite will later serve as a basis for automating the process of integration. The same can be applied to the other three main hubs in a MDV model (SAL_MASTER_LINK for H_LINK, SAL_MASTER_SATELLITE for H_SATELLITE and SAL_MASTER_ATTRIBUTE for H_ATTRIBUTE), so we can create complete and historicized “golden copy” of business and master data in PMDV, from the simple SDV raw copy of data. Regarding the reference table concept, as it exists only in a data model (it represents external or internal reference data and as such it is already consolidated and organized by internal business rules or external data standards), we have no need to further make the master concepts in the meta-model. We will simply store its meta-data in a H_REFERENCE concept in MDV.

IV. RESEARCH PROTOTYPE AND RESULTS

A. Business case example

For the purpose of theoretical validation of the proposed architecture and DW/MDM integration, as well as building a prototype, we developed a simple business case (in a similar way as in [18]), which monitors the work of the employees on projects and their participation in job trainings and educations. We have two data sources (JobDB and TrainingDB) which we integrate into a common SDV and PMDV database. This integrated DW/MDM further feeds the MDM and local DMs with relevant data. JobDB data source schema is describing employees, their bosses and projects they are currently working. TrainingDB data source schema also describes employees, but this time in the context of business trainings in which they participate and competences they achieve through them. SdvDB and PmdvDB databases integrate these two data sources into a single schema, through the use of Data Vault model. However, due to size restrictions, business case data models will not be shown in this paper.

B. Prototype description

Research prototype has been developed according to the business case examples and has been tested by running a set of queries against SDV, PMDV and MDV databases, as well as the original relational system catalog. Fig. 3 shows the architecture of a prototype. Corresponding to business case models shown in the previous section, there are two source databases (JobDB and TrainingDB) which are then integrated into a raw copy of the source data (SdvDB). A business and master PmdvDB is built and loaded from the SdvDB and it keeps “purified” data. The MdmDB is loaded from PmdvDB and it practically represents the MDM system which keeps the master data. In MdmDB the same data as in PmdvDB is stored, but organized according to a dimensional model - in the dimensional database. MdmDB is then the basis for loading the Dmdb, which is also based on a dimensional model and represents a local DM. This way, DW and MDM are integrated - MdmDB serves as the employee master data and the basis of loading the local DMs, and
has the ability to return ‘golden copy’ of employee master data back to data sources. The prototype (with all of its separate databases) is developed and implemented on the same Windows 10 Education x64 operating system and is made in Microsoft SQL Server 2012 [24] database management system using Microsoft SQL Server 2012 Integration Services (SSIS) and SQL Server data Tool for Visual Studio 2012 for extracting, loading and transforming the data between specific databases. To generate the data with which we initially loaded the source databases JobDB and TrainingDB, we used the web tool FreeDataGenerator [11].

C. Testing the sustainability of the integration

As we already stated, our main research question was “Can our new system catalog model serve to successfully integrate DW and MDM systems?”. We presume that the successful integration is a sustainable one – if a MDV model for integration is developed (which it is, shown in Fig. 2) and if: a) a new system catalog (MdvDB in the prototype) collects and stores historical meta-data about SdvDB and PmdvDB schema mappings, and b) queries defined over MdmDB and DmDB return the same results. In order to prove the integration was successful we developed and conducted two simple tests on a prototype: a) run a query on MdvDB system catalog that can return information about SdvDB and PmdvDB schema mappings, and b) run equivalent queries over MdmDB and DmDB that return the same results.

For the test A we developed 8 queries on the new MdvDB system catalog that return information on SdvDB and PmdvDB structures (hubs, links, satellites and attributes) and their mappings, as well as the mappings between data sources and SdvDB structures, or mappings between PmdvDB and MdmDB structures. Fig. 4 shows one of those queries – a query which serves to monitor the mappings and integration between base hubs in SdvDB and their corresponding master hubs in PmdvDB. This way we can monitor the transformations and the origin of master data, as well as structural changes (Change Type and LEDTS columns in Fig. 4). Fig. 5 shows the query that returns a similar information on the history of mappings between data sources’ tables and SdvDB hubs. All the queries that we have created and run by MdvDB system catalog successfully returned needed information on creation of PmdvDB structures from SdvDB structures, as well as the historical state of integration – thus we conclude the test A was successfully conducted.

For the test B we made a data change in the JobDB data source, but only after loading with start data all the databases in the prototype (SdvDB, PmdvDB, MdmDB and DmDB). An employee Desiree Farmer became Desiree Farmer-Matthews – we changed her last name. Then we propagated this data change to all the levels in the prototype architecture. Fig. 6 shows a pair of equivalent queries on both MdmDB and DmDB – queries that return the number of rows in Employee master table after the data change. We can see they have returned the same results. Fig. 7 shows the data state in the MdmDB and DmDB after the change. Two equivalent queries have been made on those databases and we can also see that the results are identical. From the results from test B (as well as test A) we have gotten the answer to our research question.
question – yes, it is possible to successfully integrate DW and MDM systems through the usage of a new system catalog and new DW/MDM system architecture.

V. CONCLUSION AND FUTURE WORK

In this paper we presented our research on a DW/MDM integration into one common business intelligence system. Seeing that the DW and MDM both integrate basically the same data sources and have the same evolution problem (preserving the history of data and structure), our goal was to integrate those two systems into one so we could in the future address the evolution problem at the common level. We have presented our MDV meta-model which serves to integrate those two systems and to provide the means for managing their evolution at a mutual level. In our proposed common solution, the data repository preserves the history of raw (DW) and master (MDM) data, as well as their schemas. Meta-data repository (i.e. system catalog) preserves the history of meta-data for the data repository. This way, the problem of the DW and the MDM evolution could be addressed at the general level and a permanent general solution on a meta-level could be developed. The end result could be a flexible, modular solution which will be able to track and manage changes in both data and metadata, as well as their schemas. In the paper we described our common integration architecture, which includes the new system catalog based on a Data Vault modelling method. We further described the integration part of underlying data model for the new system catalog and we presented our research prototype used for empirical validation of the sustainability of the proposed solution. Also, we described a couple of tests that we conducted in order to prove this kind of integration is possible and can be successfully deployed. These are also the main contributions of this paper. The benefits of this approach could be various, the least of all a development of a simpler common solution which can effectively manage data and schema evolution in both of those systems. The next step of our research is the main one – proving that the schema evolution problem can be solved more effortlessly and efficiently through the usage of our solution. In order to do so, we plan to define a final set of structural change cases, together with evolution operations and test them against the prototype, as well as the traditional RDBMS system catalog.

Sažetak - Većina podataka o elementima distribucijske mreže i postrojenjima pohranjena je u Geografskom informacijskom sustavu (GIS). Tehnički podaci o elementima mreže i podaci o njihovoj međusobnoj povezanosti postoje u GIS-u, a potrebni su kod proračuna distribucijske mreže i moraju se ponovno ručno unositi u aplikacije za proračune. Dolazi do nepotrebnih redundancija podataka i gubitka vremena kod unosa te kasnije kod održavanja podataka. U radu je opisano povezivanje dva sustava koji se praksi uglavnom rade nezavisno, a koriste isti fond podataka i bitni su za poslovno odlučivanje. Rezultati proračuna i analiza prezentirani su u GIS-u. Kao predstavnik GIS softvera korišten je Smallworld – DeGIS tvrtke General Electric, dok je kao aplikacija za proračune korišten Neplan tvrtke BCP (Busarello + Cott + Partner AG). U radu su prikazani koraci i kompromisi koje je trebalo poduzeti kako bi se navedene aplikacije povezale, te dobio jasan prikaz rezultata proračuna. Radi jednostavnije integracije sustava nužno se moraju koristiti propisani standardi, a preporuka je koristiti otvorene sustave.

I. UVOD

Električna energija predstavlja neophodan dio svakodnevnog života i često se zaboravlja kako bi bilo bez nje. Mnogo ljudi radi kako bi se osigurala sigurna, pouzdana i učinkovita proizvodnja, prijenos, distribucija i opskrba električne energije do krajnjeg kupca. Energetska sigurnost i klimatske promjene postaju sve veći prioritet u globalnim političkim programima i protežu se kroz sve sektore, te zauzimaju visoki prioritet među EU prioritetima. Kako bi zadovoljili više ulaznih varijabli i kontrolirali izlazne nužno je integrirati sustave.

U radu je opisana integracija Geografskog informacijskog sustava (GIS) i aplikacije za proračune, koji u praksi rade neovisno, a koriste isti fond podataka i bitni su za poslovno odlučivanje. Detaljniji opis dan je u radu [1]. Većina podataka o elementima mreže pohranjena je u GIS-u. Tehnički podaci o elementima mreže potrebni su kod proračuna i moraju se ponovno ručno unositi u aplikaciju za proračune. Dolazi do nepotrebnih redundancija podataka i gubitka vremena kod unosa, te kasnije kod održavanja podataka. Kako bi se ostvarilo povezivanje, potrebno je izvesti podatke iz GIS-a i uvesti u aplikaciju za proračune, izvršiti proračune i analize, te rezultate vratiti u bazu podataka GIS-a. Na taj način rezultati postaju dostupni širem broju korisnika, dobiva se na brzini i točnosti proračuna i analiza, koje su bitne u postupku kratkoročnog i dugoročnog planiranja, razvoja, investicija i održavanja, te se unapređuje gospodarenje distribucijskom mrežom.

II. OPĆENITO O DINAMIKU ELEKTRIČNE ENERGIJE

Djelatnost distribucije električne energije u Republici Hrvatskoj obavljaju tvrtka HEP Operator distribucijskog sustava d.o.o. (ODS) koja je članica HEP grupe. HEP ODS vodi brigu za pouzdanu opskrbu kupaca, prodaju, mjerenje i obračun isporučene električne energije, odgovoran je za održavanje, zamjene, rekonstrukcije i razvoj distribucijske mreže i postrojenja. Na području RH postoji 21 distribucijsko područje (DP) koji su sastavni dio ODS. Od 2016. godine HEP Elektra d.o.o. ovlåštena je za pružanje javne usluge opskrbe električnom energijom u Republici Hrvatskoj, dok je prije to ovlåštenje imao ODS. Od početka 2017. godine uveden je jedinstveni račun preko kojeg opskrbljivači naplaćuju mrežarinu za ODS.

III. GEOGRAFSKI INFORMACIONI SUSTAV

U početku informatizacije distribucijske djelatnosti tehnički i topološki podaci o elementima distribucijske mreže bili su upisivani u tehnički informacijski sustav (TIS). Energetski objekti imaju prostoru komponentu koja nije bila zastupljena u TIS-u, već se vodila na analognim podlogama. U želji da se analogna tehnička dokumentacija pohrani na računalno, grafički prezentira i atributno opise, pročelje uvođenja GIS-a.

Danas se u GIS unose elementi mreže i postrojenja svih naponskih razina, objekti infrastrukture, dokumentira se smještaj objekata u prostoru, a sustav omogućava topološko povezivanje energetski povezanih elemenata. Kroz topološku analizu uzima se u obzir položaj sklopnih aparata i dolazi do zaključka koji su kupci uz određena uklonjavaju stanja bez napona. U GIS se uvoze podaci iz drugih sustava i nakon toga dolazi problem održavanja podataka. Potrebno je dobro specifičirati i dokumentirati tko je zadužen za održavanje podataka i koji podaci se sinkroniziraju iz drugih sustava.

Velika količina podataka u GIS-u nije iskoristiva bez dnevnog održavanja podataka i korišćenja za donošenje poslovnog odlučivanja. GIS ima ugrađene alate za izradu raznih analiza i izvještaja koji se mogu dobiti na temelju pohranjenih podataka.

IV. PRORAČUNI I APLIKACIJE ZA PRORAČUNE

Za potrebe distribucije električne energije godinama su razvijene aplikacije za proračune koje se temelje na tehničkim podacima koji su sada pohranjeni u GIS-u. Uvažavajući postojeće situacije u ODS-u, moguća su dva puta u integraciji aplikacije za proračune i GIS-a:
- izrada aplikacija za proračune u GIS softveru,
- izvršiti nabavu kvalitetne aplikacije za proračune uvažavajući potrebe šireg aspekta djelovanja unutar ODS-a i povezati ih s GIS-om.

Trenutno se u ODS-u koriste aplikacije za proračune padova napona, tokova snaga i kratke spojeve (KS). Dio aplikacija radi s ciljem distribucijom mrežom (Neplan i Easy Power) dok dio radi samo sa srednjenaponskom (SN) mrežom. Za proračune niskonaponskih (NN) mreža koriste se posebne aplikacije poput NetCalc, NetLV, HPNNM, PowerCad (prije TOKSwin), WinDis, Nela. Podaci se ručno unose u aplikacije kod planiranja i projektiranja, a kasnije se ne održavaju niti se prati razvoj mreže.

U paketu novih sustava daljinskog vođenja (SDV) također postoje aplikacije za proračune (tokovi snaga i KS) koji se mogu izvoditi na aktivnoj mreži za potrebe upravljanja i neaktivnoj mreži za potrebe planiranja s aspekta upravljanja. Ostale službe nemaju pristup navedenoj aplikaciji.

Tehnički podaci o elementima mreže moraju se unositi i održavati u svakoj od navedenih aplikacija. Kako bi se to izbjeglo, potrebno je organizirati unosi i održavanje podataka u jedinstvenoj bazi podataka distribucijske mreže, iz koje operateri, preko sučelja aplikacije, dohvaćaju podatke koji su im potrebni. Jedinstvena baza podataka distribucijske mreže trenutno još ne postoji u HEP ODS-u, a u GIS-u se nalaze svi podaci potrebni za proračune električnih mreža.

V. INTEGRACIJA SUSTAVA U HEP ODS

Postojeći informacijski sustavi u ODS-u razvijani su na različitim platformama i u različitim vremenskim periodima, na različitim bazama podataka i od strane raznih izvođača. Isti sustavi razvijani su paralelno u više područja ili kupovani od različitih proizvođača.

Povezivanjem aplikacije za proračune i GIS dobivaju se rezultati proračuna i analiza koji su potrebni za uspješno vođenje poduzeća, ocjenu rezultata investicija i napretka, a olakšavaju odabir optimalnih investicija na temelju analize gubitaka i investicijske analize.

VI. OPIS SUSTAVA I APLIKACIJA ZA INTEGRACIJU

Da bi se informacijski sustavi mogli povezati nužno je imati uvid u modele podataka i objekata, način povezivanja, cilj povezivanja i koji su podaci potrebni kako bi se došlo do cilja.

Kao predstavnik GIS softvera korišten je Smallworld (SW) tvrtke General Electric (GE) s aplikativnom nadogradnjom DeGIS izrađenom od tvrtke Multisoft kroz koju su zastupljene sve specifične funkcionalnosti vezane uz distribucijsku mrežu.

Kao predstavnik aplikacije za proračune korišten je Neplan, tvrtke BCP (Busarello + Cott + Partner AG).

A. General Electric Smallworld - DeGIS

Od svoje osnovne namjene za geografsko kartiranje i atributno opisivanje elemenata GIS je danas sustav koji se koristi za planiranje, održavanje, praćenje kompletne energetske infrastrukture tokom cijelog životnog vijeka, pomoć u upravljanju mrežom, analize i proračune.

Prilikom definiranja modela baze podataka i modela mreže koji opisuju distribucijsku mrežu potrebno je znati koje se funkcije, analize i rezultati od sustava očekuju. Na temelju njih se definira ulazni skup atributnih, prostornih i topoloških podataka, te iskoriste postojeći podaci u drugim sustavima. Energetska mreža povezana je topološki preko postrojenja kroz sve naponske razine, te je na taj način povezana SN i NN mreža od izvora do krajnjeg kupca. Sama topologija još je dodatno definirana uklopom stanjima sklopnih uređaja.

SW - DeGIS posjeduje skup mrežnih analitičkih funkcija, kao što su primjerice: najkraći put, praćenje povezanosti i praćenje udaljenosti. Razna pravila mrežnog tragana mogu se definirati od strane korisnika. Rezultati mrežnog tragana mogu biti istaknuti u grafičkom prozoru, uvrušeni u različite izvještaje ili biti zajednički upravljani. Kod prebacivanja dijela podataka distribucijske mreže u Neplan koristi se funkcija praćenja povezanosti uz uvjet da se uzimaju elementi od mjesta odabira pa dalje u smjeru toka energije.

B. Neplan

Neplan je objektno orijentiran programski alat koji služi za proračune u infrastrukturnim instalacijama (električnim, plinskim i vodovodnim). Kroz rad će biti prezentiran dio mogućnosti Neplana za analizu električne mreže.

Od svih mogućnosti Neplana navedenih u [3], kroz proces integracije s GIS-om, u radu će biti prikazani proračun tokova snaga, proračun struje kratkog spoja, te određivanje optimalnog uklopnog stanja distribucijske mreže. Sve ostale mogućnosti mogu se koristiti na sličan način uz prethodno definiranje potrebnog skupa podataka. Cilj je rezultate proračuna vratiti u GIS i grafički ih

ASCII datoteka dozvoljava uvoz/izvoz svih:
- električnih parametara primarnih elemenata kao što su dionice vodova, transformatori, generatori, motori itd.
- podaci o opterećenju i mjerenjima kao predefinirani dijagrami opterećenja,
- tip i podešenja zaštitnih uređaja,
- harmonici struje i napona,
- kontrola podataka o struji (funkcijski blokovi).

GIS/SCADA sučelje je podržano od mnogo proizvođača GIS-a i to je ASCII datoteka koja sadrži samo osnovne informacije kao što je grafika, povezanost elemenata, stanje sklopnih uređaja, tip objekta i duljina voda. Tehnički podaci nalaze se u Neplan knjižnici. Mana ovog pristupa je da svaki puta treba prvo sinkronizirati podatke u knjižnici, a tek nakon toga uvesti mrežu.

U SQL bazi postoji definirani model podataka koji treba po određenim pravilima popuniti i iskoristiti za povezivanje. Koriste se tehnički podaci iz GIS-a, pa ne treba puniti knjižnicu. Nedostatak ovog pristupa je prijenos velike količine kataloških podataka.

Kao sučelje za povezivanje, u radu je korištena SQL baza, a kao uvod u nju kroz sljedeće poglavlje bit će prikazan transfer pomoću ASCII datoteke. Na slici 2 je prikazan model povezivanja. Kako je prethodno navedeno, ako se koristi SQL baza, u modelu povezivanja ne postoji “Neplan knjižnica” (označeno zelenom bojom).

![Slika 2 Model povezivanja GISa (SW - DeGIS) i aplikacije za proračune (Neplan)](image)

Sučeljem za povezivanje moguće je prebaciti:
- statički dio mreže, kao što su čvorovi, transformatori, dionice, sklopni uređaji i dr.
- dinamički dio mreže, stanje sklopnih uređenja, mjerenja, položaj regulacijske preklople na transformatoru.

Jasno je da su zahtjevi za dva prethodno navedena sučelja različiti. Prijenos statičkih podataka potrebno je provoditi nakon izgradnje novih ili promjena na postojećim energetskim objektima, pa to može biti u intervalima jednom tjedno do jednom mjesечно, dok se dinamički podaci mogu mijenjati svake sekunde, te je potrebno definirati periodičnost održavanja tih podataka.
Zahtjevi na sučelje za prijenos statičkog dijela mreže su sljedeći:
1. topološka povezanost mreže - mora biti prebačena,
2. stanje sklopnih uređaja - poželjno prebaciti,
3. naziv objekta mora biti jedinstven u aplikaciji, jednom definirano ime nije poželjno mijenjati,
4. grafička interpretacija objekata iz SW - DeGIS-a treba biti prebačena da bude pregledna u Neplanu (vizualno prihvatljiva za snalaženje),
5. varijante - poželjno prebaciti,
6. nekonzistentnost u varijantama mora biti otkrivena i informaciju o tome mora dobiti korisnik.

Koordinate elemenata u Neplanu nisu presudne za grafički prikaz ukoliko se Neplan koristi kao alat koji će izvršiti proračun i vratiti rezultate u bazu GIS-a, međutim u Neplanu su moguće dodatne analize i proračuni, rezultati kojih nema potrebe vraćati u GIS bazu. Iz navedenog razloga elemente uvezene iz GIS-a potrebno je pregledno rasporedivi. Moguće je u Neplanu zadržati koordinatni sustav elemenata iz GIS-a, ali se u tom slučaju gubi na preglednosti.

Prilikom vraćanja rezultata proračuna u GIS, koordinate elemenata nisu bitne već naziv objekta (ID) za koji su vezani.

Od dinamičkog dijela podataka prebacivat će se položaj regulacijske preklonke na energetskom transformatoru i ukupno stanje sklopnih uređaja.

D. Model podataka i mreže

Najjednostavnije je povezivanje „jedan objekt iz SW - DeGIS-a na jedan u Neplanu“, ali radi različitih modela to nije bilo u potpunosti izvedivo.

1) Model podataka i mreže u SW - DeGIS

SW - DeGIS baza realizirana je kroz geometrijske prostore, tako se osim nultog ili vanjskog geometrijskog prostora (mreža) mogu kreirati interni geometrijski prostori (postrojenje), koji predstavljaju jednopolne sheme. Kad vod ulazi u postrojenje on prelazi iz jednog geometrijskog prostora u drugi (prostor u prostoru). To znači da je interni geometrijski prostor trifastancije topološki povezan s vanjskim geometrijskim prostorom. Da bi to bilo moguće postoje poveznice između povezanih čvorista u svakom od geometrijskih prostora.

Objekti su topološki povezani i može se doći do informacija o povezanosti od izvora do krajnjeg kupca. Navedena topološka struktura potrebna je u i u Neplanu.

Model mreže u SW – DeGIS-u prikazan je na slici 3 gdje je vidljivo ponavljanje „geometrijski prostor 2“ koji predstavlja vanjski geometrijski prostor, a tu su objekti mreže, dok su ostali geometrijski prostori interni i predstavljaju postrojenja. Prikazana je i topološka povezanost energetskih objekata bez ukupnih stanja pojedinih sklopnih aparata.

2) Model podataka i mreže u Neplanu

Svaki element u Neplanu mora biti opisan s određenim minimumom tehničkih podataka kako bi se mogli vršiti određeni proračuni. Što je više tehničkih podataka o elementima uneseno, točnost proračuna je veća.

Topološke veze koje postoje u SW - DeGIS potrebne su i u Neplanu. Topološke veze moraju se nalaziti u bazi preko koje se vrši uvoz podataka u Neplan.

![Slika 3 Model NN i SN mreže u SW - DeGIS](image-url)

Mreža može biti nacrtana u više dijagrama koji se međusobno povezuju i predstavljaju ekvivalent geometrijskom prostoru u SW – DeGIS-u. Koordinate koje su u SW – DeGIS u Gauss-Krügerovoj projekciji, kod prebacivanja u Neplan, biti će množenke s faktorom (0,1) radi preglednosti prikaza. Kako je prikazano na slici 4 cijela VN, SN mreža, VN i SN postrojenja prebacuju se iz više geometrijskih prostora SW – DeGIS (slika 3) i prikazuju u jednom dijagramu - „dijagramu 1“ u Neplanu.

Povezne točke između dijagrama su objekti koji se s istim imenom (NAME) pojavljuju u oba dijagrama.

Cijela VN/SN mreža iz SW - DeGIS preslikavala se u Neplanu u jedan dijagram i završava sa SN sabirničnom trafostanice 10(20)/0,4kV. Postrojenje TS 10(20)/0,4kV i njezin NN rasplet mreže predstavlja novi dijagram.

U Neplanu postoji spoj (link). To je objekt koji povezuje objekt i čvorište, a nema tehničke karakteristike.
ka dionica. Nalazi se između transformatora i sabirnice, kako je prikazano na slici 4.

\[ \text{Slika 4 Model NN i SN mreže u Neplanu} \]

**E. Objekti i atributi**

Za svaki objekt koji je potreban za proračun potrebna je opis, podaci koji su za predmetni objekt potrebni u Neplanu, podaci koji postoje u SW - DeGIS-u i vrijednosti za podatke kojih nema u presjeku dvije baze, a koji su potrebni za proračune. Kod prebacivanja iz SW – DeGIS-a, u bazi za povezivanje, mora u svakoj tablici biti definiran primarni ključ (PK). U pravilu je on NAME za objekte, a ostali će biti detaljnije opisani kroz sljedeća poglavlja.

Ukoliko neki atribut postoji u bazi za povezivanje, a nije opisan kroz sljedeća poglavlja znači da nije obavran i ne utječe na prikaz podataka i proračuna koji se traže. U oba sustava postoje atributi koji opisuju objekte u sustavu (opći) i atributi koji opisuju taj objekt.

**F. Rezultati integracije sustava**

Kako je funkcionalnost sustava najjednostavnije prezentirati na konkretnom primjeru, izvučen je manji opseg mreže, radi ograničenog prostora za prikaz, te su kroz sljedeće slike i tablice prezentirani rezultati povezivanja, proračuna i analize. Izvor u distribucijskoj mreži, koji nadomještala višenaponsku mrežu (aktivna mreža) smješten je na 35kV sabirnicu u dvije TS 35/10kV.

Slika 5 Forma za odabir objekata koji idu iz SW - DeGIS u Neplan

Nakon uvoza u Neplan na mreži napajanom iz TS 35/10 kV izvršeni su proračuni. Budući da postojeća mreža zadovoljava sve postavljene uvjete nema dijelova označenih crvenom bojom.

Očuvanje egzistencije rezultata proračuna s podacima iz SW - DeGIS ostvaruje se stvaranjem kontrolne točke (check point) tokom izvoza podataka i provjerom istog kod vraćanja rezultata. Kod izvoza podataka stvara se kontrolna točka imena "export neplan" kojoj se pridjeljuju datum i vrijeme izvoza, a isto vrijeme je upisano u MS Access bazu za povezivanje. Kod vraćanja rezultata, izvor rezultata također treba sadržavati vrijeme izvoza iz SW – DeGIS-a. Procedura za uvoz provjerava da li je došlo do promjena u verziji iz koje su podaci izvezani. Problemi se javljaju u SW – DeGIS ako se obriše objekt ili kreira novi koji mijenja postojeću topologiju i tada nije moguće vraćanje rezultata, već treba ponoviti proces.

Rezultati proračuna u SW – DeGIS prikazani su tablicama na slici 6 i na njima su moguće dodatne analize i upiti, te njihov grafički prikaz.
učinkovit pogon distribucijske mreže, potrebno je provesti kvalitetne analize mogućnosti prihvata pojedinog DI. Potrebno je u proračun uzeti utjecaji na cijelu mrežu i mreže na DI, a ne parcialno na području gdje se DI priključuje. Svaki takav proračun je vremenski zahtijevan i zahtijeva pripremu podataka o mreži i unos u aplikacije za proračune. Integracijom prikazanom kroz rad postupak se maksimalno skraćuje i brzo dobivaju kvalitetni podaci, značajno se smanjuje mogućnost pogrešaka kod unosa u aplikaciju za proračune, te izrada vaču elaborata i studija ostaje vremena za kvalitetniju analizu problema.

DI u distribucijskoj mreži postavljaju pred ODS nove zahtjeve s aspekta zaštite i održavanja. Prilikom zahvata u mreži koordinatori radova moraju imati podatak o smještaju takvog izvora u mreži. Ukoliko je DI u SN mreži, taj podatak se nalazi u SDV i GIS-u, a ako je u NN mreži samo u GIS-u. Svi DP-i dans imaju GIS tako da je navedene podatke lakše održavati i distribuirati korisnicima kojima su potrebni.

VII. ZAKLJUČAK

Podaci o distribucijskoj mreži moraju biti ažurni, dostupni korisnicima i aplikacijama kako bi se omogućio uvid u analize, proračune i donosile dobre poslovne odluke od priprema investicija, preko izgradnje, upravljanja i održavanja u distribucijskom mrežu na obostanozadovoljstvo investitora i korisnika.

Potreba za istim podacima postoji u raznim slučajima ODS-a, a njihovo prikupljanje i unos vrši se nekoliko puta. Takav primjer su aplikacije za proračune koje rade neovisno od GIS-a i potrebno je ponovno vršiti unos istih podataka, te ih kasnije ažurirati na dva mjesta. Navedene aktivnosti dovode do redundancije podataka i povećavaju mogućnost pogrešnog unosa podataka, a navedeno se može izbjegati opisanim povezivanjem sustava i aplikacija. Budući da objekti nisu u oba sustava jednako modelirani, dolazi do problema kod komunikacije i interpretacije rezultata. Rezultati proračuna uvezeni su u GIS i grafički prezentirani uz pripadni objekt u prostoru.

Kako bi se kvalitetnije upravljalo svim naponskim nivoima i donosile kvalitetne odluke potrebno je povezati podatke iz postojećih sustava, izvršiti proračune s postojećim podacima i dobiti rezultate proračuna u sustavu gdje ih se najbolje može prezentirati, a to je GIS.

Ukoliko se povezuju tri i više sustava ili aplikacije potrebno je formirati „jedinstvenu bazu podataka distribucijske mreže“ iz koje preko sučelja aplikacije dohvaćaju podatke koji su im potrebni i vraćaju rezultate koji su potrebni ostalim sustavima ili aplikacionima. Povezivanje se vrši preko „sabirnice podataka“ uz pridržavanje standarda i preporuka kako je prikazano u radu [2].

Jedinstveni rezultati proračuna i analiza trebaju poslužiti kao izvještaj kako unaprijediti upravljanje, razvoj i investicije u mreži, te moraju biti dostupni širem broju korisnika. U HEP ODS-u izrađena je aplikacija za proračune tokove snaga i padove napona unutar DeGIS-a. Potrebno je povezati i sve ostale aplikacije koje nužno moraju razmjenjivati podatke kako bi se povećala učinkovitost sustava.

Abstract – The paper explores legal, economic, human rights and social aspects permanent life care contracts in Croatia, by which the provider of support becomes the owner of receiver’s property. Monitoring of such contracts is rendered ineffective due to incapacity and old age of one party to the contract and lack of close persons and relatives involved; thus, different unethical situations may arise, such as people not receiving the support and nevertheless being evicted or moved away from their homes. This, however, harms their human rights and is unacceptable in a social sense in developed liberal democracies. One possible solution in a strictly legal sense would be to amend the Obligations Act, and create a registry that would be available to interested persons, bearing in mind that those are essentially contracts of private law and thus not subject to public or administrative law. Thus the utilisation of distributed public governance and involvement of NGOs in the protection of human rights would be limited. On the other hand, in a purely economic sense, another solution could be the introduction of new types of insurance that would pit the life care provider against an insurance company, such as in ‘longevity’ or ‘reverse life’ insurance, and the introduction of an online solution for reverse mortgages and life care contracts (agreements).

I. INTRODUCTION

In the past two decades, the theory and practice of public service and public policy has been determined by two reform waves: the new public management (NPM) that promoted increasing the efficiency and effectiveness of executive government and public bodies, with the stress upon performance and service. The improvement was determined by the measurement of outputs and results (e.g. in Management by Results), which has resulted in deviation of traditional management by planning and clear division of tasks (inputs). In traditional government, provision of public services was enacted primarily through public bodies and public corporations, and NPM has promoted organisational models based on market and delegation of public authority on private entities operating on markets.[7] The other two reform models, new public governance and neoweberian state have shown different attitudes in terms of system, organisation, individual and central mechanisms of governance, as well as the role of state (e.g., executive director in the neoweberian state, inspector in NPM, and moderator in NPG)[3]. Within the system of social care, different reform models have been subject to such reforms, where some development was inspired by the ideas of NPM, e.g. decentralisation and subcontracting, that was added to the traditional dominance of public sector, which is clearly visible in the provision of service of housing for elderly citizens and persons with invalidity. Within the scope of reforms inspired by new public governance models, transparency empowers citizens by providing better and better quality information, thereby reducing the problem of information asymmetry between government and citizens. Transparency enables ex ante and ex post control of public bodies, preventing corruption and malversations that could multiply under the veil of secrecy. Equality and equal rights are also increased, especially in the situations where moral hazard is likely, that is, when there is a possibility of exploiting some vulnerable group or part of general population. The role of NGOs in such control can also be important, especially on the local level, when it can become further developed into a new model known in literature as distributed public governance[8], which is based on independent agencies, which in the case of social care would naturally be social care centers and alike[2]. The issue of life care agreements or permanent life support contracts for elderly citizens is highly controversial in many countries, including Croatia. The problem of the increasing number of elderly citizens without sufficient retirement savings and no relatives or children that are able to care for them may be resolved by tapping into the equity of the property they live in, such as a house or an apartment. However, in some countries, such as the US, the model used is essentially based on insurance policies, financial institutions and - which is not always immediately apparent - loans, which means that it includes interest rates, and if the person happens to live longer than the loan provided by the bank, it may foreclose and terminate the contract while the occupant is still alive in order to preserve its interests. In Croatia this legal situation is regulated by so called permanent life support contracts ‘until death’ or ‘during lifetime’, by which the provider of support may become the legal owner upon signature of the contract or after the death of the other parties to the contract (such as husband and wife). Monitoring of such contracts is ineffective due to incapacity and old age of one party to the contract and lack of close persons and relatives involved; thus, different unethical situations may arise, such as people not receiving the support and nevertheless being evicted or moved away from their homes. The Ombudsman of the Republic of Croatia proposed, therefore, in 2015, that an electronic database of such contracts should be maintained.
in order to increase transparency and monitor certain situations, such as when a single support provider takes care of several - 10 or even more - receivers of support, going after the property of the other parties to such contracts. Such database is, indeed, maintained by the City of Zagreb, but not many other local government units. As the issue has its economic, legal, as well as human rights side, it is analysed from all those perspectives in order to arrive to the optimum solution to the problem, that can satisfy both the support providers and receivers, and in our opinion such a solution makes use of ICTs and distributed public governance, allowing better control of the execution of all permanent life support contracts by interested parties, as well as better resolution of controversial situations that may arise during the execution of the contracts (non-provision of services or insufficient amount of compensation due to low value of the property or the longevity of the support receiver(s)).

II. METHODOLOGY

We analyse the legal framework of the contracts, and changes that may be necessary to enable better monitoring of life care contracts by interested parties, but also the economic incentives behind the outcomes that appear to be detrimental to human rights and to social development in a strictly social sense that pays attention to intergenerational solidarity, equal rights and prevention of criminality or illegal enrichment. We argue that the solution to the problem should be both legal and economic, resulting as a combination of activities of both government, NGO and private sectors in enabling better monitoring of the solution and a tighter-knit society that cares about social and economic values as much as human rights of the elderly as such. In order to prove the hypothesis we construct a model of distributed public governance for life care contracts on the basis of N life care receivers and n life care providers, where n should be limited and determined on the basis of actual economic and physical strenght of the life care provider, thus preventing situations in which a small number of providers takes care of a large number of receivers with properties, which can be shown to be financially untenable. By introducing a third party, such as an NGO wishing to monitor contracts or provide support, the final outcome may be shown to improve. It is then suggested that further improvement may be achieved by creating adequate economic motivation for the life care providers to increase the longevity of life care receivers by introducing a private party – an insurance company – into the scheme, which would pit the interests of the life care providers against a longevity or reverse life insurance policy, that in our hypothesis may be shown to further improve the outcomes for the life care receivers, enabling them to live longer and better lives in their properties. Finally, we elaborate whether an online solution could further improve the situation with life care agreements.

III. LEGAL AND ECONOMIC ANALYSIS

A. Legal framework

The legal framework of the contracts and the proposed distributed public governance thereof is essentially the Obligations Act (Zakon o obaveznim odnosima – ZOO), Family Act (Obiteljski zakon - OZ), Social Service Act (Zakon o socijalnoj skrbi - ZSS) and Freedom of Information Act (Zakon o pravu na pristup informacija – ZPPI). The article 580 of the Obligations Act provides that the lifelong care contract must be made in a written form and that it must be verified by the competent court or solemnized by a public notary and that parties to the contract shall be notified about the significance and consequences of the contract by a responsible person. The proposed modifications of the Obligations Act that would enable the creation of a Database or a Registry are as follows: 1) the center for social care should determine for contracts made under its the territorial jurisdiction the social background of the life care recipient and it should be made an integral part of the contract; 2) the number of contracts should be limited to the maximum of two contracts per life care provider, which should provide a written statement about the number of contracts; 3) there should be a Registrar of the contracts including the parties, the date of the conclusion of the contract and the property involved; the Registrar should be managed by the Center for social care in the territorial jurisdiction of the contract; 4) all contracts made by government social care providers should be made null and void; 5) the care provider should supply the confirmation of not being charged with criminal offenses relative to property, life or body; 6) lawsuits should be declared urgent and a decision by the court should be taken within 6 months from the day of initiating the judicial procedure. Each year roughly 2000 persons complain to the Retirees’ Union, and the most difficult situations arise from the contracts 'until death' where the care provider legally becomes the owner of care recpient's property upon signature of the contracte, i.e., while they are still living.

B. Economic incentives

It may be shown that economic incentives for life care providers amount to seizing the property of the other party to the contract while at the same time minimizing the amount of resources spent on life care provision. In the case of contracts 'until death', this is especially apparent, as the life care providers become legal owners of the properties upon signature of the contract, which enables them to evict the other party immediately and exploit the property while cutting costs on life care as much as possible. On the other hand, contracts 'during lifetime' appear to provide some guarantee to the receivers, as the property can not be legally seized while they are still alive. However, due to their incapacity to effectively contest the contract or conduct a lawsuit the other party can usually easily get away with reducing the duration of their stay in the property, and consequently also the their longevity, or duration of their lives and quality of those lives. It may, however, be said in favor of service providers that they have no guarantee of the longevity of the other party, or that their involvement makes economic sense. In case of extreme longevity, the equity of the property may not cover the resources invested by the life care provider, which may result in their losses. The right incentives should increase the duration of life of receivers in their properties, while reducing losses to providers and
motivating them financially to endure as long lifespans of their receivers as possible.

IV. PROPOSED SOLUTIONS – DISTRIBUTED PUBLIC GOVERNANCE AND LIFE CARE LONGEVITY INSURANCE

A. Distributed public governance

Within the framework of the distributed public governance, it may be possible to achieve better control of those essentially private contracts without the interference of the government bodies, such as the Centers for social care or local government units. In this scheme, the NGOs protecting human rights or associations of interested parties (such as Retirees' Union) would be able to inspect the Registrar of the contracts and provide legal services pro bono.

B. Life care longevity insurance

Only legal action and better form of governance might not work without creating the right kind of economic incentive to increase the desired behaviour. This in turn means acting upon what has become essentially a market (but illegal, or in the 'grey' zone) of life care providers and care recipients. This may be achieved by introducing an instrument of life care longevity insurance, that may at first be provided by a private or public insurance company, operating according to the strict rules and verified by the government. In that case the certified life care providers or private companies registered for such services would be motivated to increase the life span of their recipients by economic incentives or desire to collect the insurance premium, that would, however, be paid in installments. They would, however, be legally required to pay to the insurance company the required amount for the life care longevity assurance policy, which would serve as a guarantee against the life span of the care recipient(s) exceeding the value of their property.

The first solution is proposed by the Retirees' Union of Croatia, and it can be described as a solution to what is essentially a problem of assymmetric information in game theory and agency theory. The service recipient acts as principal, trying to find an agent that would provide optimum service at the least cost or at affordable cost. Due to assymmetric information about the agent, the principal in this case is not able to control for the risk involved, and on the other hand it appears to be a special problem of utility of both principal and agent, as both parties incur risks – the first one in terms of reliability of the agent and the quality of service which is translated into his quality of life and the second in terms of the longevity of the principal and the financial investment required to cover the financial burden of the service. They appear to be in a particular game theoretical situation which operates according to the scheme of 'coward game' in which parties have in incentive to cheat: the principal's interest is to cheat about his health and potential longevity, and the agent's interest is to cheat about the quality of the service and the reliability of the provision of service regardless of the cost. As there is no possibility of enforcing the contract, the game becomes necessarily uncooperative. The equilibrium (Nash) of this game is actually the one in which the agent provides the least service possible, in order to further reduce the ability of the principal to control the provision of the service, and to try to appropriate the property to himself as quickly as possible, further reducing the costs to get premium at the minimum investment (Table 1)

<table>
<thead>
<tr>
<th>Service recipient</th>
<th>Service provider respects contract</th>
<th>Service provider defaults on contr.</th>
</tr>
</thead>
<tbody>
<tr>
<td>dies in time</td>
<td>(cooperative)</td>

<td>2, 4 P, N</td>
</tr>
<tr>
<td>lives longer</td>
<td>4, 2 P, N</td>
<td>1, 1</td>
</tr>
</tbody>
</table>

However, in reality this is not completely accurate, as the service recipient is not in full control of its life, that is, it is always possible that the knowledge of his or her longevity is obscured and (s)he might not live as long as hoped. Thus, the game is assymmetric, as the players do not have the same distribution of power – the power of service provider is greater than the power of the service recipient, because the provision or non-provision of the service can impact the ability of the service recipient to live longer than expected. This could be modeled as an assymmetric dove and hawk game (Table 2)

<table>
<thead>

</tr>
</tbody>
</table>

Source: Forte, 1996: 159

The goal would thus be to create such conditions that would stimulate cooperative behaviour and also avoid Nash equilibrium in which there is a suboptimal solution for both players. The situation could be comparable to the reverse loans by some loan shark trying to maximize the returns by increasing the interest as much as possible, in the situation where the loan seeker is risk prone and not risk averse, due to urgent needs for financing his
survival; in this opposite situation, the care recipient is also risk prone and in the need of survival, so (s)he is prepared to accept disadvantageous condition of service provision, such as higher interest rates that are spread over a longer time span where the principal of the loan takes longer to be paid and the service provider acts as a loan shark, that instead of increasing the interest or trying to get the loan recipient into a situation where (s)he has to default, which means obtaining the collateral for the loan shark, instead tries to reduce the amount of financing for the service and duration of the service needed to obtain the collateral (property into which the service recipient has 'tapped' in order to obtain the financing of the service). The first solution proposed tries to create safeguards by installing a new agent in the system, that is motivated by 'ethical' or moral incentives, or that simply has some interest in the longevity and quality of life or property of the service recipient, that would effectively 'check' the service provision or be able to conduct a lawsuit on behalf of the service recipient that has lost this ability due to old age. Another problem could be the dislocation of the place of the contract conclusion into another district, so it could be effectively checked by an organisation of agents from different districts able to check the situation on different courts via a Registrar of contracts. They would also be able to check the reliability or quality of the service provider (penal records) or other facts about service providers, perhaps more effectively and efficiently than the government offices. However, this solution may not create sufficient incentives in those agents, in case there is no market and better transparency of the contracts, which could lead to just another 'vulture' trying to feed on the property of the service recipient. The more effective and efficient solution would, in my opinion, involve the creation of an actual market of such services and properties involved, which could then be entered into a registrar as well. The service providers would have to check into the registrar and prove their ability (financial and material) to support a service recipient with life care; in case they are able to prove it, more than two contracts could be allowed per single life care provider. However, this would also mean a complete transparency of the contracts, service providers' businesses and service recipients' properties not only on the level of social care centers, but also at the level of local government. In that case it would constitute a local market in which all registered service providers could participate.

It becomes apparent that the first solution is based on almost socialdemocratic principles with very little liberalism involved, the situation as is now is actually a poorly hidden libertarian solution in which one party renounces some of its human rights through a contract with another party (almost as in slavery), and the final solution introduces liberal elements back with some elements of good governance and collaborative governance of all three sectors (private, public, NGO). In this final case, human rights of the service recipients would be preserved by creating right incentives on the market. The first incentive should be that all parties have interest in increasing the quality of life of service recipients regardless of financial burden and the second would mean that they also have incentive to increase the longevity of the service recipients. The first incentive could be achieved through transparency and distributed public governance combined with competition on an open market, that would reduce the asymmetry of information and improve the control over the agent, and the second could be achieved by creating a premium through reverse life insurance, a competitive insurance market, that would be profitable both to the insurance companies, as well as to the service providers and service recipients. In that case, however, the incentives (or a game equilibrium) would be balanced in such a way that actually increases the quality of life and longevity of service recipients, also reducing the gains of the service providers and introducing some gains for insurance companies, but due to competitive nature of the market, service providers and insurance companies would still be sufficiently motivated to compete stay in business, which can be modeled as a symetric game of hawk and dove, both players trying to grab as much as possible (Table 3).

Table 3 – life care game between insurance company and service provider – symetric hawk and dove game

<table>
<thead>
<tr>
<th>Service provider respects contract (cooperative)</th>
<th>Service provider defaults on contr. (uncooperative)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Insurance company pays (cooperative)</td>

<td>2, 0</td>
</tr>
<tr>
<td></td>
<td>0, 2</td>
</tr>
<tr>
<td></td>
<td>-1, -1</td>
</tr>
</tbody>
</table>

The main problem is the cost of the operation of insurance companies, which could be covered by useful employment of property taxes (which are currently not in use in Croatia, and are generally 1-3% in EU states). In that case, the game between the service provider and service recipient would be reduced to the Prisoner's dilemma (Table 4).

V. PROPOSAL OF AN ONLINE SOLUTION FOR THE PROBLEM OF REVERSE MORTGAGE LIFE CARE CONTRACTS

It has been shown that in a life care game between a service provider and an insurance company, the outcome for the service recipient would be better than in a game that is played between him/her and the service provider alone. However, the problem of moral hazard still exists, as it would be possible to form a collusion between service providers and insurance companies, in order to divide the proceeds at the expense of the service recipient. This could be countered by making this market transparent and open, in a way that has been already considered for foreclosed properties. In case an online database of reverse mortgages is managed by a governmental institution (e.g. FINA), the problem would remain, but in case of an open market with a government regulator and competing companies, the problem of moral hazard could be reduced, if not avoided. The life care agreements should thus be governed by a new obligations law, obliging parties to a public display of contracts, in a similar way it has already been made possible for ownership (civil court registrar of properties, 'gruntovnica') and cadastre. It is, in fact, already possible to research online databases of property ownership of civil courts in Croatia and find notes (zabilježba) of life care contracts and properties that are being used as collateral. However, in its current form, it is not possible to search the property database by name or contract, in order to find out which properties are used for life care agreements and who are the contracting parties. With an online solution, this information would be made available to interested parties and stakeholders at a price or free of charge. According to Directive 2003/98/EC about the reuse of the public sector information and Access to Information Act (OJ 25/2013), private companies can use government data and a prospective database of life care agreements and reverse mortgages for their own online solutions, which would also foster cross sector collaboration, public trust and increase transparency and openness, effectively preventing fraud.

VI. CONCLUSION

On the basis of available data, legal framework analysis and economic analysis of the problem, we may conclude that there aren't any straightforward solutions to the problem of life care contracts in Croatia. Regulation of the market and making information about the life care recipients available via a public database or a registry would alleviate some of the problems of the interested parties wishing to contest life care agreements and their execution by life care providers, but economic incentives through the market forces may also be necessary to effect durable change and improve the outcomes in social and human rights terms. Thus, it may also be necessary to create legal framework that would support the development of reverse life insurance or so called longevity insurance that would also create incentives for care providers to increase the longevity of the care recipients, and at the same time increase the incentives of insurance companies to monitor the care providers, in case they want to seize the property without paying up to the promises in their life care contracts. This may include the option of paying longevity insurance in installments to life care providers in case of unusually long life of life care recipients, but also the possibility of demanding the full amount of the premium from the life care provider to be payed to the life care recipient in case they are removed from their property, thus releasing the liability on the part of insurance company, or the possibility of insurance company seizing the property or establishing mortgage rights on the property. Creating that sort of safety net would reduce risk proneness on the part of care recipients, and they would revert to a normal, risk-averse attitude, thereby preventing unethical life care providers to from profiting on the lack of their risk aversion. However, this would not solve the problem of possible moral hazard or collusion between service providers and insurance companies. In order to solve this, an online solution similar to a register of foreclosed properties would reduce, if not completely avoid moral hazard. The contracting parties would thus be obliged to agree to online publication of their contracts in a register that would be available free of charge or at a price to interested parties. Involving a central government agency, such as FINA in such a solution, without making it possible for private companies to offer similar solutions could possible create another problem of moral hazard and reduce market freedoms, without a specific gain for either service providers or service recipients.

Abstract - How smart is a 'smart city'? According to Asian examples of newly growing smart cities, usage of technology can improve life standard and reduce cost of living, improve operational efficiency, environmental sustainability, eco-friendly infrastructure, smart technology Internet of Things (IoT), smart living and direct citizen participation in decision making process. Learning, adaptation and innovation could be the future for Croatian cities by using all mentioned, which will improve social, regulatory and safety indicators for designing a better living environment for Croatian citizens. While using Public Private Partnership (PPP) models, crowdsourcing and democratic ecologies which provide better and more efficient public services by taking advantage of private sector's "know-how", cities will create long-term investment opportunities and sustain real time optimization strategies by providing safe and reliable place to invest. The intention of this paper is to show how the (local) government’s role in PPP projects is to evaluate and approve detailed execution plans of the concessionaire while the private partner’s role is to design, build, finance, and operate the facilities. In futuro, digital technologies offer numerous possibilities for citizen participation in decision making at local and regional government level.

The key words: Internet of Things, smart city, Public Private Partnership, concession models, public procurement, decision making.

I. INTRODUCTION

A common definition of a 'smart city' has not yet been determined. Many authors use various definitions to clarify what is a 'smart city'. Authors define it as a city that bets a lot on the quality of living and where the citizens are involved as main actors in decision processes [1]. At the beginning of an attempt to define a smart city, we should start by pondering upon cities and systems which operate in them. Cities have a duty to fulfill the needs of their citizens through various systems. The types of systems are by no means exhaustive, but certainly include public services such as light management, traffic and transport organization, waste and water management, administration policies, security, energy sustainability and information services. Regular cities operate and supervise every system as a separate unit, which in return produces more costs for taxpayers with slight to no improvements in the quality of living. On the contrary, 'smart cities' use Information and Communications Technologies (ICT) with Internet of Things (IoT), to create connections and interactions between some or all the systems, cutting expenses and improving the quality of life for citizens during the process.

We believe that a 'smart city' is a city where investments are focused towards smart citizens who use renewable energy resources wisely and widespread technological networks to combine sustainable economic growth whilst improving the quality of life, through the open government model by the interaction of all stakeholders. Regarding future, Croatian 'smart cities' use of renewable sources of energy, ICT and sustainability combined with usage of Public Private Partnerships (PPP) is a crucial model which could easily adapt to Croatian legislation and Croatian way of living.

In terms of innovation and quality of living a set of indicators, such as: air quality, water, greens, waste handling, energy consumption health issues, urban mobility and logistics should be analyzed. Also, the key features of the 'smart city' are: smart governance, smart mobility and smart energy as an educational and communicational tool for opinions of the citizens, the technology supporting the Social Networks like YouTube, Facebook, Twitter and others can be employed when influencing political decisions including functions in cities, urban spaces, water, waste, in one word living [2].

The aim of this paper is to set forth in which direction should Croatian cities advance in the near future, according to the successful models of smart cities worldwide, and implementation of PPP models for building smart cities in Croatia. Furthermore, the paper will recommend improvements of current legislation towards an open government.

II. DEVELOPING SMART CITIES

Today is the age of technological revolutions! Technology and science have brought many conveniences to the citizens of the world, most of which we are not even aware of. The idea of a 'smart city' has drawn
governments’ attention, especially in South Korea, Japan, India and China. They believe that ‘smart cities’ could bring more benefits to their citizens.

Cities around the world are facing the impact of series of emerging megatrends like accelerating urbanization, new technological developments, increased connectivity, demographic shifts, climate change, scarcity of natural resources and many more changes. But so, has the need for cities and regions to collaborate on global issues like climate change and public safety. In this context, it has become important for a city to understand its national, regional and global position. This enables the city and its stakeholders to set appropriate policies, develop an effective strategy and plan for actions accordingly, all aimed at the sustainable development of the city [3].

According to the research conducted by the United Nations in 2014 more people live in urban areas than in rural areas globally. As stated in Figure 1 below, in 1950, 70% of people worldwide lived in rural settlements and less than 30% in urban settlements. In 2014, 54% of the world’s population is urban. The urban population is expected to continually grow, so by 2050, the world will be 1/3 rural and 2/3 urban, roughly the population will reverse in comparison to what we had during the 1950s. Europe already consists of 73% of its population living in urban areas. The United Nations’ research predicts that over 80% of Europe’s population will be living in urban areas by 2050. [4]

Development of ‘smart cities’ requires continuous and joint effort of all participants in the process. Urban stakeholders include governments, scientific institutes, companies, citizens and NGOs who innovate together to up the quality of life of the ‘smart cities’. However, the connection between citizens, technologists, and urbanists is not strong enough. In order to improve the current urban settings Croatia needs to design a pattern to develop a universal platform between stakeholders on a local level.

Many corporations and investors assume that fixing cities is the purview of government, and that the government will proceed in that manner. But governments around the world are stuck—financially, politically, or even both. They can’t rely to single-handedly address the problems of urbanization or to start solutions, such as efficient electrification and reliable public transport which will instantly drive economic growth. By implementing those solutions large amounts of capital, exceptional managerial skill, and significant alignment of interests—all of which are often in short supply in city governments but abound in the private sector are required. That is the main reason that South Korean ‘smart cities’ like Songdo (the city built on reclaimed land) [5] used PPPs to define infrastructure types, and the roles of public and private parties when they were looking and arranging the means and ways for financing ‘smart cities’.

III. THE HOWS AND THE WHYS TO BUILD A ‘SMART CITY’

A. Financial support

The Smart City industry is growing constantly, and it’s predicted to be worth more than 20 billion dollars by 2020, while the annual global Smart City revenue is expected to reach 88.7 billion dollars by 2025. [6] In the Asian countries, funding of ‘smart cities’ have been conducted through government incentives, local subsidies and private entrepreneurship projects.1

As for Croatia, the possibilities are more diverse; other than national and local subsidies, there are European Structural and Cohesion Funds. The European Union (EU) is encouraging Member States to develop smart cities by allocating 365 million euros for this purpose. [7] Also the EU brought new financial instruments supporting environmental and climate action projects from which, cities can withdraw the funds. They include: the Financial Instrument for the Environment and Climate Action (LIFE) Programme, Horizon 2020 and Intelligent Energy Europe (IEE).

Barcelona and Amsterdam developed systems by which citizens and companies can interact on solving key city issues with ‘smart’ solutions. Barcelona’s project "BCN Open Challenge" set out six challenges for businesses and entrepreneurs to provide solutions for transforming public spaces and services. The city government sought to procure innovative solutions, support winning companies and validate projects. Winning solutions were provided with public service contracts to fulfill their solutions. [8]

B. Government’s role in the PPP projects in the ‘smart cities’ development

In the local governments sequence of events in the development of ‘smart cities’ largely depends on the mayors. If they are willing to promote sustainability, then it becomes the priority, and some of these categories of sustainability include: transportation, utilities, electricity, thermal energy, renewable energy and others. The point is; after the establishment of the ‘smart grid’, infrastructure will significantly reduce the environmental impact of the whole electricity supply system. The goal is a holistic

1 For example, IBM provides cities around the world with grants of IBM expertise and technology which will aid cities with their strategic challenges. To find out more: https://www.smartercitieschallenge.org/
approach in which all the processes are conducted by applying IoT (Internet of things) technology and application of VTV (Vehicle to Vehicle), intelligent transport systems. It’s expected a real-time optimization of traffic routes, traffic on the roads and to allow easy selection of different modes of transport and measure the effectiveness of the current system of distribution of energy available at any time on any smartphone app. E.g., in how much time does the tram or bus arrive or in which street is lesser traffic, how much moisture is in the air, what is the current outdoor or indoor temperature, CO₂ and other pollutants level? Possibility for a new clean mobility solutions that complement bicycling and public transport and the application of VTV intelligent transport systems; communications are expected within real-time optimization of traffic routes, traffic on the roads, by simply choosing between different modes of transport.

The possibility of cooperation between the public and private sector (PPP) - (following the example of South Korea’s Songo and other smart cities of Asia), which opens the possibility for withdrawal of additional funds from the EU Structural and Cohesion funds. When speaking of Croatia, investing in innovative strategies improve the efficiency, savings and promote the development of the real sector. For such operations, it’s necessary for local governments to reduce utility fees in order to encourage the construction of smart infrastructure and significant energy savings, reduction of municipal fees and increase incentives for small and medium-sized enterprises (SMEs).

As one of Europe’s examples of a proactive and ‘smart city’ oriented government - Amsterdam appointed a Chief Technology Officer (CTO) for the city. Also, they founded the Amsterdam Metropolitan Solutions (AMS) as an institute focused on applied technology. It’s built by a consortium of public and private partners. AMS aims to attract and retain talent in the field of applied technology, create sustainable connections, drive a positive economic impact for Amsterdam by innovating, developing and marketing metropolitan solutions in urban themes such as water, energy, waste, food, data and mobility. In addition, their Amsterdam Smart City [9] is an online platform which connects all interested parties in one goal: dealing with ‘smart city’ problems and solutions. [10]

C. Benefits

Smart cities aim to improve the functioning infrastructure, access to resources, and safety and security for the population [11]. The European Commission tells us that: in ‘smart cities’, digital technologies translate into better public services for citizens, better use of resources and less impact on the environment [14]. Figure 2 shows an independent and symbiotic energy management system in which the value is expanded by the next generation energy use, where the residents and city itself cooperate in conservation of renewable energy resources.

There are some small changes that can save huge amounts of energy, and it can be obtained when for instance active measures (building automation systems) and passive measure (low energy bulbs) are used constantly, furthermore, some European countries like Italy have already implemented mentioned measures and the savings in thermal consumptions for heating and cooling can bring up to 26% [2].

Sustainable strategies application should already start today since those will increase energy efficiency in the next half century. Some of the most effective models of combining the PPP in order to develop smart cities in Asia (Songo, Seoul, Fujisawa) and the EU (Barcelona, Amsterdam, Vienna) have already benefit from the implementation of ‘smart city’ strategies. Barcelona saved $58 million annually using smart water technology, and the city has increased parking-fee revenues by $50 million annually utilizing smart parking technology. The government also stated that Barcelona has created 47,000 new jobs through its Smart City efforts. [13]

Cities that implement ‘smart’ solutions for usage of energy resources, manage water supply and have a waste management system reduce pollution and use less energy—according to Cisco, their energy efficiency will increase by up to 30 percent within the period of 20 years. [16]

In the city of Songo, this is obvious throughout the city. The city’s garbage collection is so automated that it only takes seven employees to serve the current 35,000 residents. [17] The kind of efficiency which is unimaginable in European cities.

A Croatian example of implementing IoT into cities include Dubrovnik’s praiseworthy efforts. As a part of the comprehensive Dubrovnik Smart City project, in 2016 Dubrovnik opened a Smart street which features public lighting with multifunctional sensory network, alongside a variety of access technologies, from optical links and 4G network to the Wi-Fi network, cameras to identify traffic violations, parking technology which recognizes vehicles and performs contactless charging of parking fees and offers real-time information on the parking vacancy status.
in the Smart Street, but also all over Dubrovnik. [18] In addition to this, Dubrovnik also held conferences and competitions which resulted in other IoT solutions towards a smart city. [19]

Other measures for improving transport sustainability in Croatian cities are the inter-modal mobility as well as carpooling and car sharing and support to the soft mobility (on foot and bikes). Cities ‘green areas’ such as: parks, gardens, vertical gardens, green roofs and facades show not only that people prefer to live in those cities where they can breathe and see plants, trees and flowers but also contribute to climate protection (improved air quality and cooling down air temperature while producing its own microclimate and help save on heating, cooling and increasing comfort inside the building), [2] which can easily be connected and implemented by IoT (e.g. Songdo’s remote energy monitoring systems which bring the power to IoT and save the energy), especially in the Croatian cities by the sea.

IV. SUCCESSFULNESS OF IMPLEMENTATION OF PPP MODELS TO THE CROATIAN ECONOMY

The promotion of PPP projects is expected to ripple effects on the national economy through three channels:

- economic growth resulting from the inflow of private capital
- increased social welfare resulting from the timely delivery of social services and the early realization of social benefits
- reduction in the government fiscal burdens through better VFM (value for money) [12].

A. Institutional settings

In accordance with the Croatian PPP Act2, article 2, paragraph 7 the public partner may allow the establishment of the right of construction in favor of the private partner and free of charge. All issues related to the establishment or transfer the right of construction and awarding of concessions, including the question of fees, public and private partner, regulate contractually. The basic principles in the implementation of PPP projects are the principles of public procurement, the principle of protecting the public interest and the principle of economy. The PPP Act is proposed and authorized only by the public authority, and that is the reason why; primarily mayors should try to establish a setting where entrepreneurs can create solutions to improve quality of life — without added any of government expense. In order to facilitate PPP implementation, the PPP grants land expropriation rights to the concessionaire. The concessionaire may entrust the competent authority or the local government with the following responsibilities of execution of the land purchase, compensation for loss and more [12].

PPP Act, The Concession Act3 and the Public Procurement Act4 regulate the procurement procedure designed in a way to ensure value for money (VFM) of PPP projects. Korean study analyzed the efficiency of PPP project from 3 different perspectives: users, concessionaires and the government and it showed both cost savings and efficiency gains. The main problem that the study discovered was the level of user fees between government financed and privately invested projects, which decreased over the time in proportion to accumulated experience in PPP projects. For PPP projects to be carried out efficiently, one of the most important issues is prompting competition among private participants bidding for the project [12].

Agency for Investments and Competitiveness is a Croatian Agency set up by the PPP Act whose main tasks are to give investors full view of services to invest and implement in projects for the improvement of the economic growth and business environment and to promote Croatian PPP model as competitive. [20] In 2016 only one PPP project worth 4.6 million Croatian kuna has been contracted. But in 2014 and 2015 no PPP contracts have been signed. [21]

On the EU level, in 2014 new procurement directives have been adopted, replacing the 2004 directives and covering the award of concessions. The new directives open several opportunities for ‘smart city’ investments, while maintaining the basic requirements of competition, transparency, equal treatment and compliance with EU state aid rules.

The key directives are:
1. Directive 2014/24/EU on public procurement6,
2. Directive 2014/23/EU on the award of concession contracts6,

B. Open government

The E-government is changing the way in which politics interacts with citizens and the democratic processes can be enhanced but the main goal is to turn the government tools from an ‘office-centric’ mode to a ‘citizen-centric’ mode [2]. These new and innovative forms of governance have been included into the term ‘smart governance’ under which the government manages and implements policies toward the improvement in quality of life of citizens by leveraging ICTs and institutions and by actively involving and collaborating with stakeholders [22].

While it may be true that ICTs are introducing a range of new capacities for the design and planning of human urbanization, questions remain about the network

2 The PPP Act, Official Gazette [in Croatian] Zakon o javno-privatom partnerstvu, Narodne novine, nb. 152/14, (Narodne novine are an official Gazette of Republic of Croatia)
3 The Concessions Act, Official Gazette [in Croatian] Zakon o koncesijama, Narodne novine, nb. 143/12
4 Public Procurement Act, The Concessions Act, Official Gazette [in Croatian] Zakon o koncesijama, Narodne novine, nb. 120/16
5 OJ L 094, 2014, implemented by Croatia
6 OJ L 094, 2014 currently not implemented by Croatia
7 OJ L 094, 2014 currently not implemented by Croatia
capabilities of smart cities to remake systems of government. Government systems are now increasingly under pressure to develop institutional frameworks that support tools and resources for empowering citizen agency.

The overarching idea is that smart city planning should – at the very least – incorporate experimentation with new forms of community and citizenship [23]. Citizens have a leading role in designing, building and maintaining 'smart cities'. This calls for a fundamental shift when we think of our cities and about urban development in the near future. Citizen participation reduces government corruption by expanding public insight and decentralizing government power, [23] by giving them the ultimate decision in the adoption of the city’s services and the creation and management of public value out of them. Even large-scale projects can be enhanced by crowdsourcing, while cities can collect data, give answers to simple questions e.g. about how they want to use their public spaces or acquire services for bringing innovation and 'smart' thinking to acquire powerful results. [24]

In the USA, the Open Government was introduced by Ex-president Obama in 2009 in legislations such as: The Freedom of Information Act, E-government Act and The Paperwork Reduction Act. Open Government could improve and advance citizen participation in the process of building democratic ecologies of 21st century in The Republic of Croatia.

Croatian Central country portal6 and within it an E-citizen system is an example of enabling citizens’ various options within a single platform by merging and connecting IT platforms. That example should be followed on decentralized levels of cities and regions, which should include a ‘smart city’ sector for all stakeholders to interact.

C. Building ‘smart cities’ through the concession agreements and public procurement models

Decision-making within contracting authorities (especially on the local level) is generally carried out by a small number of government officials who, we believe, do not have in-depth ICT and IoT knowledge in solving a public issue. Furthermore, the process of procurement leads to nothing more than a race to the lowest price point between a small number of large suppliers. Therefore, new models offer alternatives for building 'smart cities'.

Preconditions for the application of the new Croatian Concessions Act (currently in its second reading in the Croatian Parliament) promote use of concessions through the high-quality medium- and long-term sectoral strategy, establishes safe, secure and clear rules in cases of awarding a concession in a way to protect the public interest. Also, it strengthens the competences of operators responsible for the development and maintenance of infrastructure and introduces administrative contracts into the practice which enables administrative protection during the administrative procedure.

The new Croatian Public Procurement Act introduced two new procedures which are likely to be particularly relevant as models for authorities who wish to purchase innovative goods, services or works:

- the innovation partnership - enables a public authority to enter a structured partnership with a supplier with the objective of developing an innovative product, service or works, with the subsequent purchase of the outcome and which will enable public authorities to select partners on a competitive basis and allow them to develop an innovative solution tailored to their requirements;
- the competitive procedure with negotiation - enables the procurement of goods, services or works that includes an element of adaptation, design or innovation, or other features which make the award of a contract without prior negotiations unsuitable. Unlike the competitive dialogue, it requires that the authority may specify the required characteristics of the goods or services in advance of the competition. [25]

Other important changes in the new Public Procurement Act include: increased flexibility and simplification on the procedures to follow, negotiations and time limits, use of ‘most economically advantageous tender’ as default criteria within the public procurement process, use of life cycle costing (LCC) as a method for assessing tender costs and the competitive dialogue procedure which has been simplified particularly for technically and financially complex projects.

This will in turn enable to de-risk the most promising innovations step-by-step via solution design, prototyping, development and first product testing. [26]

V. CONCLUSION

Many of the challenges faced by smart cities surpass the capacities, capabilities, and reaches of their traditional institutions and their classical processes of governing, and therefore require new and innovative forms of governance [22].

Alongside ‘top-down’ master-planning, we need to enable ‘bottom-up’ innovation and collaborative ways of developing systems. The notion of the ‘smart citizen’ as a co-creator draws on a rich intellectual backyard in both technology design and urban design. In practice, engaging citizens in these processes is immensely challenging. [27]

PPPs are the most effective way to make Croatian cities ‘smart cities’. Certainly, it’s unreasonable to expect Croatian cities to become ‘smart’ in a short period but by implementing the measures and strategies like creating walkable localities – reduce congestion, air pollution and resource depletion, boost local economy, promote interactions and ensure security bring Croatian cities step closer to the ‘smart cities’.

Cities should ensure the visibility of procurement and PPP opportunities through a single portal and use problem-based methods for solving key issues. However, it should be noted that cities cannot simply copy the best practices from successful ‘smart cities’, hence must

---

6 http://gov.hr
develop approaches that fit their own mindset, organization and culture in terms of broader strategies, human resource policies and demographics. Forming E-groups to listen to people and obtain feedback and use online monitoring of programs and activities with the aid of cyber tour of worksites. For example, making areas less vulnerable to disasters, using fewer resources, and providing cheaper services; green buildings and pooling-sharing. [28]

That is the main reason why Croatian PPP Act should intend to simplify use of PPPs and give equal possibilities to both private and public sector companies. In that manner, we believe Croatian cities will be able to develop and have similar appearance as the cities from South Korea, Japan, China, India and other countries in the world who detected and adopted wise ‘smart city’ policy and achieved advanced economic conditions and improved life of its citizens.

Abstract - Internet streaming is the type of technology that allows simultaneous reception of multimedia content and its simultaneous playback through a computer network. Global development of the Internet leads to growing demand for multimedia content. Discographers deal in distribution and sale of rights to play audio recordings (tracks), adapting their business to new technologies and modern ways of selling their products and services in order to survive in the market impacted by a large drop in demand and sales of CDs and DVDs. In the process of rationalization and automation of business processes, new standards in the electronic exchange of data are set between discographers and Internet streaming services with the goal to increase efficiency and economy. This paper describes a platform for the exchange of data and content, presents the concept and the basic methods used in the development of an automated system for the exchange of data and content between discographers and Internet streaming services and offers guidelines for future development.

I. INTRODUCTION

The process of modernisation, rationalisation and automation of business processes aimed at increasing productivity and cost-efficiency is unfeasible without continuous improvement and investment into new information technologies [1]. New technologies are forcing business entities to actively adjust themselves and follow the latest IT trends so they could survive in the market.

Multimedia (Latin multus: many, medium: means, medium). The media are: the newspapers and other press, radio and television programmes, news agency programmes, electronic publications, teletext and other forms of daily or periodic publications of editorial content by broadcasting recordings, voice, sound or picture [2].

Discography (Greek diskos disk, Greek grafo list) is a systematic list of music editions (tracks) of a certain provider-artist. Business entities engaged in distribution and sale of rights to play audio recordings (tracks) are called discographers. Availability and channels for selling multimedia contents have thoroughly changed with the development of Internet. The age of vinyl (gramophone records) as an era of recordings, playback and sale is over. It has been succeeded by magnetic recordings on CD and DVD media, which are also slowly passing into history as audio formats. The sale of rights to play audio recordings (tracks) as a type of multimedia content is gradually moving to a new digital era.

Contemporary electronic business or e-business requires the use of information and Internet technologies.

Electronic business or e-business is a form of business which, in addition to applying information and communications technologies, exchanges information as support in all business activities [3].

Business intelligence is a process of collecting the data and information from internal and external business environment and transforming them into business knowledge based on which business decisions can be made [4].

Recording Industry Association of America (RIAA) recorded an increasing trend in using streaming services, and strong growth in sale of digital music, which accounted for 77% of the total music industry revenue in the first half of 2016 [5,6]. In the same period, streaming accounted for 47% of the US music industry revenue [5,6]. These indicators provide firm grounds for the development of a platform model for exchanging electronic data between discographers and streaming services.

The precondition for defining an electronic format for the exchange of electronic data is to define standards and rules. The rules of e-business and exchange of electronic data between discographers and streaming services are defined by standards and rules of streaming services themselves.

The aims of e-business, which also includes platforms for the exchange of data between Internet streaming services and discographers, are as follows:
- greater productivity of business processes,
- faster exchange of information and content,
- reduction in operating expenses,
- higher data integrity,
- reduced risk of error,
- faster document search and archiving.

When implementing e-business, it is important to apply the latest technological methods of business intelligence in order to achieve higher dynamics of business processes. The abstract of this paper explains
the need for applying platforms for the exchange of data between Internet streaming services and discographers in business processes, and the concept will offer the answers to the following questions:

- What does the applicable solution of platforms for the exchange of data between Internet streaming services and discographers look like and how does it work?
- What benefits does the application of platforms for the exchange of data between Internet streaming services and discographers offer?

The second chapter of this paper shows the development of the platform, and the third chapter presents the conceptual platform model. The fourth chapter describes the implementation process, the fifth chapter describes the control of data import and export, as well as security, and the sixth chapter presents the conclusion.

II. PLATFORM DEVELOPMENT

The platform for the exchange of content and data between discographers and streaming services is aimed at business entities-discographers (B2B) who engage in distribution and sale of rights to play audio recordings (tracks). (Figure 1).

The platform for the exchange of content and data can be defined as business intelligence communicating between two data warehouses according to set rules. The platform is the result of individual approach in the development of the conceptual design for exchange content and data between Internet music streaming services and discographers.

Data are exchanged in a standardised format, EDI (Electronic Data Interchange) – the direct transfer of structured business data and messages between computers electronically [7]. The exchange of content and data is possible between [8]:
- B2B (business to business) – electronic business between two business entities,
- B2C (business to consumer) – electronic business between a business entity and a final consumer,
- B2G (business to government) – electronic business between a business entity and a government bodies,
- C2C Electronic business between final consumers,
- G2B Electronic business between government bodies and business entities,
- G2C Electronic business between government bodies and final consumers.

The platform is designed as a highly-automated business process. In addition to the exchange of electronic documents as a modern method of exchanging various types of documents between companies, the platform also allows for automatic electronic exchange of other digital contents accompanying electronic documents. At the same time, the platform can be seen as business intelligence consisting of a set of methodologies and concepts transforming the data into knowledge.

The advantages of selling multimedia content through streaming services are as follows:
- availability of rights to play audio recordings to a large number of potential customers,
- lower investment into audio recordings (tracks) launched on the market,
- higher earnings and profit,
- new business model,
- significant reduction in operating expenses, and increase in productivity.

In spite of evident benefits of this form of sale, the decision as to which rights to play audio recordings will be marketed through an individual streaming service is up to the business entity’s management. In order to be able to assess which rights to play audio recordings to launch into individual streaming sales channel, the management needs high quality information that will give them advantage over competition. The present-day information systems are expected to provide information whose content is necessary in the decision-making process. Business intelligence methods used in the platform development are as follows:

A. Data mining

Data mining is a process of searching for new and potentially useful knowledge from the data [9]. This process reveals relations, structures and logic between data, which facilitates decision making processes. In the process of data mining, it is decided which rights to play will be offered to which market, under what market conditions and prices, and when.

B. ETL process modeling

The process of reporting on the amount of sold rights to play audio recordings and generated traffic can be described using ETL (extract-transform-load) process [10]. This means that the data on the traffic generated from rights to play audio recordings are first brought to a staging area, and afterwards transformed and transferred into a data warehouse. (Figure 1)

Therefore, modeling requires:
- Conceptual modeling of data,
- Business process modeling according to ETL (Extraction, Transformation, Loading):
  - data extraction process,
  - data transformation process,
  - data cleansing process.

The process part consists of extracting the data from the source (from the streaming service), integrating and loading the data, and finally transforming the data into a data warehouse.

- The first step includes extracting the data from the source (the data from the streaming service). In the process of data extraction, it is crucial to trace the source of data, date and time of their entry and data on entry operators, in order to enable complete insight to auditors. Data Vault concept emphasizes the need to leave a trace of the source and time of storing data in the database [11].

- Transform means the transformation of data towards the data warehouse.
- Load is a process of loading.

In the Internet community, there is a large number of streaming services, and each service has its own rules and reporting methods, as well as rules for importing and exporting data. Due to various structures and formats of data from external sources and towards external sources, export and import need to be adjusted, which is usually performed by IT experts or data warehouse administrators. For this reason, the business process includes a large number of subjects, who are dependent on IT support. The result of such practice is a delay in the implementation of data both from the source and to the source, as well as the inability to timely analyse the results. The platform for the exchange of content and data between Internet streaming services and discographers provides business users with autonomy in controlling their business processes, so they do not depend on an implementer or IT sector.

### III. Concept of Platform

Conceptual modeling of data is a highly abstracted process of data modeling. The structure of data within the information system for tracking must reflect the structure of user’s needs. The conceptual data model is a complete, consistent and concise description of data within an information system [12]. Figures 2 and 3 show Entity-Relationship Diagram (ERD), according to Martin Entity-Relationship Diagram [13]. Entity is anything we wish to collect and store information about, entity-relationship method is a diagram of mutually connected groups of data within a system in question [14,15].

#### A. Track

Track is multimedia content of sound and text or only sound. The data on tracks, as well as corresponding digitalized documents, are located within the data warehouse. Therefore, when exporting them into the streaming partner’s system, the following control process actions need to be performed: extraction, loading, transformation and data export verification.

From the entity-relationship diagram for tracks (Figure 2), entity relationships with the following entities can be seen:

- **Digital files** – digitalised documents on the basis of tracks,
- **Date** – date of change that has occurred,
- **Operators entry** – data on persons/operators recording the document,
- **Origin** – data on the track origin,
- **Artist** – data on the track artist,
- **Genre** – data on the track genre,
- **Provider** – data on the track provider,
- **Territory** – territory of broadcasting and selling the track,
- **Album** – collection of tracks to which the track belongs,
- **Track owner** – copyright holder.

#### B. Report on Internet music streaming services

Business relations also include the segment of reporting on the results of streaming service sales, which in essence has similar attributes. The ultimate aim of the platform is to archive the generated sale into a data warehouse, so the management could make decisions based on relevant information.
From the entity-relationship diagram for traffic (Figure 3), entity relationships with the following entities can be seen:

- **Digital documents** – digitalised documents on the basis of traffic,
- **Date** – date of change that has occurred,
- **Business units** – business unit of the business entity,
- **Entry operators** – data on persons/operators recording the document,
- **Taxable period** – period of mandatory tax return on the basis of traffic,
- **Type of tax documents** – type of traffic in the sense of taxes,
- **Invoice** – invoice issued based on traffic,
- **Invoice items** – items of an invoice,
- **Customers** – streaming service acting as customer,
- **Tracks** – track for which traffic was made,
- **Territory** – territory in which traffic was made.

The reporting form for all services is related to the track structure. In order for reports to be stored, the user’s data warehouse needs to be well designed, as well as dimension tables and their attributes within the warehouse.

IV. IMPLEMENTATION

The platform for the exchange of content and data between Internet streaming services and discographers has been created in Embarcadero studio architect technology using programming language Delphi XE5, and Embarcadero InterBase XE5 database technology. Delphi development tool belongs to Embarcadero development tools, which have been among the best development tools for desktop applications for several years. The development of applications in Embarcadero programming environment enabled the development of mobile applications on the platform of the same program code. The development of applications in Embarcadero, which in addition to Delphi has C++ Builder in its portfolio, enables the same application to be delivered for various operating systems, namely for Windows, MAC, IOS Android environments, as well as for mobile devices. This makes the Embarcadero platform for the development of applications a multi-platform.

The main functionality of the platform:

- retrieval of tracks from the database,
- export of data and content to Internet music streaming services,
- import of data from Internet music streaming services.

A. Track entities

Figure 4 shows the form for entering and updating track entities, which is crucial for the functioning of the system. Within the software solution, all attributes necessary for the process of exporting the data into streaming services are designed. ISRC (International Standard Recording Code) is a code for international identification of sound recordings and video recordings, and is a mandatory track attribute. System for the automatic exchange of data between discographers and streaming services is based on the track entity and ISRC attribute. There is a large number of Internet streaming music services, some of the most visited ones, with the largest number of subscribers, being: Spotify, Pandora, Deezer, iTunes, YouTube.

B. Data export process

The process of exporting data on tracks and transferring them into the streaming service information system is supported by defined templates. Templates enable a faster and more autonomous work on an unlimited number of digital platforms. Sample template for the choice of attributes and their formats for exporting the data to Internet music streaming services. (Figure 5)

The structure of columns and formats for export can be adjusted to the needs of automated data transfer. Through the user interface, the user can choose an entity and attributes, as well as their sequence in the export file. (Figure 5)

The structure is defined by the user instruction for each streaming service, and all required attributes, as well as corresponding music and other files need to be entered. In the communication process with streaming services, contractual relations are an important component, as well as the process of proving the rights to play tracks protected by copyright. Due to a large number of plagiarisms, there is a special component of streaming services, a programming interface that challenges the right to play a track without authorization.
In the process of choosing the tracks that will be put into use, the management makes its decisions based on relevant assessments. Figure 6 shows the form for the selection of tracks to be put into use in the streaming service. Based on the template (Figure 5), the data will be exported according to the defined conditions from the template with attributes and their formats.

Figure 7 shows the XML file for importing the data into the streaming service platform, where all attributes of the streaming service are visible. By putting a track into use in the streaming service, the process of exporting data from the user’s warehouse is completed.

The process of tracking all statistical information on exploitation and use of tracks can be found below. Depending on contractual relations, the official statistical report is compiled monthly by automated data transfer.

```xml

    <TITLE>Title</TITLE>
    <ARTIST>ARTIST</ARTIST>
    <YEAR>YEAR</YEAR>
    <DURATION>DURATION</DURATION>
  </RECORDING>
</Album>
```

Figure 8 presents a form showing which data are imported into the data warehouse from which channels. The data that follow the analytical track overview for each entry are shown in Figure 9. In addition to the leading attribute, ISRC, each track contains other attributes that are partly imported from the streaming service report, and partly from the entities dependable on the track entity.

The data loaded from the streaming source will not be visible to other data users until the verifier completes the verification and validation of received data, and checks accuracy of all transactions performed.

C. Data import process

Each sales report consists of track attributes, which are an important element for recognizing data in the data warehouse. In general, this is an ISRC track attribute.

The process of importing the data starts by loading the file. This is performed by choosing columns and rows from the table implemented in the data warehouse. The original file is also saved in the archive of digitalized imported files.
This way, the verifier can review all loaded data, as well as interventions on the data before the data is available to other authorized persons in an application segment.

The overview of traffic opens the possibility to further analyse the data, by connecting multiple entities dependable on traffic, as well as their attributes.

D. Control of data import and export and security

Saving files in their original form is becoming imperative in business, since it enables insight into and control of file authenticity. It also enables comparisons and controls with the data registered into the user’s information system.

The application of Data Vault concept emphasises the need to track the source and moment of storing the data into database. This is a sort of security and control aspect performed through the entity of entry operators. The export of files from the user’s information system with tracks, before being loaded into the streaming system and realized, is performed with verification by a supervisor. Figures 6 and 8 show the form in which verification is performed. Only users with special privileges are authorized to use it.

On the other hand, the files loaded from streaming services are not visible to other operators before they are verified by a financial supervisor. Only after the verification and comparison of monetary claims and realization of sold rights to play on the basis of tracks has been performed, the data becomes visible to other operators. This way the data is protected from any errors, and track providers and management are protected from making wrong decisions.

In the process of recording the collection of fees based on copyright, financial supervisors are included, and they have insight into and overview of all data, which prevents any illegal actions by the operator. This enables multiple controls of business processes, both in the process of recording and collecting the fees for rights to play tracks.

There are no ready-made solutions for the exchange of data and content between Internet music services and discographers that would allow the level of functionality in the exchange of data and content comparable with the described platform. The disadvantages of using platforms: their use requires knowledge of advanced techniques of artificial intelligence and a high level of education.

V. Conclusion

A reliable archive of electronic business documents and multimedia content, and storage of exchanged electronic content archived into data warehouses are important elements of information system functionality. The platform for the exchange of content and data between Internet streaming services and discographers provides business users with autonomy in controlling their business processes, in the segment of import and export of data from a data warehouse towards streaming services. Such user autonomy increases efficiency and productivity, and reduces the risk of error. The ability of the platform to adapt and memorise templates allows for connecting streaming services and their rules without any additional software interventions.

The use of templates from individual streaming services enables faster and easier data manipulation. The verification of data is enabled through the system administrator, and it ensures the correct export and import of data. The aim of this paper is to help users decide on the implementation of the platform for the exchange of content and data between Internet streaming services and discographers, and to suggest guidelines and propose a model for building a platform to designers, by applying the proposed model.

The architecture and design of such platform entails multiple benefits, from more cost-effective maintenance, centralised system of tracking costs, to the overview of all reports influencing the decision making by the business management.

By implementing the platform and adopting a development model that separates the transactional part of information business system from the data warehouse itself, we increase security. We also reduce pressure on operational databases in the sense of operation, amount of data and transaction conditions.

Law and Technology in Modern Data Processing Systems: Risk-Based Approach to Data Protection and Implementation Challenges

Nina Gumzej
University of Zagreb Faculty of Law, Zagreb, Croatia
E-mail: nina.gumzej@pravo.hr

Abstract – Recently reformed EU personal data protection rules (General Data Protection Regulation) provide mechanisms to ensure that under strict legal responsibility risks inherent in modern data processing operations are appropriately and timely identified and managed. Analysis in the paper focuses on its risk-oriented rules aiming to ensure proper data security and data protection compliance from earliest data processing stages, and envisaged impact assessment procedure as an important tool toward identifying and mitigating risk in certain high-risked operations. Assessment of impacts that processing activities, as enabled by further technological advancements, may have on individuals’ rights and freedoms requires continuous consideration, in particular as some possibly cannot yet be perceived and/or assessed whether in terms of nature or severity (scope). This adds to analysed open issues requiring further clarification in the area, in connection with initiatives towards the more specific, harmonized EU procedure. Examined risk assessment solutions currently envisaged under the Data Protection Directive, as implemented under Croatian law, and lacking local practice in the area point to likely local implementation challenges of the soon directly applicable, more comprehensive and strict new EU rules, as a result of which proposals are made toward urgent and intensive awareness-raising measures.

I. INTRODUCTION

In today's era of Big Data in progress is evolution from the information economy, which focuses on content and services for consumers, to the data economy where the data mainly flow between a set of non-human actors processing such data, often in real time. This evolution further expands with the development of the Internet of Things. The data economy is built on establishing data value chains and depending on possibilities of using, aggregating and generally processing the data from different sources in an automated form. As such the data economy is strongly affected by the legal framework affecting the flow of such data. In that context Lammerant and De Hert rightly establish that visions on how technology changes economical processes are important drivers of legal change [1]. Those drivers are evident in particular through the development of new EU legislation in the area of personal data. Following a four year long complicated legislative procedure, on 25 May 2016 a breakthrough piece of EU legislation in this legal area entered into force: the General Data Protection Regulation (hereinafter referred to as: GDPR) [2]. The GDPR will apply directly in Member States as of 25 May 2018 and at that time it will repeal the currently valid EU general data protection law basis - the Data Protection Directive 95/46/EC (hereinafter referred to as the DPD) [3]. The technologically neutral rules signify a quantum leap in this legal area as they deliver on the long needed adaptation of the law to modern digital processing conditions especially in light of rapid technological developments in the ICT area and the ever-reaching, perplexed, extensive and in general more and more complex procedures for processing personal data (“processing” signifyng any operation performed on such data), in particular online. In addition to this the often fragmented domestic frameworks based on the DPD required better harmonization and more appropriate conditions to ensure legal certainty and a levelled playing field for competition, thereby strengthening the EU internal market, as well as EU-wide harmonized protection of rights of individuals.

In addition to personal data processing activities by all relevant EU-based actors (controllers and processors) the GDPR seems to apply world-wide where non-EU based in particular digital actors are processing personal data of individuals in the EU by offering them goods or services (with or without payment) or by monitoring their behaviour in the EU, which may include online monitoring activities in the context of profiling (Article 3, recital 24). Adding to this is also its wide material scope of application as evidenced by the expressly expanded concept of personal data to also include digital data such as online identifiers (IP addresses, cookie identifiers, RFID tags, and other) and location data (Article 4 point 1, recitals 26 and 30). Additionally to expanded duties and reinforced accountability of actors processing personal data, particular severity of the new legal framework is evidenced by stronger harmonized authorities of supervisory data protection bodies enforcing it. A clear example thereof are envisaged administrative fines, so far unprecedented in EU data protection legislation, which may rise to up to 20 million Euro, or where undertakings are concerned to up to 4% of total worldwide annual turnover, whichever is higher (Article 83, paragraphs 5-6). All this adds to the general appraisal of the strict, as well as detailed and complex nature of the new legal frame that will directly apply in all EU Member States.

Assessment and overall management of risks that prompts legal responsibility and accountability in data protection is a crucial area in new EU data protection legislation that the author chose to examine and critically
appraise in this paper. Analysis begins with an overview of current legal solutions in risk assessment according to the DPD and the selected local solutions. Data protection legislation and practice in the youngest EU Member State Republic of Croatia provides a case study for this analysis. This will allow an evaluation of a local implementation level of DPD’s risk assessment solutions and of possible challenges in the uptake of a more comprehensive risk-based approach to data protection under the GDPR (which itself is examined in fourth part of the paper). Third part of this paper provides an overview of selected discussions and initiatives relating to methodology and procedures identifying and assessing risks and impacts thereof on individuals’ rights and freedoms, especially in the context of data processing activities in a networked environment and with the use of newer technologies and applications. This discussion provides a basis for the ensuing examination of GDPR solutions in the risk-assessment area, which reinforce and add on the earlier analysed provisions of the currently still valid DPD.

II. RISK ASSESSMENT IN THE DPD AND ONE LOCAL IMPLEMENTATION CASE STUDY

The concept of risk appraisal and management in the DPD is evident in particular from its rules on security measures and the prior checking procedure, i.e., examination of data processing activities prior to their initiation [4]. As regards security measures, the DPD requires those measures to ensure (having regard to state of the art and implementation costs) a level of security appropriate to risks represented by the processing and the nature of data to be protected (Article 17, paragraph 1; recital 46 of the DPD). With respect to prior checking (Article 20), the DPD requires Member States to establish data processing activities that are likely to pose specific risks to individuals’ rights and freedoms. A prior check of those activities is a duty conferred on supervisory authorities upon notification by controllers (main responsible agents that determine the purposes and means of processing personal data). Data protection officers (where appointed by controllers to help them ensure data protection compliance) can also conduct such prior checks and their duty is to consult the relevant data protection body in cases of doubt. It should be noted that important aspects of the procedure, such as concrete consequences of prior checks and determination of risks are not regulated by the DPD, i.e., they are left to regulatory discretion of Member States under their respective laws [5]. To be precise, the DPD does not list examples of processing activities likely to present specific risks in any of its operative provisions (Articles), although some indicators and examples are provided in its recital 53 (elements to consider risk: nature, scope and purpose of processing; examples of risks: processing that may result in excluding individuals from a right, benefit or a contract, processing with specific use of new technologies). Exact consequences of the prior checking procedure are also not specified by the DPD, although it is clarified in recital 54 that the supervisory authorities may following the prior check give their opinion or provide approval of the processing under their national law. It is assumed that they should also be able to prohibit intended processing unless, for example, appropriate risk-mitigating measures are implemented. In my opinion this matter more generally relates to the scope of intervention powers that was granted to the authorities under their law. Namely, according to the DPD Member States must ensure that supervisory bodies have effective intervention powers, such as delivering opinions before processing operations are carried out (prior checking), and ensuring their appropriate publication, of imposing bans on processing, of warning the controller, and other (Article 28, paragraph 3). Even though it is only covered in the rule on supervisory authorities’ powers of intervention, it is clear that also appropriate publication of opinions on prior checks is a requirement under the DPD.

The Republic of Croatia implemented the DPD in its Personal Data Protection Act (further: PDPA), which was adopted in 2003 and thereon in process of alignment with the DPD up until its latest amendment in 2011 [6]. Although in line with the earlier examined DPD rule on security measures the PDPA lays down in Article 18 a duty to protect the data (from any accidental or deliberate abuse, destruction, loss, unauthorized alteration or access), it was not before its last amendment in 2011 that for the first time a method of establishing security measures at least somewhat in line with the DPD was introduced, although the implemented solution is in my opinion not satisfactory. Namely, it only requires security measures to be proportionate to the nature of controller’s or recipient’s activities, and to contents of the data filing system (Article 18, paragraph 3). Assuming that “contents of the data filing system” correspond to the nature of data to be protected (e.g. stronger security measures such as encryption should apply where the more sensitive data are processed), the PDPA solution still fails to specify that the measures need also to ensure a level of security appropriate to risks represented by the processing. Consequently, the adopted 2011 solution is in my opinion a missed opportunity to appropriately introduce the risk-based approach in local data protection legislation and practice. This concern does not, however, relate to security requirements for sensitive data (i.e., special personal data categories such as health data), which have been prescribed in secondary legislation already as of 2004, and which rely on ISO standards 27001 and 17799 (27002) [7].

Where prior checking procedures are concerned, the adopted solution is somewhat detached from the prevailing practice in the EU [8]. One reason for this are unspecified risks for which prior checks are necessary, which, although required by the DPD are not foreseen in the PDPA nor are they to the best of my knowledge foreseen in any publicly available guidance of the Data Protection Agency. Secondly, prior checking is not independently regulated by any operative provision, i.e., Article of the PDPA. Instead, the process is only implied from the provision elaborating Agency’s tasks, i.e., its duty to provide preliminary opinions if the processing presents specific risks to individuals’ rights and freedoms. Furthermore, controllers’ duty to seek Agency’s opinion on the need for a prior check in case of doubt is also awkwardly placed in the rule specifying Agency’s tasks and therefore adds on my earlier remark (Article 33, point 9). Though required by the DPD the PDPA does not
regulate the duty to publicize specifically its prior checking opinions, although some such opinions can be tracked on its internet pages [9]. Finally to be noted is that the PDPA failed to regulate in line with the DPD also the data protection officers’ duty to carry out prior checks. Combined with earlier remarks this is particularly troubling also in light of mandatory appointment of such officers for all controllers with 20+ employees (which itself is not required under the DPD) and the thereby enabled development of an entire data protection profession on one hand, and on the other failed use also of that opportunity to promote best practices in the vital area of risk assessment. All this contributes to an overall impression of the undervalued risk-based approach to personal data protection in Croatia so far.

III. RISK ASSESSMENT CONCERNS AND INITIATIVES IN LIGHT OF TECHNOLOGICAL ADVANCEMENT

In the context of data protection legislation there is a lacking consensus in scientific literature not only on what could potentially represent risks for individuals’ rights and freedoms where personal data processing operations are concerned, especially in light of the rapidly advancing technologies and applications in the online environment, but also on methods of their appraisal (e.g. objective and/or subjective) [10]. Examination of the object of protection, i.e., what rights and freedoms a certain processing activity affects, is likewise under a discussion. The inevitable evolution of privacy as the object of protection, i.e., consideration for new conceptualisations of that right in light of advances in technology affecting it should here also be mentioned. In that sense, for example, Finn and others expand on previous Clarke’s typology of privacy and propose consideration for seven types (privacy of the person, privacy of behaviour and action, privacy of personal communication, privacy of data and image, privacy of thoughts and feelings, privacy of location and space and privacy of association), all in view of various examples in current technological development (e.g. whole-body scanners, RFID-tagged identity documents, drones, next generation biometry and DNA sequencing, and other) [11].

In the context of privacy and data protection legislation the procedures to identify, assess and minimize risks, especially those embodied through the use of newer technologies and enabling various surveillance operations over individuals have up to today mainly focused on impacts on the right to individual privacy (privacy impact assessment - PIA) [12]. Certain authors even suggest that in addition to this impact (of newer technologies and applications) on ethical issues should be assessed (ethical impact assessment) [13]. This viewpoint closely relates to discussions on current inadequacies of PIAs where surveillance technologies are concerned, both in the public and private sectors, since PIAs focus on individual privacy and not on the wider scope of affected rights, freedoms and interests [14]. Certain projects co-funded by the European Commission elaborate even further on the issue, adjusting the PIA to the security impact assessment frame, which addition to privacy and personal data protection considers also ethical, social, economic and political issues during the design and implementation of smart surveillance or monitoring systems, technologies, processes and policies [15]. A need for a broader viewpoint of affected rights and freedoms and risks in the context of EU personal data protection legislation was affirmed also by independent advisory body established under Article 29 of the DPD for the protection of personal data and privacy – the Article 29 Data Protection Working Party. According to it the risk-based approach to data protection should go further than the narrow approach based on harm and it should take into account any potential and real negative effect, which can be evidenced by effect on the individual up to the general effect on society (e.g. loss of social trust). Also, the scope of rights and freedoms that could be negatively affected by data processing should not always focus exclusively on the right to privacy, since other fundamental rights (e.g. freedom of speech, thought and movement, prohibition of discrimination, right to liberty, conscience and religion) may thereby also be negatively affected [16]. A discourse should here also be added on limitations in risk assessment methodologies inter alia due to limitations of current scientific knowledge on impact (of data processing activities in the context of newer technologies and applications) on individuals’ rights and freedoms, as well as on shortcomings of potential “managerisation” of related risk assessment procedures. Thus for example certain authors point to the need to expressly include the precautionary principle (accepted in areas such as environmental law) [17] into the EU data protection law risk management frame [18] so that in case of uncertainty on existence and/or extent of risk precautionary (preventive) measures are applied without waiting for those risks to materialize [19].

Particularly in light of ongoing technological progress and data processing operations related to the use of newer technologies and applications (notably in the ICT area), all of the above noted concerns seem to justify the need to institutionalize the element of transparency into impact assessment procedures, i.e., including all relevant stakeholders as well as the general public therein [20]. Also to be noted are expert proposals nonexclusively related to the data protection field, in light of their assessment of European Court of Human Rights’ case law as pointing to development of the right to have technologies assessed before their launch. In that context and in light of recognized significance of impact assessment procedures it is proposed that not only experts and industry but also individuals are included (with public consultations to be held already in the stage of planning or shaping new technologies), impact assessment results published (without prejudice to special treatment of sensitive information) and regular checks ensured [21].

Voluntary initiatives to devise impact assessment procedures on the basis of the currently valid DPD (they are not themselves envisaged in the DPD) that should here be noted are the Privacy and Data Protection Impact Assessment Framework for RFID Applications at EU level [22], impact assessment procedures at individual Member State level [23] and industry-based proposals on impact assessments tailored for specific sectors and/or special needs of small and medium-sized enterprises [24]. Where new (GDPR) and current legal EU frame (DPD) are
concerned it can be observed that risk assessment solutions in the GDPR reinforce and expand on earlier in this paper examined DPD solutions and this is evident inter alia from the newly introduced provisions on impact assessments. Namely, as I will elaborate in next part of this paper the GDPR expressly adopts for the first time in EU data protection legislation a legal duty to conduct the so-called data protection impact assessments in certain cases of high-risk personal data processing. Especially in light of future technological developments affecting the data protection legal area, the earlier noted concerns on identification and assessment of risk, scope and object of protection and limitations in risk assessment procedures should also currently be appraised in view of endeavours toward EU-wide harmonization of the procedure to identify high risks and frame for impact assessments under the GDPR. The vital role of harmonized procedures in this area is not only that of enabling EU-wide consistency in supervisory practices, but also that of reducing associated compliance burdens both for the supervisory authorities and the controllers [25].

IV. RISK-BASED APPROACH AND DATA PROTECTION IMPACT ASSESSMENTS IN THE GDPR
The overall risk-based approach to personal data protection in the GDPR is based on identification of likelihood and severity of risks that a personal data processing activity has on individuals’ rights and freedoms with respect to its nature, scope, context and purposes. The main GDPR provision on security of processing (Article 32) establishes the duty of both the controllers and processors (who process data on behalf of controllers) to implement appropriate technical and organisational measures to ensure a level of security appropriate to risk, taking into account state of the art, implementation costs and the nature, scope, context and purposes of processing as well as risk of varying likelihood and severity for individuals’ rights and freedoms. In assessing data security risks consideration should be given to risks presented by data processing such as accidental or unlawful destruction, loss, alteration, unauthorised disclosure of, or access to, personal data transmitted, stored or otherwise processed (and which may in particular lead to physical, material or non-material damage, in line with recital 83). In fact, implementation of measures to ensure appropriate data security is now established as one of the fundamental data processing principles (integrity and confidentiality principle) and the also newly introduced accountability principle imposes a duty on the controllers to (be able to) demonstrate compliance of their processing activities with this and other fundamental principles in Article 5. Furthermore, a risk-based approach is the decisive element of the newly introduced principle of data protection by design. According to this principle appropriate technical and organisational measures must be implemented both at the time of determining the means for processing and at the time of processing itself, which must be designed to implement data-protection principles effectively and with safeguards integrated into processing, in order to meet GDPR requirements and protect rights of data subjects. Those measures must be chosen taking into account state of the art, implementation costs, nature, scope, context and purposes of processing as well as risks of varying likelihood and severity for individuals’ rights and freedoms (Article 25). Adding to GDPR’s strong emphasis on a risk-based approach is in my opinion also the explicitly introduced duty of appointed data protection officers to have in performance of their task due regard to risks associated with processing operations, taking into account the nature, scope, context and purposes of processing (Article 39, paragraph 2 in connection with Article 37). Finally to be noted are explanations of risks of varying likelihood and severity that may result from processing activities potentially leading to physical, material or non-material damage, and which are provided in recital 75 of the GDPR. Those activities include in particular: 1) processing activities that may lead to discrimination, identity theft or fraud, financial loss, damage to reputation, loss of confidentiality of personal data protected by professional secrecy, unauthorised reversal of pseudonymisation, or any other significant economic or social disadvantage; 2) where data subjects might be deprived of their rights and freedoms or prevented from exercising control over their personal data; 3) where special categories of personal data, data relating to criminal convictions and offences and data of vulnerable persons, especially children, are processed; 4) where personal aspects are evaluated, in particular analysing or predicting aspects concerning performance at work, economic situation, health, personal preferences or interests, reliability or behaviour, location or movements, in order to create or use personal profiles; or 5) where processing involves a large amount of personal data and affects a large number of data subjects. In reference to discussions on objective and/or subjective risk evaluation noted in previous part of the paper, the GDPR clarifies that assessment of existence of risk or high risk in relation to the processing should in fact be objective (recital 76).

The GDPR abolishes a general duty of notifying data processing to supervisory authorities under the DPD and introduces a risk-based system involving supervisory authorities where certain procedures show that the processing would result in a high risk to individuals’ rights and freedoms on account of its scope, nature, context and purpose [26]. In this respect it introduces data protection impact assessments (further also as: DPIA), which are mandatory only if it is likely that a type of processing, in particular using new technologies, and taking into account nature, scope, context and purposes of processing, is likely to result in a high risk to individuals’ rights and freedoms. As clarified in recital 84, DPIAs serve to evaluate especially the origin, nature, particularity and severity of that risk. In order to reduce unnecessary burden it is allowed to use a single DPIA to cover more similar processing operations presenting similar high risk. Relevant high-risked processing activities include: (1) systematic and extensive evaluation of personal aspects relating to natural persons which is based on automated processing, including profiling, and on which decisions are based that produce legal effects concerning or similarly significantly affecting him or her; (2) processing on a large scale of special categories of data or of data relating to criminal convictions and offences, and 3) systematic monitoring of a publicly accessible area on a large scale (as explained in recital 91 DPIAs are
especially required where the monitoring is taking place with optic-electronic devices). National supervisory authorities may establish further examples and in that process, as explained in recital 91, they are to evaluate if the processing activity is likely to result in a high risk in particular because it prevents individuals from exercising a right or using a service or a contract, or because it is carried out systematically on a large scale. Finally to be noted are the stipulated minimal DPIA contents in the GDPR: systematic description of processing operations and purposes thereof, assessment of necessity and proportionality of processing operations in relation to their purposes, assessment of risks to rights and freedoms and intended measures to mitigate risks and demonstrate compliance with the GDPR [27].

With the exception of publishing results of impact assessments the GDPR foresees key elements pointed to in previous part of this paper resulting from discussions on optimal impact assessment procedures where the processing entails use of new technologies (transparency – public consultations, publishing results and regular checks of impact assessments). However, the effect of those elements of DPIAs as introduced by the GDPR in reality appears minimal, since their implementation is left to controllers’ discretion. Concretely, it is prescribed that where appropriate controllers shall seek views of data subjects or their representatives on intended processing (without prejudice to protection of commercial or public interests or security of processing operations). It is unfortunate that the GDPR does not envisage the ensuing process of publishing DPIA results. As regards subsequent DPIA checks the GDPR stipulates that the controller shall where necessary carry out a review (to assess if the processing complies with the DPIA) at least when there is a change of risk represented by processing operations. It is difficult to sensibly apply this rule without acknowledging the implied need to continually review the DPIA to be able to establish possible changes to the level of risk that brought on a mandatory DPIA in the first place. On the other hand the adopted solution “as is” fails to specify such checks and as a result it is not unlikely that they could be well understated in practice.

Taking into account that the scope of this paper does not allow a more detailed analysis of the DPIA area I will next briefly discuss the envisaged prior consultations as another vital GDPR procedure, according to which controllers must consult the supervisory authority before processing where the DPIA showed that the processing would lead to a high risk in the absence of measures mitigating it [28]. A concern to which I would point is coupled with explanations in recital 84, according to which prior consultations should only take place where the controller cannot mitigate identified high risks by appropriate measures in terms of available technology and implementation costs. This would appear to allow a more narrow scope of circumstances instigating control by supervisory bodies, and possible misuses where a decision on adequacy of proposed risk mitigating measures is left to controller’s sole discretion. In any case, I consider the recital as not entirely consistent also with the prescribed task of authorities to issue an opinion and provide advice where it considers that the controller insufficiently identified or mitigated the risk, and all this in fact takes place during the already initiated consultation procedure.

Where affected rights and freedoms are concerned, the very title but also goal of the DPIA (“assessment of the impact of the envisaged processing operations on the protection of personal data”) make it clear that impact assessments required under the GDPR have a narrow object of protection, i.e., it appears their focus is strictly on the right to personal data protection. I find such a solution unsatisfactory especially in light of subject-matter and objectives of the GDPR. Namely, the GDPR lays down inter alia rules relating to protection of natural persons with regard to personal data processing and though prevailingly, guaranteed rights and freedoms with respect to such data processing are nonetheless not strictly limited to the data protection right (Article 1, paragraphs 1-2 and recital 75). It is expected that this and other open issues analysed in the paper will be resolved in the scope of work to ensure a harmonized risk assessment methodology on the basis of the GDPR and possibly specified via adopted codes of conduct at EU level or approved certification mechanisms and/or guidelines issued by the European Data Protection Board (recital 77). In respect of the latter, in fact, the Article 29 Data Protection Working Party (which will be instituted into the European Data Protection Board on the basis of the GDPR) announced publication of its guidelines on high-risked processing and DPIAs during 2017 [29]. In connection with this to be followed is also development of the DPIA Template for Smart Grid and Smart Metering Systems [30], individual DPIA initiatives as already proposed by some data protection authorities [31] and the industry-based proposals (ISO/IEC 29134 Information technology - Security techniques - Guidelines for privacy impact assessment; under development) [32].

V. CONCLUSION

As a result of an ever-close connection between law and technology the recently reformed EU personal data protection rules (GDPR) provides mechanisms to ensure that under strict legal responsibility risks inherent in modern personal data processing operations are timely identified and appropriately managed. Relevant risk-oriented rules toward ensuring and maintaining proper data security and data protection compliance already from earliest stages of data processing operations, and impact assessment procedures as an indispensable tool for recognizing and mitigating risks in certain high-risked processing operations represent a giant step in development of modern data protection legislation and should be applauded, particularly when taking into account that the road toward adoption of this piece of legislation was itself quite long, and quite difficult. The future-proof stance of these technologically neutral rules demands ongoing consideration of impacts that the various personal data processing activities as enabled by further technological advancement may have on individuals’ rights and freedoms and out of which some possibly cannot yet be perceived and/or assessed, whether in terms of nature or severity (scope). Where the envisaged data protection impact assessment procedure is concerned and taking into account high-risked processing
activities mandating them, such as systematic monitoring of a publicly accessible area on a large scale, analysis in this paper pointed to issues that should further be clarified and specified, and hopefully approached in a generally harmonized EU procedure. These include inter alia the nature and scope of rights and freedoms that should thereby be protected, methodology to identify and evaluate risks (high risks) and other procedural matters (e.g. public consultations, checks) that in my opinion significantly affect the overall effectiveness of impact assessments as an introduced legal duty. Taking into account that these procedures can utilize significant resources, all efforts toward EU-wide harmonized procedures should be seized as they could result in a significant reduction of costs of compliance, and reduced resources otherwise required in this area also for supervisory authorities. Furthermore, a harmonized methodology enables supervisory consistency, which is in any case a goal that the GDPR intends to achieve.

Examined inadequacy of (non)implemented risk assessment solutions under the DPD (which will soon be replaced by the analysed much more comprehensive and stricter, directly applicable GDPR rules) in Croatian law and practice could compromise intended harmonization aims as well as cause panic for locally responsible actors due to the generally lacking focus on this vital data protection area. Even today it can be considered to be too late for some organizations to start making appropriate adjustments to their data processing operations and allocating necessary resources in order to ensure timely compliance with GDPR requirements. It is therefore strongly recommended that as a minimum measure the Data Protection Agency as well as local experts in the area carry out intensive awareness-raising activities in the risk-based approach to data protection. Utilizing data protection officers mandatorily appointed on the basis of the Croatian Data Protection Act is a practical opportunity to work on this goal, which should not be overlooked.

Abstract - The paper deals with the methodology applied to data collection, as well as social, economic, and financial analysis of broadband investments’ effects related to the planning of broadband infrastructure development of the Primorsko-goranska County (PGC), with the City of Rijeka in focus. The analysis of the collected data and derived indicators has yielded results which can be significant for local and regional policy makers. It has been shown that investments in broadband infrastructure have a relatively high social return on investment and produce multiple socio-economic benefits that can not only accelerate the development of cities and municipalities in PGC, but also contribute to inhibiting or turning negative demographic trends around.

I. INTRODUCTION

In modern times ICT technologies have become an important prerequisite to high quality of life, and an essential tool for efficient production and business in all economic sectors. Investments in the development and implementation of broadband infrastructure do not only have a positive impact on the overall society and business, but they are also an accelerator of growth and development of local economies, thus putting their huge development potential to a concrete use. Considering a broadband network as a factor of development mainly depends on the environmental, demographic, and economic specificities of a certain local unit. Furthermore, to choose an optimal broadband network technology, type, and model of financing of its implementation or modernization, it is important to consider a broader socio-economic context of such investment projects. In doing so, decisions makers must give priority to solutions that can potentially generate the biggest multiplier benefits for the local population and economy. In accordance to this, the authors have devoted special attention to integrated analysis of demographic and economic trends, spatial characteristics, and commercial potential of broadband services to determine how investment in broadband infrastructure can contribute to responding to key challenges of future development of cities and municipalities in PGC.

Taking into consideration the intended format and volume of this paper, the authors decided that presenting the obtained results and conclusions for all the cities and municipalities that were included in their study of broadband infrastructure development plans would be too extensive. Therefore, this paper deals with the assessment and interpretation of the socio-economic effects of investment in the broadband networks implementation in the City of Rijeka - the administrative center of Primorsko-goranska County (PGC).

II. BROADBAND NETWORK - A PREREQUISITE FOR THE IMPLEMENTATION OF THE SMART CITY CONCEPT

The City of Rijeka has an extremely favorable geographical position, good transport links and an abundance of natural resources in its surroundings, of which the most significant are marine, forest and water resources. The City of Rijeka is also an important educational, cultural, health, trade, and economic center. In fact, it is the regional metropolis whose broader gravitation area extends beyond the territorial boundaries of PGC. However, considering its developmental needs, we must note that the City of Rijeka has a relatively small territory: 44 square kilometers. This considerably complicates the application of integrated urban approach in solving the key development challenges, which are primarily related to optimal planning, coordination, and allocation of development factors in accordance with the overall social and economic needs.

Considering the complex social, economic, and cultural perspective of Rijeka as the center of the county and its growing problem of lack of space, the paradigm of Rijeka makes an ideal case for the application of the so-called smart city concept, a systematic and integrated approach to the urban development management, using innovative ICT solutions and intelligent systems in integrated networking, planning, optimization and monitoring of all aspects of urban development. It aspires to socially, economically, and environmentally efficient and sustainable cities and urban areas. This enables the complementarity of investments in human and social capital and the overall city infrastructure, which provides conditions for a long-term sustainable economic development, a high standard of living, as well as an effective and efficient environmental protection and natural resources use. For these reasons, in the City of Rijeka Development Strategy for the period 2014-2020 it was emphasized that the implementation of the smart city concept is an important determinant of its future development [1]. In this regard, the broadband infrastructure projects have a strategic priority for the City of Rijeka because the realization of such projects is the basic prerequisite for the formulation and implementation of smart city applications.
III. THE ROLE OF BROADBAND NETWORKS IN STOPPING NEGATIVE DEMOGRAPHIC TRENDS

In accordance with the last Census (2011), the City of Rijeka has 128,624 inhabitants and an average population density of 2,923 inhabitants per km², which makes it one of the most densely populated cities in the region. As the data gathered in the last two censuses show, the City of Rijeka underwent depopulation, following population trends characteristic of the higher territorial levels. However, it is indicative that the depopulation process in Rijeka is much more dynamic than the average depopulation processes at the national and county level.

Graph I. Intercensus Rate of Population Change (%) in the City of Rijeka, PGc and the Republic of Croatia in 2001 and 2011 (Source: Author’s Calculations Based on Croatian Census 2001 [2] and Census 2011 [3], Data)

Since over the observed period both components of general population trend are negative, the City of Rijeka suffered the most unfavorable outcome – a decrease in population, with an especially strong influence of the negative factors. In the context of discussing the unfavorable population trends in the City of Rijeka, it is important to point out that much of the problem is created by the redistribution of population within the Rijeka circle, i.e. moving of Rijeka’s population to neighboring cities and municipalities. Such demographic trend is primarily the consequence of lower cost of living in the neighboring local units, as well as good traffic connection of these places with Rijeka. People can therefore relatively easily and on a lower budget enjoy all the conveniences of communal, sport, health, educational, cultural, business and entertainment infrastructure of the City of Rijeka, as well as its other urban contents.

The decrease of Rijeka’s population incurred the decrease of the number of private households and the average size of households, which is typical for suburbanization processes where commutation of young and working-age population leads to the depopulation of the central city and demographic growth of its surroundings. At the same time, a part of housing capacity in the central city becomes available and the share of elderly households is increased. Another negative aspect of suburbanization process with the young population leaving the central city is a damaged reproductive potential and worsened biodynamics of population. This is also confirmed by the vital index data for the City of Rijeka in the period from 2011 to 2015. The vital index of Rijeka decreased during this period by 22.4%, reaching a value of 50.9 in 2015. That means that in Rijeka in 2015 on every new born, the city had two deceased inhabitants.

Graph II. Rijeka’s Vital Index in the Period from 2011 to 2015 (Source: Author’s Calculations Based on the Official Vital Statistics [4])

In comparison to the structural characteristics of the county and state population, it is evident that Rijeka has more retired citizens and fewer young and working-age citizens.

The age structure of a population has a vital economic importance. It is primarily the young and the people of working-age who opt for migration. In the case of Rijeka, the analysis has shown that the age structure of the local population is not favorable for future economic development of the city. Most of Rijeka’s working-age population is close to retirement. On the other hand, due to a relatively small ratio of the young constituting a pool of fresh work force, the city will have to face a serious work
force problem over the next decade, which poses a threat to the future city’s development.

In comparison to the county and state educational structure, the City of Rijeka is in a somewhat better position, with higher percentages of secondary and high education, and lower percentages of people with no school.

The over-average share of highly educated people in the local population surely contains a large development potential and is one of the most significant comparative advantages of the City of Rijeka. The problem is, however, that the active entrepreneurial capacities in Rijeka’s economy are predominantly concentrated in those activities which do not offer enough possibilities for the employment of highly educated population, with the consequence that the local economy leaves much to be desired regarding the employment of highly educated work force in recent years. This indicates that the economic orientation of the City of Rijeka has so far been in disproportion with its available demographic resources, but also with spatial limitation of the city, which has led to the structural maladjustments of the local economy (cf. chapter III).

Due to the interdependence between demographic and economic trends, opening of new working places and increasing economic inclusion of the working population are distinctive factors of the economic growth and higher standard of living in the City of Rijeka. Investments in building and development of high speed broadband networks will definitely play an important role in achieving this. High speed broadband networks contribute to the development of high value added activities and more intensive investments into local economy. Consequently, this leads to the creation of new jobs, increase of employment, youth retention and immigration.

### IV. ECONOMIC IMPLICATIONS OF INVESTING IN THE DEVELOPMENT OF HIGH SPEED BROADBAND NETWORKS

When considering local economic trends in small countries such as Croatia it is important to bear in mind that conjuncture in the national economy largely determines those trends. In this regard, Rijeka’s economy was strongly influenced by the effects of the negative economic cycle in the Croatian economy between 2009 and 2015, which was considerably longer and more pronounced than in the rest of the EU. This can best be illustrated by the sharp decline in the financial results of enterprises located in the City of Rijeka (cf. Graph III).

According to Croatian Financial Agency data, in 2014 the total revenue of enterprises located in Rijeka was 16.9 billion HRK, which is 23.8% lower level of total revenue than in 2008, the pre-recession year. Total expenditures of different businesses over the same period decreased, following the total revenue trends. Compared to 2008, the total expenditures of businesses located in the City of Rijeka fell to 5.2 billion (23.7%) in 2014. This volume of business and economic activity in Rijeka is lower than in pre-recession years. As there was no disproportion of income and expenditure trends, local entrepreneurs have retained profitability achieving a positive consolidated financial result, i.e. a profit of 275.1 million kuna in 2014 (31.4% less than in 2008).

It should be noted that more than 40% percent of the revenue in the City of Rijeka is generated by retail and wholesale trade along with the car repair services, which is why the monolithic economic structure of Rijeka was extremely sensitive to the general recessionary conditions in the national economy. Trade largely employs lower-educated and lower-skilled workforce, so by the nature of its role in the social division of labor it has a relatively small contribution to the creation of added value in local economies. Also, urban area trade is primarily focused on distribution of consumer goods to local people, which is why it is characterized by an enhanced pro-cyclicality, i.e. rapid growth of turnover and new jobs in periods of positive economic cycle and vice versa, rapid decline of turnover and the loss of jobs in periods of economic crisis and reduced citizens’ purchasing power. Therefore, trade cannot be the main driver of economic development of Rijeka. This is also confirmed by the data provided by the Croatian Financial Agency on the number of employees at enterprises located in the City of Rijeka. In 2014 the enterprises of Rijeka employed 30.135 employees, which is a decrease of 17.36% compared to 2008. Over the period between 2008 and 2014 Rijeka lost as many as 6,332 jobs in the entire enterprise sector, out of which 2.295 jobs were lost in the trade sector.

Furthermore, the economic orientation of Rijeka towards trade and related service activities has led to high
vulnerability of its economy to fluctuations in the national economy. Such economic orientation has also significantly limited the options for activating the unused local human potential. This is especially true in the case of highly educated people who have fewer and fewer opportunities to find adequate jobs in Rijeka.

Similar trends are present on the national and county level, but they are particularly strong in the City of Rijeka. Such developments on the local labor market further indicate the existence of increased employment problems for young and educated population, which is primarily caused by structural maladjustment of Rijeka's economy. In this sense, it is opportune that the diversification of the Rijeka’s economic structure, as a distinguished university center that creates high-quality professionals, focuses on the development of knowledge-intensive activities within which the highly educated workforce can apply its expertise, competencies, and entrepreneurial innovation.

Following the obtained findings on economic and demographic characteristics of Rijeka, it can be argued that setting up an advanced broadband network can certainly intensify growth and diversification of the local economy, but also positively affect the stability and quality of its future development. Numerous European experiences have shown that the multiple economic effects of high speed broadband Internet access have a strong impact on economic growth and development of local government units [5]. Therefore, it is important to emphasize multilayered, multiplicative and long-term nature of contribution of the construction and development of broadband infrastructure to economic growth:

- The primary economic effect of building broadband infrastructure in local units is usually identical to the construction of any type of infrastructure and it is reflected in the growth of income and employment in the local construction sector and production and supply chains that support all phases of broadband infrastructure life cycle.

- The introduction of broadband technology greatly simplifies the deployment of innovative business processes, products and solutions for the existing entrepreneurs, which has a positive effect on the growth of their profitability and contributes to further development of their business.

- The introduction of broadband networks contributes to the development of new activities in local economies, the creation of new jobs and restructuring of the local economy towards activities that create higher added value. This particularly applies to professional, scientific, and technical activities and to activities within ICT sector. This happens because the creation of conditions for greater use of high speed information and communication technologies opens opportunities for teleworking, which significantly stimulates self-employment of highly educated young individuals and those with a secondary school. The availability of high speed broadband allows young people autonomy in terms of the commercialization of their competence, expertise and entrepreneurial innovation because they can develop and offer their services and applications on domestic, external and overseas markets and find partners and investors for their business projects by working from home. In macroeconomic terms, the main advantages of unimpeded access to high speed broadband in the local economy is the development of services that are completely independent of cyclical trends in the rest of the local economy.

- It is well known that investors are more inclined to invest in those areas where there is already a well-developed communication and information infrastructure. The main reason for this is that companies in such areas enjoy advantages such as the following: lower communication and operating costs; easier access to international markets; increased efficiency of sales, promotion, and customer relationships; provided external requirements for the development of a successful and secure e-business and for sustained training of employees through online educational programs. In this sense, the construction of high speed broadband infrastructure contributes significantly to attracting investments in the local economy.

- All previously presented multiplier economic effects of the construction of broadband infrastructure in the end lead to a rise of employment in local units, strengthening the purchasing power of the local population and an increase of their private consumption, which can generally initiate a new upward conjuncture in the local economies.

Summarizing the above direct and indirect social and economic benefits of broadband networks, and taking into account the spatial, demographic and economic specificities of the city of Rijeka, it can be concluded that investments in the implementation, development and modernization of the broadband infrastructure have an immeasurable importance for the economic prospects of Rijeka. Even more so considering their role in enabling an environment for innovative, creative and knowledge-intensive activities based on better evaluation and more efficient use of overall development potential of the city.
V. ASSESSMENT OF MULTIPLIER ECONOMIC EFFECTS OF INVESTMENTS IN THE CONSTRUCTION OF BROADBAND NETWORKS

The authors of this paper have developed a simulation model for the preparation of local broadband infrastructure development plans, and by using it they have estimated multiplier effects to the entire project life-cycle of building a high speed broadband network for the benefit of local consumers, production, employment, and the city budget.

The assessment of the increased consumers’ well-being was based on the consumer surplus concept. Consumer surplus is the total benefit or value that consumers receive beyond what they pay for a certain product or service, or the difference between the price of the product/service that consumers were willing to pay versus the price they actually paid. The development of broadband networks contributes to the consumer surplus due to the growth of competitiveness in the telecommunications market, which leads to an increase of quality and a reduction of price of ICT services. Additional benefits for users of broadband networks are created both in their private and professional lives (e.g., faster access to information, public and health services and entertainment facilities), which leads to significant time and cost savings in the performance of business and private activities, increases the quality of life and leisure, and consequently raises the general level of satisfaction of users of high speed broadband connections. A special feature of this indicator is that it measures the positive externality of economic goods, i.e. the part of the social benefits that has not been internalized in pricing, so the same cannot be identified and expressed by means of statistics and indicators of GDP. In this respect, the calculation of the discounted cumulative value of the consumer surplus for users of high speed broadband connections at the level of the local economy, and increase of the discounted value of total production in the local economy, which is directly or indirectly associated with the development of high speed broadband networks, can give a full picture of the overall socio-economic benefits of investments in the construction and development of the broadband infrastructure in the City of Rijeka.

The multiplier effects of investment in the broadband network on total output and employment in the local economy were estimated using the input-output multipliers. These multipliers are commonly calculated using specific input-output models that describe the direct and indirect links between producers in the processes of production and consumption of economic goods and services in a specific economic area. Thus, using input-output models it is possible to simulate and quantify the direct, indirect and induced economic effects of certain economic changes on total employment and production in a given economy (e.g. investment in a particular sector, the increase in demand for a particular product, price changes, etc.).

Data on the surtax and the average wage in the City of Rijeka were an input for calculating discounted value of the fiscal effects of the increase in employment in the local economy during the presumed life of the project on the budget of the City of Rijeka.

Due to the lack of quality data, necessary for the full application of methodology to assess consumers’ surplus and input-output analysis of the multiplier effects of broadband infrastructure in the example of Rijeka, the authors have used ponders, parameters and multipliers from the European Commission study on the socio-economic impact of broadband infrastructure in European countries, including Croatia [6]. Aware of the methodological shortcomings and limitations of such an approach in the assessment of overall economic benefits of the development of broadband infrastructure in the city of Rijeka, the authors’ goal was not to precisely quantify future economic effects of developing different types of broadband connection, but to consider the current demographic and economic trends in the City to simulate the direction, structure and magnitude of these effects.

The results obtained from the evaluation of socio-economic benefits of the project clearly indicate substantial differences in generating multiplier effects between different network technologies. While technological solutions based on fiber-to-the-home (FTTH) concept initially require some increased capital expenditures, network infrastructure based on such solutions has significantly greater multiplier effect on the growth of production, GDP, employment, and the city budget. This ultimately means that technologies with higher average speeds generate a considerably higher net economic benefit to the local economy. For this reason, it is not advisable to take decisions on the development of broadband infrastructure based on a conservative approach, i.e. to take implementation costs and direct financial flows of the project as the sole criteria for selection of technological solutions on which to base future broadband network. In fact, those policies that give greater importance to implementation costs rather than technological features, speed and capacity of the broadband network, have immeasurably high social opportunity costs. By doing so, decision makers reduce future production potential and possibilities of production in a local economy, as well as the ability of future generations to achieve higher standards of living in local communities.

Nowadays, a broadband network from the aspect of private and business users has, in fact, no adequate substitute because it represents the basic requirement for the use of advanced ICT tools, applications and other products and services whose performance and efficiency of use are directly dependent on network speed. Therefore, it is important to emphasize that because of its ability to intensify the impact of modern technologies and innovations that are used in all sectors on the overall economic and social development and growth, broadband has all the characteristics of merit goods. This means that the implementation and development of high speed broadband networks in a given area should not entirely rely on the operators’ market decisions and business plans, since they are typically profit-oriented. In a sense, the implementation of open, high-speed broadband networks has an even greater social significance in the context of overall development of PGC.
VI. CHOICE OF FINANCING MODEL

To ensure the maximum value for money, i.e. the achievement of the highest possible social rate of return, before deciding on the financing model, it is necessary to determine the ability to pay long-term liabilities of the public entity and make a preliminary calculation of the value for money.

Basic guidelines for calculating the capacity to assume long-term commitments are given in the manual of the Agency for Investment and Competitiveness, Determining the affordability of the local and regional self-government (LRS) in public-private partnership [7]. The process of determining the capacity to undertake long-term obligations of public institutions such as local and regional self-government (LRS) and ministries leads to consideration and analysis of their long-term debt-paying ability or undertakings of financial liabilities for long term lease, as it is the case for a contractual public-private partnership. Taking over long-term liabilities implies determining the borrowing and lease payments capacity in a way which will not jeopardize the long-term financial stability of the public sector institutions and the whole financial system.

After the analysis of the ability to pay long-term liabilities, the preliminary calculation of the value for money must be made. The main objective of this procedure is to determine which financial model provides the best value for money and the highest social rates of return. The basic steps of this procedure and general guidelines to planning public investment projects are also given in the manual of the Agency for Investment and Competitiveness Preparation and implementation of public investment (Public-Private Partnership Projects) [8]. The detailed procedures of the value for money calculation are given in the manual The meaning and process of calculating the value for money for public-private partnership projects [9].

It should be noted that if the analysis of the ability to pay long-term liabilities proves that local/regional self-government is not able to bear the liability in the context of a financial model, even if the choice of such a model provides greater value for money, the model cannot be accepted since it would be such a choice which would jeopardize the realization of the project.

Therefore, when choosing the sources of financing of investment projects, it is certainly important to give priority to financing models with private capital that consider the statistical rules and fiscal treatment prescribed by the system of national accounts ESA 2010, i.e. financing models in which the distribution of long-term financial risks between the public and private sector is such that the investments do not negatively affect the Croatian public debt.

VII. CONCLUSION

The development of high speed broadband network infrastructure in the Croatian municipalities increases the level of social standard in local communities, primarily through the practical application of smart city concept, which leads to the improved quality of public services. Investments in high speed broadband infrastructure therefore considerably contribute to stopping negative demographic trends on local, regional and state levels and enable the introduction of ICT technologies for more efficient planning and implementation of development policies for leveraging the human potential.

The results obtained from the evaluation of socio-economic benefits of the project clearly indicate substantial differences of generating multiplier effects by implementation of different broadband network technologies. While technological solutions based on FTTH concept initially require some increased capital expenditures, network infrastructure based on this technology generate significantly larger multiplier effects in local economy. This is valid both for remote rural areas in Gorski kotar and for the City of Rijeka as a regional center. Therefore, it is important to emphasize that due to its capacity to intensify the impact of modern technologies and innovations that are used in all sectors, broadband has all the characteristics of the merit good. This means that the implementation and development of high speed broadband networks in local areas cannot entirely be based on market decisions, since investments in broadband generate large socio-economic returns from which all members of society gain direct or indirect benefits.

LITERATURE

Mobile applications in communication of local government with citizens in Croatia

Dani Bunja*, Goran Pavelin** and Franjo Mlinac***

gianni@unizd.hr

Based on perceived practices in developed countries of the world, this paper deals with the theory of the mobile applications implementation in local self-government. The development of corresponding mobile applications reduces ICT expenses and the expenses of contacts with clients. The share of resources among the bodies of local self-government is facilitated and services offered to local community are modified. By providing self-service applications to their users, local self-government responds to their needs and demands while creating a platform on which other public services, profit and non-profit organisations can be upgraded with the goal of providing their services to everyone who needs them. This paper provides an explanation of most frequently used types of applications and it examines the use of mobile applications in bigger Croatian local governments.

I. INTRODUCTION

Mobile applications are related to mobile devices, such as smartphones, tablets, e-readers, wearables and other mobile devices. The use of wireless communication, either over broadband connection or over the phone, is what such devices have in common. The approximate number of devices in the world is about 7.4 billion, exceeding total human population of 7.2 billion in 2014 [1]. The number of Americans who own a cell phone increased from 83% to 91% in the period from 2011 until 2014 [2], while the number of smartphone owners increased from 35% to 64% in the same period of time [2]. The number of households without landline phones in the US largely increased, from 34% to 45% between 2011 and 2014 [3]. The number of tablet owners increased from 8% to 42% between 2011 and 2013, and the number of e-readers went from 12% to 32% in the same period [4]. Mobile applications are specific, because they are a result of the mobility of devices and their connectivity to the Internet, relying on hardware options of mobile devices, such as camera and GPS. It is estimated that about 4 millions of applications nowadays is accessible through main gateways, such as Google Play, Apple's App Store, Microsoft Windows Store or Amazon. Google Play and Apple's App Store offer about 78% of accessible applications. It is expected that the download of application will increase application will grow from about 18 thousand million in 2012 to 77 thousand million of dollars in the same period of time [5].

The usage of mobile applications is also increasing and an average user possesses between 36 to 42 applications installed on his mobile phone [6].

More than a half of the time spent online is the time spent on the use of applications [7], while 90% of the time spent on mobile phone goes for the use of applications [8].

II. MOBILE APPLICATIONS IN LOCAL SELF-GOVERNMENT

According to the research conducted by Vision Internet [9] over 50% of interviewed local self-governments in the US declares to be offering mobile-friendly services to their population, while one third of interviewed have adjusted web pages to mobile devices. Consequently, other local self-governments find it acceptable to become mobile-friendly. The representatives of the interviewed local self-governments recognize the importance of adaptation and acceptance of mobile environment [9] and they put forward three main advantages of mobile applications: citizen convenience, expanded communicational outreach and savings in time and human resources. The development of mobile applications also implies changes in budget, safety and other useful changes for local self-governments. The applications used by local self-government are mainly oriented towards local community, although there is also the possibility to create applications directed towards employees in order to improve business activities [9]. Applications can be adjusted for tourism purposes, becoming a guide through historical heritage and through local resources interesting to tourists. The applications designed for local community are primarily meant for simplified communication with local self-government and for reporting various communal and safety issues. There is a difference between mobile applications offered by bigger and smaller communities. Cities often offer applications which provide information on parks, recreational facilities (e.g. Utah County Trail Guide) or leisure activities (e.g. Portland’s Public Art PDX), which might be related to culture, society or sports. Also frequent are the applications providing information on traffic and transit (e.g. San Antonio
Official Travel Guide), as well as public engagement apps [23].

Advanced mobile applications combine QR codes and augmented reality possibilities in getting to know certain locations. Users can scan QR codes and obtain detailed information, such as interactive charts, external links or, in most of the cases, multimedia presentations. Advanced applications use QR codes as a navigation system in parks, but also to create games related to historical heritage, which can boost individual experience [10]. Public engagement applications are developed by public government as much as by private services, thanks to the open 311 protocol for reporting needs of non-emergency service by local self-government. In the US, about 300 local self-governments have organised 311 centres, which inform citizens on various problems such as potholes, locations of non-functioning street lightings, unauthorised waste disposal or similar. Problems can be reported electronically via mobile applications, social networks, online chats, e-mails, phone calls or personally. Reporting through mobile applications developed by 311 centres and commercial services such as SeeClickFix has also been noticed. Citizens also find very important the applications that enable communication with public self-government related to complaints, suggestions and praises (e.g. CityVoice), crowdfunding applications which offer possibility to support projects of local self-government (e.g. CitizenInvestor), applications used by citizens to propose redesign of particular city districts (e.g. Streetmix) and applications for public dialogue or public relations, such as Textizen and YouTOWN [23]. Local self-governments can gain benefit by cooperating with commercial local-based services in offering innovative services. A good example of cooperation is the case of the cities of San Francisco and New York with the company Yelp in 2012 [23] in providing data on safety inspections in local restaurants with the goal to increase food safety in public places. When the application was accepted by a larger number of cities, they created Local Inspector Value-Entry Specification (LIVES), an open data standard for local self-governments willing to publish the results of restaurant inspection in their area. Having upgraded such a system, commercial applications HDScores and What the Health can provide information on restaurant safety rates in 37 American states [23]. Geographically organised groups on social networks composed only of verified permanent community members can be of great benefit to local communities and public services in their areas. Social engagement through such groups may ensure relevant information for law enforcement and public safety of citizens [11]. Given that smartphones evolve in personal credentials thanks to digital bills such as Google Wallet, local self-governments create applications that smartphone users can use in order to pay various fees for the services provided by local self-government [12]. The increased availability of local governments’ API used by commercial and non-profit services lead to advanced solutions. These solutions are founded on databases used by applications with an authorisation, i.e. obtaining keys to access the databases. API is used for dynamical access to a particular database from external sources, i.e. outside local government. API represents an unobtrusive way for local public services to provide access to their data in order to increase transparency in business activities and the development of services [12].

III. TYPES OF APPLICATIONS

Applications are mostly divided according to devices they are developed for: smartwatch, smartphone or tablet, and according to program platform used by specific device: IOS, android, Windows or other. Exactly because of the specificity of a particular platform, mobile applications must be customized to each different platform if they are intended for wider scope of users, which represents difficulty for developers and increases expenses for their development [13]. In the process of particular application development, local government should pay attention to following specifications:

- complexity of task
- frequency of application use
- safety
- interoperability
- integration with hardware possibilities of mobile device
- access to the Internet
- overall price of development and ownership

The complexity of a task is related to time and intensity of users’ interaction with application in order to perform a task. Depending on duration of a desired action, people mostly choose smartphones, followed by tablets, while choosing computers for most complex actions [13]. The usage frequency affects the choice of application, because when limited by the quantity of memory, users will decide not to download an application they are going to use rarely [14]. Safety is related to the possibility of controlling safety features of an application, which mostly depends on users and their regular application maintenance in the case of recorded security flaws, when the user should install the latest version. Interoperability is related to the possibility of an application to be used in a wide range of devices available nowadays. It eases acceptance of an application by local community. Integration with hardware possibilities of a mobile device is related to the use of camera, GPS system, voice commands, mobile payments and other in order to ease and advance users’ experience of an application. The need for Internet connectivity makes the use of an application difficult, so it would be necessary to find a way to make an application usable in offline mode. The overall price of development and ownership refers to
development expenses, operational expenses, software and hardware expenses, but also to users’ training expenses and customers support [14].

IV. EXAMPLES OF GOOD PRACTICES

In 2013, Birmingham City council launched a free application, which makes a good example of overall offer of possibilities related to responsibilities and authorities of a local city government [15]. Through this application, citizens can find out whether jobs are being offered in city administration, they can find instructions on how to reach any city service or cultural institution, follow BBC news, find contact information of chairmen of the board, report problems related to waste disposal, problems with non-functioning street lighting or street sign, demand for their street to be cleaned, ask for trash bags and recycling boxes if they are new citizens, report potholes or similar. London Borough of Lewisham created LoveLewisham web and mobile application used to report different environmental problems, such as graffiti or illegal garbage disposal. Except for the reporting option, users can also keep track of their problem solving [15]. The application is integrated in the back-office system and creates reports for services of public government, contractual services and other agencies, but also facilitates problem reporting and saves times and money which otherwise would be spent on processing and resolving the complaints in a traditional way. The application contributed significantly to decrease the graffiti issues by 73% and to their faster removal from 2.78 days in 2003 to less than 0.5 days in 2013. Unauthorised waste disposal has been reduced by 53%, time spent on work with clients by 22% and call centre contacts by 33%, which has saved 500,000 pounds in the last five years [15]. Bristol City Council have used mobile applications in order to increase the efficiency of their mobile employees, by providing them with 60 mobile phones and tablets equipped with Looking Local’s MyCouncil application and with a number of several standard applications, thus enabling them to perform their daily tasks without coming to office. Within a year of implementation, 565 reports have been created, 2,356 pounds saved and the number of reports have increased. The non-profit organisation that developed the aforesaid application is completely owned by Kirklees Council, while all the revenue from subscription fees is used for the development and improvement of software solutions [15]. Local authorities in Australia are among most advanced examples of mobile applications implementation in achieving a two-way communication between the government and the population. [16] Applications may vary, from social networking platforms, content creation and sharing tools, weblogs and micro blogging tools.

V. SITUATION IN CROATIA

The review of websites showed that 21 Croatian local self-governments use commercial mobile application CityHUB [17] whose development team BetaWare is located in Osijek. After the project termination, a new company LetMeDo has been founded and it will continue to develop this application [18]. The application functions on Android and iOS platform. They offer three modules: CityService, CityNews and CityGuide.

CityService is a module which enables notifications about utility problems to local services. The application administrator verifies the notification authenticity and forwards it to municipal service in charge. The location is automatically registered so the service can react as soon as possible. It is to be remarked that automatic notification delivery to the service in charge is not possible, probably because there is no adequate internal operational structure. It includes feedback to citizens about their notifications, their status and completion. CityNews module serves to the public relation purposes and informs citizens on different city events in the, on changes in traffic situation, power outages, and water supply interruptions due to repairs, on special citizens’ rights and on services enabled by local self-government. CityGuide module enables tourists and citizens to explore the city. The module enables creation of one’s own categories (restaurants, hotels, galleries, recreation, concerts and similar) along with the possibility to add unlimited number of items with information, geolocations and walk-by navigation. This successful application is currently used by one city in Serbia, one in Bosnia and Herzegovina, one in Hungary and 39 towns in Germany [19]. After the mobile application e-Redar, made exclusively for municipal guards, the city of Zagreb developed an application called MojZagreb which enables citizens to report about utility problems, such as: non-functioning traffic signs, damages on public roads, clogged drains, damages on green areas and various other damages and failures [20]. After their notification, the citizens are informed about the course of problem resolving and on its termination [21]. The application is adjusted for Android, iOS and Windows platforms and therefore available to a wider range of users. The application developer is a commercial company Omega software d.o.o., which cooperated with company Globaldizajn d.o.o. It was launched in April 2013, having enabled numerous reports made by citizens, as well as praises for the application [22].

If the local self-government employees are experts in information technology, they can try to develop their own applications by using one of the available development tools for creation of native or hybrid applications. Some of the best known development environments for multiplatform applications are: Sencha, Phone Gap, Appcelerator Titanium, Corona,
QT, Xamarin and Alpha Anywhere [24]. Our magazine PC Chip [25] states that Xamarin is an integral part of Microsoft and it can be run in Visual Studio using one of the best known programming language “C#”. The advantage of this tool is that 90% of the code might be used on every platform (Android, iOS, Windows). Furthermore, Xamarin offers native SDKs used to adjust application to each platform. Xamarin is free “open source” tool, so everyone has the right to upgrade and modify its original code. Pone Gap, one of the most popular platforms is also an open source framework, used for fast development of mobile applications. It supports a larger number of mobile platforms, such as iOS, Android, Blackberry, Windows phone, Symbian and Tizen. Phone Gap uses HTML5, CSS3 and JavaScript programming languages. HTML5 and CSS3 are used for the development of users’ interface, while JavaScript for operating the application. Phone Gap is more adequate for those who lack experience with advanced programming languages and provides easier maintenance and application development with less code than Xamarin.

Appcelerator Titanium has three tools: tool for application development, API and analytical tool. Titanium uses JavaScript in combination with HTML and CSS, and various API, depending on the application functions. It offers support for Android, iOS, Blackberry and Tizen platforms. The owner of Croatian IT company Infinum d.o.o., Tomislav Car, emphasized in an article available on Mob.hr [26] that the development of an application for an Android platform costs 30% more than for an iOS platform, because of a larger number of devices using Android, slower Android emulators and the need to write more lines of the code than for an iOS application. It is interesting that Croatian company with American address, Southern inc., has developed Mobile App Creator, a service for mobile application development without programming skills, as well as the mobile application App Maker Academy with a detailed description of application development via their tools [27]. The instructions offer an overview of steps in the application development, a guide for the implementation of basic modules, an overview of advanced possibilities, a procedure for application launch and its integration with Shopify, WordPress, Facebook, Instagram, Twitter and other services [28]. Beside the instructions, App Maker Academy contains a collection of tips & tricks and an inspirational list of posts which demonstrate the development of most successful applications made through the use of Shoutem. The price for the development of one’s own mobile application on Shoutem is based on a yearly subscription and depends on the package of chosen services ranging from 19,90 $ up to 119,90 $.

VI. CONCLUSION

This paper presents knowledge on the mobile application role in local self-government of different countries in the world, as well as the way and purpose of their use and the validity of their development. On the basis of papers and findings of numerous authors, it is possible to make a conclusion that the mobile application development is important for democratisation of society, given that it eases the contact of local population with local government. Besides, the development of mobile applications enables significant savings in the operation of local self-government and reduces the need for administrative employees and work with customers. However, most of the so far developed applications are those used to report municipal problems and to keep record of their solving, while only a smaller number of them are used for other aspects of communication between citizens and government and for informing citizens on the work and projects of local government.

Difficulties in the mobile application development are encountered because of the presence of a larger number of software platforms used by devices and the development prices which can be high in the case of commercial companies and specific demands. We singled out two successful examples from Croatia, of which CityHUB has been accepted within and outside Croatia. This proves it to be a quality product used by 21 Croatian local self-governments. Our recommendation is to organise presentations on mobile applications utility at local self-governments, while the development price might be reduced by joining of several local self-governments in specific geographical regions. Mobile applications are expected to be subject of a growing number of professional and scientific papers, because they are going to play even more important role in the future.

The Role of Applications and their Vendors in Evolution of Software Ecosystems

Sami Hyrynsalmi and Petri Linna
Tampere University of Technology, Pori, Finland
{sami.hyrynsalmi, petri.linna}@tut.fi

Abstract - The most recent trends in the electronic commerce research have suggested that forming an ecosystem around a platform would create a winning solution. The ecosystem, consisting of vendors and external actors, would create competitive advantage for the platform owner. Furthermore, the sheer number of the actors has been used as the measure of the ecosystem’s well-being against competing ecosystems. Whereas a number of studies has been devoted to analyse the well-being indicators or structures of software ecosystems and the importance of complementors and complements are acknowledged, there is lack of studies addressing how the complements affect into the evolution of ecosystems. This conceptual analysis aims to open discussion on this topic by using the mobile application ecosystems—such as Google Play or Apple’s iOS—as the case subject. While the results suggest some implications for the platform owners and complementors, more work is needed.

I. INTRODUCTION

The summer of 2008 and the launch of App Store for smart devices using Apple’s iOS operating system will likely remain a remarkable milestone in the history of the mobile industry. Although similar application stores by different vendors had been available for several years before the launch of App Store, Apple’s marketplace— together with the new series of smart devices—was able to revolutionize the business and dethrone the old kings of the castle such as Nokia and BlackBerry [1]. Eventually, the previous market leaders were driven out from business, and Apple’s new innovation was copied to several different industrial segments [2].

While several analyses for the reasons of Apple’s iOS devices and marketplaces success have been written, e.g. [1] [3] [4], it seems to be clear that millions of applications by over hundred thousand application developers had also an important role in the outcome of the competition. The application developers and their offerings together with the platform provider and customers form a software ecosystem [1]. The concept of ‘software ecosystem’ is a descendent of Moore’s [5] business ecosystem with focus on the software industry and its special characteristics [6].

There are several definitions for software ecosystems; however, the one by Jansen et al. [7] summarizes the concept well: a software ecosystem “consists of the set of businesses functioning as a unit and interacting with a shared market for software and services, together with the relationships among them. These relationships are frequently underpinned by a common technological platform or market and operate through the exchange of information, resources and artefacts.”

Both the definition of a software ecosystem as well as the history of App Store emphasize the presence of third parties—no company alone can run an ecosystem. However, the implications of involving third-parties have been discussed only a little in the extant literature of software ecosystems.

Some previous studies have considered the third parties role in the war of competing mobile application ecosystems, a sub-type of software ecosystems [6]. On one hand, there has been an argument that the sheer number of applications and their developers would eventually be the most important factor for the success of a mobile application ecosystem [8] [9]. On the other hand, there has been argument that instead of the sheer number, it is quality of the content offered [10]. Nevertheless, both views emphasizes the application offering and suggest that, at least in this domain, the applications are holding the highest bargaining power in the ecosystem.

This conceptual paper discusses on the implications of this assumption. The mentioned mobile application ecosystems are used an example case and limitations of generalization from the case to the general type of software ecosystems are addressed. That is, while we focus on the mobile applications and their role in the ecosystems, they are only a case study subject and we aim to generalize the result to other types of software ecosystems. As a result, this study calls for further inquiries assessing in strategical management of evolving software ecosystems.

The remaining of the study is structured as follows. The following section presents the central concepts and reviews related work. The third section presents the competition of mobile applications ecosystems in the 2010s as a case and the fourth section discusses on the findings. The final section concludes the study with some suggestion for future work.

II. BACKGROUND AND MOTIVATION

The hype of different kinds of artificial ecosystems started in the 1990s when Moore [5] published his seminal article on the ecology of competition. He defined a business ecosystem as a set of companies that evolve around a shared innovation. The companies work together, both cooperatively and competitively, to satisfy customers. Moore describes that the ecosystems evolve through four
different stages: Birth, Expansion, Fight of leadership, and Self-renewal or death.

The concept of ‘software ecosystem’ is a derivative of a business ecosystem. It was first used by Messerschmitt and Szyperski [11] in their book published in 2003. Since then, the number of studies assessing different kinds of software ecosystems has been growing steadily [12]. However, due to the popularity of the new conceptualization, there are lots of definitions and views what constitutes of, and what are differences and similarities between the concepts of ‘ecosystem’, ‘platform’, ‘community’, and ‘two-sided market’. This study follows the view that a software ecosystem is formed around a platform and it consists of different kinds of actors [1] [7].

The software ecosystem conceptualization has become important in the field of electronic commerce due to the popularity of platformization, i.e., the process of establishing a platform [13], in business. Platforms and ecosystems are nowadays seen as a winning solution in the new era business [14] and the whole field has been started to call as “platform economy” [15]. Classic examples of platform economies—or software ecosystems—in the field of electronic commerce, are Apple App Store, Google Play as well as Valve’s Steam [1].

The actors are important part of an ecosystem. In their literature review, Manikas and Hansen [16] categorized the presented roles of actors (i.e., an independent person, a team, an entity or an organization) associated with software ecosystems into five main groups: 1) Ecosystem orchestrator, 2) Niche player, 3) External actor; 4) Vendor, i.e., independent software vendor (ISV) or value-added reseller (VAR); and 5) Customer. The first of these is the main actor being responsible for keeping the ecosystem functioning whereas the last one is the buying customer. The remaining three are complementors, i.e., they are offering their complementing services and products to the ecosystem [17].

The differences between three remaining groups are little and one actor can serve in several roles for the ecosystem at the same time. A niche player is often developing and adding components to the platform and thus producing value to customers. External actors use the possibilities provided by an ecosystem and create, thus, indirect value to the ecosystem. External actors can, e.g., promote the ecosystem and its auxiliaries, serve as an external tester or do parallel developing to the ecosystem platform. Finally, a vendor is an actor who makes profit by selling the products of the ecosystem. A vendor can sell, e.g., integration services, components, support agreements or licenses to the main product. [16] Altogether, the actors belonging to these groups are the complementors for the main ecosystem and the remaining of this study focuses on them.

Complementors’ ability to freely choose what ecosystem being a part with [18] [19] or even to rethink its position in the ecosystem [5], makes software ecosystems interesting study subjects. A complementor can decide to be a part of several competing ecosystems at the same time, a strategy called as multi-homing whereas the opposite decision is called as single-homing [20] [21] [22]. Furthermore, in his seminal paper Moore [5] describes, that as a part of a healthy business ecosystem’s evolution, complementors will challenge the ecosystem orchestrator for the leadership of an ecosystem. As an example, Microsoft and Intel challenged and won IBM for the supremacy of a personal computer ecosystem’s leadership in the 1980s [5].

In the field of software ecosystems, a remarkable number of literature studies have been published, e.g. [6] [12] [16] [23] [24] [25]. These studies were looked through for this study in order to map whether there are existing discussions on the evolution or not. So far, there seems to be no previous discussion on the implications of the complementors’ roles in the evolution of software ecosystems. Therefore, this study aims to open discussion on the issue by analyzing a case and discussing research avenues that it opens. In the following section, we will present the case and it is followed by analysis in Section IV.

III. EVOLUTION OF MOBILE APP ECOSYSTEMS

The mobile application stores—such as Google Play, Apple’s App Store and Microsoft’s Windows Phone Store—are frequently assessed software ecosystems [12]. In these kinds of ecosystems, there are three major actor groups: the orchestrator (i.e., Google, Apple and Microsoft, respectively), the customers (i.e., the end-users of smart devices) and the application developers (e.g., Supercell, King Digital Entertainment) [1]. Whereas there are, e.g., niche players contributing to the core platform and external actors (e.g., Samsung and HTC) adding value to the ecosystem, they are infrequently discussed in this domain.

The three mentioned mobile application ecosystems were competing for the customers as well as from the application developers at the beginning of the 2010s. In addition to the big three, also smaller ecosystems and orchestrators such as Nokia with Ovi and RIM with Blackberry World marketplaces were involved in the war of smart devices’ supremacy. [1]

Most of the orchestrators were most likely looking for, so called, the virtuous cycle effect [8]. In virtuous cycle, a high number of potential applications lure more customers to use the smart device platforms. More customers mean more sales in the marketplace, which in turn tempt more developers to join into the ecosystem. Finally, more developers mean more potential applications for the customers which start the cycle again.

Due to the virtuous cycle, it was not a surprise that the sheer numbers of application developers joined and applications offered in the marketplace have been seen as the measure of success of an ecosystem. This has often been presented in the extant literature [8] [9] [26] as well as in the news analysis and marketing [2]. However, there are some critics of using the number of applications as the measure of well-being of an ecosystem [10] [27] and also practitioners have argued for content over quality [3].
Nevertheless, after assessing the success of an ecosystem with the sheer number of applications, arguments have been moved to claim that either the best content [22] or the killer applications [1] would define the success of a mobile application ecosystem. A case in point was a sequel of a popular mobile game that was announced to skip Windows Phone platform. Market analysts quickly judged that the lack of a blockbuster game would be a significant hit against the ecosystem and endangers its future4.

While Windows Phone ecosystem still exists, it is currently silently dying out. Similarly, most of the other old challengers have given up and only the two of the largest application ecosystems survived: Apple’s App Store for iOS devices and Google Play for smart devices with Android operating system. Often, the lack of specific applications—together with insufficient devices—is credited as the source of downfall for at least Microsoft’s solution5. For example, official Facebook and Instagram applications did not offer the same set of features that a user could get with Android or iOS devices.

However, the app economy has also demonstrated that good ideas are swiftly copied [1]. For example, the Flappy bird game, published in 2013, was replicated by different developers to other ecosystems in a few days. After the withdrawal from the market, the number of copies was still growing6. Similarly, the same kinds of applications are occupying the top lists of all major mobile application ecosystems even though the applications are not necessarily produced by the same developers [22].

IV. ANALYSIS AND DISCUSSION

In the following, we will discuss on the importance of complementors for mobile application ecosystems and address shifts in relative bargaining powers. This section ends with discussion on the limitations and suggestion for future work.

A. The importance of complements

Based on the presented discussion from the mobile application ecosystems, it seems that the sheer number of applications is one of the most important measures of success in the beginning. After a certain point, adding new applications does not seem to bring as much value to the customers as previously. In this phase, content of applications seems to be more important. In other words, lacking of certain key applications such as WhatsApp, Facebook or Instagram can be a major disadvantage for an ecosystem.

This chain of thoughts leads easily to the question presented in the title of this study: Are applications holding the highest bargaining power in the ecosystem? Whereas this is, in the context of smart devices, a clear simplification of several complex phenomena occurring—e.g., physical devices, network operators are not considered here—at the same in the market, complements (i.e. applications) seem to be crucial for the ecosystems.

While mobile application ecosystems have some specific features such as the remarkable dependency on the physical devices and ubiquitous nature of smart devices to every aspect of people’s life, they still share also remarkable similarities with general type of software ecosystems. For example, the “app store” approach is spread in numerous different areas [2] and several, if not all, software ecosystems can be characterized as a two-sided platform connecting complementors to customers.

Therefore, an easy deduction is to argue that complementors and their offerings are important also for general type of software ecosystems. Furthermore, the importance of complementors to platforms of all kind of and their ecosystems has also been emphasized [14].

B. Shifts in bargaining powers

An important but still mainly uncovered, to the best of author’s knowledge, question arises: If content and complements have the greatest bargaining power, do they still need the basis ecosystem? That is, when a complement has come into such a position of power that customers make decision based on availability or absence of certain services, its relative bargaining power would be higher than the ecosystem orchestrator. Thus, the complementor could even abandon the ecosystem and form a new one when it is more valuable to the ecosystem orchestrator than the ecosystem is for it. With a quick glance, one can argue that complements cannot bypass the basis ecosystem, but the recent development has hinted that this can actually be a reasonable threat to an ecosystem.

For example, if Facebook’s project Spartan8 is considered, that would have added another layer into the top of mobile operating systems. After that, application developers would have been able to pass over the mobile operating system vendor’s marketplace and rules by producing for and distributing content by the Spartan platform. However, the rumoured project got eventually cancelled and this kind of a revolution did not happen.

The cancelled project Spartan was not the only option for reducing the power of the platform owner. In the mobile application domain, the number of new cross-platform development tools and techniques has been rising [28]. With these kinds of tools, a developer can program an application once and it will run on several different technological platforms. While these tools have some remarkable weaknesses [28], the technology is developing constantly and the cross-platform development methods are constantly improving. In the near future, these might be a reasonable alternative for native development tools.

When the cross-platform development tools have gained enough maturity, the application developers can be expected to use them to publish the same application instantly for several platforms. With these kinds of tools, a developer can achieve reasonable benefits from being first in several markets to cost savings in development work.

C. Struggle for leadership

In his seminal work, Moore [5] already addressed the evolution stages of an ecosystem. While this aspect seems to be mostly forgotten by, at least, software ecosystem researchers, the evolution model is even more topical nowadays as the software ecosystems are coming of age.

According to Moore [5], there are two conditions that must be fulfilled that the leadership struggles would occur at the third stage of the ecosystem’s life-cycle model. First, the ecosystem must be strong and profitable enough to be worth fighting for. Second, the central value-adding components of an ecosystem should be reasonable stable. According to Moore, the latter condition allows contenders to attack those components and diminish the dependence to the original ecosystem orchestrator.

For example, the mobile applications ecosystems seem to fulfil both conditions. The survived ecosystems are profitable and the components that add value to the customers are stable. Thus, according to the original theory of the business ecosystem, the fight for leadership inside the mobile application ecosystems should be expected to start. Some elements of this can be seen in Android ecosystem as the mobile phone manufacturers and Amazon has founded their own application stores and distribute the content through them.

What makes software ecosystem interesting in the light of the ecosystem evolution model is the relatively easiness of multi-homing. The same application can be offered with relatively cheap cost to several competing ecosystems [19]. When compared with, e.g., the personal computer ecosystems’ fight against each other’s and struggle for leadership, this would have mean that a vendor would have steadily worked for both IBM’s and Apple’s ecosystems. For a software vendor, this is easier than for a hardware vendor due to the intangibility, changeability and portability of software. Thus, in the software industry, it seems that vendors can challenge more easily the ecosystem orchestrator for the battle of leadership.

D. Implications and future work

To summarize the above chain of thoughts, the argument presented by Lemstra et al.’s [29] for mobile network operators is followed: Will the mobile application ecosystems become just another distribution channel when a complementor takes over the ecosystems? Based on the original theory of the business ecosystem, a struggle of leadership is expected as the preconditions seem to be fulfilled.

The conceptual analysis presented in previous sections has certain implications for practitioners. First, if the presented hypothesis, that in software ecosystems battle for leadership is more probable holds true, the ecosystem orchestrators should carefully follow their position in the market as well as in their own ecosystem. While giving more power to complementors might be a good tool in the war against other ecosystems, it can cause that the orchestrator loses its own bargaining power against its cooperators. In this case, the initial platform can turn to be only just another distribution channel.

Second, if the presented argument holds true, it questions some of the hyped platform economy arguments. By ‘platforming’ company’s old product and opening them for cooperation, a company might also accidentally weaken its own position. However, based on the presented conceptual analysis, this seems to be only a case in software ecosystems and in the field of electronic commerce, where the role of a physical device is a smaller. Nevertheless, companies should also pay attention to this aspect when they are deciding to go or not to go in the platform economy.

Finally, to the best of author’s knowledge, not much has been studied in the evolution of software ecosystems. Therefore, this study calls for further work on analysing and theorizing 1) an evolution model of software ecosystems whether they follow the same pattern and conditions that business ecosystems; 2) assessing the role of complementors and complements in the evolution of the ecosystem; and 3) investigating counter-measures for ecosystems’ orchestrators to mitigate contenders’ actions.

E. Limits of generalization

There are a few major questions related to the presented ideas in this paper. The first is related to software ecosystem studies itself. The software ecosystem conceptualization has been used in a wide array of different context ranging from World of Warcraft to SAP [12]. Thus, it is not a surprise that the software ecosystem literature seems to be started to diverge into different sub-communities [23].

Two large sub-communities are rather easily identifiable when the results by Suominen et al.’s [23] and Manikas’ [12] bibliographical studies are combined: On one hand, a stream of literature is devoted to study large-scale software, often open-source, projects consisting of hundreds if not thousands of auxiliary projects, such as R and Python programming languages, and their packages. On the other hand, another literature stream is devoted to understand marketplace-centered ecosystems, such as Google Play and Apple App Store.

This paper contributes mainly on the latter literature stream and the division between these two literature streams is meaningful to this study: The application developers belonging to the former group are often motivated with a different set of reasons ranging from meritocracy to fame and improving the CV or just contributing for the society. Whereas these reasons are also available in more business-oriented ecosystems [30], often financial benefits are the main reason.

In the open-source related software ecosystems, the first condition presented by Moore [5] for the struggle of leadership might not be fulfilled: while the ecosystem is healthy according to its own indicators, the ecosystem might not be interesting to fight over. Thus, software ecosystems should be selected with a care for empirical stud-
ies as well as generalizability of results should be well justified.

Second, the argument presented in this conceptual study is deduced from only one case. It might be that the case is not representative enough that general rules of an ecosystem’s lifecycle could be identified. It can be, for example, that there are certain specific features of mobile application ecosystems that cause the seen shifts in bargaining powers. Therefore, more case studies about different ecosystems fields are needed to verify the found observations.

V. CONCLUSION

This paper presented and analysed a case of mobile application ecosystems. Based on analysis, it can be argued that applications are likely to increase their relative bargaining power in the mobile industry due to their impact even on the sales of different phones. This conceptual analysis, however, raised the question whether complementors and complements—i.e., the applications—can obtain such position that they start to threat the initial ecosystem orchestrator for the leadership of the ecosystem. While this analysis hinted that such a phenomenon might occur in the software ecosystems due to the improvements in cross-platform development tools, this analysis also emphasized that not much is understood about the evolution of business or software ecosystems. Therefore, this study calls for further work to analyse and clarify the role of complements in the evolution of artificial ecosystems.

Open Data Based Value Networks: Finnish examples of public events and agriculture

P. Linna, T. Mäkinen and K. Yrjönkoski
Tampere University of Technology/Pervasive Computing, Pori, Finland
petri.linna@tut.fi

Abstract - In recent years, several countries have placed strong emphasis on openness, especially open data, which can be shared and further processed into various applications. Based on studies, the majority of open data providers are government organizations. This study presents two cases in which the data providers are companies. The cases are analyzed using a framework for open data based business models derived from the literature and several case studies. The analysis focuses on the beginning of the data value chain. As a result, the study highlights the role of data producers in the ecosystem, which has not been the focus in current frameworks.

I. INTRODUCTION

Openness and open data have been appearing as development trends in recent years [1-5]. The transition to openness in international agendas and agreements has been agreed. [6-7] As can be observed currently, these decisions have an effect at both national and local levels. Some of the indicators of openness are a list of application programming interfaces [8], open data datasets [9], and Census services [10]. At this moment, data releases mainly come from municipalities or government organizations.

Recently, some companies have started to take on board the ideology of openness. They have begun to pick up on this innovation and accelerate their R & D by opening up some of their production processes, and organizing so-called industrial hackathon competitions for coders. Individual data openers can also be found in the corporate world, of which perhaps the best known is Google and its maps. No cases are known where many companies in the same sector are opening up the same kind of data.

This paper presents two different cases, which at the same time represent two different starting projects. The aim is to promote openness in these projects. A single data opening would have no business meaning, but when hundreds of companies’ open data via a common data format, it will generate business benefits for many different parties. Thematically, these two cases are completely different. In the first case, the focus is on the openness of public event organizations and in the second case, the focus is on the openness of agriculture.

In the second section of this paper, the business ecosystem and value network are examined from the open data point of view. Projects and cases are introduced in the following section. The concluding section contains a summary and discussion of the presented open data roles and some thoughts on the future.

II. OPEN DATA BUSINESS ECOSYSTEM AND VALUE NETWORK

A business ecosystem is a dynamic structure of organizations utilizing business potential influencing and influenced by each other, in a certain business environment. It consists of a heterogeneous set of firms that are interconnected through a complex, global network of relationships. A data-based business ecosystem is formed by organizations where each has its own part and know-how in the data-based business. The ecosystem’s actors affect and are affected by the creation and delivery of the offerings of the other actors. Each actor also has a role in the flows of information, material, money, and influence the relationships between one another. [11-13]

Today, value creation is more and more seen to happen at the level of networks and alliances, instead of relationships or dyadic chains. A value network is a structure formed by all the actors that could benefit from a certain product or service offering, and add value to it. In the value network, different economic factors – supplier, partners, allies, and customers – work together to reinvent and co-produce value. [14-17] In addition, in an ecosystem, value is not created in a chain but more in a network of actors inside a certain ecosystem [13].

Business model literature has been developed in many different domains. Therefore, many different insights exist - but in general, the business model is a single-company-level concept that takes a stand on three matters: what does the customer get? (value proposition, products and service offering); how does the customer get the value? (value network, delivery channel), and how does the company get the money (cost structure, revenue models). [18-19]. The Business Model Canvas [20] is one of the most stable, most referred to and most generic business model tool. Immonen et al. [13] have identified it as suitable for use in the open data domain.

As part of their open data research program, Deloitte has published a review, which also introduces (Fig 1) five archetypes of open data business models [4]:

- Suppliers: organizations that publish their data via an open interface to allow others to use it
- Aggregators: organizations that collect and aggregate open data, typically on a particular sectoral theme
• Developers: organizations and software entrepreneurs that design, build, and sell applications
• Enrichers: organizations that use open data to enhance their existing product and services through better insight
• Enablers: organizations that facilitate the supply or use of open data, but are not themselves users of open data

The event information is already open data, but usually it is not in machine-readable format, and information is on the event organization’s website or social media accounts. The main point would be to capture the complete attention of potential customers. The event organizations spend a lot of money on marketing and resources to get event information out via various channels.

In the near future, event data will be digitized, structured, filled automatically on an event database, and divided automatically into different applications via an open interface. At the same time, event organizations need to modify work practices and transfer their workforce to other tasks. Event data can be managed with the centralized model, where one trusted organization maintains a service where event organizations can transfer the event information. The event information can be delivered via an open interface to websites, services, or mobile apps.

In Finland, an open source event interface was developed by the City of Helsinki, called Linked Events [21]. This interface will be used in the events case in the region of Satakunta in the west of Finland. In the spring of 2017, a project will begin, called “the digital leap of events” (in Finnish, tapahtumien digioliikka), where this case will be implemented. The database and open events interface will be built by the City of Pori. The project supports the export of data to the database and aims to find solutions do this automatically. The second part of the project will be piloted in the form of a variety of ideas that take advantage of the event interface. The project is the first step of digitalization to support tourism in the region of Satakunta. [22]

The project promotes the realization of the below-mentioned structure in the pilot area in Satakunta. The project includes a new kind of funding mechanism, which seeks solutions for high-speed pilots that are aware of problems. In this case, the problem is the poor availability of transaction data from the perspective of the customer, and the event organization’s waste of resources in event information management.

III. CASE A: THE PUBLIC EVENT DATABASE

An event organization may be, for instance, established purely for a specific music event, or the event organization may be a small unit of a bigger organization, which arranges various events, such as in municipalities and universities. Event organizations normally promote their coming events (e.g. music festivals, concerts, markets, races, seminars) via multiple channels, utilizing, for example, newspapers, radio, newsletters, and social media services. The aim is to reach potential customers, but in practice, advertising reaches many people who have little or no interest at all in the event. At the same time, event organizations compete for the attention and free time of potential customers. From the customer's point of view, newsletters in particular are challenging, because customers receive a lot of them and usually they are irrelevant.
centralized events database. In this case, the event organizations are data producers.

- Event data is connected with location information so event data can be retrieved / displayed on a map
- Event information can be profiled
- More information on the event can be included
- Event organizations may collaborate with each other more

To explain the last point further, collaboration means, for example, easier opportunities to hire manpower or facilities when more precise information is known about each other event organizer’s needs and services.

IV. CASE B: DATA-BASED AGRICULTURE

Agriculture is one of the oldest business sectors in the world. Throughout history, the harvest yield has increased per hectare. Now agriculture is in a new stage of development, where it seems to be difficult to find significant ways to improve production via mechanical improvements. Instead of developing mechanical implements, farmers should focus on data. Data sources can be satellites, drones, harvest sensors, field sensors, and working machines with special equipment like hyperspectral cameras and many kinds of sensors. The various sources of data make it possible to see the details of the fields and find the trouble spots, and so farmers can adjust the actions to be taken to an accuracy of almost one meter.

In Finland, the development of agriculture is still more mechanically oriented than data oriented. For example, it has been evaluated in the Satakunta region that there are less than ten harvest sensors, even though there are about 3500 working farms. On average, farming has shown a loss for the fourth consecutive year in Finland. However, the average distorts the truth, because some of the farmers do not invest in cultivation of crops, instead their focus is for example on cattle. For farmers, whose main focus is on cultivation, the situation is better. However, from the business point of view, there are several kinds of threats like intensification of extreme weather events, global competition, and data ownership.

Naturally, data management is not the core skill of farmers. For this reason, data should be supplied to a trusted organization, which knows how to collect data together, to make the necessary algorithms and analyze them, and give this processed data back to the farmers. In this case, we call this trusted organization the data operator. The data operator could be a commercial company, the government, or another organization. The data operator should also provide the processed data where appropriate as open data. Opening the data allows precise monitoring of the origin of grain, such as the revision of the criteria related to grain quality. It also allows for more accurate assessment of the condition of the fields, which affects the rental and sales prices for the fields. The quality of grain increases its sale value, especially if it is possible to verify the purity of the soil and the purity of the crop. Ensuring the quality of the crop also affects products made from it, for example, specialty bread products.
In this paper, the second case is based on the project, “Agricultural business development with intelligent data analytics” (the Finnish abbreviation, MIKÄ DATA), which is developing a data collection of fields, and the consolidation and display of intelligent data analysis server data items to the user. The project promotes the use of data in farming. The project also educates farmers about the introduction of technology and shows the benefits of data management. [23] In this case, the project is extended hypothetically with the Select Open Datasets process, which is not directly an original project aim.

The project highlights the value chain where a data operator (Rural Expert Organization) is required, who will take over the management of the data and its analysis. The data of individual farms is not useful, but when many of the farmers open their data to a data operator, the data operator receives a significant mass of data to be analyzed. For example, if cultivation plans are exported to the service early, the plans can still be changed if it seems that the world market is full of a particular variety of crop.

Figure 5. Project structure extended with Select open datasets process.

Farmers in this case are companies, which could open up their data via the data operator. Their role is to be data producers, but there are considerations that a single opener is not relevant. In the Finland case, there are about 50 000 farms, which could open their data to a data operator. It is essential that farmers also own the right to the data after they have given it to the data operator. There is needed to define mydata use in agriculture.

Figure 6. Case B structured in Deloitte’s archetypes.

Figure 6 depicts Case B structured in Deloitte’s archetypes (Fig. 1). In this figure, the Farmer has been interpreted as a Supplier, opening data related to the harvest yield of the farm. The Rural Expert Organization is acting as an intermediary between the Farmer and Final Consumer, e.g., by aggregating data from several farmers and enriching it with data from the Rural Database. However, by analogy with Case A, data from a single farmer is not openly available before it has been aggregated with other farmers’ data. Thus, the Rural Expert Organization seems to be the Supplier rather than the Farmer. Such an interpretation is depicted in Figure 7, in which the Farmer represents the archetype Producer, which is not in Deloitte’s model (Fig. 1).

Figure 7. Case B re-structured using archetype Producer.

Below are listed a few of the potential motives of farmers to open up their data.

- Traceability of the origin of food is improved
- Productivity is improved when the farmer can better respond to the world market situation
- Farmers can get a wider variety of analyses from various providers
- Reliance on any particular service provider is reduced
- New products may emerge that take advantage of open data on agriculture
- Farmers do not need to specialize as data experts
- Knowledge of the actual conditions of the fields will help the sale and lease of fields

To clarify the last point, larger regeneration activities can be done for fields when it is known that this would also increase the value of the field.

![Diagram](https://via.placeholder.com/150)

**V. CONCLUSION**

This paper presented two cases, where data openers were companies. One individual data opener is not relevant in these cases, but several dozen openers start to become relevant. The number of openers will create new types of ecosystems. These two cases present very different sectors. The public event database case focused on event information. The data-based agriculture case focused on data on fields. There are not so many data openers that are companies and no other cases like the ones in this paper are known. Data openers are normally municipalities or various government organizations.
Figure 8. The archetype Producer placed at the beginning of the value network of open data.

Figure 8 presents a generalization of Figures 4 and 7. It suggests Producer as an additional archetype for Deloitte’s model. While Supplier is an organization that publishes data via an open interface, Producer delivers a piece of data to the Supplier in order to make it openly available.

The data producers have a stronger role in these two cases than in Deloitte’s value chain model, which is based on government open data. The data producer’s role needs to be separated from the data supplier role. The structure is then a little different, because in these cases there are many data producers, while in Deloitte’s open data model there is only one data provider, i.e., a municipality. In practice, this chain model has not yet been tested, but in this paper, we have briefly outlined the events organization and agriculture development projects, which will contribute to the development of these value chain models.

In both cases a trusted third party is needed to build and provide a service between the data producers and end-users. In the event case, the trusted organization is the City of Pori. In the agriculture case, the entity has not yet been resolved. This service will be built during the project, but, at the end of the project, one of the trusted organizations should take over the service.

The reasons and motivation for opening up data are quite clear when government or municipalities open data. Openness is required in international agreements. Of course, there are also other motivational aspects, such as municipalities hoping to create new businesses via open data. In business cases, motives are not based on international agreements on openness. The reasons for opening up data will probably have to be related to the profitability of the business. In both our cases, the fact was emphasized that there should be numerous data openers in order to generate sufficient data to be analyzed. For these two cases, it is still not clear which matters motivate companies to open up their data. During these two projects, the real motivations might be seen. In the report on a data ecosystem for agriculture and food, made by Godan, the motives of other organizations to open their data for use in agriculture have also been discussed [24]. In other words, when building an ecosystem many players are needed, but each has their own motives for opening up their data.

The rising value of the network can also be considered through the Virtuous Cycle theory. When there are sufficiently large data openers, it generates interest for service developers. Before a critical mass can be reached, a lot of work is needed to achieve it. The benchmark is the mobile phone sector, where there are different competing platforms.

In the future, there is a need to examine how the business model canvas would be suitable for testing the value chain for each business case. The canvas model could provide a better detailed understanding of how each company operates and can find success of open data ecosystems.

The public event case also has a significant cultural purpose. The project is part of a larger objective to promote tourism in the area. Tourists can receive comprehensive and experienced regional services. Tourists can be made increasingly aware of events in the region and its diverse culture. Digital services like Airbnb is one of this kind, which enables closer experiences of the local culture.

Abstract – Application of scientific forensic methods in ICT has become a mainstream methodology not only in criminal and civil proceedings, but also in preventive maintenance of various aspects of ICT systems used by corporations, governmental and other institutions. However, despite efforts of solution providers to create forensic hardware, software and procedures that are purported to be easy to use even by those that are not forensic experts, in most cases forensic proceedings are connected with high utilization of financial and temporal resources. Accelerated changes in information technology and architecture also require additional regulation that will pre-emptively ensure adequate amount and form of forensic trail left for possible future investigations. This paper is an attempt to describe current state of affairs of forensic proceedings, the latest trends and to provide comment on their financial impact and consequential real-world feasibility.

Key words: forensic proceedings, forensic investigations, financial impact, ICT

I INTRODUCTION

Generally, forensic science or forensics is the application of scientific principles and techniques to matters of criminal justice especially as relating to the collection, examination and analysis of physical evidence [1]. The main characteristic of forensics is that it produces results and reports suitable to be used in courts or judicature, and for public discussion or debate. Therefore, forensics is indubitably tied to the legal context and explaining complex facts and their mutual connection in simple, straightforward language and layman terms to those who are not subject experts, but have to reach certain conclusions or make decisions based on the presented facts.

Digital forensics is one of the latest branches of general forensic science dealing with digital traces and artefacts. One of possible definitions of digital forensics is given by the following: “The application of computer science and investigative procedures for a legal purpose involving the analysis of digital evidence after proper search authority, chain of custody, validation with mathematics, use of validated tools, repeatability, reporting, and possible expert presentation” [2]. As it is clearly visible from comparison of definitions of “general” forensics and the digital one, digital forensics deviates from general definition because it does not analyse material (physical) evidence. Material nature of evidence was initially included in the definition of forensics because reliance on physical properties of the evidence clearly demonstrated validity of the used method. While one can argue that evidence digital forensics is dealing with is material, in a sense that it is usually inextricably tied to material media that contains them, their nature is clearly not material. This demonstrates how technical developments of the present and near future will test and challenge some definitions that seemed to be solid in the past.

Over the past two decades, dematerialization of the IT world has caused detachment of the data, media that contains them and physical locations where such media is stored. Internet became a new transport layer for such evidence, crossing geographical barriers and further pushing the envelope of well-established legal framework whose jurisdiction is usually defined by physical national borders. While crime and other events are always one step ahead of codified legislation, described course of events made it very difficult even for those very best in the legal profession of digital forensics, and those who use their services (district attorneys, lawyers and courts) even to apply existing legislature, let alone understand the presented facts that are usually dealing with very complex technical architecture, facts and conclusions.

Most authors agree that until events of 9/11 [3], separation of non-material world of digital networks and systems according to national and geographical borders was one of the main obstacles in front of experts in the field of digital forensics and users of their services. After 9/11, new legislative acts have been passed all over the world to support the agenda of “fight against terrorism” [4], further facilitating cooperation between national bodies in charge of ICT infrastructure and legislative bodies of various countries, in provision of digital evidence during investigations. However, facilitation of this process has caused some major concerns among privacy advocates. Civil liberties implications of counterterrorism policies are a hot topic of debate in the European Union whose directives still protect the privacy of its citizens’ citizen. Findings of Julian Assange’s WikiLeaks organization and those of Edward Snowden have clearly demonstrated how pre-emptive acting on behalf of the governments creates a myriad of more or less coordinated global surveillance programs with cooperation of telecommunication companies and European governments [5] that are clearly creating breaches on behalf of privacy of their own citizens.

It is clear that there are several concerns to be addressed by experts in digital forensics and legislative branches outlining the operational framework. Privacy of citizens and security of corporate business information has to be leveraged against national and international security; digital evidence is extremely volatile in nature, therefore it has to be carefully...
collected and examined, and it has to be done quickly, in order to avoid data expiration. Requirements related to digital data handling have to be respected. Furthermore, international cooperation is often the main prerequisite for most forensic investigations.

The described situation requires regular engagement of significant resources: time needed to perform analysis and create reports, sophisticated software and technology to analyse media and networks, and skilled experts who are able to explain digital findings. Therefore, both the required technology and time of experts are major constraints in forensic examination of digital evidence and if improperly utilized, they could result in sunk cost or even misinterpretation of findings.

II DIGITAL FORENSICS PRINCIPLES AND LAWS

Modern forensics has its roots in ancient China, with Song Ci being the most famous forensic media! expert during Southern Song Dynasty whose book “Collected Cases of Injustice Rectified” is still regarded as a seminal book of forensic science in China. Developments in the field of forensics in Europe became rapid only in the 19th century and especially in the beginning of the 20th century with wide adoption of fingerprint analysis invented by Juan Vucetic in 1891. Widespread adoption of forensic and scientific methods and introduction of expert witnesses in most legislative systems had as a consequence the dissemination of forensics in almost all fields of human life (and related legal proceedings).

Digital forensics is only a logical development of the above mentioned and became a discipline with the introduction of computers first used as mainframes for mass data processing. In the past two decades and with further development of information society, computers, smartphones, networks, servers and Internet usage are very usual the usual and even expected part of many other legal proceedings, in the areas of both the criminal and civil law.

Digital forensics adheres to several classical laws of forensics sciences that are also used in other areas of science. While different sources quote different versions of these laws, they can be summarily explained in the following way when applied to the digital world:

1. Law of individuality, stating that every digital artefact has the characteristics that are not duplicated in any other object.

2. Principle of exchange (otherwise known as Locard’s Exchange Principle, as a hommage to its founder, professor Edmond Locard) according to which when the perpetrator or the instrument (s)he uses comes in contact with the victim or surrounding objects, they leave traces, but they also pick up graces from them. This principle is extremely important in digital forensics.

3. Law of progressive change applied to digital forensics means that every digital trace changes with the passage of time. The impact of this principle in digital forensics is immense because the passage of time logarithmically alters it. Digital data evidence is among the most volatile evidence forms [9].

4. Law of comparison states that only the likes can be compared, meaning that only like samples and specimens can be compared.

5. Law of probability claims that all definite or indefinite identifications made consciously or unconsciously are based on probability.

6. Law of circumstantial facts, otherwise known as “facts do not lie, men can and do” requires reliance on digital data and evidence and not oral evidence, power of observation or suggestion.

Except basic forensic laws that are more or less common for all forensics disciplines, there are a few more principles of digital forensics that are specific for the field of digital investigations [10].

1. No action taken during the forensic investigation should change data which may have to be relied upon in court

2. In case that an investigator has to access original digital evidence, he has to be competent to do so and give evidence explaining the relevance and implications of their actions. Considering that operating systems and programs alter the content of digital evidence without the user being aware of such change, forensic analysis is usually performed using relevant media images.

3. An audit trail has to be created and preserved demonstrating that the chain of custody over digital evidence is maintained. An independent expert should be able to examine the utilized methodology and achieve the same result.

4. There has to be a single instance in charge of investigation and ensuring that the forensic laws and principles are being adhered to.

The golden standard in digital forensics nowadays is the Abstract Digital Forensics Model, created as a generic, technology-independent model, composed of nine different phases (Figure 1).

![Figure 1. Abstract Digital Forensic Model [11]]
This model assumes that the incident type is well recognized and determined. In comparison to previous models, this model consists of detailed pre- and post-investigation procedures.

III FINANCIAL IMPACT OF DIGITAL FORENSICS

Digital forensics trends are largely dictated by rapid advances in information technology over the past decades. In the latest period, we saw rapid growth and development of concept of Internet of Things (IoT), where ubiquitous computing principles are applied to a variety of devices and sensors in media, manufacturing, energy management, medical and healthcare, transportation, building and home automation, environmental monitoring and personal use. Each of these devices may serve as a source of digital data stream to be analysed as part of forensic process. With the introduction of IoT, literally almost anything can become an object of digital forensic investigation, from wearable technologies and cars, to sensor grids. An interesting analysis of diverse topics in journals covering different areas is shown in Figure 2.

![Figure 2. Coverage of digital forensics topics in journal papers](image)

While the number of overall papers shown in Figure 2, is low and its sum is not statistically significant, it shows a variety of topics covered by digital forensics. Some other papers show that 77.8% of all cases deal with single user computers, 44.4% with network forensics, and 55.6% with mobile forensics [13]. It is worth noticing that the sum is above 100% because in some investigations, there are multiple objects. So, despite variety of various objects of digital forensic investigation, some less complex or "traditional" objects still make up the majority of all investigations. This can partially be explained by the latency that is still prevalent in this field: there is a significant passage of time since the moment when certain digital evidence is created until the time it is fixed for analysis. So, forensic investigators are still working with delayed data.

On the other hand, there is an entire industry made around log data analysis and even predictive algorithms, aimed especially towards large enterprise server and network systems that are creating automated environment for large-scale data acquisition, analysis and alerting of administrative and other personnel in relation to potentially occurring anomalous events. These systems are in fact forensic in nature: they create forensically viable environment for analysis of various events. In most cases it is even possible to program various actions that will be triggered by events. These systems are primarily used to facilitate day-to-day operations and administration of various ICT systems, and to provide audit trail for compliance purposes, but they can also be used in forensic analysis and provide a valuable source of information, especially if their usage and data storage follows forensic principles and laws.

Legislative branch is also placing forensics-motivated requests in form of various laws and requirements, especially aimed towards telecommunications and IT service providers. In most telecommunication acts, there are articles and provisions requiring service providers to install and maintain systems and software (often at their own cost) that tracks its usage and provide full access to the police and investigators. This trend is widespread in the United States and more and more present in the European Union. Privacy is still one of the main concerns and only communication meta-data and not its content is preserved, unless measures of wiretapping or surveillance are ordered by the court. It is reasonable to expect that in the future there will be more and more implementations of legislation-driven systems that will monitor patterns of usage of various information systems in order to collect data for later forensic analysis.

Anticipative inclusion of data logging in laws does not only provide audit trail and basis for further forensic investigations, it can also lower the cost of forensic analysis because it contains data that would otherwise have to be extracted using other, more costly methods, or it would not be available at all. The cost of forensic investigations in the USA is typically in the range of 10,000 USD - 100,000 USD with hourly rates in the range between 125 USD and 650 USD [14]. These costs can be significantly lowered with greater inclusion of logging tools, some of which can also be obtained as a open source data loggers and maintained as such. It is worth noticing that there is significant overlapping between solutions that are behind implemented controls in systems of information security and forensic logging tools. Organizations that have higher achieved levels of information security will also have less security breaches, and probably even less those that will result in serious consequences that might be a matter of forensic investigation. Even if that occurs, forensic investigation might be faster or easier, thus incurring less related cost.

Inclusion of legislative requirements seems to be especially important in the case of cloud computing forensics. The National Institute of Standards and Technology of the U.S. Department of Commerce has recognized this importance and has included forensic science challenges in the draft of its NISTIR 8006 standard. This draft anticipates almost all steps of forensic process described in this paper and recognizes that cloud forensics possesses certain specific traits and challenges arising from the distinctive nature of the computer cloud [15]. It further defines cloud computing stakeholders and their roles, and collection and aggregation of challenges, along with additional observations. The most distinctive are:

1. Time, either in terms of consistency or data volatility in time,
2. Location, where even locating an evidence may be a major hurdle in forensic investigation, and
3. Data sensitivity, where pervasive use of cloud computing environments by users and employees could elevate the risk of incidents that might end up as forensic investigations.
Additional requirements for laboratories performing forensic investigations in ICT and especially data acquisition are arising from some applicable ISO standards, and especially the new edition of ISO /IEC DIS 17025: General requirements for the competence and testing and calibration laboratories, slated for the next revision issue in May 2017 [16]. In United Kingdom, there will be a mandatory required certification of ICT forensic laboratories according to this standard [17] – something that was until now reserved for “wet evidence” laboratories dealing with DNA testing and organic evidence. This procedure will have far reaching consequences for all involved parties because, at this moment, four year long backlogs for analysis of seized computer equipment are not unheard of in the industry [18]. Currently, the market of digital forensics field consists of a small number of large players, and a large number of one- man forensic investigators who are very important in the process of provisioning forensic assistance to district attorneys, police and judicial system, and decrease of current forensic backlog. The anticipated certification of the process will both increase the cost of service due to less competition and lengthen (at least initially) the process of forensic investigation until the market is fully consolidated.

VI CONCLUSION

Digital forensics deviates from general definition of forensics because its procedures are done over a set of non-material evidence, which is one of the prerequisites of the traditional forensics. However, media where such evidence resides is still material in nature (hard drives, memory cards, network storages, volatile memory).

There are several other characteristics that separate digital forensics from other, more traditional forensic disciplines, some of them being evidence volatility, remote geographical placement of evidence, transition over several legal jurisdictions, reliance on legal framework and implemented measures of information security to obtain digital evidence, and constantly changing technology.

Digital forensics follows the same well-established laws and principles known in the other forensic fields. However, the amount of analysed material, the inability to make data acquisition automatic, high level of required skills, knowledge, specialized hardware and software and time required to perform the analysis are the main obstacles placed in front of forensic investigators. Modern digital forensics also has to perform the analysis of the new systems, like data acquired from sensor arrays and grids connected to the Internet of Things, personal devices like mobile phones or cloud computing systems. Such forensic analysis is often very complex and costly.

One possibility of control of possible forensic cost and facilitating forensic analysis is the implementation of various controls aimed to elevate the achieved level of information security. These measures often provide a good level of audit trail that has to be kept under forensically sound conditions and it could be later used as such. Therefore, there is a significant level of overlapping between the information security management systems and tentative subsequent forensic usage.

There is a noticeable global effort to standardize practices in digital forensics by using standards already applicable to other forensic fields and especially DNA and crime trace analysis. The introduction of these standards will further increase the cost of forensic services, and might render small forensic investigation teams unable to compete with large accredited laboratories, who possess capabilities to forensically analyse large volumes of ICT equipment and data.

Abstract - The implementation of RFID technology in computer systems gives access to quality information on the location or object tracking in real time, thereby improving workflow and lead to safer, faster and better business decisions. This paper discusses the quantitative indicators of the quality of the computer system supported by RFID technology applied in monitoring facilities (pallets, packages and people) marked with RFID tag. Results of analysis of quantitative indicators of quality compute system supported by RFID technology are presented in tables.

I. INTRODUCTION

The development of elements of RFID technology leads to an improvement of its application in many sectors of the economy, such as: maritime (tracking of containers, etc.), auto industry, production processes, identification and/or tracking animals, implantation in humans, etc. [1,2,3]. According to research by IDTechEx, during 2015 8.9 billion tags were sold, while in 2016 year around 10.4 billion will be sold [4]. Most selling tags are passive UHF tags. In addition to this rapid growth in the application of RFID technology, the problems with the reliability and availability of the system elements are still present thus leading to restrictions apply in many applications in the economy. Therefore, this paper analyzes the reliability, availability and security of critical elements of RFID technology (RFID reader) and a computer system.

Reliability and availability of RFID technology depends on the reliability and availability of the reader, or moreover, depends on the reliability of reading tag’s content. Reliability of tag is probability that content of tag will be read accurately for a particular operating environment, while the reliability of the reader is probability that reader will successfully read all the data from the tag in time t (reader is in working condition at the time of observation t) for a given work environment, and, as an indicator, mean time between failures is usually given.

Reliability of computer system supported by RFID technology (CSSRFIDT) refers to the ability of the system to maintain its operational state without delay or the ability to prevent the degradation of characteristics for a certain period of time, and as an indication, most often the mean time between failures is given. The total availability of CSSRFIDT system is an integral part of the availability of all system elements. Security of CSSRFIDT system is probability that system will either function properly or will terminate in a safe manner and is calculated so that the calculation takes all work and correct states as well the state of safe failure.

By inspecting the scientific and professional papers and practices can be observed that a lot more attention is given to privacy and data security while the reliability of the elements of RFID technology and the reliability of the entire computer system supported by RFID technology is rarely analyzed.

The low level of confidence lead to compromising the security of data and information, dissatisfaction of subjects in the business process because they cannot perform all the functions CSSRFIDT system, and due to higher maintenance costs and so on. It is obvious that the availability of 99% (the system is in failure three days and 15 hours and 40 minutes in one year) or 99.95% (the system is in the cancellation of 1 day, 19 hours, 48 minutes in one year) is not permissible but values of 99.99% (the system is in the cancellation of 52 min and 36 sec. in one year) or 99.999% (the system is in failure 5 min., 15 sec. in a year) are the values to be pursued in the exploitation of the system.

Increase of reliability CSSRFIDT system has its price and economic justification. Correction after the occurrence of failure must be as short as possible. It is necessary to implement new maintenance strategies or a combination of the new strategies supported by information system for maintenance management. The application of new strategies leads to increased reliability and availability, failure prevention and reduction of maintenance costs.

The new strategy of maintaining integrates RFID technology and CMMS (Computerized Maintenance Management System) system. Elements of RFID technology enable the storage and transmission of data for maintenance in the CMMS system [5].

II. RELIABILITY OF ELEMENTS CSSRFIDT SYSTEM

Achieving the target reliability of CSSRFIDT system requires undertaking certain activities at all stages of the life cycle of the system. During exploitation of the system
reliability can be increased by applying the techniques of fault tolerance and dodge failures.

By incorporating redundancy system availability is increased so price of system with partial or complete redundancy is quite understandable issue. However, if the analysis starts from the criteria of safety of object that is tracked, additional cost on basic redundant structure, and the price difference from the simple structure of the system and the complex structure that is tolerant to failures, remains to an extent that justifies the goal.

The planned failures are caused by planned and regular maintenance of elements CSSRFIDT system and therefore it is required that certain elements of the system to be inactive for other elements and users (installing new or upgrading existing systemic functions, update the operating system or systems for database management, etc.). Unplanned failures are the result of human errors, bugs in software, hardware failure (replacing the hard drive, replacing network cards, etc.) and environmental conditions (dust, humidity, vibration, high/low temperature and voltage fluctuations).

A. Reliability of elements of RFID technology

Tags differ in shape, size, power, capacity, protocol, the radio frequency wavelengths and the method of data storing [6, 7].

The tag can store n bits of useful information of tracked object. The probability that the content from tag will be properly read depends on the probability that each bit won’t be accurately read ($P_{em}$) and can be represented by the equation (1) [8]:

$$P_r = (1 - P_{em})^n$$

(1)

Readers are different in complexity depending on the type of tag with which they communicate, and the functions to be fulfilled, such as error checking and correction. The reader can be fixed or mobile. Fixed readers are mounted on a fixed structure and most commonly they use external antenna (longer range), while mobile readers are handheld readers and antenna is implemented in the reader (shorter range). The position of the antenna significantly influences the characteristics of the antenna and thus the reliability of the reader. Readers can be distinguished between the implemented protocols, the possibilities of networking multiple readers, the operating frequency, the management capabilities with multiple antennas, etc.

The reliability of the elements of RFID technology is influenced by several factors: speed, environment, distance, orientation, encryption techniques, strength, sensitivity and debugging. Many of these factors are the result of signal attenuation, which reduces the signal to noise ratio [9, 10].

The efficiency of reading content from tag depends on the reader’s radio frequency beam which shape is elliptical. Therefore, as the distance from a reader increases it is possible that within the zone of reading more than one tag exists. Consequently, as result of an increase in the number of tags there might be an issue about collision of tags. Reliability of reading depends on the distance between the tag and the reader, and the distance between the reader and antenna. Maximum read range is controlled by the power and sensitivity of reader. The choice of power levels and sensitivity reader depends on the application.

Environment has large influence on the reliability of readers, because the presence of metal, water or objects that absorb or reflect the radio frequency signal may affect the accuracy of reading the content from tag. In addition, the presence of wireless networks and other sources of noise also affects on the reliability of the reader. Furthermore, the accuracy of reading also depends on the type of matter in which tag is packed especially for tags operating in the UHF and MF frequency range. It is necessary to take into account the number of people in the work environment of reader because people like silencers signals have an effect on the accuracy of the reading.

Orientation of tag refers to a position of tag to reader. Tags that are not sensitive to the orientation can work regardless of the orientation. RFID systems that operate at higher frequencies are sensitive to the orientation of the tag. Best reading reliability is achieved when the tag is set toward the reader, while the lowest reading reliability is achieved when the tag is placed on top of the object being monitored [11]. The sensitivity on the orientation is visible with a linear polarized antenna and the best reading is achieved when the tag is parallel to its axis and then provides maximum read range.

Encryption involves the use of codes for changing the original data in a different format for storage or transmission. To store data on the tag unipolar and polar techniques are used. From polar technique being used there are irreversibly to zero (NRZ-Non-Return-to-Zero Level) and Manchester method. Unipolar encryption is the simplest. Generally, one voltage level is assigned to a binary zero, and the second level is assigned to binary unit. Polarity refers to whether the impulses are positive or negative. In methods irreversibly to zero, the signal is always positive or negative. There are two types of this type of encryption: NRZ-L (Level) where the signal level depends on the state of the bit, and NRZ-I (Inverted) where the signal turns when it encounters a binary first. Manchester methods are two-phase encryption type in which signal is changed to opposite pole in the middle of one bit interval.

Emitted power of reader has a big impact on the reliability of the reader. If the energy level falls below a certain threshold (the sensitivity of the reader) the reader will not read correctly the content of the tag and thus affect the reliability of the reader.

In order to increase the reliability of readings two or more tags are implemented to the tracking object. By increasing the number of tags the reliability of reading is also increased. In such applications position and distance
between two or more tags must be taken into account [11, 12].

B. Reliability of computer system

Reliability, availability and security of the computer system are directly linked with the emergence of failures in hardware, software modules or errors in the database. Indicators of reliability of hardware are usually linked to a period of normal operation, which is the longest. Reliability of software subsystems increases over time because its errors are detected and corrected so their numbers are decreasing. In addition, changes in the operating profile or environment may cause a change of reliability and then decreases the reliability of software. Therefore, the measure of reliability software must be linked to the operating profile and the environment in which the system works [13].

A computer system that tolerates failures must be designed so that operates properly at all times, regardless of the defects in the hardware or software, or there must be a module that will dynamically check for accuracy and proper function. Research has shown that the module for fault detection does not detect or does not detects 100% of all failures resulting in operational work, but it only "covers," or detects all possible defects (the definition of this concept have made Bourciers, Carter, and Schneider [1969]) with a coverage factor C (0 < C <1) [14].

In order to increase reliability, availability and security of computer systems in hardware and software modules appropriate diagnostic program (self-diagnosis) is incorporated and it generates a warning at the time of detecting errors. System failure occurs by failure of hardware or software components or it is caused by human error.

III. MODELING RELIABILITY, AVAILABILITY AND SECURITY OF CSSRFIDT SYSTEM

Analysis of quality indicators of CSSRFIDT system is made by the simulation methodology used to describe the behavior of the system using the Markov method. To use the Markov method two basic conditions are met, namely: the exponential character of the probability density function of failure, i.e., a constant function of frequency of failure and the exponential character of the probability density function of the correction, i.e., a constant function of frequency of repairs [15, 16].

Modern implementation of the power supply system use uninterruptible power supplies. Therefore, with the simulation considering the quality indicators of critical elements 100% reliability of the power supply system will be assumed.

Due to the specific functions that CSSRFIDT system executes; special attention is paid to the reliability, availability and security of critical elements. The changes of the critical elements as well as the frequency of transition from one state to another are described. Elements, in order to perform their function, each state that passes from the state of the work in another state, must restore back to the state of work. Disturbing the static balance between the states, changes the reliability, availability and security of the system, but in every element of the event dynamic processes occurs.

Analyze the transitions that can take place to elements of the system under certain assumptions:

1. Failure rate λ and repair rates μ of modules are constant and not dependent on time. Failure rate of a computer system is a total failure rate of hardware (λ6), failure rate software (λ3), failure rate of operators (λ4), and failure rate of database, i.e. hardware λPC = λ6 + λ4 + λ5 and frequency of RFID reader λRFID.
2. All failures are mutually independent, i.e. any failure is independent from other failures.
3. Probability of occurrence of two or more failures in the time interval Δt is negligible.
4. The system starts in a completely proper operating condition where all system modules operate properly.

Failure of CSSRFIDT system can be in two basic conditions. One condition is defined as "safe" and another as "precarious" condition. Safe state (SO) of CSSRFIDT system means that the operator, after receiving a warning from the diagnostic program, performs a sequence of actions to close the database and system shutdown. Uncertain state (NO) of CSSRFIDT system means that diagnostic program has not detected the error and computer system simply "freeze" their work. In addition to these two states, in the analysis of quality indicators following states are also examined: SP state (initial state where all elements of the system are correct), SR state (primary RFID reader is in the failure but reserve RFID reader is active) and state SPC (primary computer is in failure but backup computer is active). If the diagnostic program detects a failure on standby RFID reader, and the recovery of the primary computer is not completed, it is possible the transition from state SR to state SO or transition from a state SR to a state NO. The transition from state SR to state SO is safe transition, and that means that diagnostic program generates a warning on the mandatory exclusion of reserve RFID reader and the operator performs the procedure of closing the database and system shutdown. The transition from a state of SR in the state of NO will occur when a diagnostic program does not detect a fault on standby RFID reader so the reserve reader "freezes" work. In such situations may arise malfunctioning hardware (RFID reader/antenna, it is impossible to program the tags or microchips) or software of reader (RFID reader cannot read the contents of a tag). Other passes are exactly the same as in the previous analysis so there is no need to repeat.

Equations for Markov model of reliability, availability and security may be written in matrix form:

\[ P_{\text{CSSRFIDT}}(t + \Delta t) = P_{\text{CSSRFIDT}}(t) \cdot T_{\text{CSSRFIDT}} \]  

(2)

where every element of \( P_{\text{CSSRFIDT}}(t) \) is the probability of elements of CSSRFIDT system with hot standby in a particular state at time t. \( T_{\text{CSSRFIDT}} \) is the transition matrix from state to state, while \( P_{\text{CSSRFIDT}}(t+\Delta t) \) is the probability
that each element of the system is in the proper state at time \( t + \Delta t \). Consequently, we can write:

\[
P_{CSSRFIDT}(t + \Delta t) = \begin{bmatrix} P_{SP}(t + \Delta t) \\ P_{SC}(t + \Delta t) \\ P_{SR}(t + \Delta t) \\ P_{SO}(t + \Delta t) \\ P_{NO}(t + \Delta t) \end{bmatrix} = T \begin{bmatrix} P_{SP}(t) \\ P_{SC}(t) \\ P_{SR}(t) \\ P_{SO}(t) \\ P_{NO}(t) \end{bmatrix} + \begin{bmatrix} \lambda_{SP} \Delta t \\ \lambda_{SC} \Delta t \\ \lambda_{SR} \Delta t \\ \lambda_{SO} \Delta t \\ \lambda_{NO} \Delta t \end{bmatrix}
\]

(3)

The initial conditions at \( t = 0 \) are:

\[ P_{SP}(0) = 1, P_{SC}(0) = 0, P_{SR}(0) = 0, P_{SO}(0) = 0, P_{NO}(0) = 0. \quad (4) \]

Substituting the appropriate values for the frequency of cancellation and correction, and solving matrix equation of Markov model, gives the value of \( P(\Delta t) \) by multiplying the vector of initial value \( P(0) \) and the matrix \( T \), \( P(\Delta t) \) multiplying the \( P(\Delta t) \) and transition matrix TRSS. General solution of equation of Markov model is given as:

\[ P_{CSSRFIDT}(t) = T^n \cdot P(t). \quad (5) \]

In accordance with Markov model reliability of redundant CSSRFIDT system is the probability that the system is in a state of SP, SR and SPC, which are the only states when a redundant system is operating correctly, i.e. the reliability of a redundant system with hot standby can be written as:

\[ R_{CSSRFIDT}(t) = P_{SP}(t) + P_{SR}(t) + P_{SPC}(t). \quad (6) \]

CSSRFIDT system is safe as long as it is in one of three states: the state of the SR, state SPC and state SO. Security of redundant system with hot standby can be written as:

\[ S_{CSSRFIDT}(t) = P_{SP}(t) + P_{SR}(t) + P_{SPC}(t) + P_{SO}(t). \quad (7) \]

Using software packages Isograph Reliability Workbench 11.0 - Markov model was created and simulated and performed experiments to data from MIL HDBK 217\(^1\): catalog and operational data for the real system and obtained numerical data for the relevant indicators of quality of CSSRFIDT system.

Development of the simulation model is made in several steps. In the first step a model of the critical elements of the system (RFID reader and personal computer) was created. In the second step was created a model where was added a reserve RFID reader and in the third step one spare computer is added to the model. Table 1 shows the results of quality indicators of CSSRFIDT system inputs for the frequency of cancellation of RFID reader and a personal account or \( \lambda_{RFID} = 5.3 \times 10^{-4}, \lambda_{PC} = 2.2 \times 10^{-4} \) from MIL HDBK 217 catalog and manufacturers, or elements of moderate reliability [17, 18, 19].

Based on the analysis of several maintenance contracts of CSSRFIDT system (from few companies who have contract of maintenance of CSSRFIDT and similar systems) frequency of repair ranges from 2 h\(^{-1}\) (repair executed by staff of organization with a telephone or Internet customer service help), 0.25 h\(^{-1}\) and 0.125 h\(^{-1}\) (repair executed by customer service staff).

\(^1\) MIL HDBK 217 is a military standard for assessing the inherent reliability of electronic equipment and systems based on the intensity of the cancellation of components.
Maintenance of CSSRFIDT system is combined, e.g. preventive and some simple repairs can be done by user, and corrective, adaptive and perfective maintenance executed by the manufacturer or service technician with certificates for repairs or maintenance. Repair of defective element is performed by one serviceman (if repair is performed by more than one serviceman than $\mu = \mu_k \mu$, where $k$ is number of servicemen). The values of availability, reliability, security, uptime time and time in dismissal of CSSRFIDT system for a year of work are shown in Table 1.

Looking at table 1 it can be observed that as the shorter the mean time to repair failure is, availability and security of CSSRFIDT system grows, and that during the cancellation time is reduced, while the reliability remains same. In order to increase the quality indicators of CSSRFIDT system redundant reader and personal computer are installed. Best availability and system security are achieved when the frequency of repairs is 2 h$^{-1}$ and MTTR (mean time to repair) is 30 min. By increasing the mean time to repair, the value of quality indicators of system are being reduced. Such a mean time to repair can be achieved only if the user has the IT knowledge that can perform certain operations of corrective and perfective maintenance, particularly when replacing the hardware module (RFID reader), installation of system and application software with the telephone or Internet support from customer service. It can also be noted that without maintenance and with increase number of elements the indicator "time to failure" increases.

Tables 2 and 3 shows the results of the quality for the input value of the operating frequency of failure of the RFID reader and the cancellation of the personal account or $\lambda_{\text{RFID}} = 9.6 \times 10^{-4}$ and $\lambda_{\text{PC}} = 2.7 \times 10^{-4}$ for the system consisting of a 10 readers deployed at different locations and the master server in the operative work. In this experiment the indicators of the quality of the system are observed after 8760h and 17520h.

Looking at tables 2 and 3, it can be observed that the availability, security and system in the cancellation are increasing, and the system in operation is reduced by increasing MTTR or by reducing the frequency of repairs. By increasing the number of electronic elements (redundancy) the quality indicators are being reduced. The worst results are obtained when redundancy of critical elements is not integrated and maintenance is not organized. Satisfactory indicators of the quality system are obtained by adding redundant system elements. Best system availability (99.9999%) and safety (99.9603%) for work time 8760h is obtained when both critical elements are redundant and the intensity repairs is 2h$^{-1}$ and MTTR is 30 minutes. If the problem cannot be solved by the staff of the organization, intervention of authorized service is required where MTTR ranges from 4 hours to 8 hours depending on the type of fault and location of customer service.

A major impact on quality indicators of CSSRFIDT system has and the quality of the used tag. Corrupted, damaged and poorly executed tags directly affect the quality indicators of CSSRFIDT system. By increasing the time to use the system (table 3), all indicators of quality systems fall indicating that the organization needs to carry out all maintenance activities and continuous IT educate their workers. Performance of tag depend on several factors, including the matter of which is made until the environment in which they are used (temperature, humidity, physical limitations, etc.). From the practice and research conducted at AT&T laboratories it is known that low quality tags can reduce the quality indicators of CSSRFIDT system from 20% to 30%. In order to maintain the value of quality indicators of system shown in Tables 2 and 3, it is necessary to take into account the quality of the tag. Therefore, it is necessary to use cheap redundant tags or high functional tags.

The quality and level of use CSSRFIDT system greatly depend on the quality of critical elements of the system, diagnostic programs, staff and system maintenance.

Looking at the value of quality indicators of CSSRFIDT system can note the following: availability, security of system in the cancellation increase, and the system in operation decreases with increase mean time to repair, or by reduce the frequency of repairs.

The analysis has shown that CSSRFIDT system configured with elements of moderate reliability and warm standby is highly available in the tracking systems. Availability of 99.9999% and 99.9996 achieved when both critical elements are redundant and intensity of repairs is 2 h⁻¹ and MTTR is 30 minutes.

These results can be achieved and maintained only if CSSRFIDT system is maintained by professional staff that will, at all times, respond to any hardware and/or software problem at work. Furthermore, in the system of CSSRFIDT it is necessary to use highly functional tags whose price go to 6$ or cheap redundant tags whose target price may range from 20 cents to 1 $.

For availability of CSSRFIDT system maintenance strategies, and quality of the organization and management of preventive, corrective, adaptive and perfective maintenance has a big impact.

III. CONCLUSION
Transportation and Power System Interdependency for Urban Fast Charging and Battery Swapping Stations in Croatia

Abstract – An increasing penetration of electric vehicles in recent years has been driven by government and municipal subsidies, tax exemptions, parking access priority, as well as by the citizens’ increased environmental awareness. Electric vehicles indisputably bring benefits to their drivers and society in general, indirectly through global warming and greenhouse gas emissions mitigation and directly through financial savings and cleaner microclimate. However, integration of electric vehicle charging spots at home or work, especially fast charging stations and battery swapping stations, without prior analysis can have a negative effect on power system. In order to predict and eliminate power grid issues before they occur, a detailed analyses should be made through a common understanding of both transportation and recharging needs of electric vehicles’ users and of the power grid constraints. Power and transportation system interdependency becomes of high value for correct placement and sizing of charging stations and for overall increase of social welfare. This paper analyzes electric vehicles charging needs at the basic level, through both the power system and the transportation system. An urban transmission and power grid in the vicinity of the Croatian capital Zagreb is used as a study case. Driving and electricity consumption curves are compared, locations for charging infrastructure are selected (fast charging spots and battery swapping station) and power grid’s available capacity is defined.

I. INTRODUCTION

Electric vehicles (EVs), over the past few years, made a breakthrough into personal and commuting vehicles market worldwide and they are starting to hold a meaningful share. Their rapid market sales increase at the global level can be seen from Figure 1 [1]. The highest market share occurred last year with percentage of more than 0.86% of total vehicles sold. When plug-in EVs market shares are observed in Europe by the country, Norway is “off the chart” since no other country comes even close to 24% share as it can be seen on Figure 2 [1]. Figure 3 displays estimated number of electric vehicles in use in five countries with highest EV share in total vehicles fleet [2]. Norway, even as a small country with population somewhat more than five million, is listed fourth. Such high penetration of EVs is a highly probable future scenario for all European countries, including Croatia, especially as touristic country.

Figure 1 Plug-in EVs market share from 2010 -2016. [1]
EVs are a powerful tool for greenhouse gas emissions’ mitigation and reduction as it is recognized through European regulations and directives such as Directive 2009/33/EC on the promotion of clean and energy-efficient road transport vehicles [3]. The greenhouse gas emissions’ cuts to at least 40% (from 1990 levels) are one of the main key targets within 2030 climate and energy framework [4].

Figure 2 Plug-in EVs market share in Europe [1]

Globally, EVs decrease greenhouse gas emissions only when electricity is generated in carbon-free power plants. Therefore, impact on urban microclimate is far more beneficial EVs’ feature since it does not depend on energy mix of power system, i.e. EVs can be observed as a new participant in the war against smog and urban pollution.
since they can reallocate emission sources from local transport sector to global electricity generation sector.

Charging of electric vehicles in urban areas should be considered from two different aspects. First one is from the transportation system viewpoint, i.e. observing usage of road vehicles, and the second one is from the power system perspective, which is related to the utilization of power system capacity [5], [6]. The interdependency of the two systems, transportation and power, is important when dealing with fast charging and battery swapping stations placement and sizing problem [7].

![Figure 3 Estimated electric vehicles in use in selected countries as of 2015 (in 1000 units)](image)

Furthermore, one of the main aspects that should be considered is the proper selection of the location. The location needs to be chosen in way that it enables profitable use of the charging infrastructure and alleviates the problem of range anxiety connected with limited range of electric vehicles [8]. There are several other problems associated concerning planning and operation of the fast charging stations and battery swapping stations such as optimal dispatch between two charging types [9] or provision of additional ancillary services [10], [11] but they are outside the scope of this paper. This paper will deal with initial analysis of selection of appropriate charging infrastructure capacity from both transportation and power system perspective and test mentioned interdependency on case of an urban area between Croatian cities of Zagreb and Velika Gorica.

II. TRANSPORTATION AND POWER SYSTEM INTERDEPENDENCY

Transformation from fossil-fueled internal combustion vehicles (ICE) to EVs, in urban environment, should not impact transportation habits of their user. The range anxiety, fear form insufficient EV’s battery capacity, is not so profound in urban centers where short range commuting is the main transportation feature as it is in long-range traveling. EVs, in regards to ICE, offer more flexible way of refueling/recharging. ICE can only be refueled at gas stations by stopping during their trip. An EV, on the other hand, can be recharged on fast charging stations (FCS) or battery swapping stations (BSS) by stopping during their trip analogous to an ICE, but also when parked at home or work. The difference is frequency of the charging, where ICE vehicles in general require much less frequent refueling. In accordance, urban centers can be divided into different zones regarding transportation and recharging possibilities:

- **Roads:**
  - Main roads with high transportation density;
  - Secondary roads with medium transportation density – streets interconnecting specific neighborhoods;
  - Local roads with low transportation density – streets within specific neighborhoods;

- **Parking lots:**
  - Parking lots with short vehicle’s stoppage times (up to max two hours), frequent exchange of vehicles and everyday usage – parking lots designated for consumers next to commercial buildings and next to public buildings;
  - Parking lots with short/medium/long vehicle’s stoppage times (up to few hours), not so frequent exchange of vehicles and periodic usage – parking lots designated for consumers next to buildings with periodic activities;
  - Parking lots with medium vehicle’s stoppage times (up to 8 hours), not so frequent exchange of vehicles and everyday usage – parking lots designated for employees;
  - Parking lots with long vehicle’s stoppage times (whole day, night), infrequent exchange of vehicles and everyday usage – parking lots designated for residents (residential buildings, student dormitories).

Refueling of conventional ICE vehicles requires short charging time and therefore gas stations are strategically located next to the main roads with high visibility and high transportation density. It provides both profitability to station owners and satisfaction of station users without fear of fuel shortage. The existing gas stations are also the most suitable locations for rapid DC FCS with ultra-high installed power (above 50 kW, charging up to 20 minutes) and BSS since they are already next to highly frequent road segments. Other benefit of placing FCS and BSS on existing gas stations is the availability of power grid, which entails investment cost reduction since no larger investments are needed.

Power grid is highly branched and additional infrastructure installation is easier compared to other forms of energy, e.g. heating system or gas distribution system. As mentioned before, electrification of road transport brings additional benefits for the vehicle’s owners, because vehicles can be charged when they are parked on different locations. Depending on parking lot characteristics electric vehicles charging stations of different characteristics can be profitable and beneficial. Therefore, three-phase AC charging stations with high installed power (more than 20 kW, charging up to two hours) can be installed on parking lots with high frequency, fast one phase AC charging stations of medium installed power (around 10 kW, charging up to 8 hours) can be installed on parking lots with medium frequency, while slow charging stations of low installed power can be
installed on parking lots with low frequency. In order to be competitive to refueling of the ICE vehicles, battery swapping and fast charging infrastructure is required. The two technologies complement each other since they deal with the different business cases and can together offer more flexibility to the drivers.

Besides the transportation aspect, electric vehicles charging station integration should be observed from the viewpoint of the power grid. The fast charging stations infrastructure require high power needs at the same time when the EVs are recharging, while battery swapping stations can recharge its battery stocks in periods when the electricity price is lower or when power system constraints are not bounding. Distribution network in Croatia is supplied through substations 110/kV or 35/kV to 10 or 20 kV voltage level. Most of the distribution substations under peak demand have loading of less than 50% of their rated power. The same thing applies to the most of 10 and 20 kV lines and cables supplied by distribution substations with their loading also less than 50% of their rated power (most of them even less than 25%). In other words, for Croatian case, distribution grid usually has sufficient redundancy for integration of new demand like electric vehicles charging stations. If congestions on some locations occur during peak periods caused by FCS there is a possibility to use battery storage in combination with FCS to improve distribution network conditions [12]

III. CASE STUDY

A. Considered Transportation System

As a test case for this paper road next to north entrance of city Velika Gorica has been chosen. Reason for such selection is highly urbanized area next to city of Zagreb with high transportation density. It can be found in [13] that traffic counting place number 2014 named “Velika Mlaka” is the third transportation density counting place by average density in whole of Croatia, and first in the vicinity of the Croatia capital Zagreb. Since counting place (CP) number 2035 named “Velika Gorica Northern Bypass” is geographically close to CP 2014 it is also taken into consideration. Locations of observed CPs are shown on Figure 4. It can be seen that differences between summer and annual peak are not significant.

![Figure 4 Locations of observed counting places](image)

General information about average traffic on analyzed CSs is presented in Table 1. Acronyms AADT and ASDT are referring to Average Annual Daily Traffic and Average Summer Daily Traffic, respectively.

<table>
<thead>
<tr>
<th>CP number</th>
<th>CP name</th>
<th>AADT</th>
<th>ASDT</th>
</tr>
</thead>
<tbody>
<tr>
<td>2014</td>
<td>Velika Mlaka</td>
<td>37.260</td>
<td>35.160</td>
</tr>
<tr>
<td>2035</td>
<td>Velika Gorica</td>
<td>7.958</td>
<td>7.119</td>
</tr>
</tbody>
</table>

Figure 5 and Figure 6 display average daily vehicle driving profiles at observed counting places. It is clear that daily driving profiles are matching typical daily behavior. At night hours, there are no activities and very few vehicles are on road. On both CPs two peaks exist, the morning peak – around 08:00 AM, and the afternoon peak – around 17:00 PM. It can be considered as “go-to-work” peak, and “back-to-home” peak.

![Figure 5 Charging place number 2014 “Velika Mlaka” - daily profile average hourly traffic](image)

The daily period between peak hours is full of activities and the driving profile curve is very high. After the afternoon peak, driving activities are decreasing together with other daily activities. The minimum of driving profile curve can be found around 3:00 AM.

![Figure 6 Charging place number 2035 “Velika Gorica Northern Bypass” - daily profile average hourly traffic](image)

Figure 7 and Figure 8 are taken from Google maps application where positions of the existing locations of gas stations are pointed out. As the existing gas stations are situated on the main road with two separate driving directions two gas station are commonly located on the same location on the opposite sides of the road. Traffic conditions at peak hours are colored on the same figures, morning and evening peaks, respectively. Main roads are not suffering from heavy congestion unless unexpected
maintenance, car accidents or other unexpected events occur.

![Figure 7 Traffic congestion and gas stations on observed area – morning peak 08:00 AM [14]](image)

For the selection of appropriate charging infrastructure and taking into consideration future increased shares of electric vehicles, it can be assumed that 1% to 2% of all vehicles on the road will be in need for recharging. This means approximately 10 vehicles at each hour would be stopping to fast charge their vehicles or swap the batteries depending on the user preferences of the charging mode philosophy.

![Figure 8 Traffic congestion and gas stations on observed area – afternoon peak 17:00 AM [14]](image)

**B. Considered Power System**

As it was mentioned before, power system infrastructure in the considered part of the distribution system and used in the test case contains one main 110/20 kV feeder transformer substation TS 110/20 kV Botinec and associate set of smaller distribution substations 20/0.4 kV as it can be seen on Figure 9. Only the main supply route is depicted, while all the area has an alternative route of supply (less efficient one) from the direction of TS 110/20 kV Velika Gorica. For this analysis, only the main supply route is relevant. The area of the interest next to the main traffic route is supplied through two 20 kV feeders marked with different colors. The peak loading of all distribution elements does not exceed 50%. There is one 2 km long weak overhead line in the distribution network that would require reconstruction if the demand requirement increase. If a congestion occurs, it can be easily located with this kind of analysis. The transformer capacity for the transformation form 20 kV to 0.4 kV does not represent great share of the investment and can be easily, if needed, replaced on the location of possible fast charging and battery swapping stations.

![Figure 9 Distribution power grid supplied from feeder substation TS 110/20 kV Botinec](image)

Daily loading curve of the relevant transformer is shown on Figure 10. Total installed capacity is 2x40 MVA. Maximum loading is 28.86 MW, or approximately 35 MVA (~89%). At every moment n-1 reliability requirements must be held, which means that all demand can be supplied through either of the existing 40 MVA power transformers. Considering that fact, there is an additional capacity of approximately 10 MW available (green circle) and the reliability margin is preserved. When comparing daily curves from transportation system to the daily curves in the power system it can be seen that the shape coincides but the peaks (morning and afternoon) for the power curve lag for about two hours behind the transportation curve peaks circled in red (8 AM and 5 PM).

![Figure 10 Daily loading profile for TS 110/20 kV Botinec](image)

Power flow for conditions for maximum historic demand with additional 2.25 MW as the highest amount
of possible demand increase (where no network investment is required) are visualized on Figure 11. In other words, additional capacity of 2.25 MW is the borderline capacity that can be integrated in the area of potential charging station locations marked with blue circle. The red circle identifies the weak spot in the network.

![Figure 11 Power flow analysis shows the loading of elements and overloaded segment (overloaded 35 mm² cross-section AlFe over-head line)](image)

The maximum number of charging spots that can integrated into the power grid without additional network investments is approximately 18 charging spots and a battery swapping station with projected peak demand of 150 kW. The analysis conducted is conservative and is done under the assumption of coinciding loads.

### C. Comparison

In the planning phase both the average and maximum expected loading/traffic should be considered. As it can be seen from figures above (Figure 6, Figure 10) the variability of the daily curve is not so distinguished. For example, the maximum hourly traffic is around 650 vehicles while on average during the day the number is around 500. The increase in share of electric vehicles on the road is projected to be as high as 50%. As mentioned before, the assumption of max 2% of all on road vehicles will be charged each hour, therefore the number of required charging spots is 6. This accounts for the fact that charging on the supercharger still takes approximately 45-60 minutes (5-10 times longer that gas refueling) and the process of battery swapping takes up to 10 minutes (competitive to gas refueling). Additionally, what should be considered is that the road Zagreb-Velika Gorica has two directions and preferably if the charging needs increase dramatically both directions should be covered to avoid the few kilometers detouring that is else required. Two peak hours that are presented occur in different directions. With proposed 6 fast charging spots and with battery swapping infrastructure enough redundancy in charging capacity would be achieved.

<table>
<thead>
<tr>
<th>Traffic hourly peak</th>
<th>Average hourly traffic</th>
<th>Number of charging spots + BSS</th>
<th>Power system available capacity</th>
</tr>
</thead>
<tbody>
<tr>
<td>650 vehicles with increase potential</td>
<td>500 vehicles</td>
<td>6x120 kW + 150 kW</td>
<td>2250 kW</td>
</tr>
</tbody>
</table>

The assumed peak power of a charging spot is 120 kW (Tesla superchargers used as a reference [15]) which means that total additional capacity to be integrated into the power grid is approximately 720+150 kW. The typical transformer capacity of 1000 kVA is appropriate to be selected and added. As the analysis shown above, the power grid with minimum investment can withhold approximately 18 charging spots and a battery swapping station under the assumption of full range simultaneous charging. It is expected that the needs and power requirements would be lower.

The decision on number of the charging stations is dependent on additional factors that mostly deal with the general selection of the wider area of influence to locate the charging station and decide on the number of charging spots. The Tesla experience, as the biggest pool of fast charging stations, shows that on average 6 to 7 charging spots (810 stations with 5195 charging spots) are being installed per location. The ones that are built or under construction in Croatia consist of 4 and 6 charging spots.

Additionally, the test case for the Zagreb-Velika Gorica road concurs well with the requirements of the large populations that frequents this road daily and do not have available plug-in slow charger due to configuration of large residential blocks they live in. Furthermore, the gas station infrastructure is abundant which makes the integration process of superchargers a lot easier.

### IV. Conclusion

The paper presents the basic analysis of both transportation system and power system with the aim of integrating fast charging stations and battery swapping stations for electric vehicles. The case study on a road connecting Zagreb and Velika Gorica shows the interdependency between two systems. The requirements set by the transportation sector need to take into consideration limitations stemming from the power system infrastructure capabilities and configuration.

To enable further integration of electric vehicles urban designers, transportation and electric power engineers should cooperate. The long term interdependent transportation and electric power system analyses is prerequisite for effective and efficient transformation to electrically driven transportation. The future work will be focused on detecting vehicle traffic distribution and density using GSM/UMTS networks [16] in the cases when traffic counters are not available on some urban locations, and exploring the characteristics (throughputs, delays) of public mobile GSM/UMTS networks for advanced control of electric power network in order to avoid power disruptions, avoid congestions in the network, reduce losses, and improve overall stability of the power network.

Croatian Qualification Framework – Data Model and Software Implementation in higher education

Željko Kovačević, Mladen Mauher and Miroslav Slamić
Zagreb University of Applied Sciences
Vrbić 8, 10000 Zagreb, Croatia
e-mail: zeljko.kovacevic@tvz.hr

Abstract - Project „Politehnika 2025“ was started by Tehničko veleučilište u Zagrebu in cooperation with APIS IT, IN2 GRUPA and SPAN companies. The goal was to analyze future market needs until year 2025 and to upgrade existing and to develop new study programs that would modernize polytechnic studies. Project success depended on collecting and analyzing a large amount of data, and to do that it was required to develop appropriate information system. That included to create a conceptual database model and later to write applications that would allow all project participants to work with data. The goal of this paper is to describe database model and its parts, all applications used in the process of gathering and reviewing data and their features. Information system was one of the key elements of the project since without it the project would not be able to complete in desired period and its results may be prone to errors.

I. INTRODUCTION

The Croatian Qualifications Framework is a reform instrument for regulating the system of qualifications at all levels in the Republic of Croatia through qualifications standards based on learning outcomes and following the needs of the labour market, individuals and the society [1]. Using that idea project ”Politehnika 2025“ was started at Zagreb University of Applied Sciences to prepare our future students for incoming needs and demands of the market until year 2025 [2]. Project included many participants, from faculty staff to employers trying together to find the best solution for future study programs and educational standards.

One of the first goals was to collect data from all participants of the project in a single centralized repository (database) using appropriate application. To create a database that can contain all required data first it was necessary to identify all entities used in the project and determine their relationships. That was a basis to create a conceptual and later a physical database model.

Primary goal of the application was to enable data input for all project participants. Also, application provides many other features like various types of data analysis, reporting, class syllabus generator etc. Application is connected to a previously created central database and allows multiple users to input, review and analyze data at the same time.

II. DATABASE MODEL

When considering all required entities to develop conceptual database model first we analyzed The European e-Competence Framework (e-CF). It provides a reference of 40 competences as applied at the Information and Communication Technology (ICT) workplace, using a common language for competences, skills, knowledge, and proficiency levels that can be understood across Europe [3].

![Figure 1. Basic part of the conceptual model](image)

Entire conceptual model consists of 50 entities and basic part of the conceptual model (figure 1) displays key model entities and their relationships. Model supports
having data from multiple higher-education institutions each having multiple study programs. Each of those institutions can input their own data which would also be useful in analysis when comparing same or similar study programs on different higher-education institutions.

**Figure 2. Knowledge domain, branch, field and area**

In the continuation of the basic part of the model knowledge domains are related to branch, field and area of expertise (figure 2). For example, one area of expertise can have multiple fields, while one field can have multiple branches. Each branch can be a part of only one knowledge domain.

During the project “Politehnika 2025” Tehničko veleučilište u Zagrebu as a higher-education institution enumerated over 330 knowledge domains for 23 study programs. All these knowledge domains were part of 116 branches and 57 fields.

**Figure 3. Competence and its relationships**

Competence is in the middle of the entire model (figure 3) which shows its importance. Competence is related to generic competences, like ones from e-CF Framework and can be mapped to multiple knowledge units, responsibilities, professions and skills. Also, each competence can be a part of one or more set of competences. This part of the model is also used when creating qualification standards where each qualification standard is related to competences through set of learning outcomes.

Project participants defined 1405 competencies connected with 29 professions, 1583 knowledge units, 826 skills and 80 set of competences. This data made it possible to analyze market needs until year 2025 and what higher-education institutions currently offer and need to change to satisfy those needs.

Sub model in figure 4 contains all entities required to describe any class and its learning outcomes. As a result we are able to create a class syllabus containing learning outcomes and its granules, skill granules, methods of learning etc. Class syllabuses for entire study programs are generated based on this part of the model.

For total of 23 study programs there are 552 classes containing 2092 learning outcomes. All learning outcomes are matched with appropriate granules (4161) and skill granules (2180). Learning outcome is in the center of this part of the model and class syllabuses are generated based on their description.

After creating conceptual model it was necessary to create physical database model that would replace entities with tables and describe them with appropriate attributes.

Physical database model is created using Microsoft SQL Server 2012 and Microsoft SQL Server Management Studio (SSMS). Microsoft SQL Server 2012 is Microsoft’s first cloud-ready information platform. It gives organizations effective tools to protect, unlock, and scale the power of their data, and it works across a variety of devices and data sources, from desktops, phones, and tablets, to datacenters and both private and public clouds [4].

Resulting physical model consists of 87 database tables and 603 attributes. Physical database also contained 40 stored procedures which provided most of the features in HKO desktop and web application. Physical database also contained user groups and permissions, database and application roles, custom schemas, triggers and aggregate functions.

III. "HKO" DESKTOP APPLICATION

All participants of the project "Politehnika 2025" use desktop HKO application to input, review and analyze the data. Due to complexity of the conceptual database
model main user application interface is the picture of the model itself.

![Diagram of main application interface](image)

**Figure 5.** Part of the main application interface

Each entity is represented with a button where in the upper-right corner is the current number of existing records (figure 5). Upon clicking a button a dialog appears enabling a user to review, add, edit or delete records.

![Data dialog](image)

**Figure 6.** Data dialog

Since there are many users working with data at the same time application forces some usage rules. For example, user can only delete or edit its own records or records of other users that allowed him to do so. Also, adding or changing any data is automatically recorded by application by writing the author’s full name and time of the change. That information is later used for user’s activity analysis and statistics. Currently, application’s statistics show over 53,000 existing records from over 50 project participants.

Application contains main menu that enables users to see a variety of different data analysis. For example, it is possible to see all skills for some profession, professions per institutions, study programs for some job type etc.

One of the main usage of the application is to create syllabuses for study programs. Application can create a single syllabus for a specific class or a complete set of syllabuses for entire study program. For example,
Figure 7. A part of class syllabus

Syllabus is automatically generated document that contains several sections describing the class and its learning outcomes (figure 7). Each learning outcome is described by its granules, skill granules, methods of learning and type of examination.

Application is written using C++ programming language and C++ Builder XE6 integrated development environment (IDE) from Embarcadero.

C++ programming language is more flexible than other languages because you can use it to create a wide range of applications—from fun and exciting games, to high-performance scientific software, to device drivers, embedded programs, and Windows client applications [5].

Figure 8. C++ Builder – VCL Forms application

C++ Builder is in development from year 1997. At the time Borland was developing Delphi and C++ Builder as RAD (Rapid Application Development) tools which supported Windows 16 bit platform. Today, C++ Builder is C++ application development toolset for native Windows, Mac, and Mobile development, with broad Cloud and IoT support. [6].

IV. "HKO" WEB APPLICATION

Existing database also enabled the creation of HKO web page titled "Studijski programi" (eng. Study programs) [7]. Visitors can browse through study programs created in desktop HKO application, listing its classes, syllabuses, skills, competences, professions etc.

Web page targets three types of visitors: new students, students who graduated looking for work and employers seeking employees.

Figure 9. Browsing through study program classes

New students could be informed about study programs which support their desired professions (figure 9). They could see the classes and their syllabuses, job and job types, competencies, skills etc. Also, students who graduated and employers seeking employees could connect each other automatically. Each student can store its profile and would automatically see employers job offers while employers could search employees by searching through student profiles.

Figure 10. Visual Studio 2015 Community Edition

Web page is created using Microsoft Visual Studio 2015 (figure 10). Microsoft Visual Studio is an integrated development environment (IDE) from Microsoft. It is used to develop applications for Windows platform, web sites, web applications and web services. Also, it supports development of mobile applications. Visual Studio uses Windows API, Windows Forms, Windows Presentation Foundation, Windows Store and Microsoft
Silverlight, and can produce both native and managed code.

HKO web page is created using ASP.NET web application framework. It is an open source web framework for building modern web apps and services with .NET. ASP.NET creates websites based on HTML5, CSS, and JavaScript that are simple, fast, and can scale to millions of users [8].

This modern framework provided all required features to build the HKO web page and all its functionalities.

Project also uses another web page “Politehnika 2025” [2]. It is a project’s main web page containing all relevant info about the project and its results. Visitors can find information about all project participants, partners, project results, events and press releases.

V. CONCLUSION

During 15 months of project “Politehnika 2025” existing database and corresponding desktop application helped to analyze over 53,000 records and generate thousands of documents and reports. This helped to improve three existing qualification standards for polytechnic specialist, develop 4 new educational programs in the specialist polytechnic fields of prosthetics and orthotics, information security, forensics and mechatronics and 16 new comprehensive qualification standards for polytechnic specialist. Also, 9 study programs in the specialist polytechnic fields of polytechnics have been improved – computer science, information systems, energetics and electronics, graphic design and technology in printing and civil engineering.

One of the results of the Project is a study of demand for interdisciplinary and unidisciplinary competences and professions on polytechnic job market in 2020 and 2025. It is based on anticipated technologic trends, platforms as well as transformations of real and public sector.

Project helped to improve educational skills by development of innovative teaching methods and the application of the principles of the Croatian Qualification Framework. By putting these results into practice, the Project contributes to development of the educational system in the fields of high education, improvement of human resources in education, research and development of polytechnics, creation of propositions for sustainable employability at the end of educational as well as comprehensive social inclusion at the job market. Application of the acquired competences contributes to the quality of everyday life of a modern person and reminds of permanently needed and present „human face of polytechnics” [9].

Although the project is officially complete the existing database and applications will still be used for the future improvement of existing and for the development of new study programs. All data will be available to public in interest of better communication between employers and future employees thus trying to improve employment of our students.

Abstract - The intensive development of technology, the global availability of the Internet, the overall network coverage and increasing of computer literacy within the population, are growth factors that contribute to popularization and importance of electronic commerce. Moreover, electronic commerce is described as an effective way of communication with consumers in terms of money and time expenditures, and, therefore, in recent decades its role is growing rapidly both in general and specialized retailing. There are numerous research studies that describe and analyze the growth and general potentials of e-commerce. However, the level of development and potential in the field of special commodity groups are not yet sufficiently explained nor practically explored. The aim of this paper is to fill this gap through explanation of Internet as a purchasing source in a particular field of children’s products retailing.

I. INTRODUCTION

Electronic commerce as a term denotes using the Internet or other computer networks to conduct purchase transactions, or facilitating the process of buying or selling products or services via computer networks. In retailing, the process of purchasing consists of several phases: (1) seeking information about products in stores or via Internet, (2) buying products that can be done online or in traditional retail outlets, then (3) payment for products or services by cash or electronic money transfer and (4) collecting of product within the store or delivery of the purchased product to the consumer in case of online retailing.

In addition, the fact that the significant proportion of powerful consumers today are the part of so called “information society” generation that, from its early primary school days, intensively use information and telecommunications technology and have no fear nor puts it into a question in any segment of its application, contributes to the belief that electronic commerce has great potential for further rapid development in near future. Moreover, taking into account that this generation is the generation of today’s young and future parents, we can also conclude that it is realistic to expect an increase in the application of electronic commerce in specialized retail of children’s products as well.

In recent literature it is recognized that e-commerce and the use of the Internet as a source of purchasing information is growing rapidly in all product groups, without exception, however, the level of development and potential in the field of special commodity groups are not yet sufficiently explained nor practically explored.

Therefore, this paper aims to show the potential of the Internet as a source of purchasing information in the field of one specific commodity groups, such as baby and children’s equipment. Also, the paper aims to emphasize the obstacles of Internet usage in this particular product group.

The primary research was conducted on a sample of 217 buyers of children’s equipment between 20 and 44 years of age. The paper analyzes and discusses research results in terms of: the length of Internet usage, frequency of Internet usage for the purpose of finding information on the products and for the purpose of children’s products purchasing together with the tendency to use the Internet for these purposes in the future. For purchases made via the Internet information on the type of products purchased and features web stores used to purchase products are described. And finally, there is and critical overview on attitudes of the respondents on benefits and obstacles of seeking information and purchases via Internet for this particular kind of products.

The paper starts with an overview of contemporary streams in e-commerce research and then, based on the results of the primary research; it switches to a particular field of e-commerce.

II. AN INSIGHT INTO E-COMMERCE RESEARCH

E-commerce as one of the major fragments of e-business concept is very well researched in many scientific papers recently. E-commerce is defined as buying and selling of product, services or information via the Internet and other digital networks. When discussing forms of e-commerce, B2C e-commerce is dominant form measured by number of transactions done in some period and B2B is dominant form measured by generated revenues. Both forms of e-commerce are growing rapidly even in time in deep economic crisis. However in this paper we will focus on B2C e-commerce or electronic retailing or e-tailing and its narrow form which uses Internet as a basis for transactions with consumers.

The Internet economy presents many benefits. It offers the ability to create an environment where buyers and sellers meet to exchange goods and services without experiencing any geographical boundaries. [1].
The key to achievement in the Internet business lies in how you carry out the combination between virtual and physical channels [2]. Furthermore, e-commerce offers functionality and new ways of doing business that no company can afford to ignore [3]. Confidence that electronic markets have the potential to be more efficient in developing new information-based goods and services, finding global customers and trading partners to conduct business is the basis for moving to an e-commerce. Therefore, we can claim that e-commerce and Internet presence in various industries is a contemporary imperative.

An important part of everyday life for consumers during the twenty-first century is e-commerce. Furthermore, the variety of services in e-commerce has increased in recent years and consumers have adopted those services as part of their everyday lives. An important factor in attracting potential consumers, encouraging first-time purchases and retaining repeat purchases is the quality of e-commerce Websites. The quality of e-commerce Websites is an important piece for consumers in selecting the most favored Website that ultimately results in more revenue for the service suppliers [4].

Yen [5] explored how perceived risk affects customer loyalty in e-commerce and how switching costs mediate in the relationship between perceived risk and customer loyalty and he found that the relationship between perceived risk and customer loyalty is not directly significant in e-commerce. On the other hand, e-service quality and logistics service quality are strongly linked to customer satisfaction [6]. Moreover, Yen [7] examines quality satisfaction between transactional and relational customers in e-commerce, and it also explores the moderating effect of perceived control and perceived enjoyment on quality satisfaction and his results show that system quality satisfaction is more significant for transactional customers, but information quality and service quality satisfactions are more important for relational customers.

Trust and information sharing are very important for doing e-commerce business, in order to adopt e-commerce, managers should spend some energy on building up a trust based corporate culture and a trust based transaction relationship, both within the firm and when cooperating with external partners [8].

Purchase intention and website satisfaction positively influence conversion rates in B2C e-commerce and website satisfaction positively influences purchase intention. [9]. In addition, nowadays, ratings and reviews of products in e-commerce websites usually exert strong influences over the purchase decision of other customers. [10].

E-commerce is growing fast, and the use of the Internet has accelerated value innovation in service dimensions of speed, convenience, personalization and price [11]. The exponential growth of e-commerce has favored the upsurge of codes of conduct pointing at bringing down the barriers of consumer distrust when it comes to online purchasing. Customers are using the Internet for their purchases no longer need to be physically present when their transactions occur, they can buy products from their homes or offices. Also, consumers are able to explore goods and products on their computer monitors and view information about how the products are manufactured. Therefore, e-commerce has created major changes in the retail and service industries [12].

Despite the fact that online sales as a percentage of overall retail sales is still below 15 percent in developed economies, its absolute value and average growth per year are increasing rapidly. If we measure growth in sales over the last five years, clothing and consumer electronics have become the most important industries in the B2C e-commerce scenario [13].

As numerous research studies show, e-commerce is changing the way in which consumers are searching for purchasing information and the way of buying, no matter which specialized assortment is involved. However, research studies focusing on different product categories or specialized retail sub-industries are very scarce. In order to fill this gap, in advance we will focus on a particular commodity group or product category in order to explain how Internet is being used in retailing in the field of children’s products.

III. RESEARCH METHODOLOGY AND SAMPLE

The survey was conducted in Croatia during 2015 through a questionnaire containing 25 questions. The survey questionnaire included questions on demographic information such as age, gender and education, then questions about Internet purchase, the reasons why respondents are or are not inclined to purchase products via the Internet or the reasons for which prefer to purchase over the Internet in comparison to traditional retail stores, together with their preference to shop online in the future. In addition, respondents are questioned about brands bought through the Internet and about web preferred web pages for Internet purchases.

The survey results were collected through Google Forms and responses were collected in one spreadsheet. The link to the survey was placed on Facebook page, the official groups within some post-graduate courses at University of Zagreb, but also distributed by other Facebook users to obtain as soon as a larger sample of respondents. Statistical analysis and visualization of data was made in MS-Excel and SPSS for Windows, version 17.0.

The designed questionnaire was based on previously conducted research in the field of general e-commerce [14], [15], [16], [17], [18], [19], but is partially modified according to specific issues related to retail of children's equipment in order to collect data relevant for this product group. The questionnaire consisted of one-choice, multiple choice and open-ended questions, while the Likert scale questions were used to measure the satisfaction of respondents who buy through the Internet.

The questionnaire consisted 25 questions, of which the first five were focused on demographic characteristics of the sample, the following three concerned the experience in using the Internet and frequency of purchase on the Internet, following 6 questions examined the purchasing preferences of consumers on the Internet, types of online-stores and products which are preferred, as well as other issues including the strengths, weaknesses and future potential of Internet retailing of children's products. Ten questions were with one-choice questions, ten with a multiple choice, one question was open-ended, and the rest were in the form of Likert scale.

The research was conducted on a representative sample of 217 customers of children's products. The buying habits of consumers differ from customer to customer depending on their demographic characteristics, particularly by gender. Previous studies have shown that customers in retail of baby and children equipment are mostly women and they are the object in marketing activity of most retail companies in this field [20], [21], [22]. Also, purchasing decisions depend on the purchasing power of customers and their education that affects their level of IT knowledge required for purchases via the Internet. Therefore, the research included questions about these demographic characteristics of customers. The survey was conducted in 2015, and the target group was buyers of children's products between 20 and 44 years of age.

Of the 217 respondents, 189 (87%) were women, and 28 (13%) men. The most represented age group in the sample is 30-34 years, which includes 103 respondents, i.e. 47% of the respondents. Following group by frequency is 35-39 years old and it includes 74 respondents or 34% of the respondents. None of the respondents was younger than 20 years, and only one of the respondents was older than 45 years. Age of majority of respondents in the sample (81%) is between 30 and 39 years. The most common group according to education is the group that had completed high school, which includes 96 respondents or 45%. Followed by the group with secondary education and includes 58 respondents as 27% of the total sample. Majority of the respondents have one child, 111 of them or 51%, of which, 6 of them are expecting a new baby. Second group is with two children, including 75 respondents or 35% of the sample, while those with three children include 17 respondents (8%). In the sample there are no respondents with four or more children.

IV. DISCUSSION OF RESULTS

The most frequent way in which respondents are informed about new web stores or the new offer is an independent search 77.4%, followed by social networks 54.4% and through friends / family 43.8% of respondents, as shown in Table I.

The data shown in Figure 1 demonstrate popularity of Internet as channel for researching information about children's products before making a purchasing decision.

According to the frequency of online information search, those who seek such information every week, 110 of them or 51%, are the leading group. Second group consists of 53 respondents (24%) who search for information on children's products 1-2 times a month. So we can conclude that ROBO principle is the common way of behavior in the field of children's products as well as in general e-commerce. The acronym ROBO stands for “Research Online and Buy Offline” and it describes the importance of online presence and availability of online published information which is used by consumers before actual purchasing in a traditional retail store. It includes actions as searching for information on products and services, information on company, information on stores location, but also exhaustive action of information comparison regarding product characteristics and product prices. ROBO way of behavior causes the effect of fully educated and completely informed consumer and its consequences on retail processes is discussed frequently in contemporary literature in the field of retail management and marketing.

On the other hand, the frequency of online purchases of children's products is somewhat less frequent. Equal number of respondents purchase via the Internet 1-2 times in 3 months, as well as 1-2 times per year, 53 respondents or 24% (see Figure 1). Only 1% of respondents state that they purchase every week. However, there is a significant proportion of those who purchase rarely or never (total of 35%). This represents a potential for future development of e-commerce in this product category, as the share of these respondents use the Internet to search for information about children's products.
In Figure 2 product categories within children’s products are ranked. We can observe that the most frequent category is “new children’s clothes” which is bought by 51.4% of respondents, then follows category “toys” bought by 49.5% of respondents. The third category is “Gifts for other children” (31.8%) and so on (see Figure 2). Among other data, it is interesting that specific children’s cosmetic products were bought by 10% of respondents, while only 1.8% of respondents bought children’s food online.

Figure 3 shows the general satisfaction of the purchase of children's products on the Internet. On a scale of 1 – completely unsatisfied and 5 – completely satisfied, the majority of respondents (39.1%) assessed their satisfaction with a score of 5, while 37.3% rated satisfaction with grade 4, while only 3.6% respondents declared as completely unsatisfied. Therefore, we can draw conclusion that the respondents are generally satisfied with the completed purchases of children’s products via the Internet.

In addition, according to our findings, there is great potential for growth of this form of retailing for this particular product group. Specifically (see Table II), 34.10% of respondents believe that they will continue to use electronic commerce on the same level as today; while 65.44% think that they will intensify their usage of e-commerce as a purchasing channel for children’s products. Thus, specialized retailers have to get more engaged into development of online sales channel.

Out of eleven offered options regarding benefits of online purchase, three main benefits of buying children's products through the Internet were recognized by our respondents are: (1) lower prices and / or discounts (63.2%), (2) the possibility to shop 24/7 (55.9%) and (3) solution to the lack of time via home delivery (51.8%). These findings do not correspond to findings delivered in research on general e-commerce [23] where three major benefits were as follows: "I can purchase products which are not available at my city/country", "It is easier to compare prices and product information" and "I can shop abroad without traveling costs". Therefore, we can conclude that for particular retail product category (in our case children’s product) perception on benefit differs in comparison to usual and common perception on benefits of e-commerce in general. Thus, for future e-commerce research we could recommend focusing on e-commerce sub-industries (in accordance to online offered product categories).

On the other hand, out of ten offered options, respondents outlined the three major disadvantages of online purchasing of children's products: (1) I am afraid that the delivered product will not be of appropriate quality (55.8%), (2) I like to see and test the product before purchasing (49.3%) and (3) the return process is more complex than in traditional stores (37.8%). This finding is to somewhat in line with previous research conducted for general e-commerce [23] where it was shown that three main obstacles perceived by young consumers in Croatia are: “return of a product is more complicated”, “I prefer shopping in traditional store because I can touch product” and “It is difficult to check out validity of offer and online shop”. Therefore, in near future retailer should particularly pay more attention to return policies and creating virtual environments in which consumers will feel the same or similar shopping experience as in traditional stores.

V. CONCLUSIONS

Contemporary consumers in the field of children's products are digitally literate young people, open to the Internet as a channel of communication, sales and distribution. In the primary research it was observed that majority of them Internet as a channel for collecting information before purchasing (according so called ROBO principle), but also as a purchasing place to buy children's products.

According to the primary research, three sub-categories that are most prevalent in e-commerce of children's products are: (1) the new children's clothes, (2) toys and (3) gifts for other children.
A high degree of consumer satisfaction with the completed purchasing transactions of children's products is observed. A large number of respondents believe that they will use e-commerce as a source of supply of children's products even more frequently. Therefore, we can conclude that Internet as an additional sales channel has good prospects for greater implementation and application in retail market of children’s products. Therefore, we could recommend specialized retailers to integrate this channel into their overall business strategy more strongly as an imperative goal and to pay more attention on changed information needs and information behaviour of their future consumers.

Perception on e-commerce benefits for particular product groups varies in comparison to perception on e-commerce in general. Therefore, in future researchers should focus on particular retail product categories offered online, rather than general e-commerce attitudes.

However, there are some limitations regarding the primary research that reduces the possibility of generalizing the results. Here we can outline: given limited time of the survey and a relatively small sample of respondents, consisting mostly of respondents in the same age group and similar education level. Moreover, used methodology is based on pseudo-random sample due to the intensive usage of Google forms and social networks for data collection which negatively influences the possibility of generalization of conclusions for whole population of young families with children in Croatia. Therefore, in future research should be broadened and should include more randomized approach of sample selection. Also, the future survey by using the written form of questionnaire could improve input data as well. In addition, the research could be broadened geographically to other EU countries in order to observe similarities and differences between developed and developing economies and in order to make results more robust regardless to the geographic origin of the sample.

LITERATURE
Valuation of Common Stocks
Using the Dividend Valuation Approach and Excel

Abstract - The valuation of common stocks using the dividend valuation method is useful for stocks in so called no-growth or constant-growth situations.

In the case of constant-growth the stock price should be equal to the discounted present value of all future dividends, but in the case of non-constant growth the case becomes more complicated.

In both cases the use of Excel is a straightforward method for solving such calculations efficiently.

I. INTRODUCTION

Educational software is very important in finance courses at universities for students to better understand equity securities, like stocks, which represent a share in the ownership of a joint stock company.

To evaluate stock prices and dividends with no growth, constant growth and non-constant or variable growth rates in the future, complex calculations are to be done to get acceptable and realistic results.

Since students at universities, especially faculties of economics are usually trained in using spreadsheet programs, the authors decided to use Excel and develop spreadsheets for evaluating stocks in cases of different dividend payouts mentioned above.

To get better compatibility with future versions of Excel and increased portability on other computers and operating systems, so called plain vanilla Excel spreadsheets, containing only authors’ custom-made formulas and common financial and statistical functions, were programmed like in two other articles at earlier MIPRO Conferences. [6], [7]

An additional reason to apply Excel as the preferred spreadsheet program is that a lot of excellent textbooks exist, so the time period for learning and applying such programs should not be a long one. [1], [4], [10]

II. THE BASICS OF INVESTMENTS IN STOCKS

Stocks are securities that represent a share in the assets of a joint stock company.

In this respect, they differ completely from bonds which represent a claim against the issuer or the debtor.

Beside that, there are four basic differences between stocks and bonds and the markets in which they are traded: [5]

a) stocks are securities without maturity
b) due to the lack of maturity most of the turnover of stocks is happening on the secondary market
c) turnover in the secondary market is mostly in the form face to face (over the counter - OTC) and on the securities markets, while bonds are generally traded on the OTC market or on the phone
d) while bonds are characterized by fixed interest rates and value on maturity, in case of stocks no pre-determined rate of return does exist.

In addition to ownership, stocks in a joint stock company provide certain additional rights, including the rights: [3]

- to get dividends
- of priority purchase of new issued stocks
- to vote at the general meeting of the joint stock company
- to be informed and
- to get a share of the liquidation mass if the joint stock company goes bankrupt.

Depending on the type, there are essentially common stocks (ordinary shares) and preferred stocks (preference shares).

While the rights of ordinary or common stockholders are determined by laws of a country and certain internal regulations of joint stock companies, if it comes up to preference stocks best known forms are, ones which give priority to:

a) in case of dividend payment (e.g. in the form of increased or priority dividend payments)
b) in the case of liquidation (e.g. covering its rights before common stockholders)

Given these characteristics, common stocks are or should be the rule and preferred stocks should be an exception.
There are also advantages and disadvantages of financing with common stocks. Financing companies with common stocks has two major advantages. First of all, this form of financing requires minimum restrictions in the operations of a company. The company is contractually not in the obligation to pay dividends, nor at any time obliged to pay the principal.

In addition, financing by issuing additional common stocks increases the future ability of companies to take loans. For a company, which has a higher proportion of equity, it should be much easier to apply for additional loan when needed. Thus, it comes to a reduction of possible insolvency - inability to pay due liabilities - and an increased possibility of profitable investments.

However, financing by common stocks has also some disadvantages. Issuance of new stocks usually affects the reduction in earnings per stock and the reduction in the price of the stock. Therefore, companies issue common stocks especially when market demand is increasing and common stocks and their prices are rising, because only then they can obtain the necessary amount of new capital with a relatively small volume of new stocks.

Issue of new common stocks further causes that existing ordinary stockholders have to share the control over the company with new stockholders. If control is an important right of ordinary stockholders, the gradual loss of control could become so important that a company would not issue new common stocks. In addition, the costs of issuing new common stocks and their required rate of return is higher than in the case of preferred stocks or debt capital, i.e. by issuing bonds.

Normally, to a certain degree financing companies by issuing common stocks has more advantages than disadvantages, but after a certain level the disadvantages rise and further financing of the company in the form of common stocks is no longer meaningful. [8]

III. VALUATION OF STOCKS AND THE DIVIDEND GROWTH MODEL

Concerning the value of stocks it is necessary to distinguish their nominal value, book value and market value. [8]

The nominal value (par value) is printed on the stock and it defines the share of the joint stock company, especially in the case of liquidation of the joint stock company, the owner of the stocks is entitled to share of the liquidation mass only up to the nominal value of the stocks regardless how much he had paid for it.

Most corporations assign a nominal or par value to their common stock. Today it is not very important, but in the past it was very common for companies to determine a value to each stock when the company went public. Today, this value is used only for bookkeeping and it is not in any way correlated with the book value and market value of a stock.

The book value of the stock, in case that the nominal value exists, is calculated by adding the reserve per stock on the nominal value or, if it does not exist, as sometimes in Anglo-Saxon countries, by dividing the total capital and reserves of the company by the number of stocks.

So, the book value could be defined as the accounting value of a share of common stock, i.e. common stock plus paid-in capital plus retained earnings divided by the number of stocks outstanding.

Market value of the stock or the stock price is determined on the secondary capital market (stock exchange), in the first place according to the expected future income of the respective joint-stock company.

In addition to this main factor that has a key influence on the movement of stock prices there are also other factors which are important, like a general upturn in the stock market, inflation, profitability of the company, etc.

Regarding stock valuation it has to be pointed out, generally speaking, that stock does not give ownership to any specific physical asset of a joint stock company, rather it gives a claim on the company’s future flow of earnings.

Therefore, one can look at the value of the stock as the present value of future earnings of the company that the stockholders will receive. If the future flow of earnings of the company is known as well as the adequate discount rate for converting those future earnings into today’s value, the stock could be easily evaluated. Or to put it in another way, it could be said, that the value of a stock or the real stock price should be the present value of the future dividends due to the stockholders.

The very first explanations of the stock price or market price of the stocks can be found in the publications of J. B. Williams. Based on the theoretical foundations set up by A. Marshall, E. von Böhm-Bawerk and I. Fisher, J. B. Williams has defined the market value, or as he called it the present value of the stocks, as the sum of all dividends discounted at an appropriate interest rate.

While J. B. Williams claimed that the dividend is the only basis for determining the value of stocks, others primarily B. Graham and D. L. Dodd, argued that instead of the dividend the category of income (profit) can be used, because the change of the market value or stock price will affect the income or profit and therefore also potential future dividends.

Although most authors supported J. B. Williams’ approach, i.e. the dividend growth model or the so-called “Growth-stock school” as it was called by B. G. Malkiel, they still thought that income is important, especially in the case of companies that have a high growth rate.

Based on that, the intrinsic value of stocks can be presented, provided that there is no future dividend growth expected, in the form of: [2]
\[ P_0 = \sum_{t=0}^{\infty} \frac{D_t}{(1+r)^t} \]  
\[ P_0 = \text{stock price at period 0} \]
\[ D_t = \text{expected dividends at the end of period t} \]
\[ r = \text{expected rate of return} \]

According to equation (1) the price of stocks depends on the expected future dividends discounted by an appropriate discount rate or rate of return.

However, if it is expected that dividends in the future will grow at a constant rate \( g \), then the expected dividends can be calculated as:

\[ D_t = D_0 \cdot (1+g)^t \]  
\[ D_t = \text{expected dividends at the end of period t} \]
\[ D_0 = \text{amount of the dividends at period 0} \]
\[ g = \text{growth rate of dividends} \]

Substituting equation (2) into equation (1) the following equation is obtained:

\[ P_0 = \sum_{t=0}^{\infty} D_0 \cdot (1+g)^t \cdot \frac{(1+r)^t}{(1+r)^t} \]  
\[ P_0 = \text{stock price at period 0} \]
\[ D_0 = \text{amount of the dividends at period 0} \]
\[ r = \text{expected rate of return} \]
\[ g = \text{growth rate of dividends} \]

Provided that \( r \) is greater than \( g \), equation (3) can be presented as: [9]

\[ P_0 = \frac{D_1}{r - g} \]  
\[ P_0 = \text{stock price at period 0} \]
\[ D_1 = \text{expected annual dividends at the end of period 1} \]
\[ r = \text{expected rate of return} \]
\[ g = \text{growth rate of dividends} \]

Although the model given in equation (3) and modified according to the equation (4), or the so called Gordon Model, can explain the market value of stocks, it also has certain restrictions. It cannot be applied to stocks of companies that currently do not pay dividends; the result becomes infinite if \( r \) is less than \( g \) and requires prediction of future dividend growth rates.

These difficulties and the fact that, in practice, the growth rates of dividends do not increase at a constant rate of growth, but that this rate can again decline, alternative models for determining the value of stocks were developed.

In the case that the dividends grow on the basis of two different growth rates such a model valuing stocks can be presented as: [2]

\[ P_0 = \sum_{t=0}^{\infty} D_0 (1+g_s)^t \cdot \frac{1}{(1+r)^t} + \sum_{t=1}^{N} D_N (1+g_y)^{t-N} \cdot \frac{1}{(1+r)^t} \]  
\[ P_0 = \text{stock price at period 0} \]
\[ D_0 = \text{amount of the dividends at period 0} \]
\[ g_s = \text{first growth rate} \]
\[ g_y = \text{second growth rate} \]
\[ r = \text{expected rate of return} \]

These equations will be used for the calculations in three subsequent Excel spreadsheets.

IV. EXCEL SPREADSHEETS

For the calculations of the dividend growth models presented above Excel spreadsheets with custom-made formulas developed by the authors and containing only standard financial and statistical functions will be applied. [11]

The basic dividend growth model presented in equation (1) and its modifications explained in equations (4) and (5) will be implemented to take into account the fact that common stock dividends could grow at different rates, therefore three different cases will be considered: [12]

a) zero dividend growth model
b) constant dividend growth model
c) non-constant or variable dividend growth model

Every model will be explained by an example and calculated in Excel spreadsheets.

A. Zero dividend growth model

In this case the common stock dividend remains the same and by applying equation (4) the growth rate of dividends has to be set to 0.00%.

Example: The common stock dividend of company XYZ is 2.50 USD and remains the same in the future. What is the value of this stock if the expected rate of return is 12.00%?
After typing all the necessary data in the “input data” field of the spreadsheet model (Stock-Dcg.xls), the result is calculated and displayed in the “output data” field. (Fig. 1)

![Figure 1. Common stock - zero dividend growth](image)

The result shows that the value of the stock, if the expected rate of return is 12.00% and the dividend is constant 2.50 USD, is 20.83 USD.

B. Constant dividend growth model

In this model, also equation (4), the dividend grows at a constant rate, where the rate of growth is smaller than the expected rate of return.

Example: Calculate the value of common stock of the ABC company if it expects to increase its common stock dividend, being 2.00 USD last year, by 6.00% annually. Assume an expected rate of return of 8.00% is given.

After typing all the necessary data in the “input data” field of the spreadsheet model (Stock-Dcg.xls), the result is calculated and displayed in the “output data” field. (Fig. 2)

![Figure 2. Common stock - constant dividend growth](image)

The result shows that the value of the stock, in case that last dividends of company ABC were 2.00 USD, with a growth rate of 6.00% annually and an expected rate of return of 8.00%, is 106.00 USD.

C. Non-constant or variable dividend growth model

To overcome the disadvantage of the constant growth dividend model, which does not allow any changes in the growth rate, a more elaborated (up to 5 stages) variable dividend model discussed in equation (5) will be presented in an Excel spreadsheet (Stock-Dncg.xls).

Based on the current market price, the projected cash dividends will grow for the first two years and after that, they will drop. An example of a four stage model is presented below.

Example: In a four year period the company USX has paid dividends in USD (1.00 D1, 1.25 D2, 1.50 D3 and 1.75 D4) with an estimated stock price in year 4 of 48.00 USD and estimated rate of return of 17.00%. What is the value of the common stock?

After typing all the necessary data in the “input data” field of the spreadsheet model (Stock-Dncg.xls), the result is calculated and displayed in the “output data” field. (Fig. 3)

![Figure 3. Common stock - non-constant or variable dividend growth](image)

The result shows that the value of the stock, in case that dividends of company USX were first growing faster from 1.00 USD to 1.25 USD, and then slower from 1.50 USD to 1.75 USD with an expected stock price in year 4 of 48.00 USD and an expected rate of return of 17.00%, is 29.25 USD.

V. INSTALLATION OF THE SPREADSHEETS

Since all procedures and calculations are implemented in two Excel spreadsheets (Stock-Dcg.xls) and (Stock-Dncg.xls), it is only necessary to copy these files in the working directory of the PC where Microsoft Excel program can access them. In addition, the installation of the Excel Analysis Toolpak Add-In could help to improve the programming of some specific functions, but is not necessary.

VI. CONCLUSION

In this article the valuation of stocks using the dividend growth model was elaborated for so called no-growth, constant-growth and non-constant or variable growth situations.

For this purpose two spreadsheets were developed using only plain vanilla Excel, i.e. by implementing only custom-made formulas that were elaborated by authors and standard financial and statistical functions already built in basic Excel.

The examples and results show, that by using Excel even more sophisticated cases in business finance can be solved quickly and efficiently.

Abstract – Nowadays, information technology is condition sine qua non of every successful business in information economy surroundings. The implementation of daily tasks is aggravated or impossible without use of information technologies (IT). In this sense, many questions emerge – can companies use information technology as their competitive advantage? Is IT potentially the generator of increasing the financial result of a company? Specifically, the object of consideration in this paper is software, which is indispensable in terms of giving functionality to company’s assets – hardware. In terms of finance and accounting, software is considered as intangible fixed asset which will be used for period longer than one year. The era of companies mainly focused on tangible assets has passed, and that implies that the average intangible assets to total assets ratio is rapidly increasing nowadays. At the same time, there is also a growth of industries which are greatly dependent on this category of assets. Bearing in mind that software is developed by the programmers, its quality can vary significantly. When developing specialized business software, it is not only important to have skilled programmers, but also to include experts who have the knowledge of certain business processes. If we take into consideration abovementioned facts, it is evident that the quality of software is inherent to successfully established business process that could potentially lead to optimal use of resources, i.e. save time and money. Statistically, the main aim of this paper is to examine the relationship between investment in software and financial performance of a company. In other words, determine if investment in information technology is significant stimulus in terms of improving financial performance of a company. The research sample was formed using companies listed on Zagreb Stock Exchange (ZSE). The data used in the statistical analysis was gathered from the financial statements publicly available at ZSE’s official website.

Key words: financial performance, information economy, information technologies, investment, statistical research, software

I. INTRODUCTION

From ancient times the people have been trying to find ways to improve business, increase productivity, expand the market and simultaneously reduce costs and gain more profits. Going in that respect for centuries was extremely small because of the linguistic and spatial limitations and the low level of technological development that did not allow these limits to go beyond. Only the industrial revolution and the development of information technology (with the emphasis on the development of high technology) have enabled the development of new forms of business communication, organization and cooperation as well as the emergence of new types of services and thus the improvement of traditional business. [1].

A new, interactive way of communication who doesn’t know spatial and time constraints, has enabled the emergence and development of new forms of communication and business and their widespread introduction into everyday work in all areas of action – as well in finance and accounting sector which is special interest of this paper. Such business does not exclude traditional forms and ways of work and business, on the contrary, it complements and improves them. Thus, the development and application of high technologies become the strategic goal and the commitment of every advanced society, and their implementation in business processes is a condition of economic and any other progress that defines the modern information economy.

Few decades ago, intangible assets were not important as they are today. Nowadays, traditional reliance on fixed assets is replaced with “high – tech paradigm” that implies high share of IT intangible assets. Some companies mainly rely on intangible assets (e.g. tech start-ups), and other companies with significant share of
fixed assets are forced to invest in intangible assets in order to keep their competitive edge.

II. INFORMATION ECONOMY

The new, information economy has emerged in the last decades of the 20th century at the global level. Castells has defined that it is called information (or global) to establish its fundamental distinctive features and further emphasizing of their perception. It is informative because the productivity and competitiveness of units or factors (whether they are companies, regions or nations) basically depends on their ability to efficiently create, process and apply knowledge-based information. It is global because it is the core of production, consumption and circulation activities, as well as their components (capital, workforce, raw materials, management, information, technology, markets) organized globally, either directly or through the network of links between economic factors. It is information and global because, in new historical conditions, productivity is generated and competition exploited in the global network of interactions. And the new economy emerged in the last quarter of the twentieth century because the revolution of information technology creates the necessary, material basis for such a new kind of economy. It is the historical link between knowledge-based and information-based economy, its global reach, and the revolution in information technology that creates a new, distinct economic system.[2]

Thus, the foundation of productivity and competitiveness of companies in the information economy depends on their ability to create, process and apply knowledge-based information, and relies on the intensive use of information technology in today’s digital single market.[15]

III. PREVIOUS RESEARCHES

Constantly increasing importance of intangible assets made the research about investment in that part of company’s assets very frequent topic among scholars all over the world. But, it must be highlighted that scientific papers which are focused exclusively on software as part of intangible assets are not so frequent. One of underlying reasons is that researches in this field are very particular due to numerous forms of intangible assets. Apropos, researches in this field can be categorized into two large groups: researches which analyse intangible assets as aggregate category and researches which focus on certain part of intangible assets. Some of researches are presented in this chapter chronologically.

Sheng and Mykytyn (2002.) have stressed the importance of the „quality of the output of the implemented IT systems“, because systems don’t have to function optimally. [3]. Although Kim (2004.) has found positive relationship between investment in IT and productivity of a company, he pinpoints some debatable issues ( „utilization of IT is closely related with firm-specific factors“ (e.g. management ability), biases in results due to samples which are not comprehensive enough, „technological differences among industries“ etc.). [4] Doms et al. (2003.) have founded “significant relationship between IT investment intensity and productivity growth“. [5] Lim et al. (2004.) highlight conflict between some previous findings in terms of profitability and investments in IT. Besides that, they have founded „more positive returns of IT investment in information-intensive industries than non information-intensive industries“ and that „the small size of the firm tends to have statistically more positive returns of IT investment than the large size of the firm“. [6] Stewart et al. (2007.) suggested that „profitability and productivity have not always emerged as a result of IT investments“, and pinpointed several key factors such as firm’s strategic advantage and innovative technologies. [7] Mithas et al. (2012.) have founded that „IT has a positive impact on profitability“ and that „firms have had greater success in achieving higher profitability through IT-enabled revenue growth than through IT-enabled cost reduction“. [8] Guzić (2014.) founded statistically significant positive relationship between intangible assets and profitability and also has proven that their importance in financial statements of Croatian companies is increasing. [9] Bubić and Šušak (2015.) analysed relationship between investment in intangible assets as aggregate value (research and development, patents, software, goodwill, advance payments for purchase of intangible asset and other intangible assets) and have founded that “companies which invested in intangible assets were less likely to open the bankruptcy proceeding” and that “there isn’t strong evidence in favour of positive relationship

Figure 1. Information economy and information society (Source: Trauth, E. M., The Pennsylvania State University (2008), http://slideplayer.com/slide/5198224/ (last viewed 15. 03. 2017.)
between investment in intangible assets and profitability”. [10]

Despite the fact that logical reasoning and majority of previous researches indicate that there should be positive significant relationship between investment in IT and profitability, there is significant number of papers opposing aforementioned relationship. In process of hypotheses forming, authors of this research have accepted the prevailing group of findings and presumed positive relationship between those variables. [11]

IV. HYPOTHESES

Having in mind previous theoretical findings and practical experiences, hypotheses for this research were formed as following:

- **Hypothesis 1** – there is statistically significant positive relationship between company’s financial performance and investment in software.
- **Hypothesis 2** – there is statistically significant difference between investments in software compared to the previous financial year (increase of investment in intangible assets).

Hypotheses have been formed using findings from previous researches, but one must be cautious when analysing these relationships. IT can be (and in most situations is) irreplaceable support which contributes to optimization of business procedures. But, on the other hand, inadequately implemented IT (e.g. inadequate or poorly designed software) can cause situations with serious repercussions on financial performance of a company (e.g. delays, loss of goodwill, insufficient inventories etc.).

V. DATA, STATISTICAL METHODOLOGY, FINANCIAL RATIOS AND RESULTS OF RESEARCH

The research sample was formed using 125 non – financial companies listed on Zagreb Stock Exchange (ZSE) in financial year 2013. (commercial banks, insurance companies etc. were excluded from the sample due to the difference in financial reporting and the nature of their operations in comparison to other, non – financial companies). Approximately one half of companies included in sample (53 companies) have disclosed the structure of their intangible assets in detail. The data used in the statistical analysis was collected from the financial statements publicly available at ZSE’s official website [12] and Croatian Financial Agency official website.[13] Correlational statistics was used to determine the relationship between variables – methods used were correlation and regression. Also, t – test for dependent samples was used as method which is part of group statistics.

Financial ratios included in research can be classified into two groups:
- Assets Ratios (table 1),
- Profitability Ratios (table 2.).

*P.C. – Pearson Correlation
** Sig. – Sig. (2-tailed)

Correlation analysis (table 3.) indicates that there isn’t statistically significant relationship between software investment ratios (Software to Total Assets and Software to Long – term Assets) and profitability ratios (Return on Assets, Return on Equity and Net Profit Margin) at the 5% significance level. Intensity of correlation is mostly positive but extremely weak.

<td>0.678</td>
</tr>
</tbody>
</table>

The independent variables coefficients of linear regression models are positive for all analysed financial ratios (ROA, ROE, NPM) and it means that increase in one of these ratios will be accompanied by an increase in one of ratios used as dependent variables (S/TA, S/LTA) (table 4). But, coefficients for all analysed ratios are not statistically significant at the 5% significance level.

TABLE 5. PAIRED SAMPLES TEST

<table>

<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Table 5. shows Paired Samples Test which indicates that there is no statistically significant difference between investment in software in financial year 2013. and 2012. The value of software intangible assets in year before was even slightly higher than in financial year 2013., i.e.

value of software decreased in comparison to the year before.

VI. HYPOTHESES ACCEPTANCE

According to the results of research, both initially established hypotheses were rejected (table 6.).

<table>
<thead>
<tr>
<th>Hypothesis</th>

<td>Hypothesis 1 – there is statistically significant positive relationship between company’s financial performance and investment in software.</td>
<td>Rejected</td>
</tr>
<tr>
<td>H2</td>
<td>Hypothesis 2 – there is statistically significant difference between investments in software compared to the previous financial year (increase of investment in intangible assets).</td>
<td>Rejected</td>
</tr>
</tbody>
</table>

VII. RESEARCH LIMITATIONS

Firstly, when gathering information about company’s intangible assets, significant part of companies haven’t disclosed the structure of their intangible assets in detail. That is the reason why the share of software in their intangible assets could not be determined. Consequently, those companies couldn’t be included in research sample.

Secondly, information was gathered from financial statements which are an end product of accounting. Accounting information is focused on past events and susceptible to manipulation.

Thirdly, economic events are very complex and sometimes it is very hard to resolve what influenced financial performance of companies because there are many macroeconomic and microeconomic variables that can possibly be connected with analysed variable.

Second and third limitation are inherent to every economic analysis of this kind.

VIII. CONCLUSION

The main aim of this paper was to statistically try to examine the relationship between investment in software and financial performance of a company. In other words, to determine if investment in information technology is significant stimulus in terms of improving financial performance of a company. The research sample, which was formed using companies listed on Zagreb Stock Exchange (ZSE) and used in the statistical analysis was gathered from the financial statements publicly available at ZSE’s official website showed that both of our hypotheses: Hypothesis 1 which said that there is
statistically significant positive relationship between company’s financial performance and investment in software and Hypothesis 2- that there is statistically significant difference between investments in software compared to the previous financial year (increase of investment in intangible assets) and according to the results of research, both initially established hypotheses were rejected meaning that by data used in research showed there is no (direct) interconnection between investment in software and financial performance considering given research limitations. But one fact still remains, information technologies have become the most important part of companies assets and business infrastructure on whom the financial performance relies on so many levels so even though we can’s statistically prove the direct interconnection between software investment and financial performance they present the groundings of every business in information economy surroundings.

LITERATURE
[7] Stewart, Walter; Coulson, Sheri; and Wilson, Robert (2007) "Information Technology: When is it Worth the Investment?" Communications of the IIMA: Vol. 7: Iss. 3, Article 11. Available at: http://scholarworks.lib.csusb.edu/ciima/vol7/iss3/11
Elektronički dokaz is osvrtom na zakonska rješenja elektroničkih dokaza u Bosni i Hercegovini

Dioničko društvo BH Telecom Sarajevo, Bosna i Hercegovina

e-mail: feriz.gabela@bhtelecom.ba;

Sažetak: - Razlike između pravnih sustava država članica Ujedinjenih naroda nametnule su problem usklađivanja pravne regulative kao prioritet međunarodne zajednice. Problem prepoznavanja određenog ponašanja kao ilegalnog u jednoj državi i tretiranje istog tipa ponašanja kao legalnog u nekoj drugoj, pruža prostor za izbjegavanje krivične odgovornosti. Drugi problem koji se javlja je problem nadležnosti. Kod ove vrste problema se ne može koristi tehnologija koja omogućava rad s udaljenih lokacija, odnosno upotrebu resursa u jednoj državi za obavljanje aktivnosti u drugoj. Zbog toga se izvršava krivični proces u jednoj državi.

I. UVOD

U radu se analiziraju novi izazovi koji su se otvorili novim informacijskim i komunikacijskim tehnologijama. Nova komunikacijska sredstva otvaraju mnoga pravna pitanja koja se postavljaju pred pravnu znanost. Glavni cilj istraživanja je razumijevanje krivičnog djela iz područja računalnog kriminala, a samim time i nova zakonska rješenja u području elektroničkih dokaza.

* dr. sc. Feriz Gabela
** mr. Adnan Gabela, dipl. ecc.
*** mr. Jasmina Gabela, dipl. ecc.
II. MEĐUNARODNI ASPEKT ELEKTRONIČKOG DOKAZA

Razlike između pravnih sustava država članica Ujedinjenih naroda (UN) nametnule su problem usklađivanja pravne regulativne kao prioritet međunarodne zajednice u borbi protiv računalnog kriminala. Problem prepoznavanja određenog ponašanja kao ilegalnog u jednoj državi i tretiranje istog ponašanja kao legalnog u nekoj drugoj, pražna prostor za izbjegavanje krivične odgovornosti. U tijelima Ujedinjenih naroda ne postoji odredjivanja većne potrebe da odrede pojedina računalna djela povezana sa zloupotrebom identiteta.

Za pravno reguliranje elektroničkih dokumenata, odnosno elektroničkih dokaza na nivou Europske unije (EU), značajna je Direktiva o čuvanju podataka koji su dobiveni ili obrađeni prilikom pružanja javno dostupnih usluga komunikacije iz 2006. godine [3]. Cilj Direktive 2006/24/EU o čuvanju podataka jest da se usklade odredbe država članica koje se tiču obaveze davaoca javno dostupnih usluga e-komunikacije da daju podatke koje dobivaju ili obrađuju, kako bi se osiguralo da ti podaci budu dostupni u svrhu odlučivanja, otkrivanja i progona poznatih i krivičnih djela. Direktiva 2013/40/EU od 12.08.2013. godine, od država članica zahtijeva uspostavu CERT (Computer Emergency Response Team) timova koji će se baviti problemima zloupotrebe računa, i propisuje postupanje u slučaju većih incidenta [4].

III. ELEKTRONIČKI DOKAZ

Elektronički dokazi su često primarni dokazi u postupku koji se vodi protiv izvršnika krivičnog djela u postupcima koji se vode pred nadležnim sudovima i arbitražama. U odnosu na materijalne dokaze, elektronički dokazi imaju nekoliko prednosti. Od elektroničkih dokaza je moguće napraviti točnu kopiju koja se naknadno može istraživati kao da se radi o originalu. Prilikom ispitivanja kopije, izbjegavaju se ošetrenje i miješanje koje je potrebno zaštiti. Pomoću alata moguće je odrediti je li elektronički dokaz uništen ili promijenjen, upoređujući ga s originalom. Elektronički dokaz je teško uništiti, a kada su dokazi i “obrisani”, mogu se povratiti na računalni disk ili neki drugi medij za pohranu podataka. Računalni podaci se brisanjem fizičkih podataka uništavaju, dok elektronički dokazi lako se mogu izmijeniti, što zahtijeva pažnju i adekvatan pristup u odnosu na materijalne dokaze,

A. Ujedinjeni narodi

Ujedinjeni narodi su u vezi rješavanja problema računalnog kriminala, donijeli rezolucije (br. 55/63 i 56/121) o borbi protiv zloupotrebe informacijskih tehnologija, koje je Generalna skupština UN usvojila 22.01.2001. i 23.02.2002. godine, a kao jedan od ciljeva utvrdile su potrebu da se usvojila 22.01.2001. i 23.02.2002. godine, a kao potreba odredbe država članica koja uređuje elektroničke dokaze.

B. Vijeće Europe

Vijeće Europe je 1999. godine usvojilo eEurope inicijativu, kojom je osigurano povezanost među državama i građanima. Elektronička inicijativa je osiguralo povezanost među državama i građanima EU, a opredjela su pravila za brisanje elektroničkih dokaza.

C. Europska unija

Za pravno reguliranje elektroničkih dokumenata, odnosno elektroničkih dokaza na nivou Europske unije (EU), značajna je Direktiva o čuvanju podataka koji su dobiveni ili obrađeni prilikom pružanja javno dostupnih usluga komunikacije iz 2006. godine [3]. Cilj Direktive 2006/24/EU o čuvanju podataka jest da se usklade odredbe država članica koje se tiču obaveze davaoca javno dostupnih usluga e-komunikacije da daju podatke koje dobivaju ili obrađuju, kako bi se osiguralo da ti podaci budu dostupni u svrhu odlučivanja, otkrivanja i progona poznatih i krivičnih djela. Direktiva 2013/40/EU od 12.08.2013. godine, od država članica zahtijeva uspostavu CERT (Computer Emergency Response Team) timova koji će se baviti problemima zloupotrebe računa, i propisuje postupanje u slučaju većih incidenta [4].
Ovo se može izvršiti na sljedeće načine:
- prilikom uključivanja uređaja u struju ili na mrežu, aktivira se softver za brisanje podataka;
- prilikom isključivanja uređaja, pokreće se softver za brisanje podataka;
- kako bi se otvorila zaštićena datoteka, prilikom unosa odgovarajuće lozinkе aktivira se njegov uništenje.
Važno je da elektronički dokazi budu prikupljeni u skladu sa zakonom, jer će ih u suprotnom istražni sudac izuzeti iz spisa kao nezakonite dokaze.
Računalna istraga obuhvaća postupak dolaženja do elektroničkih dokaza i utvrđivanja vremena kada su bili umjeti, uskladišteni, skljonjeni, kao i vremena kada su datoteke bile kreirane, postavljene, punjene, ili kada im se pristupilo.
Vrste analiza elektroničkih dokaza su:
1. vremenska analiza - određuje kada se određeni događaj desio i stvara sliku o razvoju zločina;  
2. analiza skrivenih podataka ukazuje na vlasništvo;  
3. analiza datoteka - ukazuje koje se mjere moraju poduzeti da bi se analiza završila.
Prilikom izvođenja istražnih radnji, moguće je kopirati elektroničke podatke ili klonirati podatke. Kopiranje podataka predstavlja repliciranje neke elektroničke datoteke s jednog nosača podataka na drugi. Iz razloga što mehaničkim kopiranjem korisni podaci ostaju na nosaču podataka, svrlа se kloniranje podataka kojim mogu pristupiti istražitelji koji posjeduju posebne alate za njegovo izvođenje. Klonirati sadržaj znači napraviti njegovu potpunu repliku, zajedno sa svim elementima koji se pri kopiranju ne bi vidjeli, odnosno ne bi prenijeli na kopiju. Elektronički dokazi prolaze dvostrukom provjeru u postupku - jedna je ocjena njihove dokazne snage, a druga je provjera njihove oformljenosti. Oformiti se može elektronički dokaz tako što će se uz sadržaj e-maila dodati i sekundarni dokazi, koji potvrđuju kome e-mail nalog pripada i nedvosmisleno dokazuju da je e-mail poslan s odgovarajućeg uređaja u određeno vrijeme. Uz ove činjenice moraju se dodati i zapisnici da je izvršena analiza podataka i da je potvrđeno da je to uređaj koji je nosio istu IP adresu s koje je e-mail poslan u vrijeme kada je poslan. Na taj način je oformljen elektronički dokaz. Analiza dokaza, kao i čuvanje elektroničkih dokaza, trebale bi voditi stručne i obučene osobe.

IV. PRAVNA RUJESENJA ELEKTRONIČKIH DOKUMENATA I DOKAZA U BOSNI I HERCEGOVINI

Donošenjem Zakona o elektroničkom dokumentu („Sl. glasnik BiH“ broj 58/14), Zakona o elektroničkom potpisu („Službeni glasnik BiH“, broj 91/06) i Zakona o elektroničkom pravnom i poslovnom prometu („Službeni glasnik BiH“, broj 88/07), kao i njihovih podzakonskih akata, omogućeno je uspostavljanje elektroničkog pravnog i poslovnog prometa u postupcima koji se vode pred tijelima uprave Bosne i Hercegovine. Zakon o elektroničkom dokumentu propisuje da se upotreba i promet elektroničkog dokumenta vrši samo na osnovu slobodno izražene volje i pravne važnosti kao dokumenta sačinjenog na papiru. Elektronički dokument mora imati informacijsku cjelovitost i biti u formi zapisa koja omogućava jednostavno čitanje sadržaja. U postupcima koji se vode pred nadležnim tijelima, kao dokaz mogu se koristiti i elektronički dokumenti. U svim radnjama dokumentacijskog ciklusa elektroničkog dokumenta mora postojati mogućnost provjere njegove vjerodostojnosti, originalnosti i nepromjenjivosti. Ako se nadležnom tijelu dostavi dokaz jedino u obliku elektroničkog dokumenta, to ne može biti razlog njegovog odbijanja odnosno osporavanja. Pri ocjeni ispravnosti elektroničkog dokumenta moraju se uzeti u obzir pojedine o njegovoj izradi, skladištenju, prijenosu, čuvanju, vjerodostojnosti i nepromjenjivosti [6].

Bosna i Hercegovina je ratificirala Konvenciju o kibernetskom kriminalu i Dodatni protokol uz Konvenciju 2006. godine [7]. Ratificiranjem Konvencije u odnosu na BiH, slijedila je implementacija odredbi krivičnog prava Konvencije u državni i nedržavni krivični i krivično procesni zakone. Sadržajem odredbi Krivičnog zakona BiH, za razliku od ostala tri nedržavna Krivična zakona (Federacije BiH, Republike Srpske i Brčko Distrikta BiH), nisu implementirane preporučene odredbe krivičnog prava već je to „dogovorno prepušteno“ u nadležnost nedržavnim krivičnim zakonima F BiH, RS i Brčko Distriktu.

Krivična računalna djela uvedena su Krivičnim zakonom Federacije BiH, gdje su predviđena „krivična djela protiv sustava obrade podataka“ (čl. 393-397) i sankcije za krivična djela kod oštećenja računalnih podataka i programa. Krivični zakon RS predviđa kao krivično djelo upad u računalni sustav,
ka „krivična djela sigurnosti računalnih podataka” (čl. 186a - 186e). Analizom se sadržaja odredbi nedržavnih zakona može zaključiti da se obaveza preuzeta ratifikacijom Konvencije u pogledu krivičnog materijalnog prava ispoštovala i da su krivična djela predviđena Konvencijom ugrađena u odredbe nedržavnih krivičnih zakona u BiH.

Zakon o krivičnom postupku BiH u člunu 51. propisuje pretres računalnih sustava, ugradnje za pohranjivanje računalnih i elektroničkih podataka, kao i mobilnih uređaja. Osobe koje se koriste ovim uređajima dužne su omogućiti pristup i predati medij na kojem su pohranjeni elektronički podaci. Analizom sadržaja računala i mobitelja uređaja, dolazi se do važnih podataka o komunikaciji između osumnjičenih, i osumnjičenih i trećih osoba [8]. Zakon o krivičnom postupku BiH trebao bi se dopuniti uvođenjem posebnih odredbi, nakon člana 52., koji bi se nazvao „Forenzička analiza sadržaja računarskih sustava, uređaja za pohranjivanje računarskih i elektroničkih podataka i mobilnih telefonskih aparata”[3]. Navedenim članom bi se jasno propisao postupak forenzičke analize računarskih sustava, uređaja za pohranjivanje računarskih i elektroničkih podataka i mobilnih uređaja koji se privremeno oduzimaju. Nakon što budu privremeno oduzeti, navedeni uređaji se proslijeduju na analizu u forenzički laboratoriji, gdje se pristupa analizi sadržaja. O forenzičkoj analizi sadržaja sačinjavao bi se izvještaj, u kojem se opisuje predmet forenzičke analize, postupak forenzičke analize i dobiveni sadržaj forenzičke analize. Trebalo bi propisati da su ovlaštene službene osobe, prilikom oduzimanja računarskih sustava, uređaja za pohranjivanje računarskih podataka i mobilnih uređaja, dužna iste zapakirati i zapčatiti, te prosljediti putem suda na forenzičku analizu [9].

V. ZAKLJUČAK

LITERATURA

[8] Zakon o krivičnom postupku, prečišćeni tekst („Sl. glasnik BiH“, br. 3/03, 32/03, 36/03, 26/04, 63/04, 13/05, 76/07, 58/08, 12/09, 16/09, 72/13).

PAPERS
Abstract - The purpose of this study is to give an overlook and comparison of best known data warehouse architectures. Single-layer, two-layer, and three-layer architectures are structure-oriented one that are depending on the number of layers used by the architecture. In independent data marts architecture, bus, hub-and-spoke, centralized and distributed architectures, the main layers are differently combined. Listed data warehouse architectures are compared based on organizational structures, with its similarities and differences. The second comparison gives a look into information quality (consistency, completeness, accuracy) and system quality (integration, flexibility, scalability). Bus, hub-and-spoke and centralized data warehouse architectures got the highest scores in information and system quality assessment.

Key words: data warehouse architecture classification, organization structure, information quality, system quality

I. INTRODUCTION

None of the business organization is the same. They all have their own unique processes and actions. In the databases of this organizations, the data has to be in every moment updated and available for processing. To be able to perform analytical processing for business decision-making, the organization needs to have a data warehouse where certain data are firstly being processed, and then permanently stored for future actions. The data warehouses provide support to managers in the management and decision-making. Before the implementation of a data warehouse, it is necessary to determine the criteria to be satisfied, and on the basis of determined, select the appropriate data warehouse architecture that satisfies the needs of organization.

The purpose of this paper is to give an overlook and comparison of best known data warehouse architectures. The main features for each architecture will be presented, and architectures will be compared based on organizational structures, as well as on system and information quality.

II. DATA WAREHOUSE ARCHITECTURE CLASSIFICATION

The authors [1] gave the best overlook and explanation of various data warehouse architectures. They put data warehouse architectures into two categories. The first one includes single-layer, two-layer and three-layer architectures that are structure-oriented one and are depending on the number of layers used by the architecture. The second classification consists of independent data marts architecture, bus, hub-and-spoke, centralized and distributed architecture where the main layers are differently combined.

A. Single-Layer Architecture

Single-layer architecture is not frequently used in practice. The goal is to minimize the amount of stored data by removing data redundancies. Data warehouse is virtual and implemented as a multidimensional view of operational data. The main weakness of a single-layer architecture is its failure to separate the analytical and transactional data processing.

B. Two-Layer Architecture

In the two-layer architecture, there is a separation between two layers: a layer of data sources and data warehouse layer. Although it is called a two-layer architecture to emphasize the separation of the two layers, it is actually consisted of four data flow stages: source layer, data staging, data warehouse layer and analysis. In contrast to single-layer architecture, in this one there is a separation between analytical and transactional data processing.
C. Three-Layer Architecture

Three-layer architecture is characterized by the fact that three layers are physically implemented: source layer, reconciled layer and data warehouse layer. Reconciled data layer materializes operational data after integrating and cleansing source data. As a result of passing through the reconciled layer, data is integrated, consistent, accurate, correct, and detailed.

D. Independent Data Marts Architecture

As the name implies, independent data marts architecture consists of various data marts being separately designed and implemented, in another words, they are not integrated. Data marts usually have inconsistent data definitions and use different dimensions and measures, making data analysis difficult. This architecture is usually replaced by another one in order to achieve better data integration and cross-reporting.

E. Bus Architecture

The bus architecture is recommended by Ralph Kimball and is similar to independent data marts architecture with significant difference – data marts are logically integrated and there is an enterprise-wide view of information.

F. Hub-And-Spoke Architecture

The hub-and-spoke architecture consists of data sources, reconciled data and data marts. Enterprise data warehouse, called the hub, is created with a set of data marts, called spokes. Atomic, normalized data is stored in a reconciled layer that feeds a set of data marts made of summarized data in multidimensional form. In hub-and-spoke architecture the emphasis is on scalability and extensibility, as well as on retrieving large amounts of information.

G. Centralized Architecture

The centralized architecture is recommended by Bill Inmon. This architecture can be seen as a specific implementation of hub-and-spoke architecture, where in contrast to hub-and-spoke, there is no dependent data marts. It consists of one centralized data warehouse which contains integrated data and data marts.
H. Distributed Architecture

The distributed architecture is sometimes adopted in dynamic contexts where existing data warehouses should be integrated to provide a single solution. Each data warehouse/data mart is in this architecture logically or physically integrated using joint keys, global metadata, distributed queries, and other methods.

III. DATA WAREHOUSE ARCHITECTURE COMPARISON

We start with comparison based on organizational structure. Visible features in the organizational structures of architectures were taken as comparison criteria. Is the source data being processed with ETL tools before being stored? Are the users getting data directly from data warehouse, or through data marts? Do the data marts depend on data warehouse?

In Table 1 the results are presented. In all architectures, except in single-layer architecture, data is stored and retrieved only after it has been processed by ETL tools. In single-layer and centralized architecture, data is accessed directly from data warehouse. In all other architectures, data for specific business area is being retrieved from data marts. If there is a data mart after data warehouse in the organizational structure, we can say that data mart depends on data warehouse. We can found independent data marts in independent data marts...
architecture, bus, centralized, and distributed architecture. Hub-and-spoke architecture has a data warehouse made of set of data marts.

For the second comparison we used numeric tables [3] to take a look into consistency, completeness, and accuracy of information, and integration, flexibility, and scalability of system. Based on these tables, Chart 1 and Chart 2 were created, representing results for independent data marts architecture, bus, hub-and-spoke, centralized and distributed architecture.

In information quality assessment on Chart 1, independent data mart architecture has the lowest results. The next one is distributed architecture. For bus, hub-and-spoke and centralized architecture, there are similar results. Independent data marts architecture has relatively small result for information completeness, what confirms the fact that this architecture is particularly weak in providing all data needed to make decisions. Hub-and-spoke and centralized architectures have higher values for information completeness. These architectures provide more comprehensive data source in decision support. The bus architecture has proved to be the best when it comes to the information accuracy.

In system quality assessment on Chart 2, the average results are analog to results in information quality assessment. Independent data marts architecture got also in this case the lowest results, and that is why this architecture is soon being replaced by another architecture. The distributed architecture has some better results. Bus, hub-and-spoke and centralized architectures also achieved similar results. Although centralized architecture got the highest result for scalability, bus and hub-and-spoke architectures have proven to be the best when it comes to all three measures of system quality.

In [4], [5] and [6] we can find more features that were used to assess the success of the architectures. The given conclusions are similar to ours.

IV. CONCLUSION

This paper gave an overlook of best-known data warehouse architectures: single-layer, two-layer, and three-layer architecture, independent data marts architecture, bus, hub-and-spoke, centralized and distributed architecture.
distributed architecture. Looking at the organizational structures of these architectures, we can conclude that in the beginning there is source data. Data is then being processed by ETL tools (extraction, transformation, load) and then stored in data warehouse. Data marts can follow data warehouse for retrieving data required for analysis of particular business area. Using different tools, end users receive the required information.

The contribution of this paper is in comparison of best known data warehouse architectures. Bus, hub-and-spoke, and centralized architectures have shown the best results in assessing information quality, as well as in system quality assessment. The reason for that is that these architectures have developed over time and have become similar. We believe that architectures in the future will be very similar. Over time, there will be less disadvantages and every architecture will successfully satisfy needs of their clients.

For further work on this paper, one can pay attention to the future of data warehouse, due to the increasing popularity of NoSQL databases.

Abstract - The database management system is a software that enables easier work with databases i.e. to define database structure, retrieve stored data, enter data into the database and process the previously stored data in the database. In this article we have compared 3 relational database management systems (RDBMS) - Oracle 11g, MySQL and PostgreSQL. They are compared according to the simple criteria that we defined, such as the comparison of basic data, syntax, data types and speed performance. The main contribution of the article is a comparison of 3 different RDBMSs by our own score criteria.

I. INTRODUCTION

Databases today are widely used in the field of information systems. Databases allow working with multiple levels of data, unlike conventional programming languages. They are made with the purpose to eliminate the weak points of automatic processing of data that have been most used during the 60s and 70s. Growing usage of databases has enabled the development of quality and reliable applications. The definition of a database according to [8] is a collection of interrelated data and stored in computers external memory. According to [8] system for database management is a server for a database, and with it you can create a database to display the required logical structure. It is also used to perform operations on data that its client tasks. In this paper we were working with database management systems that are based on the relational model. The relational model was designed by E. F. Codd in the 60s. The model uses mathematical concept of a relation and data and links between data are shown in table form.

II. SPECIFICATIONS

A. MySQL

According to [1] MySQL is the most popular open source database in the world, because it has cost-effective delivery of data, with high-performance, stable e-commerce and online transaction processing. According to [1] MySQL is an integrated, safe for transactions, an ACID compliant database with full support for a return to the old data, the recovery after the destruction of the base and the possibility of row-level locking. MySQL provides ease of use, high performance, scalability, as well as packet drivers of the database and visual tools to help developers (database administration). MySQL database has the following characteristics:

- High performance and scalability - to satisfy the exponential growth of data loads and a number of users.
- Self-healing cluster replication - to improve the performance, stability and availability.
- Online modification of the scheme - in order to satisfy changing business requirements.

B. PostgreSQL

According to [2] PostgreSQL is an object-relational system for database management and is based on PostgreSQL version 4.2 that was developed at the University of California at Berkeley IT department. PostgreSQL has developed many concepts that have become available only in some commercial database systems much later. PostgreSQL is an open-source successor of the original Berkeley code. It supports a large part of the SQL standard and offers many modern features, such as:

- Complex queries.
- External keys.
- Triggers.
- Transaction Integrity.
- Multi-version concurrency control.

Because of its liberal license PostgreSQL can be used, modified and distributed completely free for any purpose (private, academic or commercial).

C. Oracle database 11g

According to [3] Oracle Database 11g is a full-featured database manager for the needs of medium-sized companies. Within Oracle 11g is an Oracle Application Express, a unique online development environment that enables rapid construction of a database using a web browser. It also supports Oracle Developer graphical tool for database development, which allows the developer to browse database objects by running SQL queries, SQL scripts and editing PL / SQL statements. Oracle Database 11g is well integrated with Visual Studio through Oracle Data Access components that allow the developer to easily build .NET applications and Web services based on Oracle 11g database.
III. COMPARISON OF A DBMS

A. Comparison of basic data of DBMS

The first comparison that we will make is the comparison of basic data for each RDBMS. According to [7] below in the text is an overview of Table 1 which contains a comparison of basic data RDBMSs.

From the attached Table 1 we can see that MySQL and Oracle 11g have the same developer, Oracle 11g is the only commercial RDBMS, PostgreSQL is supported on the variety number of operating systems, even 9. Oracle supports most programming languages. In the table we mentioned some of the most popular programming languages, although there are lesser-known languages that Oracle supports. All RDBMSs have ACID.

B. Comparison of syntax

The second comparison is the syntax between MySQL, Oracle 11g, and PostgreSQL which is shown in Table 2. The commands are creating two tables Manufacturer and Tires, the input of data in tables and queries that run against created tables and which are written according to the syntax of the corresponding RDBMS. From Table 2, we can see that the difference in the syntax for each RDBMS is negligible. All that is changed is just one word, and that is NUMBER, which reads NUMERIC for MySQL and PostgreSQL. We tested the examples only with two data types (VARCHAR and NUMERIC) in this paper – in the future work we will broaden the scope.

TABLE I. COMPARISON OF BASIC RDBMS DATA

<td>ACID</td>
</tr>
</tbody>
</table>

Source: [7]

C. Data types

The third comparison is the difference between the data types that a particular RDBMS is using. For easier and more user-friendly presentation we will use Table 3. According to sources [4], [5] and [6] we pulled out all the essential information for the comparison of data types. Below we will describe the advantages and disadvantages of different RDBMSs for certain types of data which they have or do not have. Data type ARRAY MySQL doesn't have, but the alternative that users of MySQL are using is the temporary table. All three RDBMSs have CHAR - it is used because it is fast, space efficient and it is practical to use when the rows are the same or approximately the same length.

The CHARACTER in MySQL is a longer version of CHAR, there is also a variant of CHARACTER SET binary for character data type. It causes the column to be made from the appropriate binary data types so that the char becomes a binary char, varchar becomes varbinary while the character in PostgreSQL is a string of fixed size.

DATE is supported in all three RDBMS and it is used to save the date in the form of strings or numbers. CHARACTER VARYING is only supported in PostgreSQL and its advantage over regular character is variable length.

DECIMAL is supported in PostgreSQL and MySQL, and MySQL also supports DEC. Oracle solves the lack of decimals in a way that converts decimal to numeric data type. In PostgreSQL user precisely defines the decimal numbers ranging from 131072 figures before the decimal point and 16383 numbers after the decimal point. In MySQL decimal determines the exact number of digits before the decimal point and the number of digits after the decimal point. The maximum number of decimal digits is 65 while the number of supported decimals is 30. It also has an option that prevents unsigned negative values. DEC is synonymous for decimal. DOUBLE is supported in MySQL and PostgreSQL. Alternative for the DOUBLE which is used by users of Oracle is BINARY_DOUBLE, and it is 64-bit floating point NUMBER or BINARY_FLOAT. In PostgreSQL is used DOUBLE PRECISION, and it consists of 15 decimal numbers. In MySQL DOUBLE is the number with the moving point of normal size, a range can be less than that is specified in the documentation, but it all depends on the hardware and operating system.

ENUM is supported in MySQL and PostgreSQL, but in Oracle it isn't. MySQL ENUM is a string object with a selected list of allowed values that are listed in the column with specifications at the time of creating the table. PostgreSQL ENUM is a data type that includes statically ordered set of values, and they are equivalent to ENUM type that is supported in many programming languages. In Oracle using PL / SQL users can make their own type that has a similar logic to Enum.
FLOAT is not supported in PostgreSQL. The alternative to FLOAT in PostgreSQL is a REAL, DOUBLE PRECISION or NUMERIC. In MySQL FLOAT is the value of the approximate numerical value data with a movable section, and his precision is from 0 to 23 results in a 4-byte one-precision float column. FLOAT is a subtype of number data type and it has a precision in the range from 1 to 126 binary numbers. INT is supported only in MySQL.

Oracle solves this problem so that INT converts into NUMBER data type. PostgreSQL uses instead of INT use an INTEGER for values whose size of storage is 4 bytes and BIG INT for values that require storage size of 8 bytes. MySQL supports SQL standard integer types and the size of its storage is 4 bytes. LONG is supported only in Oracle. The columns that we declare as LONG can be stored as signs of adjustable length and a length is up to 2 gigabytes of information. MySQL alternative for LONG would be text that can store up to 4 gigabytes of character, and the effective maximum length is less if the value contains multibyte signs. PostgreSQL also used TEXT data type as a replacement for LONG, and the size is undefined.

### TABLE II. COMPARISON OF SYNTAX RDBMS

<table>
<thead>

</tbody>
</table>
VARCHAR is a string of variable length, and its length is limited to a maximum line length which is 65,535 bytes. VARCHAR in PostgreSQL is the character type of general purpose variable length with a limit. VARCHAR in Oracle is the same as varchar, but it is recommended to use VARCHAR2 because the VARCHAR is designed to redefine in a separate data type. It will be used for variable length strings compared with different comparison semantics. In PostgreSQL, VARCHAR2 is supported only in Oracle. VARCHAR2 is a data type that specifies the character string of variable length, once when the VARCHAR2 is created column has an available maximum number of characters or bytes of data that can be kept. The equivalent of VARCHAR2 in MySQL and PostgreSQL is VARCHAR.

YEAR is supported only in MySQL. YEAR is the data type of 1 byte and it is used to represent the values in the form yyyy, and the range is from 1901 to 2155. Oracle and PostgreSQL use DATE data type instead.

TEXT is not supported in Oracle, but the alternative in Oracle is long. TEXT in PostgreSQL, in the beginning, had a TEXT data type, but when was transferred to SQL language for compatibility, instead of being renamed they added a new type VARCHAR, but both types use the same C routines internally.

TIME is supported in MySQL and PostgreSQL while in Oracle as an alternative is used a DATE. TIME in MySQL is a data type that can be used not only to represent the time of the day but also the elapsed time or the time interval between two events. In PostgreSQL, TIME data type saves the time of day. Storage size is 8 bytes. TIMESTAMP is supported in all three RDBMS. TIMESTAMP in MySQL is a data type and is used for values that contain both DATE and TIME intervals. In PostgreSQL, TIMESTAMP has two variants, one is without time zone, and one is with the time zone, and both of them store date and time. TIMESTAMP in Oracle has three variants, the ordinary one, with the time zone and with local time of time zone.

UUID is only supported in PostgreSQL. UUID is written as a series of small hexadecimal digits through several groups separated by dashes, a separate group of eight digits followed by three groups of four digits followed by a group of 12 digits, and all that together is the thirty-two digits that represent one hundred and twenty-eight bits. In Oracle, the UUID is obtained using a function in PL / SQL, while in MySQL is used the UUID() function that returns the value of hundred and twenty-eight bit as utf8 string of five hexadecimal numbers in the form of aaaaaaaaa-bbbbb-ccccccc-ddddd-eeccccccccccccc.

VARCHAR is supported in all three RDBMS. VARCHAR in MySQL is very similar to char, but the difference is in the storage and retrieval of data. VARCHAR is a string of variable length, and its length is from 0 to 65,535 while its maximum effective length is limited to a maximum line length which is 65,535 bytes. VARCHAR2 in MySQL is the data type for compatibility, instead of being renamed they added a new type VARCHAR2, but both types use the same C routines internally.

D. Speed performance

In the last comparison we will compare the speed of execution of certain commands in each of the RDBMSs. The hardware resources that were used during testing are: CPU: Intel (R) i5 2400K, RAM: 8GB DDR3 RAM, HDD: WD 1T, OS: Windows 7 64-bit. To view the runtime we used commands within the RDBMSs. For Oracle, the commands are set timing on and set autotrace traceonly, and for PostgreSQL is 'timing, while for MySQL command was not necessary, because it already has that option within itself as part of the MySQL Workbench. We must mention that the speed comparison done in this paper is pretty simple (with simple statements and simple database with small number of tuples). Table 4. shows our comparison of the speed performance of the simple RDBMS queries. More comprehensive speed performance will be done in the future (with larger and more complex database, as well as more complex queries).

In Table 4. we can see the results of comparing the speeds which will be described in more detail below. The first command create table was performed fastest by Oracle for only 0.03 ms. After Oracle was MySQL and it performed a query for 0.22 ms and at the end is PostgreSQL. The second command insert into was performed fastest by Oracle for 0.001 ms, followed by PostgreSQL for 0.006 ms and at the end is MySQL with 0.05 ms. The third query select was performed fastest by MySQL for 0.001 ms, followed by Oracle with 0.01 ms and at the end is PostgreSQL with 0.02 ms. The fourth query select was executed equally fast by both Oracle and MySQL for 0.001 ms, while the PostgreSQL performed it for 0.009 ms. The fifth query join was performed equally fast by both MySQL and Oracle in a time of 0.001 ms, while the PostgreSQL performed it in 0.006 ms. The sixth command update was performed fastest by Oracle for 0.001 ms, followed by PostgreSQL with 0.004 ms and at the end is MySQL with 0.06 ms. The seventh and final command drop table was performed fastest by PostgreSQL for 0.08 ms, followed by MySQL with 0.16 ms and at the end is Oracle with 0.44 ms.
create, insert, select, drop, join for all three RDBMS, and the only difference appears in the writings of certain types of data and how the values within them are written. The third criterion of comparison of RDBMSs is data types. We compared 22 types of data for each RDBMS. For each of the systems, if there is no particular type of data supported, another type of data is supported, that performs multiple functions or has an alternative solution using a different data type or the combination of several. So on the basis of that, there is no best RDBMS, it all depends on what a person who works with database management prefers to use. The fourth and last criterion of comparison is the speed performance of queries in RDBMSs. According to Table 4, it can be seen that the speed of execution is prevailed by Oracle which is the best to use in large and complex systems, while immediately behind it is MySQL intended for free users, education and business, to the fact that MySQL is the most widely used open source system database management. PostgreSQL is also very popular open source system for managing databases and it applies the same as MySQL, only it is much less prevalent in contrast to MySQL. After all the comparisons, Oracle would be the best option for RDBMS, if to the user who uses it the speed and performance of complex operations is the most important thing and is willing to pay, while MySQL is our recommendation for the open source version which is slightly slower than the Oracle by the tests we made. However, we must state that our conclusions are based on a very simple database and benchmark - more comprehensive syntax and data type comparison, as well as speed performance will be done in the future (with larger and more complex database, as well as more complex queries).

A Tool for Simplifying Automatic Categorization of Scientific Paper Using Watson API

Luka Cvetković, Boris Milašinović and Krešimir Fertalj
University of Zagreb, Faculty of Electrical Engineering and Computing, Zagreb, Croatia
{luka.cvetkovic, boris.milasinovic, kresimir.fertalj}@fer.hr

Abstract – More than a decade many scientific papers have been dealing with automatic categorization of documents. Until recently there were no widespread tools or libraries that could be integrated in a custom application. Recent cloud solutions for cognitive computing eased such integration, but it still requires a lot of work. An idea of extendible library for simplifying document parsing and categorization using IBM Watson API is developed and presented in this paper. As a proof of concept nearly one hundred of scientific papers in a scientific journal were parsed and analysed using Watson API to detect key topics and concepts of each paper which were then compared with keywords provided by the author.

I. INTRODUCTION

Significant data growth in past few decades has been the main driver for increased interest in text analysis. Many scientific papers (e.g. [3], [4], [5], [7]) have dealt with automatic categorization of documents in different areas. Various types of documents have been analysed, from scientific papers to newspaper texts. Motivation for document analysis varies: to detect plagiarism [26], help librarians to categorize scientific papers by providing additional information beyond authors’ keywords [6], assigning disease code in medical documents [5], etc.

Until recently there were no widespread tools or libraries that could be easily integrated in a custom application. Recent cloud solutions for cognitive computing eased such integration, but it still requires a lot of work for adaptation and integration in proprietary application. Furthermore, introduction of any new technology can be a misleading hype and what looks appealing at the first sight can cause many problems during development or in a production environment. Notwithstanding the fact that cloud solutions offer monthly payment plans (or some other pay per usage method) switching technology is only theoretically easy and cheap. Change of technology requires many modifications in existing applications, which requires a lot of additional work. An idea presented in this paper is to utilize one of cloud services for cognitive computing and to develop an extendible library that would encapsulate interaction with chosen service, thus easing possible switch of technology.

In the next section, we reflect on the related work followed by short description of present cloud technologies for cognitive computing. In the Selection IV architecture of a proposed solution is elaborated, followed by the description of developed prototype and presentation of obtained results. As a proof of concept nearly one hundred of scientific papers from a scientific journal [1] was parsed and analysed using IBM Watson API [2] in order to detect key topics and concepts of each paper. Comparison of obtained results and author keywords was a first step of documents categorization (i.e. clustering based on key topics). The paper ends with conclusion elaborating future work.

II. RELATED WORK

For more than a decade many scientific papers have dealt with automatic analysis of various documents but an accent was mostly on well-structured documents like scientific papers. Scientific papers are suitable for analysis due to similar formatting. However, any document with semantic tags could be a good source for analysis (e.g. META tags in HTML documents [3]).

A typical application is automatically categorizing papers in one of predefined categories or assigning one or more tags to documents. Examples are [4], having predefined keywords for each category and [5] trying to automatically assign international disease codes to medical documents. An idea to observe not only abstract but rather complete text to extract information about document was a motivation for [6]. X. L. X. Lu et al. [7] went further trying to categorize figures inside a document and add additional information to the document in the categorization process.

Although most of the work is related to documents in English language which was found more suitable for text analysis, there is much ongoing research for other languages. Authors introduced new approach [8] for Croatian language that extracts keywords from news articles.

During document indexing process, scientific papers are usually paired with predefined descriptors. Authors of [9] analysed keywords given by authors with the descriptors assigned to the papers. However, it is reasonable to question author keywords because it can be misleading in some cases. Authors in [10] compared keywords with automatically generated keywords and differences were not negligible. Various techniques of keywords extraction and text classification are described in [11], [12], and [13].

Automatic extraction of key concepts and categorization is not only limited to scientific papers and
motivated by ease of later information retrieval but it was used to detect religious and political sentiment of a document [14].

Emergence of cloud solutions for cognitive computing opened a whole new perspective of appliance. Thus authors of [15] and [16] developed an interactive application that can answer user questions by analysing the question and finding related facts. I. Wesley-Smith et al [17] used cognitive services to rank scientific papers.

III. TOOLS AND LIBRARIES FOR COGNITIVE COMPUTING

Cognitive services and computing widely gained popularity over the past few years. Most popular services are provided by Microsoft, Google and IBM. Those services are available to developers for making their applications more intelligent, engaging and discoverable. Services are used not only for text analysis but also for picture and video analysis. The main idea behind these services is to make computer experiences more personal and to increase productivity aided by systems that progressively can see, hear, speak, understand and even begin to reason.

A. Microsoft cognitive services

Microsoft cognitive services [18] work across devices and platforms such as iOS, Android, and Windows. API methods are categorized over few categories: Vision, Speech, Language, Knowledge and Search. Each category contains additional API methods providing services like: Computer Vision, Content Moderator, Speaker Recognition, Bing Spell Check, Language Understanding and more. Overview of Academic Knowledge API is given in [19].

B. Google Cloud Platform

Google Cloud Platform [20] provides multiple categories to work with and improves application with new features. Categories that Google provides are: Compute, Storage & Databases, Networking, Big Data, Machine Learning and Identity & Security. Machine learning is one of the most popular API which provides pre-trained models and services to generate own models. In machine learning Powerful Text Analysis reveals the structure and meaning of the text. It is used to extract information about people, places, events and much more, mentioned in text.

C. IBM Watson

IBM Watson [2] offers a variety of services for developing cognitive applications with Alchemy Language application [27] as one of applications. It is a collection of text analysis functions that derives semantic information from context and it works with input text, HTML, public URL or leverage sophisticated natural language processing [28] (NLP) techniques to get a quick high-level understanding of content and obtain detailed insights such as keywords, sentiment, concepts, authors and more.

D. Open Calais

Thomson Reuters Open Calais [21] is a web service that provides intelligent tags to text and thus provides text analysis. It is a natural processing engine that automatically analyse and tags input text so that relevant data from the text can be used in further analysis. Open Calais depends on statistics, machine-learning, big data and custom pattern-based methods so that analysed text is analysed in detail. It searches a text for things like companies, people, cities, industries, products, details and more.

Brief overview of input and output types for previously mentioned cognitive libraries can be found in [22].

IV. SOLUTION CONCEPT

Control flow of a proposed solution consists of four main components: input text (e.g. scientific article), text parser, text analysing component and an analysed data that can be represented in multiple ways (e.g. output file) as shown in Figure 1.

![Figure 1. Control flow of the proposed solution](image)

Main idea is independence and possibility of replacement with different implementations due to inheritance of provided interfaces allowing ease of replacement with recent versions and different implementations without changing other components.

Input text is not predefined by any format. For each text format and document type there is a parser compatible with that type of document (e.g. pdf, txt, doc) and document formatting (e.g. standard scientific paper format) must be predefined.

The parser is used for extracting text from a file and preparing text for further analysis. Also, the parser is used
to determine if given text has written keywords provided by the author of the paper. Parser output is structured text that is machine processable and list of author keywords. Parser is implemented using the external library iTextSharp [23] that has methods to extract text from documents like pdf, doc, txt.

For a given machine processable (structured text) analysis component can determine text entities, keywords, concepts, language and more. This is the main part of the architecture and it is designed to be open for changes. It is replaceable so that text analysis component can be replaced with custom one. Provided implementation is created using IBM Watson cognitive service that can detect keywords from text. For a given text API call is made to retrieve information about the text. Result from analysis component is analysed data retrieved in JSON format and structured for further analysis

Analysed data is a custom result type. It is structured with same structure regardless of the analysis component implementation. This data can be represented in multiple ways. One of the most used is file representation (e.g. csv files with found keywords). Processed data can be used for further analysis.

Figure 2. Class diagram

Figure 2 shows main interfaces of the proposed solution. A complete source code can be downloaded from [24]. Idea is that AnalysisComponent contains implementation of IParser and ITextAnalyser so it can perform actions on a given text. AnalysisComponent handles all the work, calls IParser methods to get text represented as a String and analyses it with ITextAnalyser component. After getting information about the text it structures given data so that result is uniformed and further analysis can be done or data can be exported.

V. EXPERIMENTAL EVALUATION

An experiment was done by examining a hundred documents from ComSIS journal [4]. ComSIS has been chosen due its relevance (the journal is indexed in Science Citation Index Expanded) and availability of well-structured documents (PDFs of each paper for each journal volume).

Each document was parsed and analysed using Watson API. Keywords returned from Watson API were compared with author keywords. Resulted accuracy defined as number of hits divided by number of words in total was varying between 0% and 100%. The 0% results were examined and it was discovered that some of the keywords were not mentioned later in text or abbreviation was used instead of the whole keyword.

An example:

Given text have 4 author keywords: clustering, requirements engineering, survey, tools. The same text was parsed and analysed with Watson API and result was 30 keywords from the same text: analysis, category, classification framework, cluster analysis, current re tools, data, data analysis itself, descriptive analysis, differences, features, global software development, globally distributed development, gsd, gsd features, hierarchical cluster analysis, information inter-rater reliability analysis, iso/iec tr, new features, number, process, rational doors, requirements scenario plus, study, survey, tool, tool capabilities, tool vendors, tools.

Even though Watson API found significantly more keywords and keywords are more detailed not all author keywords were found. Out of four given author keywords only three was found by the API.

| Average number of author keywords | 4,43   |
| Average number of found keywords  | 29,73  |
| Average accuracy score            | 0,622449 |
| Standard deviation of accuracy    | 0,2393 |

Table 1. Number of keywords

The table shows statistics the program got when papers were examined. Even though system found a lot more keywords (Average number of found keywords row in table) than authors provided (Average number of author keywords row in table) themselves, results are not as good as expected. Average accuracy score calculated as sum of every accuracy divided by number of papers is 0,622449 whereas standard deviation of average accuracy is only 0,2933 which means that there are a lot of papers having low accuracy. The reason for that is keyword comparison method. The system is using exact string matching for comparison. Analysis showed that when there are too few keywords the system is not as accurate as when there are more keywords. When having too few keywords the authors tend to put multiple redundant keywords as one (e.g. one of the keywords was: crawling systems and search engines). If comparison was replaced with approximate method like Jaccard similarity [25] results could be much better. Other options for comparison are yet to be implemented and further analysis is required.
VI. CONCLUSION

Occurrence of cloud solutions enabled wide spread usage of cognitive features in custom applications. An example of such application was shown in this paper to detect difference between keywords authors have provided in papers and keywords detected by cloud cognitive services. As there are several cognitive cloud solutions with different input and output formats and idea of presented work was to develop such system that can ease switching between various cloud solutions. The same approach is utilized for parsing various documents.

A future work would be oriented in simplifying integration of this tool in custom applications, defining plugin interfaces to create an extendable tool simultaneously providing several usage scenarios (e.g. detecting keywords, clustering text, etc.).

A potential risk in future work and significant obstacle could be related to language use. Although there are many natural language processing (NLP) tools for language, current cloud solutions are primary oriented on English. This means that various forms of the same word could be recognized as different words. One of the possible ideas to work around this problem could be to use some domestic NLP processor to parse text and instead of sending raw text to analysis, use a new text combined from words without grammar cases.

The Role of Redundancy and Sexual Reproduction in the Conservation of the Genetic Information Tested on a Cellular Automaton

Viktor Kovács, Valéria Póser
Óbuda University / John von Neumann Faculty of Informatics, Budapest, Hungary
viktorhoz@gmail.com, poser.valeria@nik.uni-obuda.hu

Abstract— Pixel evolution is a framework created to study various evolutionary mechanisms. It consists of a cellular automaton with programmable and highly mutable cells and a customizable dynamic environment. We modeled the basic aspects of sexual reproduction to test our hypothesis about its role in information integrity and in the curse of evolution in general. Our findings also suggest that if there is a reasonable cost of reproduction, a selective pressure emerges in favor of short genome sizes. We examine the implications of our findings in a bottom-up evolutionary model.

I. INTRODUCTION

In our simulation we tested the adaptiveness of organisms on different levels of complexity. We were particularly interested in the accumulation/deletion of genetic information in case of sexually and asexually reproducing entities. We then compared our findings with the results from other fields of science, and examine how these results fit in bottom up, or a top down evolutionary model.

II. THE STRUCTURE OF THE CELLULAR AUTOMATON

A. Design goals

Our main goal was to create a model which is sufficiently complex to simulate higher level evolutionary phenomena (Such as resource management and optimization, comparing the fitness of organisms on different levels of complexity, role of sexual reproduction and the effect of these factors on adaptability), while its computing and memory requirements are low enough to make evolutionarily significant simulations on decent population sizes. It was also important to make our system flexible, mutable, and not to rely on hard coded mechanisms. Thus there should be evolutionary path between asexual and sexual reproduction and between simple and sophisticated resource management.

B. Evolution model

The basic unit of our model is “Matter”, which could be either a resource or an organism. Organisms can transform resources to other organism through reproduction and they themselves become resources upon their death. Since the amount of resources is fixed during initialization, we have a closed system in which there is a competition for resources.

The resources are implemented as pixels, which also helps in the visual demonstration of our environment. These resources are determined by the 3 color channel of the corresponding pixel (Red, Green, and Blue) and by the amount of matter they represent. An organism can consume a resource if it meets three criteria:

- It has a corresponding “enzyme”, which means there is a gene in its genome, which is coding for the RGB channels for the given pixel.
- If its size allow to consume the given amount of resource.
- If the organism occupies the same cell as the resource.

Genes carry 3 bytes of information. This 3 byte can code for an enzyme, can serve as a memory unit, or code for an instruction. In the case of enzymes, as we suggested, the bytes represent the 3 color channel of a pixel.

Every organism carries a virtual processor, which is capable to process the instructions encoded in its genes. This means, that the sequence of genes represent a Turing complete machine. Our organisms therefor can use sophisticated decision making algorithms. However, there is a limited amount of instructions each organism is allowed to process in a given cycle. This means processor time is another factor which plays a role in optimization and adaptation.

There are three ways an organism can contact its environment:

- Movement
- Sensation
- Consummation
- Reproduction

The cost of movement is dependent on the size of the organism, and the size is determined by the number of genes it carries. Sensation allows for the scanning of the information about neighboring cells, and it is independent of the size. This means that it is more efficient for a bigger entity to scan all the neighboring cells and with the help of a decision making algorithm to chose a cost efficient path.

There is no predation in the system yet, therefore to avoid the depletion of resources and reaching stasis, each organism has a specific lifetime determined by the number of its genes. When an entity dies the resources it possesses are redistributed in the environment in the form of spawning new pixels. In summary, the large genomsize leads to more expensive reproduction and movement, but it is compensated by a longer lifetime.
Environmental changes and climates can be simulated if the resources are not distributed randomly. If in a given area a certain color dominates, then in that area a way smaller but specific gene pool can be sufficient for survival. (Figure 1.)

The byte base genes are easily mutable. Because of the small interval, there is a smaller mutation space for each gene. We can use point mutations, gene and chromosome duplications and deletions.

Every organism that has an even number of chromosomes is recognized as a sexually reproducing species by the system and upon reproduction it is paired up another entity which has the same number of genes and chromosomes.

C. The architecture of the framework

To achieve programmability we had to design a processor which utilizes the 3 byte based genes. This processor has the following instruction set:

- Invert, Write, Add, Subtract, Compare, And, Or, If, JumpIf, PushByAddress, PopByAddress, Push, Pop, RegA, RegB, RegC, ProgramPointer, ChromosomePointer, Move, Sense, Check, Consume, Divide.

The first byte of a genes represents the memory address, the second byte can be used for storing data or to pass a parameter, and the third byte is used for instruction codes.

In every organism the first six genes are reserved for registers and pointers which store data in the second byte, the third byte of these genes are never used for instructions, therefore we can further utilize these genes by using their third byte as a stack instead.

Addressing was another issue to solve. Addressing by bytes allow only very limited programs to work, so we had to implement some kind of paging system. This is implemented by using chromosomes. Each chromosome can hold 256 genes, and there can be only one procedure on a chromosome.

Furthermore, we had to separate the enzymes from the instructions. To do so, we use a quite arbitrary constraint. If the last byte of a genes has a value greater then 100, then it is recognized as an enzyme. The last byte otherwise would code for instructions, but the instruction set requires values only from 0 to 21, therefore a value beyond 100 would be unknown for the processor anyway. In addition we wanted to reduce the variability of pixels, because to cover all possible color combinations we would require 256^3 (~16 million) genes. The chance of an organism to carry a pixel specific enzyme would be negligible. Therefore we reduced to problem space by three magnitudes, by the following method: We neglect the hundred decimals on each byte, then we use modulo 25 on the remaining value. Of course the values of the resources also had to obey this role. This results in a much smaller problem space (~16 thousand). In order to display more distinguishable colors, the display method multiplies the 25 based color values by 10 (as seen on figure 1).

To optimize performance each organism also carries a lookup table for its enzymes. When its processor executes the Check instruction, it uses this lookup table to decide whether a resource can be consumed or not.

One of the main features of the Pixevolution framework is the ability to use a higher level script language to program its entities. Writing code by using bytes, would be increasingly inconvenient as the complexity of a given problem rises, so we created the 8Script language as a higher level mediator.

```
block = ["var" ident ["," ident]]
["procedure" ident ":=" block ] statement.

statement =
| "call" ident
| "begin" statement { statement } "end"
| "if" condition "then" statement
| "while" condition "do" statement.

condition =
expression(""=""|"<"|">"|"!="|"=") expression.

expression = ["(" term ["+"|"-"|"*"|"/"|"%"|"^"|"!"|"~"|"@"|"#"|"$"|"&"|"*"|"|"|"\"|"^"|"\"|"\"|"\"|"\"|"\"")
| term
| number
| "(" expression ")".

variable =
| ident
| indexed-ident

indexed-ident =
| ident ":[" expression "]
```

Figure 2. Extended Backus–Naur form (EBNF) of the 8Script
The framework contains a parser and a compiler to transform 8script code into a sequence of genes. The parser implemented by a recursive decent parser algorithm.

III. RESULTS FROM RUNNING SIMULATIONS

A. Selective pressure toward shorter genomes

While running the simulation, the most remarkable phenomenon was the inevitable selective pressure towards shorter genomes. This pressure can be reduced by different parameters but seemingly cannot be eliminated. We also observed that less complex initial state results stronger pressure towards short genomes. The question naturally arises whether this phenomenon is a particularity of our model or is it a more general trend? To investigate this issue, we examined the documentation of one of the most successful evolutionary simulations, the Avida project. [1] The following remarks can be found in the configuration documentation:

“SIZE_MERIT_METHOD: This setting determines the base value of an organism's merit. Merit is typically proportional to genome length otherwise there is a strong selective pressure for shorter genomes (shorter genome => less to copy => reduced copying time => replicative advantage). Unfortunately, organisms will cheat if merit is proportional to the full genome length -- they will add on unexecuted and uncopied code to their genomes creating a code bloat. This isn't the most elegant fix, but it works.” [2]

In the case of Avida, the program compensate the selective pressure in question with this parameter. But it seems in every system in which there is a real cost to reproduction this pressure also arises. The next question is if this pressure exist in the actual living biosphere as well.

B. The role of sexual reproduction

In the case of sexual reproduction, the pressure in favor of the shorter genomes was much less prevalent. At the same time the sexually reproducing population was more prone to extinction. Our hypothesis is that the main evolutionary aspect of sexual reproduction could be its role in conserving genes as it seems.

IV. THE BIOLOGICAL SIGNIFICANCE OF THE RESULTS

It seems the selective pressure in favor of shorter genomes indeed exist in actual living systems as well. [3] “When analyzed in a molecular phylogenetic perspective, every clade of bacteria with genome sizes of <2 Mb was derived from ancestors with substantially larger genomes”  
The article also confirms that the selective pressure strongly biased in favor of gene deletion. [3]

From the standpoint of resource management this result is actually not at all surprising. The organism which uses its resources, time and energy (ATP) to copy pseudo genes and unnecessary ones is in a disadvantage against those, which copy only the essential set for survival. This resource cost is particularly significant amongst simple prokaryotes, because here the cost of DNA replication represent a large proportion of the cost of the whole reproduction process. In other words, the reduction of DNA-replication-cost significantly effects the overall cost of reproduction.

Ocman remarks “This pattern dispels the long-held notion that bacteria evolved by the successive doubling of small-genomed progenitors, and raises numerous questions about an evolutionary process that seems to affect all bacterial lineages” [3]

This statement has implications to the whole bottom up evolutionary paradigm. There is much more at stake then the evolution of certain bacterial lineages. The primary proposed mechanism of DNA accumulation in the early stages of evolution is in question. If the selective pressure towards short genomes is prevalent amongst simple organism, the gene and genome duplications can’t account for the accumulation of genetic information.

These results cast a fresh light on the very basics of genetics as well, such as the optimization of the universal codon table.

From the standpoint of mutation resilience the codon table is optimized to such a degree, that it is said to be at least one of a million. [4] This means that there is a good chance that a potential point mutation doesn’t effect the function of the synthetized protein. This resilience is achieved by optimizing the redundancy found in the coding system. A codon provides 4^3=64 possible state, while it has to code only for ~20 amino acids. The question is how did this system evolve? The possibility of chemical or physical necessity is out of the question, so we have to rely on natural selection. However a selection based optimization would gain millions of equally resilient but completely different codon tables, it doesn’t answer its uniformity. To answer uniformity we have to assume, that there was a strong pressure for optimization.
of the coding system for a while, then after a genetic
bottle neck, only one version remained. Then this
optimization basically stopped. This account seems a bit
too specific, but other than that, it assumes that the
pressure is in favor of mutation resilience, while based on
our results we can argue that in fact there would be a
pressure for shorter genome sizes, with a less redundant
coding system.

There are experiments for creating non natural base
pairs since the 90s. In 2014 a team successfully expanded
the DNA of E coli bacteria with artificial base pairs,
which could reproduce and carry the new base pairs for
successive generations. [5]

If codons would use 6 different bases instead of 4 (A,
C, T, G) then 2 base would be sufficient instead of 3 to
code for all the amino acids and for all the syntactic
function. This would result in by 33% shorter genomes.
The organism which would use this less redundant
coding would be in a huge advantage against its more
redundant peers. Probably it would effect negatively only
the way more complex forms of life, where the much
more intricate systems of gene expressions are more
sensitive to genetic errors. During the human ontogenesis
for example, in the first trimester there is a 20% chance
for miscarriage due to genetic deficiencies. Us, humans
seems to need to mutation resilient, redundant coding, but
this should be irrelevant in a bottom-up evolutionary
process.

A similar case could be made for the inefficiency of
sexual reproduction. It appeared more than 1,2 billion
years ago, way before the first multicellular life, [6] and it
introduced a huge level of redundancy, and increased the
cost of reproduction by a magnitude. The supposed
advantage was the possibility of new gene combinations
in a given population. New gene-combinations provide
selective advantage only if it increases the level of
adaptability. However sexual reproduction is not
optimized for adaptability, but quite the contrary as it is
recognized in the form of recombination load. [7]

New gene combinations could be achieved by
horizontal gene transfer, without the increased cost of
reproduction and the recombination load. We would
rather expect this method to evolve as the main source for
new gene combinations in the light of the pressure against
larger genomes.

V. CONCLUSION

Our findings, particularly the selective pressure in
favor of short genomes seem to suggest, that the
accumulation of genetic information in the early stages of
evolution in a bottom up process is strictly impossible.
The existence of the universal codon table and the
mechanism of sexual reproduction are also inconsistent
with such a process and more in accordance with a
genetically top-down approach.

Developing MOBA games using the Unity game engine

D. Polančec, I. Mekterović
University of Zagreb, Faculty of Electrical Engineering and Computing, Zagreb, Croatia
domagoj.polancec@fer.hr

Abstract - MOBA (Multiplayer Online Battle Arena) games are currently one of the most popular online video game genres. This paper discusses implementation of a typical MOBA game prototype for Windows platform in a popular game engine Unity 5. The focus is put on using the built-in Unity components in a MOBA setting, developing additional behaviours using Unity’s Scripting API for C# and integrating third party components such as the networking engine, 3D models, and particle systems created for use with Unity and available through the Unity Asset Store. A brief overview of useful programming design patterns as well as design patterns already used in Unity is given. Various game state synchronization mechanisms available in the chosen networking engine, Photon Unity Networking, and their usage when synchronizing different types of game information over multiple clients are also discussed. The implemented game retains most of the main features of the modern MOBA games such as heroes with different play styles, skills, team versus team competition, resource collection and consumption, varied maps and defensive structures. The paper concludes with comments on Unity 5 as a MOBA game development environment and execution engine.

I. INTRODUCTION

MOBA games are match based multiplayer online games in which a team of players competes against another team in fulfilling one or more objectives in closed games environment usually referred to as maps. What differentiates MOBA games from similar games such as FPS (First Person Shooter) games is usually the heightened strategic aspect borrowed from RTS (Real Time Strategy) games from which MOBA games evolved. This includes resource collection and isometric game view. Most often, the primary objective of a MOBA game match is the destruction of the opposing team’s defensive structure. However as more and more MOBA games are developed, alternative objectives can be found. [1]

Today MOBA games are one of the most popular online game genres. Riot Games, the publisher of arguably the most popular MOBA game League of Legends, claims that the game had over one hundred million active players monthly in 2016 [2].

This paper discusses the implementation of a prototype of a MOBA game in the Unity game engine. Game engines are software tools for game development. They offer complete implementations of software components commonly used in game development such as the physics engine, the rendering engine, the sound engine, network support and other. They also allow the game developers to develop components specific to the game that is being developed on top of or within these systems.

The Unity game engine was chosen because its most basic version is free to use and because there are many learning resources online available for it. Unity is also one of the three currently most popular commercially available game engines, the other two being Unreal Engine and CryEngine. Unity is developed by Unity Technologies based in Denmark [3].

The implemented game is called Moghi Battles and retains most of the MOBA features which will be mentioned in Section III.

II. RELATED WORK

There hasn’t been much work on the topic of MOBA game development in particular except for a couple of online video tutorials and a recorded presentation given by the lead architect of League of Legends [4]. The work on online games in general, however, is more easily found ranging from papers discussing architectures and algorithms used in online games to online video tutorials offering implementation suggestions. For example, the work by Prabha [5] discusses architectures and login methods used in online games implemented in Unity. The work also discusses implementing authentication in the Photon Unity Networking engine [5] which is also used in the implementation discussed in this paper. The work by Bharame, Pang, Seshan and Colyseus [6] discusses a different, distributed, architecture for online games and ways of synchronizing the game state in such architectures. Another work that discusses distributed architecture in online games is work by Assiotis and Tzanos [7] which focuses on MMORPGs (Massively Multiplayer Online Role Playing Games) with large virtual worlds. The work by Hsu, Ling, Li and Kuo [8] compares the traditional client-server server architecture, the peer-to-peer architecture and the mirrored-server architecture concluding that the client-server architecture is the best fit for latency sensitive online games and proposing a clustered-server architecture to improve scalability. The work also discusses the two main approaches to game state synchronization: the conservative and the optimistic approach [8]. The former attempts to prevent inconsistencies in the game state over multiple clients completely, while the latter tolerates small amount of inconsistencies [8].
There are a number of papers covering Unity engine itself. Some of these papers discuss using Unity as a tool for developing applications which aren’t games. An example of such work is a paper by Craighead, Burke and Murphy [3] which discusses implementation of a robot simulator in Unity. Official Unity page also offers plenty of tutorials aimed at helping new Unity developers to get started and to understand basic Unity concepts [17]. Finally, there are plenty of video tutorials available on popular video sharing sites such as YouTube which explain how to use Unity to develop certain types of games. One very useful such video uploaded by user quill18creates that shows how to make an FPS game in Unity using Photon Unity Networking [12].

It is not known, to the best of our knowledge, whether there are commercially successful MOBA games developed in Unity.

III. BASIC MOBA CONCEPTS

It is difficult to precisely define the MOBA genre due to an increasing number of diverse titles on the market, however the basic concepts found in most MOBA games are: heroes, teams, different skills for different heroes, resource collection and consumption, bases with defensive structures, creeps and lanes [1].

Heroes are player controlled units. Each player usually controls only one unit, their chosen hero, and there is no army management aspect which is present in RTS games [1]. MOBA games usually allow the players to choose from a range of different heroes with different play styles, skill sets and roles. Heroes can have different resources at their disposal of which the most common is health. Health is a resource which, when depleted, causes the hero to die. In most MOBA games, heroes can respawn at specified locations called respawn points.

Teams in MOBA games are usually two to six players in size and there are usually two teams in a match [1]. Teams are competing against one another in achieving the main objective of the match which can vary from having to destroy the opposing team’s defensive structures to having the highest number of kills. The team which achieves the main objective is the winning team.

Skills are hero-specific actions available to players which are usually the only way to interact with other player’s heroes, as well as to provide boosts to one’s own hero. In most MOBA games skills can be activated by a specified keyboard shortcut. Activating a skill usually costs a certain amount of non-health resources. Skills also have a cooldown time which starts immediately after the skill has been activated and during which that same skill can’t be activated again. Skills can vary greatly between different heroes and they define a hero’s play style.

Resources other than health are used to perform certain game actions such as activating a skill, resurrecting a hero or purchasing other benefits. Resources are usually automatically accumulated as the time passes, but can also be gained by defeating other players or destroying secondary defensive structures [1].

Bases are areas where players start the match and where main defensive structures are located. Each team has their own base. Defensive structures in the bases can also have health and some of them can also damage the enemy team’s heroes. The main objective of a MOBA match is most often to infiltrate the enemy team’s base and destroy the main defensive structure.

Lanes are paths that lead from one base to the other. The number of lanes can vary but there are usually three: the top lane, the bottom lane and the middle lane. The middle lane is usually the shortest path between the two bases.

Creeps are units controlled by artificial intelligence and which also have health. Creeps usually spawn in the base of the team that they belong to and travel across lanes to the enemy base. Creeps can damage the enemy team’s heroes or other creeps. [1]

The MOBA prototype implementation discussed in this paper implements all these concepts except creeps as artificial intelligence controlled units were out of the scope of the implementation requirements.

IV. IMPLEMENTATION ARCHITECTURE

The typical components of the client-server architecture in network games are: the game client, the session server, the user database, the game server and the game database [5] (Figure 1).

Game client is an application running on the player’s computer which enables the player to observe the state of the game which is simulated elsewhere or to simulate the game themselves. [5]

Session servers (also called lobby servers) are servers that open a session between a client and a game server [5]. This is usually done only after the player provided valid authentication credentials through their game client or a special launcher application by comparing the given credentials with data stored in user database.

Game server is a server which either simulates a game and/or facilitates communication between clients [5]. Commercial MOBA games usually have more than one game server to improve scalability by distributing matches over servers [4]. Game servers may have access to game databases if the game needs to store persistent

![Figure 1. Traditional client-server architecture for online games](image-url)
The architecture of the implemented game differs slightly from the described client-server architecture. The game and session servers aren’t part of the implementation, instead, the Photon Cloud service is used (Figure 2). Photon Cloud [9] service acts as both a session and a game server when working with PUN (Photon Unity Networking) framework. PUN will be discussed in more detail in Section VI. Furthermore, due to the simplicity of the implemented game, there is only one database which stores user and match participation data. This database is accessed using the JDBC (Java Database Connectivity) API through the data server which is implemented in Spring. Spring is a popular Java web development framework. Part of the League of Legends server stack is also implemented in Spring [4]. The data server offers HTTP endpoints for registering a new user, obtaining authentication tokens and reporting game results. Both the client and the Photon Cloud service access the Data Server. As the Photon Cloud service is generic and game-agnostic, it doesn’t implement any form of authentication on its own, which means that it must delegate that task to a specialized authentication service that implements the PUN authentication interface [10]. The data server’s HTTP endpoints for authentication implement that interface and the Photon Cloud is configured to use it as an authentication service. After successful authentication, the data server sends the authentication token to the Photon Cloud which relays it to clients. The clients communicate with Photon Cloud either through TCP or UDP protocol. Section VI goes into more detail on which of these protocols is used in which situations. Since data server’s implementation is relatively simple, this paper will henceforth focus on client implementation.

V. BASIC UNITY CONCEPTS

This section explains the most important concepts and features in Unity. Since the implemented game is a 3D game, this section focuses on Unity features for 3D game development. The Unity Editor is a desktop application used to create games based on Unity engine [11]. The Editor user interface is composed of a scene view in the centre of the screen, a file explorer on the bottom of the screen, a hierarchy view on the left of the screen, a game object or an asset inspector on the right of the screen and a menu bar on the top of the screen (Figure 3).

A. Projects

All work in Unity is stored within Unity Projects. When a new project is created, a folder with the same name is also created in the directory specified by the user. The newly created project will contain the Assets folder which contains all game-specific data such as 3D models, sounds, scripts, etc. The Assets folder is initially empty but all assets which are accessed dynamically during runtime must be put in the Resources subfolder within the Assets folder.

B. Scenes and Game Objects

A scene is a 2D or 3D space that contains game objects [13]. Scenes can be menus, game levels or anything that is being shown to the player [13]. Creating a new project automatically creates the initial scene. New scenes can be created through the menu bar. Scenes have a .unity file extension [13].

Game objects are objects that exist within a scene. When a new scene is created, it will already contain two game objects: a camera and a light source [13]. Having at least one camera in a scene is necessary for the scene to be shown to the player. Users can add additional objects to the scene through the hierarchy view, the main menu or by dragging-and-dropping objects from the file explorer on to the scene view. Another game object can be attached to a parent game object.

C. Components

By themselves, game objects don’t do anything and they need to have components attached to them to have a function. This means that Unity by design enforces using the component pattern. The component pattern is a decoupling pattern that is used when a class interacts with many domains and it is necessary to keep domain-specific functionalities decoupled from each other or when different objects share same functionalities, but one doesn’t strictly inherit another [15]. Unity provides an easy way to facilitate inter-component communication either through the Editor or programmatically.

In Unity, game objects can be activated and deactivated and components can be enabled and disabled. The components attached to deactivated game objects are disabled. This provides an easy way of implementing the state design pattern. The state design pattern is an often-
used design pattern in games that allows implementation of state-machine like behaviour in object-oriented paradigms [16] (each state in the state machine is modelled as an object). In Unity, this pattern can be implemented by simply activating an object that models the current state, and deactivating other state objects.

D. The Scripting API

Although Unity ships with many built-in components, most games require additional game-specific behaviours. These behaviours can be implemented programmatically in special components called Scripts by using Unity’s Scripting API. Scripts can be written in either C#, JavaScript or Boo. In this implementation, all Scripts were written in C#. The Scripting API is an IoC (Inversion of Control) framework, which means that the Scripts written by developers can’t control the execution of the game. Rather, the developers have to implement certain methods in the Scripts and Unity will call those methods under certain conditions [18]. The most common methods found in Scripts are Start and Update methods. Update method is called before a frame is rendered and as such the bulk of the game logic is usually executed within Update methods. The Start method is called before the first time an Update method is called on the Script [18].

E. Unity Asset Store

The UAS (Unity Asset Store) is a web marketplace that allows Unity users to buy and sell custom assets that can be used in Unity. The UAS is available through the Editor. The Editor offers an easy way of importing assets obtained through the UAS. The newly downloaded assets are placed in their own folder within the Assets folder. Assets such as 3D models often come attached to game objects which can even have some simple scripts or other components attached to them. Other assets come in formats compatible with Unity.

VI. PHOTON UNITY NETWORKING

PUN (Photon Unity Networking) is a framework for online game development in Unity. PUN is available through the UAS in two versions, the free one and the more advanced paid one. Moghi Battles uses the free version. PUN is generally very easy to use as most of the framework’s functionalities are exposed through static members of a single class that acts both as a façade in the façade pattern and a singleton object in the singleton pattern.

There are two main concepts in PUN: rooms and lobbies. Connecting to a lobby conceptually corresponds to connecting to a session server, while connecting to a room corresponds to connecting to a game server. This means that a player must connect to a lobby before they can connect to a room. After successful authentication, the player joins a lobby from which they can join or create a room. Photon Servers do not simulate the game. They only provide a means of sending data from one client to the other that fully simulate the game and use PUN to synchronize the game state between themselves. This communication is achieved through the following synchronization mechanisms: object synchronization, PUN RPCs (Remote Procedure Calls) and custom room properties [19].

Object synchronization [19] is used to synchronize simple game object states (such as current health status or location) and to instantiate game objects over the network. This is done by attaching a specialized script to the game object [19]. PUN periodically synchronizes this data between clients. PUN can be configured to either use UDP or TCP for game object synchronization. Most often, UDP protocol is used because responsiveness is often more important than, for example, the exact position of the object. This is also the case with Moghi Battles.

PUN RPCs [19] allow calling script methods on other clients. This provides an easy way to synchronize events between clients. PUN RPCs always use the TCP protocol to ensure events are synchronized correctly. PUN RPCs can be either buffered or unbuffered. Buffered RPCs will be called on all clients that are currently in the room and the clients that join a room in the future. Unbuffered RPCs are only called on clients currently in the room.

Custom room properties are key-value pairs used to synchronize values that do not belong to any objects [19].

VII. MAPS

In the implemented game, players can choose to play on one of two maps with different main objectives. Maps are implemented as Unity scenes. These scenes contain game objects that can be conceptually divided into three categories: controllers, active objects and passive objects. Controllers are empty game objects that contain scripts that implement game-specific logic which isn’t a part of any other object’s behaviour. Both active and passive objects are objects that have components which enable them to interact with other objects in the scene or make them visible to the players. In this case the physics related components are all built-in Unity components, while all 3D models, textures and particle effects are objects that are third-party assets obtained through the UAS except for the terrain which was sculpted with the built-in terrain editor. Active objects also contain scripts that implement game-specific behaviours for those objects. For example, active objects are the camera and the defensive structures while passive objects are terrain and non-damageable environment objects. The background music playing on

Figure 4. Scene view in the Editor showing the Sacred Forest map with invisible walls highlighted
both maps is also a third-party asset obtained through the UAS.

Players are kept within the boundaries of a map by invisible walls. The invisible walls are game objects without textures but with components that enable collision (Figure 4). Players can only join matches that are still in waiting phase or preparation phase. Every newly-created match begins in the waiting phase and the player that created it joins a new room and sets the current server time as a custom room property and sends out a buffered RPC call that increments the player counter on all clients. When other players join a map, they join the same room and increment the player count via buffered RPCs as well. As soon as both teams have a minimum number of players, the match moves to the preparation phase which lasts one minute. After the preparation phase the match moves into the combat phase and teams can begin competing. If a Hero dies during the combat phase, they are respawned at their base.

The maximum number of players in a team on both maps is three, while minimum is one. The current number of players in the team, as well as the information about the current phase of the game is displayed to players at the top of their screens. The players within the same team can also send messages to each other via a chat function located in the bottom left part of the. The chat function also uses RPCs to synchronize messages.

A. The Sacred Forest map

The Sacred Forest map has three lanes and is set in a forest setting which is a common theme among MOBA games. The main objectives on this map are different for each team, which is unusual for MOBA games. The offensive team’s objective is to destroy the defensive team’s main structure within ten minutes. The structure that needs to be destroyed is located at the heart of the defensive team’s base while the defensive team’s main objective is to hold off the offensive team’s efforts. The defensive team is helped by defensive structures in form of walls which surround the defensive team’s base and rotating fire towers that damage nearby offensive team players. The fire damage effect on the fire towers is implemented as a rotating non-collideable child object that notifies offensive team players to take damage through the RPC mechanism. This map contains a relatively large number of objects compared to the other map (823 game objects in total, many of which were manually placed).

B. The Desert map

The Desert map is set in a desert setting and features only one lane. The main objective of both teams is to be the team with highest number of kills. Whenever a hero deals enough damage to another hero to cause that hero to die, that counts as a kill for the team of the player who controlled the hero that dealt that damage. This map also includes power ups strewn across the map which can be picked up. These power-ups are also game objects with collider components set in trigger mode. This map is much smaller than the other map to provide more action-packed and less strategic experience.

VIII. HEROES AND SKILLS

Players can choose between two heroes implemented in Moghi Battles. These heroes have different attributes and sets of skills which give them somewhat different playstyles. Hero attributes are starting health, attack, defence and speed. Heroes are composed of the main game object and two types of child objects. The first type defines static hero appearance (3D models, and textures). The second type are objects that define area of effects of skills. The 3D models, textures and animations are third party assets obtained through the UAS. The built-in physics components are attached to both the main object and the second type of child objects. The main object also contains the PUN script required for synchronization and the built-in component which is used to control animation transitions. Initially, this component contains no transitions and they should be defined by game developers. Other scripts attached to the main object implement game-specific logic such as movement, resource and attribute tracking and skill-related logic. All skill icons, skill particle effects and hero sound effects are third-party assets obtained through the UAS.

Hero movement is eight-directional and is achieved by pressing W (forward), A (left), S (backward) or D (right) keys. The same key combinations for movement are commonly found in many games. Pressing each of these keys results in a corresponding direction vector applied to the Hero main object. If more than one key is pressed, the direction vectors are all summed up and normalized. The final movement vector is a result of multiplying the total normalized direction vector with the speed attribute.

Activating skills costs gold. Gold is an expendable resource in Moghi Battles which is auto-generated with the passage of time. Players can gain additional gold by destroying enemy defensive structures and killing enemy heroes. Both heroes have three skills, two damage skills and one buff skill. One damage skill is weak with very short cooldown and very cheap gold cost. The other damage skill is much stronger with much longer cooldown and much higher cost. The buff skill is very powerful on both heroes and as such it has the longest cooldown time and the highest gold cost. Both types of skills are represented by scripts that extend an abstract class that implements everything that is required by both skill types such as listening to player input and managing particle effects. The extending classes need only implement three methods which are called at different points in the skill lifecycle. This is an implementation of a template method design pattern [20]. Skill bar at the bottom of the screen indicates to players which skills can be activated and which skills are either on cooldown time or the player doesn’t have enough gold to pay their costs. The current amount of gold the player has is displayed in the top right corner.

Damage skills are skills that are used to defeat other players and destroy enemy defensive structures. These skills have an array of damage effects with defined starting times. The starting times are defined as offsets from the time when the skill is activated. Each damage effect has one area of effect associated with it. When the start time
for a damage effect passes, the game looks up all damageable objects (opposing team’s defensive structures or opposing team’s players) currently within the area of effect and uses the RPC mechanism to notify those objects that they should take damage. Each damageable object has a health bar that indicates how much damage that object has taken (indicated by red colour) and how much more it can take (indicated by red colour).

Buff skills alter the current player attributes when they are activated and restore them to the previous state when they are done. In Moghi Battles this behaviour is implemented in accordance with the command design pattern [14].

IX. TESTING WITH OTHER PLAYERS

The game was tested by a group of four people. Two testers were familiar with MOBA games and had experience playing them while the other two weren’t. There were two tests in total and tests consisted of playing out a full match. The second test was also recorded (Figure 5) [21].

A. The first test

During the first test, several issues were discovered. The game sometimes didn’t place players in teams properly and the transition between the waiting phase and preparation phase happened before the necessary prerequisites were met. This issue was caused by a bug in the code that synchronized the number of players among clients. Another issue that was discovered was that one of the heroes was too strong compared to the other one.

B. The second test

The second test was conducted after the issues discovered in the first test were fixed. No further significant issues were discovered, only minor performance related issues due to insufficient optimization.

X. CONCLUSION

Although there are many online tutorials for working with Unity and the Unity Scripting API is very well documented the general impression is that Unity has a very steep learning curve which means that many concepts must be learned by absolute beginners before any more advanced projects can be undertaken. Performance wise, the games built with Unity run reasonably well even without optimizations. Some movement choppiness was observed with V-sync on, however, the problem was resolved by turning V-sync off. The Scripting API is very intuitive and easy to use as well, though the fact that it is an Inversion of Control framework limits what kind of algorithms can be implemented. What makes choosing Unity worthwhile is the UAS which has a very large number of third party components, both paid and free, readily available to developers. In total, 59 classes were implemented and 7 unity scenes were created (two maps and five menus).

Comparative analysis of tools for development of native and hybrid mobile applications

Summary – One of the main reasons for wide acceptance of smartphones are mobile applications that offer a wide variety of features. This paper deals with types of mobile applications: hybrid and native, as well as tools that enable their development. For purposes of this paper, a total of eight simple, identical applications were made for Android, iOS and Windows Phone. Native applications for Android, iOS and Windows Phone were made in integrated development environment, or so-called IDEs: Android Studio, Xcode and Visual Studio. Hybrid applications for Android and iOS were made in Ionic, PhoneGap and NativeScript framework. The paper compares tools used for development through following criteria: supported computer operating system, supported mobile platforms, programming languages, official documentations and community of programmers, installation and development. Goal is to research the advantages and disadvantages of the tools used for development of native and hybrid mobile applications and to find out which applications are the most profitable.

I. INTRODUCTION

Features and options offered by smartphones through mobile applications are immense. Purpose of the application is to resemble a standalone application, not a web site, and it would be preferred for it to be interactive. At first, mobile applications were created for information purposes and productivity, such as electronic mail, calculator, weather forecast, calendar and similar, but their diversity and number have increased enormously in the past couple of years [1].

There are three categories of mobile applications: native, web and hybrid. Choice of the appropriate one depends on the requirements that need to be met [2].

Native mobile applications are specific to a certain mobile platform and they are developed in an "official" programming language of that platform, for instance, native Android applications are developed in Java programming language. Such applications are installed directly on a device and they communicate with its operating system. For that reason, they can utilize the features of the device to a maximum [2]. One of the main characteristics, as well as advantages, is application’s speed of performance on the device, and a disadvantage is that users of such applications must update them regularly [2]. Considering the fact that in application development on different platforms one must use different programming languages, expenses of developing it are often higher. However, despite the aforementioned disadvantages, native applications offer by far the best usability, features and overall user experience [3].

The second category is comprised of web mobile applications based on technologies and languages such as HTML5, CSS and JavaScript [3]. These applications are actually web sites adapted to smaller screens that can be opened in any browser [3]. Therefore, the only condition, which can also be a disadvantage, is the fact that Internet connection is necessary for starting such applications. Furthermore, they are independent of mobile platforms, which means that development programmer simultaneously creates an application for several operating systems or mobile platforms and that the duration of the process and expenses are smaller [3]. Web applications could not, until recently, access native features of mobile devices, but with HTML5, there is a feature of accessing, for instance, a camera or a microphone. Web applications perform slowly and they do not appear in official application stores [2].

As an excellent blend of native and web applications, the third category represents hybrid mobile applications. Hybrid applications use frameworks which enable development programmers to create applications that behave like native ones, using technologies such as HTML5, CSS and JavaScript [3]. These applications are installed on a device just like native ones and they have access to most features of a device: camera, GPS, and similar [2]. Their main characteristic and a great advantage is that they can be started on several different platforms, so the price and time necessary for development are significantly decreased. However, considering the fact that hybrid applications are developed using the aforementioned technologies, they do not perform completely native-like, which results in somewhat slower performance [2].

1 HTML 5: camera access, http://stackoverflow.com/questions/9431475/html5-camera-access (2017-02-02)
In creating applications, development programmers can use various IDEs\(^2\) and frameworks. During the development of native mobile applications, it makes most sense to use the official IDE for a certain platform. On the other hand, for development of hybrid applications, there are different frameworks.

For needs of developing native applications, the following IDEs were used: Android Studio\(^3\) for developing Android applications, Xcode\(^4\) for developing iOS applications and Visual Studio\(^5\) for developing Windows Phone application. In developing hybrid applications for Android and iOS, Ionic\(^6\), NativeScript\(^7\) and PhoneGap\(^8\) frameworks were used. Out of all the aforementioned frameworks, Ionic was largely focused on the appearance of the application and user interface, and is considered a front-end work environment, so it needs a so-called wrapper, such as PhoneGap, in order for the application to get native characteristics – in other words, to access a microphone, phonebook, phone (calls) and similar. These technologies or tools are compared and analyzed according to six criteria: supported computer operating systems, supported mobile platforms, programming languages, official documentation and community of programmers, installation and development. Goal of this paper is to answer the questions: what are the advantages and disadvantages of tools used for development of native and hybrid mobile applications and which ones are the most affordable.

A. Related works

Khandeparkar, Gupta and Sindhya compared frameworks for development of hybrid mobile applications: Ionic, Famo.us/Angular and OnSenUI according to four criteria: documentation, performance, community and learning curve. On average, Ionic had the best rating. According to criteria interface design, user experience and performance, safety, tools and debugger, native applications are a better choice, while according to criteria expenses, time necessary for development, maintenance and independence of platforms, hybrid applications represent a better solution [4]. Y. A. Redda in his paper states the criteria according to which one could compare tools for development of hybrid applications, or criteria that would help choosing the appropriate tool. Criteria are: supported platforms, features of the device of access, programming languages and license [5]. D. Markov states 7 frameworks, and for each one states advantages and disadvantages, but he compares them according to several criteria: native appearance and feeling, prerequisite, community, documentation, tools. Ionic and NativeScript, which are analyzed in this paper as well, are according to his criteria two most powerful frameworks, and the only criterion in which NativeScript got weaker rating is community, while in others it was even better than Ionic. However, at the end he concludes that there is no ideal framework because each one has its advantages and disadvantages [6].

On a webpage, Mobile frameworks: comparison chart there is a list with more than 20 frameworks for development of mobile applications. Also, there are criteria: platform, type of application, programming language, device’s options, user interface, license and other, and they offer a feature of choice of the appropriate demand. Based on the elements chosen, if there is work environment that corresponds to all demands, a person who cannot decide while choosing a framework, this way can find a solution easily [7]. Comparisons of IDEs are mostly done according to criteria of license, computer operating system and according to various features they have, such as debugger, GUI\(^9\) builder, autocomplete and similar [8]. It is stated how the best IDEs are determined according to customer satisfaction and various measures, based on which they are put into four categories on the grid: Leaders, High Performers, Contenders and Niche products. Examples of leading IDEs are Visual Studio, Xcode, NetBeans, IntelliJ IDEA and such, while examples of niche products are Aptana Studio and Code::Blocks [9].

B. Comparison according to criteria from works related

World wide web has many articles that compare Android and iOS applications according to various criteria, and less of those dealing with Windows Phone applications. Several articles states how development of Android applications can take 2 or 3 times longer than development of iOS applications, according to which number of lines in code is larger, which is often a result of Android fragmentation. It means that Android devices come in various shapes and sizes with large differences in performance. Furthermore, it includes a multitude of various Android versions that are active at the same time. Taking the aforementioned into consideration, it turns out that development of Android applications is more expensive than developing iOS applications [10, 11]. Tomislav Car presents statistical data proving the aforementioned. He analyzed 6 applications meant for both platforms and measured working hours and number of lines in code. In the end it was concluded how Android applications have about 40% less code than iOS application. It is interesting how in some application that percentage amounted up to 189%, while one of the projects had a difference of 4%, which was not as significant. Comparison also indicated how about 30% more working hours are necessary for developing Android applications [12].

Adam Sinicki and several other authors of different articles state that iOS simulator is better and faster for debugging than Android emulators, which enhances the speed of development [11, 13]. Furthermore, emulators for Windows Phone applications are considered better and faster than Android's [14].

When it comes to publishing applications in official stores, situations differ significantly in different platforms. Firstly, it is necessary to register on platform’s official stores. Registering on Google Play for publishing Android applications costs 25$ and it is permanent, which means that it does not have to be paid on the annual basis [13, 15]. Apples for annual fee in App Store requires 99$ [13], while registration in Windows Store for individuals amounts 19$, and 99$ for a company, and it is also permanent [16]. After the application is sent, i.e. uploaded, it goes through a phase of testing. In Google Play Store, the process between testing and accepting takes several hours to several days [13, 17]. Situation is similar with publishing Windows Phone applications, where process takes a couple of hours up to maximum 3 working days [18]. Process of testing iOS applications can take up to two or three weeks, after which there is a great chance of rejecting the application because of Apple's high standards [13].

Nic Raboy analyzed Ionic and NativeScript. NativeScript enables access to any component of a device or API directly with JavaScript, which means that if a necessary plugin does not exist, development programmer can independently create his own plugin with knowledge of JavaScript. Ionic is different, because it must access API through Apache Cordova, which is the same in PhoneGap. While for NativeScript it is possible to create plugins using only JavaScript, in Apache Cordova, Ionic and PhoneGap, it is necessary to create plugins in Java or Objective-C programming languages. Raboy also gives advantage to NativeScript when it comes to curve of learning, and the reason is that there are Ionic 1 that uses Angular 1, and Ionic 2 that uses Angular 2, which are drastically different. It is a problem for development programmers who have to learn everything from the beginning, which is very demanding [19]. Prantik Vaghela also compares these two frameworks, but he, unlike Raboy, gives advantage to Ionic when it comes to curve of learning. He considers Ionic easier to learn, especially if programmers have experience in web development. Furthermore, he states that debugging experience is easier and faster in Ionic, considering the fact that it is possible to debug parts of application that do not use native device features in a browser. When it comes to speed of performance, NativeScript is faster. However, one of important factors for application users is size of the application, which is a lot smaller in Ionic [20].

A. Technical circumstances

For needs of this paper, a practical part was done first by developing a simple mobile application that enables simple mathematical operation of adding two numbers. The goal was to show the principle of functioning of six different development tools: IDEs and frameworks. The following IDEs were used: Android Studio (version 2.1), Xcode (version 6.4) and Visual Studio (version Community 2015). In development of hybrid applications for Android and iOS, Ionic (version 1.7.14) and PhoneGap (version 6.3.0) were used, while the application in NativeScript (version 2.2.1) framework was, due to technical limitations, developed only for Android.

Due to the fact that technical characteristics of a personal computer affect greatly the quality and speed of development, installation of IDEs and framework as well, it is necessary to state the characteristics of computers used. Native application and all hybrid applications for Android were created on a laptop computer with installed memory (RAM) of 4 GB and Windows 7 Professional operating system. Furthermore, personal computer with 8 GB of installed memory and OS X Yosemite operating system (version 10.10.5) was used to design all iOS applications, one native in Xcode and two hybrids in PhoneGap and Ionic frameworks. Native application for Windows Phone was developed on a laptop computer with installed memory of 4 GB and Windows 10 (it is important to state that it is not Professional).

B. Criteria and results observed

- Supported computer operating systems – operating systems of computers used for development of applications.
- Supported mobile platforms – operating systems of mobile devices on which it is possible to install and start an application.
- Programming languages – languages in which the main code of the application is written. They differ depending on platforms for which the application is developed.
- Official documentation and community of programmers – official documentation is available on web sites of the IDEs and frameworks mentioned. Detailed documentation is extremely important for programmers, especially for those who are beginning to work with certain technology. Alongside documentation, one of the key elements is the community of programmers who use the same technologies. In evaluation of official documentation and community, mark 1 means that documentation is not transparent, detailed and that it is difficult to be found, so the community itself is not wide and it is almost impossible to find an answer to any question posed. Mark 5 means that documentation is
detailed, well organized and available on web sites, the community is very widespread and for all concerns and problems, one can find an answer. It is necessary to take into consideration that marks are assigned from a subjective point of view.

- Installation – complexity itself is observed, as well as time necessary for installation of a certain IDE or framework. Prerequisites and requirements necessary to fulfill before the installation are observed as well. In analyzing and assigning marks in this criterion, mark 1 means that installation is complex and takes a lot of time, while mark 5 means that installation is simple and short.

- Development – refers to the main part in which the application is developed. In other words, complexity of making an application in certain technology is compared from a subjective point of view. Mark 1 means that technologies used are non-intuitive, non-organized and that the programming language is very difficult and incomprehensible, and mark 5 means that technologies are very intuitive, organized and that programming language is simple and comprehensible.

### C. Analysis

According to the first criterion, supported computer operating systems, Android Studio is one of the IDEs that gave the best results because it can be installed on Windows, Mac OS X and Linux operating systems. It means that native Android mobile applications can be developed regardless of the operating system of a computer. While analyzing frameworks, Ionic and NativeScript can be installed on all operating systems, while development of hybrid applications in PhoneGap framework is still impossible on Linux operating system. Possibility of installing certain IDEs and frameworks and development of mobile applications on different computer operating systems significantly contributes to lowering expenses, so it is not necessary to invest in operating systems the company does not already own – it is possible to work with the ones already available at the company.

According to the criterion supported mobile platforms, it is sensible to compare and analyze only those frameworks that are used for hybrid applications, because, as it was stated before, native ones are developed separately for every platform. PhoneGap offers the widest spectrum of mobile platforms: Android, iOS, BlackBerry 10, Windows and Windows Phone, Firefox OS, Ubuntu, Tizen, Amazon Fire OS, while Ionic and NativeScript support Android and iOS (although newer Ionic 2 supports Windows 10 Universal App as well). Taking into consideration this criterion and the analysis results, it is evident that it is more profitable to develop hybrid applications, especially using PhoneGap framework that enables development for more than five mobile platforms simultaneously. Native applications are developed in "official" programming languages for individual platforms. Applications for Android are developed in Java programming language, while C# or C++ are used for native Windows Phone applications. Objective-C or recently Swift, are programming languages for development of native iOS applications. For needs of this paper in creating native mobile applications, Java, C# and Swift programming languages were used. The introduction stated how hybrid applications are developed using HTML, CSS and JavaScript technologies, which facilitates their development. Therefore, all hybrid applications are developed using JavaScript programming language, and

TABLE 1. REPRESENTATION OF IDES AND WORK ENVIRONMENTS ACCORDING TO CRITERIA ANALYSED

a. iOS, BlackBerry 10, Windows and Windows Phone, Firefox OS, Ubuntu, Tizen, Amazon Fire OS
some frameworks require certain JavaScript frameworks. For instance, Ionic requires use of Angular JS. NativeScript recommends, but does not require, most recent Angular 2 framework. Advantages of hybrid applications are in those technologies or languages used for their development. Developers do not need several different programming languages to develop applications for different platforms, as it is the case with native applications. Also, if it is necessary, developers who are familiar with JavaScript can easily transfer from one framework to another because of similar principle of work. From all IDEs used according to criterion of official documentation and community of programmers, the most intuitive and most quality rated were documentations of Android Studio and Visual Studio. That means that all steps were described in detail starting from installation, development, up to publishing, structure of application, starting the emulator, debugging and much more. Furthermore, advice for improvement of code writing are offered. While making the application, of great help were communities of programmers that are very widespread, which is significant when a developer has a problem and when he knows that there is someone who has certainly already had the same problem, and even if he has not, there is someone willing to help. Based on the analysis of frameworks used, it is concluded that they all have excellent intuitive and detailed official documentations. However, concerning the fact that NativeScript is a relatively young framework, the community itself has not been developed and spread yet, and it is difficult to find a solution and an answer when it is necessary. Installations function as regular installations of standalone applications. Of course, it is necessary to take into consideration the speed of Internet of which depends the speed of downloading. While installing Android Studio and Visual Studio, it is possible to choose what tools and elements are to be installed, while by installing Xcode, everything is done automatically. Time of installation of analyzed IDEs drastically differs. Also, it should be taken into consideration that installations were done on different computers with different random access memory and characteristics, and that different elements to be installed were selected (Android Studio and Visual Studio). Installing Android Studio on Toshiba laptop took about 20 minutes, while the Xcode installation on a Mac computer took about 7 minutes. The longest and the largest installation was the installation of Visual Studio on Asus ZenBook. It took between 4 and 5 hours, which is a lot compared to the previous two. Taking into consideration extreme differences in duration of installation, and the complexity as well, Xcode was assigned the best mark, and Visual Studio the worst. Installation of frameworks were done using CLI on Windows computer and Terminal on Mac computer. Duration of all installations is very short and simple. All installations – Ionic, PhoneGap and NativeScript, demand preinstalled Node.js. Furthermore, other prerequisites necessary to be fulfilled are stated in official documentations. For instance, versions of Android SDK, Git and similar, which depends of the computer on which the application is made, or of what is perhaps already installed. Installations of all frameworks were assigned the best mark because they do not require too much effort and they do not take up too much time. Marks in this criterion do not necessarily mean that the IDE that requires more time for installing is bad. On the contrary, it can have excellent features, as it is case with Visual Studio. It is only one minute disadvantage of the analyzed IDE. It is difficult to make an objective statement on the process of development itself and on its complexity because it all depends on the developer and his previous knowledge. This paper, in a relatively objective way, is trying to conclude about the complexity of development in a certain IDE and framework, which depends on the programming language, intuitiveness, features of the IDE and so on. Developing a native Android application went without greater problems and Android Studio turned out to be an excellent IDE because it has all characteristics of a quality IDE: it is free, it has syntax and error coloring, autocomplete, code generator, debugging. WYSIWYG editor, simplicity of starting the application in an emulator and on a device, simplicity of adding an icon, and much more. Mark 4 was assigned due to complicated Java programming language. Xcode was assigned the same mark as Android Studio because it also turned out as a quality and well organized IDE. However, the problem in developing these simple applications appeared during changing the icon, which was a bit more complicated. Designing a native Windows Phone application also turned out to be a more complicated. The first problem appeared when Visual Studio was installed on Toshiba laptop. Then, it was completely impossible to create a Windows Phone application and the problem was incompatibility of the operating system and necessary SDKs. A virtual machine was started, onto which Windows 10 was installed, but despite the fact that it was then possible to create a mobile application, it was not possible to start the emulator since it was a virtual machine. At the end, Visual Studio was installed on Asus laptop with operating system Windows 10, but despite all that, it was still not possible to start the emulator due to limitations of working with this operating system. As an alternative solution, a Universal Windows Platform application was designed, that was able to start on different devices: mobile devices, computers, Xbox and similar. Regardless of the limitations and strict requirements, integrated developmental environment has shown equally good as the rest. Problems prior to development and impossibility of starting the emulator are disadvantages due to which Visual Studio was graded worse than other IDEs. During the development of applications in frameworks analyzed, CLI were often used because if one wants to create an application, add a platform, start an application, sign it and such, it is necessary to input commands for certain actions. Code was written in Sublime Text 3 application for text editing. Structures of project in PhoneGap and Ionic are very similar. Files are logically sorted, which makes browsing
through the directory of the project much easier. Structure of NativeScript project differs from previous two, and another difference is that XML markup language was used, not HTML. PhoneGap and NativeScript applications were written in "clear" JavaScript, while for Ionic, AngularJS was used. Since applications for Android were first made on Windows computer, in making iOS applications it was only necessary to transfer directory of the application on Mac computer. Of course, it was necessary to first install a framework, after which it was only necessary to make a position in the directory of the application, add iOS platform and build an application. Application developed in NativeScript could not be built for iOS due to the limitations of the computer itself for now, so it was, unlike Ionic and PhoneGap, assigned a lower grade.

III. CONCLUSION

From all IDEs analyzed, Android Studio made the best impression. During the installation and development there were no bigger problems and difficulties, and even if there were, solutions could be found relatively quickly, which is connected to a widespread and active community of programmers. One of great advantages of Android Studio is that it can be installed, and native applications can be developed on all computer operating systems. When talking about frameworks for creating hybrid applications, and taking into consideration the analyzed criteria, they all turned out to be powerful tools. However, PhoneGap is a tool with the greatest comparative advantages, mostly due to a wide spectrum of supported mobile platforms. Although native applications offer by far the best user experience and can use all features and functionalities of devices to a maximum, nowadays tools for creating hybrid applications are continuously developed. One of the reasons is that "only" knowledge of JavaScript programming language is necessary, and not of all programming languages that one needs to know for developing native applications: Java, Objective-C, C# and similar. Also, time necessary and expenses for developing the application are becoming shorter, so it is more profitable to develop hybrid applications. The discrepancy between hybrid and native applications is smaller every day, and hybrid applications are starting to resemble native ones, so the difference will surely disappear completely very soon.

Comparative analysis of tools for development of native and hybrid applications has shown only some advantages and disadvantages of tools used for development of mobile applications. Analyses through different criteria would certainly bring different results, but it is without a doubt that such analyses can be of great use to manufacturers in order to develop the aforementioned tools even further, and to make them more powerful and better on one hand, but also help users in choosing tools for work on the other.

Exploring HTTP/2 Advantages and Performance Analysis using Java 9

Abstract - As websites have become bulkier and serve more larger files to end users, it has become harder for the HTTP/1.1 protocol to provide adequately short page load times. The HTTP protocol, in its previous versions, is a generic stateless application protocol most often used for distributed, collaborative, hypermedia information systems. The newest version, HTTP/2, introduced an updated protocol feature set based on Google’s SPDY/2 protocol, aimed at improving the speed at which modern web resources load, reducing network congestion and additionally enforcing security standards. With header compression, new server push responses, and fully multiplexed connections, HTTP/2 solves the major issues previous versions were unable to overcome. This paper presents performance analysis results comparing both protocol versions in the upcoming release of Java 9 programming language, as well as describes key differences in development between versions. Analysis was run on the open source Jetty web server and benchmark code was compiled using JDK 9 Early Access. This paper shows benchmark results using different scenarios and typical usage performance gains. It outlines the major improvements and recommendations switching to the newer protocol version provides, specifically in general use object-oriented programming languages such as the new version of Java language.

I. INTRODUCTION

The Hypertext Transfer Protocol (HTTP) was introduced as an application protocol for distributed, collaborative, and hypermedia information systems [1]. It is currently the most common way to send and receive data across the Internet, making it essential to the World Wide Web as we know it.

Originally, when the Internet was a much newer technology, web pages were primarily text-based with perhaps a few embedded still images to make the web page more attractive. The HTTP/1.1 protocol, the latest version of the 1.x series, was finalized in 1999 as RFC 2616 [1] and was designed to optimally service web communications of its era. Later, in June 2014, numerous improvements to the protocol were introduced in the form of six RFCs 7230-7235 [2], which collectively update and obsolete RFC 2616. In total, these updates to the original protocol addressed 553 issues, which can be found at [3].

The Internet has steadily grown with time, however. Today, the average web site is not a few kilobytes in size but, rather, a few megabytes. Specifically, as of December 2016, the average website is roughly two and a half megabytes in size [4]. Most of this page size increase can be attributed to web pages incorporating more images into their design; however, there is also a noticeable increase in the sizes of styles (CSS) and scripting code (JavaScript) being sent to the end client.

As can be seen in Table I, from the end of 2014 to the end of 2016, websites have increased from 1931 kB to 2479 kB: an increase of 28.4%. Not included in Table I is HttArchive’s data from the end of 2010, when the top websites were, on average, only 716 kB in size. From those numbers, websites have increased in size by 246% in the last 6 years.

This increase in file size and quantity is something that HTTP/1.1 cannot overcome and is the main reason for creation of the new version of HTTP protocol. HTTP/2 was designed in RFC 7540 [5] with the modern web in mind and aims at removing the need for web developers to work around HTTP/1.1’s shortcomings in today’s age.

With this paper, we compared the improved performance one can expect to see when migrating Java web servers from HTTP/1.1 to HTTP/2 and also to present the current state of HTTP/2 implementation within the Java ecosystem.

II. HTTP/1.1 LIMITATIONS

The HTTP/1.1 protocol is able to adequately service small size, relatively simple HTML pages. When used to serve modern web sites, which can be significantly larger than the original specification was designed for, HTTP/1.1’s deficiencies become far more noticeable. Among these are: head-of-line blocking, uncompressed headers, and the Slow Start mechanism.
A. Head-of-Line Blocking

Head-of-Line blocking is the phenomena which occurs when multiple packets are held up due to needing to wait for the transmission of another packet [6]. This can occur in various scenarios, due to:

- Packets being lost, requiring that further packets wait until the lost packet is resent
- Port contention, where two packets are being sent to the same port and one must go first while the other is blocked until the next cycle
- Ordered packets being sent out of order, causing out of order packets to be delayed until the required packet is transmitted.

B. Uncompressed Headers and Slow Start Mechanism

The HTTP/1.1 standard imposes no limits as to the size of each header field contained in a request; however, most servers and clients impose some sort of limit for both practical and security reasons. Per research conducted by Google [7], header sizes range from approximately 200-2000 bytes with an average size of 750 bytes. Considering that these numbers were gathered in 2009, and with Table I and Fig. 1 showing more than an 11% increase in web site size for 2016, as well as Fig. 2 presenting an average web page size of 2479 KB, we can give a conservative estimate of typical header sizes being approx. 1500 bytes or more.

![Total Transfer Size & Total Requests](image1)

**Figure 1.** Total Transfer Size and Total Requests for all web pages (URLs) Jan 2014 – Dec 2016 according to httparchive.org [8]

![Average Bytes per Page by Content Type](image2)

**Figure 2.** Average bytes per page by content type for all web pages (URLs) as of 02-Dec-2016 according to httparchive.org [4]

The size of these headers is important due to the fact that large headers may take multiple round trips from server to client before being fully transmitted. If a website has, for example, 100 assets to download (e.g. images, script files, stylesheets, embedded videos, and text content), each request will require headers to be sent between the server and client. Using a conservative estimate of 50 round trips [9] to transfer the contents of a web site, this amounts to 75 KB of header data being transferred, most of which is repeated data.

HTTP/1.1’s Slow Start mechanism, defined in RFC 5681 [10], is a congestion-control feature built into the TCP protocol. With Slow Start, every connection starts with an "initial congestion window," which defines how many packets may be sent during the first round trip over the network. With each successful ACK response from the client, the window is increased, allowing more packets to be sent at once until, ultimately, the peak transfer rate of the connection is found [11]. This feature, specifically designed to limit data transfer in order to prevent router overload, causes problems as it introduces more round trips than would normally be necessary over the course of a connection. Each round trip is affected by the connection’s latency, meaning that a 100 ms latency in the previous example would result in a total wait time of 800 ms just to open and close all of the congestion windows; the time to transfer the data contained carried within the packet payloads is not included. In addition, each window requires that headers be sent over the network, the end result being that the client must wait not only due to the latency of the connection, but it must also transfer additional, redundant data with each request.

The initial window, as specified in RFC 3390 [12], is between two and four segments, with a maximum segment size of 1460 bytes. This strict limit bottlenecks modern connections, and, as a result, many connections are never able to reach their maximum speeds. Google petitioned that the initial congestion window be increased to 10 segments based on their research that showed user-visible latencies could be reduced by up to 10% with no noticeable increase in congestion problems across the net [13], which was later accepted in the HTTP/1.1 standard.

III. MODERN WORKAROUNDS

As of writing this paper, HTTP/2 usage statistics [14] show that only 11.7% of all the websites support it as the new standard (Fig. 3).

![Adoption rate of HTTP/2 for websites as of 06-Feb-2017 according to W3Techs.com](image3)

**Figure 3.** Adoption rate of HTTP/2 for websites as of 06-Feb-2017 according to W3Techs.com [14]
Ergo, web developers today still must find ways to improve their website performance while remaining in the confines of the HTTP/1.1 protocol. Most of these solutions are considered "hacky" as these techniques work around the protocol’s limitations rather than overcoming them. It should be noted that all of them are aimed at circumventing head-of-line blocking and the Slow Start initial congestion window.

A. Domain Sharding

Instead of hosting all of a site’s content on one domain, domain sharding is a method of hosting content on multiple domains in order to allow the end user’s client to open more connections and download content in parallel [15]. With this method, should one domain slow down due to head-of-line blocking, the other domains will still transmit their data to the client. For example, a site may have an additional domain that starts with "img" to host its image files and yet another domain that starts with "vid" to host its video files.

B. CSS/JavaScript Concatenation and Asset Inlining

CSS/JavaScript concatenation involves merging all of a site’s CSS files into one, singular file and doing the same for all of a site’s JavaScript files. By reducing the number of files served to the client, this method alleviates some of the problems of the HTTP/1.1 Slow Start feature.

In a similar vein, asset inlining calls for all CSS and JavaScript to be embedded directly into the web page’s HTML code. This can be automated by tools such as packify [16] or asset-inliner [17]. Much like file concatenation, this method helps alleviate Slow Start issues. A more extreme version of this is image embedding, where a desired image is embedded into HTML encoded in Base64. Combining image and CSS/JavaScript inlining could potentially greatly reduce the number of HTTP requests a client needs to send; however, it is not always possible to inline CSS styles and JavaScript code. Additionally, embedding images causes both latency and caching issues on the client side as the client browser must decode every embedded image and it is not possible to cache such images as they become part of the HTML file, itself.

C. Image Spriting

Image spriting involves making a single image mosaic of many, smaller images [15]. For example, on a music streaming site, instead of downloading four separate image files for "previous," "stop," "start," and "next," a single image containing all of these sprites would be downloaded. Using JavaScript, the client then processes the image and displays them where necessary. As with image embedding, this method puts more computational load on the client side and must be repeated every time an image mosaic is loaded.

IV. NEW FEATURES IN HTTP/2

A. Binary Protocol

HTTP/1.1 and its predecessors are based on plaintext communication. However, HTTP/2 has made a shift towards using binary, which is more condensed when compared to plaintext, and is easier to parse. It should be noted that, due to this change, HTTP/2 is not usable through Telnet.

B. HPACK Header Compression

As discussed previously in this paper, HTTP/1.1 has the problem of sending redundant data contained in its headers over the course of a connection. HTTP/2 mitigates this problem through the use of its HPACK mechanism [18] which utilizes Huffman encoding to compress the binary header values. In addition, the HPACK mechanism uses two tables to further reduce bandwidth usage: a static table which contains a cache of commonly-used headers, and a dynamic table which references other headers used in the current session. This dynamic table reduces header size by sending pointers to pre-existing values instead of the values themselves.

C. Multiplexing

HTTP/2 introduces streams [5]: independent, bidirectional sequences of frames between the client and server within an HTTP/2 connection. This technique both reduces the number of connections a server needs to handle and solves the issue of head-of-line blocking.

D. Flow Control

Streams can be further prioritized using HTTP/2’s flow control algorithms [5]. Flow control enables the receiver to impose flow control limits that the sender must respect. In practice, flow control is designed to protect endpoints under resource constraints: such as when a server is under heavy load, which causes it to have a slow upstream connection while maintaining a fast downstream connection. In this scenario, flow control can allow the server to process data on the less-burdened stream while the other stream is busy.

E. Server Push

Typically, upon receiving a request for a web page, a server can predict that the client will make further requests for all the page’s external resources including style sheets, scripts, and images. In HTTP/1.1, the server cannot send these dependencies without the client explicitly requesting each resource. HTTP/2 enables the server to bundle page dependencies it knows the client will need into a "push", which it can proactively send to the client [5]. Afterwards, the client has the ability to refuse or accept the data.

V. JAVA AND HTTP/2

The maintainers behind the community-based open source version of Java Development Kit (JDK) aka OpenJDK [19] have specifically targeted HTTP/2 support for JDK 9 as one of their stated goals in JEP 110 [20]. This is not only due to the desire to support the new protocol, but also to improve the existing application programming interface (API) which currently implements HTTP/1.1. These classes currently suffer from multiple problems such as: undocumented behavior, difficult maintainability, and a base connection API that was
designed with multiple, now defunct, protocols in mind during its creation.

Although the Apache Software Foundation and Eclipse Foundation provide HTTP/2 implementations in the form of the Apache HttpClient and the Web server and Servlet container Jetty, respectively [21] [22], the native HTTP/2 implementation within the JDK 9 is designed with a smaller footprint in mind [20]. Furthermore, Java maintainers have expressly stated that the internal implementation of their HTTP/2 client API must be "friendly" towards newer language features, such as lambda expressions.

VI. TEST ENVIRONMENT

Out test environment consist of two different Jetty servers version 9.4.0.v20161208: one configured for the HTTP/1.1 protocol, and the other configured for the HTTP/2 protocol. Source code for the Jetty server was developed using the IntelliJ Idea integrated development environment (IDE) early access version 2017.1. The operating system used for hosting the servers was Windows 10 x64 Anniversary Update. Chrome version 57.0.2987 run on Ubuntu Linux version 16.04 was used as the browser of choice for the following benchmarks. As of writing, no major web browser supports HTTP/2 without encryption. As such, in the interest of fairness, the HTTP/1.1 server was also configured with TLS encryption in order to more accurately portray the latencies between protocols.

To obtain page and resource load times, Chrome’s built-in network logger was used. In order to more accurately simulate a real-world scenario, Chrome was configured to simulate a typical 4G mobile connection. This added a 20ms delay to requests and limited downloads and uploads to 4 Mb/s and 3 Mb/s, respectively. Page load benchmarks were conducted in three different setups:

- Over the localhost interface
- Over a Local Area Network (LAN) between a Windows host machine and Ubuntu virtual machine guest

In the first setup, both Jetty servers were hosted on the same machine as the Chrome browser. Web pages were loaded 10 times each using both the HTTP/1.1 and HTTP/2 protocol and the resulting load times were then averaged.

The second setup kept the Jetty server on the same windows machine, but moved the client onto a local virtual machine created by VMWare Workstation Pro 12 running Ubuntu Linux. This test is conducted in order to quantify the performance loss when transmitting packets over a virtual Ethernet interface in addition to a real interface. As with the first setup, each web site was loaded 10 times using each protocol and the results were averaged.

A previous study conducted in 2015 [23] cloned 15 websites in order to provide a more accurate depiction of the performance differences between the protocols in real world scenarios. Using this method as a framework, this study also cloned 15 different websites, 5 of which were benchmarked previously in the aforementioned study.

Table II lists every site included in benchmarking. Websites were obtained by saving them directly within the Google Chrome web browser. This method of locally saving the websites comes with the drawback of not fully downloading dynamic content and content located on external content distribution networks (CDNs); however, the purpose of this study is to showcase the differences between HTTP/1.1 and HTTP/2, not to accurately clone commercial web pages.

A. Notable Issues

At the time of writing this paper, the JDK 9 was in early access Build 153 [24] with a slated release date estimated at July 2017. As it is still in active development, certain features don’t yet function as expected. One such feature is built-in Application Layer Protocol Negotiation (ALPN) support [25]. The build of the JDK used in this paper does not have an automatically loaded ALPN library, which is used for establishing connections in HTTP/2. In order to circumvent this, a Java Virtual Machine (JVM) argument must be passed with the path to a suitable ALPN JAR file, as shown in Fig. 4:

```
-Xbootclasspath/p:/path/to/alpn/jar
```

Figure 4. The template for the JVM argument required to load the Jetty ALPN jar file before JDK 9.

This argument instructs the JVM to prepend the supplied JAR file before the standard library classes. It is important to note that the /p: section of the command is the section that specifies to prepend the JAR file. Omitting this section will cause the JVM to overwrite all standard library files with the provided JAR. As no standard library classes will have been loaded in this case, the JVM will forcibly close.

With JDK 9 and the modularity provided by the project Jigsaw, the above argument is deprecated. Attempting to start the JVM with said flag will result in the JVM refusing to start, with an explicit error stating the deprecation of the Xbootclasspath flag. In the final
With remote content disabled, the load times for HTTP/2 were able to improve by a small margin. On average, websites loaded 1.4% faster when transmitted through the HTTP/2 protocol. Most notably, Yahoo.com gained a 20% performance improvement in this test, reducing its load time from 9.187 to 7.638 seconds. YouTube.com also gained a significant performance boost and lowered its load times by 8.2%: from 4.716 to 4.356 seconds.

Unfortunately, the host machine’s Ethernet adapter could not be disabled for tests involving a guest OS: disabling the adapter also prevented the operating systems from being able to communicate with each other. Results were less favorable than the first set of tests when the client browser was moved to a locally-run Ubuntu Linux virtual machine, as shown on Fig. 6:

![Figure 5. Load times for locally hosted websites](image)

The above results were run while the host computer was still connected to the internet, meaning that each website’s script files could still perform remote content requests, which may not necessarily be transmitted with the HTTP/2 protocol.

In Fig. 6, the host’s Ethernet adapter was disabled within the Windows operating system in order to prevent the mentioned scripts from requesting additional data.

![Figure 6. Load times with the host machine’s ethernet adapter disabled](image)

Sites with the worst load times were those that created many asynchronous requests through JavaScript during the page loads. In the case of The Economist, there was one specific script file that was dedicated to loading advertisements which slowed load times by up 5 seconds, regardless of whether the host was disconnected from the Internet or not. Given the delay introduced by this file, it is obvious that HTTP/2 is not a replacement for optimized web page design.

**IX. Future Work**

The current research was of limited scope and leaves much room for future study. Namely, while Chrome’s simulation of slower connections is useful, it is still not as useful as a truly slow connection on a slow device: such as
an older smart phone. Additionally, as only a server was created, extra data could be collected through the use of a Java HTTP client instead of using the Chrome browser. This would have the benefit of allowing more granular benchmarks through the use of low-level HTTP programming APIs.

Moving the Jetty web server along the test web sites onto an externally hosted virtual private server would also be a desirable change for future work as it would root results more in real-world situations. If a service such as Amazon Web Services is used, then there is the possibility to hosting the website in multiple different locations around the world and benchmarking performance differences.

X. CONCLUSION

HTTP/2, at this current point in time, is not enough on its own to improve web site load times. Web sites must be designed from the beginning with HTTP/2 features in mind, such as server push, in order to fully take advantage of the benefits that the newer protocol can provide.

As shown in the results, switching to the newer protocol without any other changes may actually prove detrimental to performance, particularly when accessing web sites through a virtual Ethernet interface. Given that most of the technologies shown in this paper were in early access or beta at the time of benchmarking, it is possible that, given a few years’ time or less, default HTTP/2 server configurations will be enough to provide noticeable performance gains with little work on the part of developers. Frameworks or analysis tools could particularly be of use should they be able to intelligently and automatically determine which files should be pushed together.

Software Supporting International Student Exchange Program in Higher Education

Zvonimir Gračak*, Ljiljana Brkić*
*University of Zagreb, Faculty of Electrical Engineering and Computing, Zagreb, Croatia
zvonimir.gracak@fer.hr
ljiljana.brkic@fer.hr

Abstract - International student exchange programs allow students to study in various countries and experience challenges in new academic environment. International student exchange processes are complex and accompanied with extensive administrative tasks involving many higher education institutions (HEI). These administrative processes can be facilitated with the help of an appropriate software. This paper presents a software designed for managing data required for various processes in student exchange programme. The software, allows the user to manage data about HEI, bilateral agreements signed between institutions in European Higher Education Area (EHEA), applications of the outgoing students for an annual tender and the outcome of the competition. It supports automatic procedures for student ranking considering their choices, achievements and propositions of the tender. The main outcome of the software is the ranking list of the students with associated outgoing HEI complied with the quotas agreed in bilateral agreements and student’s preferences.

I. INTRODUCTION

International exchange of students allows students from all levels and all subject areas to study abroad for a semester or an academic year and gain credits that will subsequently be recognized at their home institution. Students can participate in mobility at any time during their degree. In 1987 the European Commission established a programme for student mobility in Europe called Erasmus. This programme is constantly being improved and enhanced especially with the advent of the Bologna process which brings the advantage of the use of the ECTS credit transfer system. The most prominent student mobility program, active since January 2014, at EU level is the Erasmus+ Programme designed to, among other, support higher education and targeting EU Member State countries (Programme Countries). Programme Countries are those countries participating fully in the Erasmus+ Programme [1]. Each country participating in Erasmus+ set up a National Agency and contribute financially to the programme.

Erasmus+ Programme functions under a number of inter-institutional agreements signed between higher education institutions, through which the partners agree upon exchange quotas and the duration of mobility for students and staff. Quotas are set up on the basis of a specific number of students (and staff) to be exchanged each academic year within a specific subject area. By signing the agreement, the partner institutions commit themselves to respect the principles of the Erasmus Charter for Higher Education (ECHE) [2] in terms of the organisation and management of mobility.

The European Commission, through the Croatian National Agency for Erasmus+ (Agency for Mobility and EU Programmes), provides Erasmus+ students with grants to help them financially while studying abroad. The University (e.g. University of Zagreb - UNIZG) receives the Erasmus+ funding from the Agency for Mobility and EU Programmes, based on the number of Erasmus students sent out in the previous academic year. The University further allocates funding to its constituents. The actual grant amount each student will receive (in case he/she receives it) is dependent on where they are going and how long they will stay.

Since the early beginnings of the institutional exchange of students in the year 2006, when a total of 5 students went on exchange, the number of exchange students is constantly growing. The number of bilateral agreements between FER and prestigious higher education institutions (HEI) in European Higher Education Area is constantly growing too. Currently, the number of agreed places for exchange students at all levels of study (244 available places) in a total duration of 1545 months surpasses the needs.

II. OUTGOING MOBILITY IN ERASMUS+ FOR PROGRAMME COUNTRIES - THE PROCESS FLOW

The most massive student exchange, incoming and outgoing, takes place through the Erasmus+ Programme for Programme Countries. In this paper we set focus on outgoing mobility process since it currently involves more students than the incoming mobility and requires much more administrative and organizational engagement.

The tender for the selection of students intending to participate in the exchange as outgoing takes place annually, usually at the beginning of a calendar year for the next academic year. An important part of processing the tender is awarding Erasmus student mobility grants to financially facilitate students studying abroad. These grants are given to Universities by the National Agency also on an annual basis. The tender processing is coordinated work of International Relations Office (IRO) of the University and corresponding offices of its constituents. The tender sets common framework applying to all university students who will submit an application and is announced by the UNIZG
IRO. Some segments of the tender processing are the responsibility of constituents and university leaves them to prescribe rules and implement those parts of the process. Students submit applications online, using web application of the UNIZG. They apply for certain institution, study level, subject area, beginning and duration of stay. Since quotas at institutions in certain degree level and subject areas are limited, sometimes it is not possible to send all students to their first choice of institution. For that reason students are allowed to submit application for up to three HEI. After the application deadline, HEI obtain data on student’s applications from IRO and carries out the ranking of applicants. The ranking of students - as well as the procedure for awarding them a grant - must be transparent and documented, and also available to all parties involved in the selection process.

Each HEI determines the ranking criteria for its students. The ranking criteria are set out in a fair and transparent way before participants submit their applications. HEI usually ranks students considering the academic performance of the candidate (cumulative GPA), English skills, previous mobility experience, motivation, experience in the receiving country, etc. Once ranking procedure is completed, the list of selected students will be sent to the IRO to consolidate partial lists of individual constituents and assign funds to students. Due to the finite funding only limited number of students can receive Erasmus scholarship. Students who will not be awarded Erasmus scholarship will be offered zero-grant placements. Zero-grant is a possibility for students to participate in Erasmus exchange program on the same terms (pay no tuition fee, benefit from mentorship program, receive academic recognition) but without Erasmus scholarship.

Many parts of the described processes are performed manually or semi-automatically. There is no unique criteria for ranking students at the institutions and majority of constituents assess applications manually. Also, the data exchange between the IRO and the mobility offices at the constituents is carried out via an email. Given the increasing number of applications, there is the need for process automation in order to accelerate and facilitate the entire process of application processing. In the rest of the paper the architecture and implementation of system supporting the application ranking is described.

III. SYSTEM ARCHITECTURE AND DATA MODEL

A. System architecture

In the architecture of the system three main components stand out: client application, web server and a Database Management System (DBMS) as a repository for a database (Figure 1).

![Figure 1 System architecture](image)

End users access and manipulate data via a web browser using web application developed following the MVC architecture [3]. A web server via a HTTP protocol responds to users’ requests, which are forwarded by their computers’ HTTP clients. To be able to answer the clients’ requests, web server, when needed, communicates with DBMS to gather and change data stored in the database. As a web server Microsoft’s Internet Information Server (IIS) [4] is used, while Microsoft SQL Server [5] serves as a relational DBMS.

The client application is developed using ASP.NET programming framework, and programming languages C#, JavaScript, HTML and css. Entity Framework [6] is used as an object-relational mapping framework.

B. Data model

The database has been designed following the principles of the relational data model. We believe that the relational data model is the most suitable for this business process because the data is structured and the amount of data is small. Figure 2 shows tables used to store data occurring in the process of the Erasmus+ outgoing mobility.

![Figure 2. Relational data model](image)
Data about HE institutions and the details of bilateral agreements signed between them are kept in tables *HEI, studyLevel, studyField, bilateralAgreement* and *agreementQuotas*. Data on students, their applications as well as the results of the ranking process are stored in tables *student, studentTender, studentTenderChoice* and *studentCategoryPt*.

The database design allows to store data from different HEIs in one database. A centralized database containing data from all members of the university allows the uniform processing of data and easy distribution of results. With proper software, besides members of UNIZG, database can be used by the University and thus the exchange of data via e-mail can be avoided. Of course, in simpler variant data of only one HEI will be stored in the database, and that is currently the case.

IV. BASIC TYPES OF SCREENS IN THE WEB-APPLICATION

Ensuring the ergonomic quality of user interface (UI) is one of the major concerns in developing interactive application. While developing web application we followed guidelines for good and ergonomic software interface design [7] with an emphasis on the content of screens and the way in which typical data operations take place. Special attention was paid to ensure that the flow of data from screen to screen is consistent and corresponds to user expectations. By keeping the application consistent, users learn more quickly since they recognize and re-apply the usage patterns. For the sake of consistency and simplicity, all screens designed to enable same operations on different data (rows from different tables) look exactly the same and support the same set of functionalities. In the application it is possible to see two types of screens: a) screens designed for performing CRUD operations on data stored in a single table and b) master-detail screens. Master-detail screens allow performing CRUD operations on master row and also on detail (slave) rows related to master row in a one-to-many type relationship.

The acronym CRUD refers to create, read, update, and delete operations - the major operations that should be implemented over data stored in data repository. In our case data is stored in relational DBMS but that need not be the case. Each, of the above mentioned, operation can be mapped to a standard SQL statement or HTTP method.

A. Typical screen layout for performing CRUD operations in a single database table

Typical screen layout that serves for browsing and updating data stored in a single database table can be seen on Figure 3. In application described in this paper such screens exist for tables usually called catalogs such as: *state, city, academicYear, studyLevel, studyField* etc. Data is displayed in a form of a list and initially only a certain number of rows is visible.

Besides the possibility of viewing data, each page contains additional functionality, such as adding new or editing and deleting the existing rows, sorting rows, filtering rows and viewing a certain number of items per page (paging).

On all screens, equivalent operations are activated in the same way - either by clicking on the option (eg. Add) or by clicking on the appropriate icon. The Table 1 shows the icons that appear on each screen.

<table>
<thead>
<tr>
<th>Icon</th>
<th>Operation</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image" alt="read" /></td>
<td>Read - see details</td>
</tr>
<tr>
<td><img src="image" alt="update" /></td>
<td>Update row</td>
</tr>
<tr>
<td><img src="image" alt="delete" /></td>
<td>Delete row</td>
</tr>
<tr>
<td><img src="image" alt="filter" /></td>
<td>Filter rows</td>
</tr>
</tbody>
</table>

Number of rows displayed on each page is a parameter and can be easily changed by selecting value from drop-down list. If there are more rows than the selected parameter (for display per single page), the rest is displayed on other pages that can be accessed by clicking on the page number or on the icon for the next page (>>).

Data filtering is enabled by clicking the funnel icon, after which the editable textboxes below the columns appear (Figure 4).

![Bilateral agreements](image)

Figure 3. Typical screen layout for a single table
Textboxes serve for entering the selection criteria. After applying the selection conditions by pressing the button Filter, only the records that meet the given criteria will be displayed.

B. Master-detail screen layout and functionality

In master-detail relationship, for one master tuple always exist N detail tuples. On the master-detail screens, in the simplest case, two logical parts can be noticed: 1) master data in the upper part of the screen and 2) detail data on the lower part. This type of screen is more complex than previously described screens as it has to allow the CRUD operations on both - master and detail data. Typical master-detail screen can be seen on Figure 5.

![Figure 5. Example of master-detail screen](image)

This screen enables manipulation on data regarding bilateral agreements (contracts) and the agreed quotas for student exchange. In this case, the master data are general data on the contract (partners in the contract - HEIs, the date of signing the agreement, the valid period – in dates and academic years, etc.). The detail data (tuples) presents quotas agreed with the contract for the study levels and subject area. Specific for master-detail screens is that master data can’t be deleted while there are detailed data referencing master data. Besides in application, this rule, is also implemented at the database level by defining integrity constraint - foreign key.

V. WEB-APPLICATION FUNCTIONALITY

Web application is, currently, designed solely for HEI’s employees participating in the process of receiving and ranking students' applications for mobility at a foreign institution. For keeping data private and preventing non-authorized access, a login system via account name and password for each user, given by the application administrator, has been implemented. User has the possibility of viewing data about HEI and students, bilateral agreements signed between sending and receiving institutions, exchange quotas per study level and subject area, student applications and the outcome of the tender. Besides viewing, users have the possibility of inserting and editing data.

Application menu allowing access to the listed data can be seen on Figure 6.

![Figure 6. Application header and footer](image)

Unlike foreign higher education institutions, majority of the members at UNIZG don’t have mobility offices and this process is supported by one or more ECTS coordinators who are the targeted users of this software. They commonly have no data about the student's achievements, which are necessary for the applications ranking. These data must be delivered from other HEI’s department and thereafter be imported into database via software. Besides department in charge for students’ grades, process supported with this software involves UNIZG IRO so the exchange of information between all parties involved must be easy. For easier data manipulation, user has the possibility of importing student applications and their scoring via an Excel file.

Figure 7 shows the screen for importing students’ applications from excel file that faculty gets from UNIZG IRO. All persons' names on Figure 7.

Figure 8, Figure 9 and Figure 10 are fictitious due to protection of data privacy.
Figure 8 shows the screen for importing different categories of points students gained. The screen shows importing points won on the basis of motivational letters that are read and evaluated by ECTS coordinators.

![Application scoring](image)

**Figure 8 Importing application scoring via an Excel file**

We are aware that there exists a much better solution for data exchange than importing from Excel files, e.g. the use of web services. We haven’t used advanced technologies for data exchange because we could not reach an agreement with our partners in the process to develop the necessary software on their side. In our case, it would be a complete failure to develop a web service because there would be no compatible software with which they can communicate.

Main part of the application refers to processing all student applications, in terms of ranking applications considering students’ scoring and assigning corresponding selections to students. After all students’ applications and their scoring are imported into the system, the user has the ability to run a procedure to process all applications for a specific academic year. The applications are ranked based on the achieved scores and in accordance with calculated rank, applications are assigned their achieved selection (foreign HEI according to student’s choice). The process starts with sorting all applications by their scoring and then by their priorities. After that, the system selects applications in descending order. Each application has one or more desired foreign HEI ordered by priorities. For each desired institution on the application, system is checking if there is any space left to fulfill on the selected institution. The first institution on the application that has available space will be automatically selected and application’s status for that institution will change to **Selected**. If there isn’t any space available on any of the institutions in the application, application’s status will change to **Reserved**. After all the applications have been processed, user is presented with the results (Figure 9).

![Competition results](image)

**Figure 9 Competition results after processing applications**
Besides Selected and Reserved, student’s application’s status can also be Declined for some specific reasons (e.g., due to lack of needed documentation). Also, there’s always a possibility that someone whose application was selected for a specific institution will pass the selection, which means that the best scored Reserved application will automatically be Selected. That part has to be manually operated by user, so besides processing the applications, user has the possibility to modify the final results by changing applications’ status to either Selected, Reserved or Declined.

After processing the applications and generating the final results, user can export results to an Excel file to enable easier data manipulation and exchange with the UNIZG IRO (Figure 10).

VI. CONCLUSION

In this paper we have presented the software developed to support processing students’ applications in the outgoing student mobility in Erasmus+ Programme for Program Countries. This software facilitates the work of HEI’s staff responsible for the ranking of students’ applications and assignment of foreign HEI chosen by the student intending to study abroad.

Relational data model proved to be a good choice for this type of process because the data occurring in the process is structured, of simple type and the amount of data is not overwhelming. Also, consistency and durability of data is a necessary requirement and RDBMS is the best database system for ensuring the ACID properties of transactions. A web application, compared to a desktop application, is a better choice because of the easier installation, deployment and maintenance.

The process involves participants from different institutions that have to exchange data at different stages of the process. The data is currently exchanged semi-automatically via excel files. The plan is to change this part in the future, but to succeed we must reach an agreement with the other participants who will have to adapt their software.

Abstract—We present a new method for segmentation of retinal blood vessels in color fundus images. The method utilizes Hessian eigenvalues and eigenvectors calculated for each pixel to obtain a measure of vesselness. The measure is similar to the Frangi vesselness but we use a different combination of eigenvalues, while keeping entire Hessians for further processing. Hessians are calculated at different scales, where each scale targets a certain width range of blood vessels. We perform a scale selection procedure to pick the most appropriate scale for each pixel. Hessians from the selected scales are treated as tensors and used as input for tensor voting procedure to further reduce the influence of noise and highlight the blood vessels. Green channel of color retinal photographs is used as input to the method due to better blood vessel contrast. We also present promising experimental results obtained on a test database with manually segmented retinal blood vessels of healthy patients only.

I. INTRODUCTION

Retinal image analysis provides important information for detection of several diseases with most common being Diabetic Retinopathy (DR). In order to detect the disease symptoms successfully, they must not be confused with normal retinal structures. Hence it is helpful to obtain segmentation results of all normal retinal structures prior to symptom detection. This paper presents a segmentation method for one such normal retinal structure, the blood vessel tree. Figure 1 shows an example of retinal image in which the blood vessel tree can be seen.

Analysis of a retinal image can be performed by an experienced ophthalmologist, but the process is time consuming. On the other hand, diabetic patients, which are at risk of DR, need to perform regular retinal checkups, and their number is constantly increasing. This indicates a clear need for computer vision-based retinal image analysis and a lot of algorithms have been and still are being developed. Besides providing full diagnosis, computer vision-based analysis could serve as an aid to ophthalmologists and optometrists and reduce the time required to interpret retinal images and overcome possible biases that may skew the clinical assessments [1]. Automated algorithms for retinal blood vessel segmentation have specific issues due to blood vessel tree structure with a lot of branches and some very thin vessels. Also, images can have low resolution, poor contrast and significant amount of noise.

One other issue is that other structures can be misinterpreted as vessels because of similar characteristics. Those structures can be other parts of retina, fovea and optical disc, but also disease side effects, like hemorrhages, lesions or exudates. In this paper, we segment blood vessels in retinal images of healthy patients with no central light reflex within vessels. We use a procedure inspired by Frangi vesselness [2]. We are using a stickness feature from tensor voting framework [3] as a measure of vesselness. The obtained measure resembles Frangi vesselness but is not limited to [0,1] interval. Hessian matrices are calculated at different scales and we use this data to perform tensor voting [3]. Two different steps of tensor voting are applied to suppress the influence of noise and other retinal structures, and to highlight retinal blood vessels.

II. RELATED WORK

There are a lot of different methods that have been developed for segmentation of blood vessels in fundus images [4], [5], [6]. They mostly use DRIVE and STARE databases, which are both publicly available [5]. Vessel segmentation techniques can be supervised or unsupervised. Supervised methods exploit some prior labeling information to decide whether a pixel belongs to a vessel or not, while unsupervised methods perform the vessel segmentation without any prior labeling knowledge [5]. In this section we give a short overview of such techniques. In [7] an unsupervised approach has been...
used for vessel segmentation. Authors use 2-D Gabor wavelet transform for image enhancement followed by sharpening filter to reduce the blurring side effect. Vessels are segmented using Canny Edge Detector with pixel dilation to fill the gaps. Accuracy of 0.9439 ± 0.0253 was recorded when tested on STARE database. Unsupervised method that uses gradient orientation was exploited in [8]. They use Sobel operator at three different scales and the results are integrated into final image. Morphological operations and thresholding are used to segment blood vessels. This method is not affected by low contrast or poor illumination and it performs with accuracy of 0.9358 on DRIVE database and 0.9423 on STARE database. A supervised approach based on a multilayered feed forward neural network has been proposed in [9]. Tested on DRIVE database it has scored average accuracy of 0.9452, while tested on STARE it has achieved accuracy of 0.9526.

Linear combination of line detectors at various scales are used to segment retinal blood vessels and to reduce noise in [10]. Our method uses linear combination of Hessians at various scales. In [11] authors also use tensor voting procedure along with other techniques to reconstruct only small blood vessels in high resolution images. Both tensor voting stages are used while we use only the second stage. Larger blood vessels are tracked using a multi-scale line detection from [10]. In [12] authors calculate their vesselness measure based on standard deviation of Hessian eigenvalue’s orientations across several scales. Then they apply clustering procedure to obtain vessel segmentation. Our approach also uses multi-scale Hessians, but we combine scales in a different way.

III. METHODS

Figure 2 shows the procedure we use for blood vessel segmentation. We use green channel from input RGB images, as it provides the best contrast between vessels and background [9]. We use multi-scale Hessians to estimate a measure of vesselness at each pixel and thus detect blood vessels. We perform a simple form of tensor voting to reduce the influence of the noise, followed by a scale selection. Hessians of the appropriate scale, and the scale are used to perform a full stick tensor voting to further reduce the noise, fill the gaps and increase our vesselness measure for pixels belonging to blood vessels. The measure is thresholded, and simple morphological opening is used to further enhance the results. We continue with descriptions of specific steps.

A. Vessel Detection

Vessels, and other tubular structures can be detected using gradients of the image, which can be estimated by convolving an image with partial derivatives of Gaussian. The second order partial derivative of a Gaussian kernel at scale \( \sigma_g \) generates a probe kernel that measures the contrast between the regions inside and outside the range \((-\sigma_g, \sigma_g)\) in the direction of the derivative [2]. Gaussian kernel is defined by

\[
G(x, y, \sigma_g) = \frac{1}{2\pi\sigma_g^2} e^{-\frac{(x^2+y^2)}{2\sigma_g^2}},
\]

(1)

where \( x \) and \( y \) represent pixel coordinates. It’s second order partial derivative by \( x \) variable is described by the equation

\[
G_{xx}(x, y, \sigma_g) = \frac{1}{2\pi\sigma_g^4} \left( -1 + \frac{x^2}{\sigma_g^2} \right) e^{-\frac{(x^2+y^2)}{2\sigma_g^2}}. \tag{2}
\]

The shape of Gaussian and its second order partial derivative are shown in Figure 3. In our approach, we apply a range of scales at every pixel, as different scales are better suited for different vessel widths. For each pixels and for each scale, a 2x2 Hessian matrix \( H \) is calculated:

\[
H(x, y, \sigma_g) = \begin{pmatrix}
  r_{xx} & r_{xy} \\
  r_{xy} & r_{yy}
\end{pmatrix}.
\tag{3}
\]

Each element of the Hessian matrix is an estimate of the second order partial derivative of image \( I \) at specific scale, according to the following equations:

\[
r_{xx} = G_{xx}(x, y, \sigma_g) * I(x, y) \tag{4}
\]

\[
r_{xy} = G_{xy}(x, y, \sigma_g) * I(x, y) \tag{5}
\]

\[
r_{yy} = G_{yy}(x, y, \sigma_g) * I(x, y). \tag{6}
\]

For each Hessian matrix, eigen decomposition is performed to obtain two eigenvalues \( \lambda_+ \) and \( \lambda_- \), and two eigenvectors \( \vec{e}_+ \) and \( \vec{e}_- \). As Hessian matrix is symmetric, two eigenvectors will always be perpendicular. The eigenvalue with the largest absolute value is denoted \( \lambda_+ \), and the most significant eigenvector as \( \vec{e}_+ \). According to the geometric interpretation of the Hessian matrix, \( \vec{e}_+ \) will point in the direction where intensity changes the most. Hence, \( \vec{e}_+ \) will be oriented perpendicular...
to the vessel direction. Using eigenvalues and eigenvectors we calculate a measure of vesselness and an estimated orientation of the vessel normal. As our measure of vesselness, we use stickness from the tensor voting framework [3], which is defined by following equation:

$$ s = \lambda_+ - \lambda_- . $$

The orientation $$ \beta $$ that we use is the orientation of $$ \vec{e}_+ $$.

$$ \beta = \text{angle}(\vec{e}_+). $$

Pixels belonging to linear structures will have large absolute values of $$ \lambda_+ $$ and lower absolute values of $$ \lambda_- $$. Blob-like structures will produce similar absolute values for $$ \lambda_+ $$ and $$ \lambda_- $$. Frangi vesselness uses eigenvalues of the Hessian in a slightly different way than the stickness does, but both of them will exhibit higher absolute values for linear structures, and lower absolute values for blob-like structures. If the image compositing is such that vessels are dark on brighter background, the larger eigenvalue $$ \lambda_+ $$ will be positive.

Stickness orientation $$ \beta $$ of pixels inside blood vessels tend to change only slightly in between scales, while noise generated stickness of the background pixels tend to change significantly in between scales. We perform an addition of collocated Hessian matrices (a simple form of tensor voting) from three consecutive neighboring scales. Stickness of resulting Hessians in blood vessel pixels will be amplified by this procedure, while noise induced stickness will not get amplified as much. This results in better highlighted blood vessels.

Then, for every pixel we find the scale $$ \sigma_G $$ with the highest stickness value. In [13] authors have demonstrated that such maximum along the scale axis can be expected, and corresponding scale can be linked to the width of the linear structure (blood vessel), at least for simple profiles of linear structures.

We use these maximum sticknesses and corresponding orientations as input for final tensor voting procedure.

### B. Tensor Voting

Tensor voting is a method of information propagation where tokens convey their orientation preferences to their neighbors in the form of votes. Each vote is an estimate of orientation of a perceptual structure consisting of just two tokens: the voter and the receiver [3]. We can describe a tensor with a symmetric 2x2 matrix (rank 2 tensor) which can be decomposed into its eigenvectors and eigenvalues as shown in:

$$ T = \lambda_+ \vec{e}_+ \vec{e}_+^T + \lambda_- \vec{e}_- \vec{e}_-^T. $$

Every tensor has three properties: orientation ($$ \beta $$), stickness ($$ s $$) and ballness ($$ b $$). Stickness and orientation are defined by equations (4) and (5). Ballness is defined with:

$$ b = \lambda_- . $$

The stickness $$ s $$ is interpreted as a measure for the orientation certainty or a measure of anisotropy of the ellipse in orientation $$ \beta $$. The ballness $$ b $$ is interpreted as a measure for the orientation uncertainty or isotropy [3]. Since we are considering tubular structures, we are mostly interested in stickness property. In Figure 4, a rank 2 tensor is illustrated with its eigenvalues, stickness, ballness and orientation. A tensor with ballness value of zero is called a stick tensor, and a tensor with zero stickness is called a ball tensor. For vessel segmentation purposes, we use voting fields that consist only of stick tensors. Figure 5 shows an example of a stick voting field amplitude. Here, pixel intensities are interpreted as a measure of likelihood that a feature at some position $$ x $$ belongs to the same curvilinear structure as the feature positioned in the center of the voting field, i.e. the voting tensor. The orientation of tensor vote at position $$ x $$ is the presumed orientation of the curvilinear structure at that position. In [14] authors assume that the curvilinear structure should be a circular arc. The size of a voting field is determined by a scale parameter $$ \sigma_{ctx} $$, which controls the amount of affected neighboring pixels. Resulting stickness will be calculated considering all of the received votes.

For each voting pixel, it’s orientation $$ \beta $$ has to be determined prior to vote casting, to orient the voting field properly. This can be computationally expensive, so we use steerable filters combined with bandlimited voting field, as proposed in [15].

The voting field is defined by:

$$ \tilde{V}(r, \phi) = \frac{1}{G} e^{2\sigma_{ctx}^2} \cos^2(\phi) \begin{pmatrix} 1 + \cos(4\phi) & \sin(4\phi) \\ \sin(4\phi) & 1 - \cos(4\phi) \end{pmatrix}. $$

Gaussian decay function is used to penalize distance, and $$ \cos^2(\phi) $$ to penalize high-curvature arcs. Parameters $$ r $$ and $$ \phi $$ represent relative euclidean distance and angle of corresponding neighboring pixel. Speed of decay as a function of $$ \phi $$ is controlled by parameter $$ n $$, and $$ G $$ is a normalization constant. Appropriate scale $$ \sigma_{ctx} $$ of the voting field can be selected in many ways. In the most simple case, a fixed value can be chosen, but it is reasonable to presume that dynamically adaptable scale should provide better voting results. It is also reasonable to presume that voting scale should change with blood vessel width, i.e. scale of the largest stickness. Wider blood vessels are expected to be less curved as opposed to thinner blood vessels so we want wider vessels to have larger voting field that will favor longer, less curved structures. This relation can be described in different ways, including linear relation, but based on our experiments the following relation provides best results:

$$ \sigma_{ctx} = \sigma_G^2. $$

For speed of decay, we used fixed value.

### IV. RESULTS

In order to test the given algorithm, we have used a small subset of DRiDB [16] database containing only 13 images of healthy patients. Currently we use only images of healthy patients to demonstrate effectiveness of our blood vessel segmentation method. An example of such image is shown in Figure 6a with corresponding manually segmented image.
shown in Figure 6b. Resolution of images is $576 \times 720$. For Gaussian kernel, we have used $\sigma_g$ in the range $[1, 3]$ with step 0.1 and for speed of decay $n = 2$. For the thresholding step we are using threshold intensity value of 3. In post-processing step, we first erode the image with a disk structuring element with radius of 1 pixel, after which a dilation is performed with the same structuring element.

In evaluation of our algorithm, we used accuracy and $f$-measure as effectiveness indicators. They are defined with equations:

$$F = 2 \cdot \frac{\text{precision} \cdot \text{recall}}{\text{precision} + \text{recall}} = 2 \cdot \frac{TP}{2TP + FN + FP}$$  \hspace{1cm} (13)

and

$$\text{accuracy} = \frac{TP + TN}{TP + FP + TN + FN}.$$ \hspace{1cm} (14)

Where precision and recall are defined with:

$$\text{precision} = \frac{TP}{TP + FP}$$ \hspace{1cm} (15)

and

$$\text{recall} = \frac{TP}{TP + FN}.$$ \hspace{1cm} (16)

When tested on all healthy images, our algorithm performed with accuracy of 0.9400 and $f$-measure of 0.6319. Table I shows accuracy and $f$-measure for each individual image used for testing.

Figure 7c is an example of image segmented with our algorithm that scored well, with accuracy of 0.9380 and $f$-measure of 0.7183. Input image that gave this result is shown in Figure 7a and corresponding manually segmented image is shown in Figure 7d. This image had some noise left, which hasn’t been removed by morphological operations. Also, there are some smaller vessels, or parts of them, that remained undetected, but even though the accuracy for this image is lower then the accuracy scored on whole database, we consider it to be a well segmented image because of higher $f$-measure, since $f$-measure is a better measure for successfulness of vessel pixels detection. This is due to the fact that, unlike accuracy which gives equal importance to negative and positive results, $f$-measure gives higher importance to positive results. This context can be deduced from their formulas defined in (13) and (14).

It can be seen that wider vessels have been successfully detected as well as the most of smaller vessels. To detect higher percentage of small vessels, a lower threshold can be applied, but with side effect of weaker noise suppression. Our choice for the threshold value is based on experimenting with different thresholds and evaluating their accuracy and $f$-score. This effect is shown in Figures 8b, 8c, 8d, 8e and 8f where results with different thresholds applied are shown. With lower thresholds, some of the wider vessel’s endings haven’t been detected or they contain gaps. It can also be seen that a significant part of the optic disc has been falsely detected as a part of the vessel tree.

Figure 9c shows an example of lower quality result with input and manually segmented image in Figures 9a and 9d. Accuracy for this image is 0.9343 and $f$-measure is 0.5367. Aside from small vessels being poorly detected, there are some bigger vessels on which the algorithm hasn’t performed well. This is caused by low contrast between the vessels and the background. It can be seen in the input image that the regions where bigger vessels haven’t been successfully segmented, have darker background.

Figure 10 is an example where our algorithm provides good detection of vessel, even the thin ones, but a lot of noise is present. On this particular image, a higher threshold could give better results in term of noise cancellation. Circular edge of retinal images would also produce high stickness values, but the edge is easily detected and appropriately masked out from results.

In future, additional post-processing steps should be applied to alleviate the problem of false segmentation of the optic disc. The low contrast issue should also be addressed and contrast enhancement preprocessing techniques should be explored. Also, other noise removal techniques should be considered to remove remaining noise. Various retinal disorders do interfere with blood vessel segmentation, so further post-processing steps are planned for future work, to enable successful segmentation in presence of such disorders.

V. Conclusion

Retinal vessel segmentation is important in ophthalmological diagnostics and there are a lot of different automated methods proposed. In this paper we have used Hessian matrix and tensor voting to detect the vessels. Our preliminary results on a limited database indicate that our algorithm performs well, with results comparable to other published methods. However, care must be taken when comparing the results, as they are obtained with different databases. In the future we plan to expand the method to enable good segmentation result in problematic images and in the presence of diabetic retinopathy symptoms.

Abstract - Developing technologies and meeting the demands and needs of a wide range of different users had rather important influence on design of user interfaces of web applications. In such a dynamic context, storytelling in web interfaces design represents a new approach which aims to realize a more attractive interfaces that also ensure and encourage the participation of the users themselves. This paper examines the pros and cons of such an approach as well as its effectiveness and impact on the development of interfaces designed for a good user experience. Developed theoretical aspects are applied on design and implementation of selected web application, whose usability as well as user experience was tested with future users by applying relevant methodology.

Keywords: web design, user interfaces, storytelling, usability, user experience

I. INTRODUCTION

Website design has changed over the years. As technology evolved, design always followed by changing and adapting to the new requirements. As information became widely approachable it has become a real challenge to easily find valuable and accurate information on the Internet. Now web designers must find other ways to attract users’ attention. In general, users are attracted by interesting and creative websites that offer different search experience. Users value experience, rather than facts. There comes an important element, which is also the topic of this paper - the story. Namely, “stories are important cognitive events, for they encapsulate, into one compact package, information, knowledge, context, and emotion” [1]. In this paper we developed a web application in which we’ve put the story as a main element of getting users attention. We’ve noted down the idea and the whole process of design, implementation and finally evaluation with potential end users.

II. PSYCHOLOGY BEHIND A STORY

A. The history of stories

The story plays a big role in our existence. More than before 27,000 years, since the discovery of the first pictures in the caves, storytelling was one of the most basic communication methods. People were gathering around the fire and telling their life stories and teaching the youngsters. To leave a mark for the next generations they were also drawing pictures on the walls, trying to mark down their knowledge. Thanks to those pictures, we know about their occupations and customs even today after all these years.

After a while, humans started writing, and then books appeared. Years later, humans invented radio, after that television, and finally the Internet. It all came from the need of communication which was always in some form of a story.

B. How human brain reacts to a story

People strive to understand, to process, connect and learn from stories. The human brain reacts instinctively to information seeking it, trying to simplify the whole complex so that it is simpler to interpret the experience and construct systematized view of the world. If we listen to a PowerPoint presentation with boring bullet points, certain parts in the brain get activated. Scientists call these Broca’s area and Wernicke’s area [2]. Overall, it hits our language processing parts in the brain, where we decode words into meaning. And that’s it, nothing else happens.

When we are being told a story, though, things change dramatically. Not only are the language processing parts in our brain activated, but any other area in our brain that we would use when experiencing the events of the story are too. A story, if broken down into the simplest form is a connection of cause and effect. And that is exactly how we think. We think in narratives all day long, no matter if it is about buying groceries, whether we think about work or our spouse at home. We make up (short) stories in our heads for every action and conversation. Whenever we hear a story, we want to relate it to one of our existing experiences. That’s why metaphors work so well with us. Whilst we are busy searching for a similar experience in our brains, we activate a part called insula, which helps us relate to that same experience of pain, joy, disgust and the like (see Figure 1).

Figure 1 Connecting experience with an emotion [3]

In this way we connect current events with metaphors, all of our brain associate reasons and the effects of the previous experiences [3].
C. The power of a persuasive story

Philip Pullman once said that “after nourishment, shelter and companionship, stories are the thing we need most in the world” [4]. There are few mediums more captivating than a well-told story. From “what happened next?” to personal connections we make through characters and events, everyone loves them. Stories are also a very integral part of being persuasive. Those in sales and marketing have known for a long time that stories trump data when it comes to persuasion because stories are easier to understand and relate to. How you say something is just as important as what you are saying. Refusal to recognize this places you at risk of having your good information become lost in a sea of less-worthy content. You also miss out on the connections to be made via a strong narrative. Here’s the thing: While we are all often resistant to the idea of being told what to do, we are very susceptible to agreeing with the “moral of the story” due to how it is presented to us.

According to research by psychologists Green & Brock [5], stories work so well on us because we are susceptible to getting “swept up” in both their message and in the manner of their telling. Quite literally, stories are able to transport our mind to another place, and in this place we may embrace things we’d likely scoff at in the “harsh, real world” [6]. Consequently, if we include story in our websites, no matter how, we can be almost absolutely certain it will get better impact than if we didn’t. No matter the purpose of the website, we want it to be persuasive. That’s how political campaign works, that’s how commercials work and that’s how we should approach the process of creating a website.

III. HOW TO USE A STORY IN THE WEB DESIGN

A. Basic elements of a story

Every story has a number of basic elements that makes it a whole [7, 8]:

The content – as a set of ideas and events in the story, usually formed around the conflict of the main and the side character, but sometimes even as an internal conflict of the main character. In a context of the website, content is the goal which we want the user to achieve and the process that gets him there.

The theme – the central topic, subject or concept of the story, one of the basic components.

The characters – comes in a form of a person, a place or an object that have human characteristics and function in the story. Actions and thoughts of the character lead the story forward. A well-developed characters help the audience to connect with the story. The characters in a website may be organizations, groups or companies, team members, users, mascots and similar entities.

The genre – the type of the story.

The atmosphere – well-designed atmosphere creates a greater connection between the audience and the story. In web design this element is achieved through the tone, style and colours of the design.

Imagery – the author’s attempt to create a mental picture (or reference point) in the mind of the reader. Visual, strong and effective imagery can be used to invoke an emotional, sensational (taste, touch, smell etc.) or even physical response. If we talk about the website, this is a very important part, because it includes photography, illustrations, typography and all the other visual elements. It complements the atmosphere.

The highlight – the central part of the story, which is the most dramatic. It mostly causes a turning point or a change in the characters.

The outcome – comes after the highlight and gives a conclusion. In this part, the story goes back to normal by decreasing the tension and excitement of the audience.

To tell a story through a website, we need to keep in mind all aforementioned elements of the story. Firstly, create the content and the theme, then create characters and bring in the right atmosphere and imagery. Finally, we should bring users to a “call-to-action” – the goal that we wanted her/him to reach. By adding one additional element – an animation, we create a whole new palette of ways to tell our story. It allows us to include motion, which allows us to include gestures and create deeper emotions, which leads to a deeper connection with the audience, which, at the end creates a much better user experience. And that is precisely what we want to achieve.

B. Animation in a story

Initially it is important to plan well the whole animation. This section is probably the most important, because if we have to subsequently make changes, there may be situations in which the need to change such a big part of the animation so that we, mind as well, better start again. Therefore, this step is necessary for it to work out well. We should proceed only when we are certain that we have it planned exactly as we want. Accordingly, (i) we describe briefly the whole story, create the characters and determine the goal which we want to achieve, (ii) we create storyboard or a sequence of frames that will interchange during the animation and lastly (iii) we develop the atmosphere by creating well styled ambient [9]. After we have a basic parts created, we need to determine the rhythm of the animation. It’s key to find the right speed and variations. If it’s too fast, the viewer can feel lost, but if it’s to slow it may be boring. We need to decide which scenes are more important or require more time to process. To be sure that the user can follow up with the story, we can simply let him decide the rhythm of the scenes interchanging. That’s why we decide to use a new trend in web design and development – the parallax animation.

C. Parallax

Animation activated by scrolling is a relatively new trend in web animation. In 2014, web designers started giving a little more “feel” to websites by adding subtitle movement effects to elements on the sites using jQuery programming language. It easily gave them fresh, modern and appealing look [10] although it was just a start. In rather short time, websites started looking more and more like animated movies, but controlled by the user.

The idea of parallax design is simply an awareness of movement. More specifically, the word “parallax” is used to describe the perception of distance between objects while moving along a line of sight. For example, the objects nearest to you in space will seem to move quicker and more dynamically than “background” objects. So parallax is just a
measurement of the difference in position between two points from the viewer’s perspective. Since the objects aren’t really moving, it’s just a type of illusion like 2D animation [11]. The feeling of involvement in the content of the websites improves the user experience. It makes browsing through the web a whole new experience. If it looks eye-pleasing and also tells a good story, letting them feel as they can move the elements, makes it more fun and entertaining. If it stimulates a whole package of positive emotions, it will sure be an experience they won’t forget. There are all kinds of great examples of those effects implemented on the web.

Bizbrain is an advanced long one-page website that skilfully demonstrates statistical data via amazing colourful infographic. Each section includes its own piece of information that is wonderfully bolstered by activated animation (Figure 2).

![Figure 2 Bizbrain - www.bizbrain.org/coffee](image)

Merry Christmallas, like the previous example, is creative website aimed to give its loyal customers and regular users a warm and hearty congratulation. The story begins with a clean sheet of paper and ends up with a vibrant fully-illustrated scene; the whole transformation is pulled by a scrolling technique (Figure 3).

![Figure 3 Merry Christmallas - ihatetomatoes.net/merry-christmallas](image)

Make Your Money Matters is a promotional website that graphically showcases benefits of joining a credit union. You will become an active participant of its journey. The technique allows holding the theme alive and brings the better user experience (Figure 4).

![Figure 4 Make Your Money Matters - makeyourmoneymatter.org](image)

Artem & Julia Wedding is a wedding invitation made by a designer and a programmer. Page tells their story and invites viewers to their wedding. This is an example of how websites are fully involved in our lives and can be used for all kinds of purposes (Figure 5).

![Figure 5 Artem & Julia wedding - artemjuliawedding.com](image)

IV. WEB APPLICATION DEVELOPMENT: CASE STUDY

The aim was to create a web application for the HCI (Human-Computer Interaction) group at the Faculty of Science, University of Split, Croatia; to present the group itself, its members, their activities, projects and collaborations (refer to http://hci.marijanapivac.com). Since the HCI is still rather unfamiliar concept to people who are not related to the design and technology, the idea was to design a page that will introduce the concept through the parallax animation. Although, this kind of web application is not really the best scene for parallax animation website, we were eager to try and implement it anyway and hopefully get a good feedback for this approach when the consequences are not ideal.

Hence we created the “Intro page” which tells a narrative story about the HCI. Furthermore, beside the HCI story, additional relevant group information was provided in additional webpages. To ensure high usability of the web application, the target users were firstly considered. For this case, a target user is a person who wants to be informed about the HCI group, find appropriate information and be potentially engaged in collaboration. So, as a homepage we set the “About page”, while the “Intro page” was set as the first element in a menu, specifically highlighted so that it draws attention but still doesn’t interfere with users’ browsing. For the main story we decided to illustrate few examples of an everyday frustration caused by a bad design, and present a whole discipline dedicated to exploring the little things that make our lives easier (see Figure 6).

![Figure 6 Storyboard in our web application](image)

A. Design: atmosphere, style and characters

The design was cosy, relaxed, little childish, with illustrated and animated elements. The main character is a
ordinary, common user, drawn in plain clothes, without facial features, in order to clearly shown the “generality”. The style which was used is called a “flat design”, which relies on a 2D look, minimalism and symbolism, avoids excessive use of overflow colour, texture, shadowing. This style has its roots in Bauhaus, modernism and so-called Swiss style which became popular back in the 1950’s and 1960’s. “Flat design” earned general popularity in the 2013 when Apple started using it [12]. Since the character we made didn’t have facial features, we have paid special attention in creating an emotion in the story (see Figure 7).

![Figure 7 “Flat design” and visualization of emotions](image)

**B. Implementation**

Given that today the use of a wide range of devices that are viewing the website, in the design is necessary to take account of all sizes and proportions of the screen of the device. Since it is important to provide the same experience across all screens, different techniques have been developed to cope with that issue. The most commonly used is responsive design (Figure 8). It is an approach aimed at allowing desktop webpages to be viewed in response to the size of the screen or web browser one is viewing with. A site designed with responsive design adapts the layout to the viewing environment by using fluid, proportion-based grids, flexible images and CSS3 media queries.

![Figure 8 Responsive principles](image)

The main downside of parallax concept is often the behaviour on mobile phones. It is considered really heavy and slow for this kind of devices since the JavaScript is used for calculating the sizes and position of elements which slows down the loading of the website [13]. It is also hard to scale the design down so it is responsive to different sizes, and it is now a common practice to make a whole other solution for those devices.

In our example we’ve used Skrollr, a JavaScript library made especially for parallax, which made the developing part so much quicker and easier [14]. Also, we made the whole design adjust to different screens using CSS. Since we needed an ability for the group members to be able to insert new content, we decided to use WordPress CMS (Content Management System) to implement the idea. So, after we have adjusted the design to multiple screen sizes, we created a WordPress theme that will give us desired abilities.

**V. EVALUATION OF THE USER INTERFACE**

In general, human-centred design is an approach to system (application, product or service) development that focuses specifically on making systems usable. Consequently, for the success of a website in particular is necessary to raise the level of its ease of use i.e. usability what will automatically have an influence on positive user experience. Keeping in mind users’ needs, experience and limitations, we need to create user interface that is transparent, intuitive and easy to use. Since the visual experience is closely linked to emotions, it is something we should pay particular attention to.

Emotions provide us with instant information about our environment: where's the risk, where a potential pleasure; what is beautiful, what is bad. The emotional system, which is changing the way the cognitive system operates, is closely related to behaviour, preparing the body to a suitable reaction to a given situation [15]. Given that all humans are different, what might work for one person may not for another. We can do our best to predict their reactions, but can't really predict the real experience. Additionally, we can't determine the effectiveness of the design based on statistics, visit rate or bounce rate; we can only create assumptions. Nevertheless, in order to get the best measurement for user experience, we must ask the users themselves.

**A. Evaluation methods**

When evaluating website usability, it is important to determine whether the users of the website achieve their goals and whether they have a positive experience while using the site. These parameters cannot be determined with only one evaluation method. In line with these reasoning, we conducted two evaluation studies – one related to the usability and the other of the user experience.

1) **SUS questionnaire**

SUS (System Usability Scale) questionnaire was developed as a simple way of assessing the usability of the system, which uses a Likert scale. It is represented by ten items on which the user completes the degree of agreement or disagreement with the statement [16]. Number of stages is always an odd number, so that the mean value is always indefinite, and extreme values are always complete agreement and complete disagreement with the statement.

2) **AttrakDiff questionnaire**

AttrakDiff questionnaire serves as a method to assess the user experience, as subjective user satisfaction with the service system [17]. The model separates the four essential aspects:

- The product quality intended by the designer.
- The subjective perception of quality and subjective evaluation of quality.
- The independent pragmatic and hedonic qualities.
- Behavioural and emotional consequences.
To measure the attractiveness, we applied an instrument of measurement in the format of semantic differentials. It consists of 28 seven-step items whose poles are opposite adjectives. Each set of adjective items is ordered into a scale of intensity, while every middle value of an item group creates a scale value for:

- Pragmatic Quality (PQ),
- Hedonic Quality (HQ),
- Attractiveness (ATT).

At the end of measurement, the average value of each group claims is taken to get a clearer picture of the user experience. This theoretical model is researched and tested in a number of studies which showed that the hedonic and pragmatic quality independent of each other, and both equally affect the level of attractiveness.

B. Evaluation results

The preliminary evaluation was conducted on a sample of 12 participants (six males and six females). Given that the target audience and future users are younger people interested in HCI issues and possibly collaboration and future work in the field, the participants were also mostly students. For the task they had to visit and browse through web application and then fill-in SUS and AttrakDiff questionnaires. All respondents completed both questionnaires without difficulties. Results of the SUS questionnaire showed a biggest diversity of responses for two claims: (i) “I found the website unnecessarily complex” and (ii) “I found the various functions in the website were well integrated” (see Figure 9). Other claims mostly got similar, positive results.

![Diagram of average values](image)

**Figure 10 Pragmatic and hedonic quality results**

In the “Diagram of average values”, we see that the attractiveness (ATT) reached the highest level and pragmatic quality, as the two aspects of hedonic quality, (stimulation and identity) reached equal results (see Figure 11).

![Diagram of average values](image)

**Figure 11 Diagram of average values**

In the “Description of word-pairs” diagram the values are presented in claims with two extremes. All the values were in the right half of the diagram, which is the desirable one (see Figure 12).
However, when planning the design and development is necessary to pay attention to the way the story is included. Whether by using the parallax animation, or any other animation, and perhaps without it, the visual elements, as the textual, always tell a story.

REFERENCES

Figure 12 Description of word-pairs diagram

The lowest value reached terms of unpredictability and price value. The highest value reached concepts of clear structure, particularity, creativity, attractiveness, motivation and attractiveness.

VI. CONCLUSION

In web design creating something that differ from similar projects can make a better impact on users if it’s done by following well-known principles. Experimenting with new elements demands smaller steps applied gradually, so that users can adapt. It is crucial to know the right moment and way to implement new things that might challenge users’ behaviour. In such a process it’s important to evaluate the outcomes by testing users’ impressions.

By adding animated story we’ve tried to find a new way to keep users attention, which we, by our results, have accomplished. Given that this was a preliminary evaluation participants were all students as they were target audience. However, for further evaluation studies it would be more accurate if we include users of all ages so that we have a clearer picture of the real user experience.

Although there are believes that it is difficult to integrate the storytelling in all types of sites, this web application proves that the story is the one element that can (and should) be included if we are to attract user’s attention.
Abstract - Idioms are well known for posing problems to non-native speakers, let alone machines. A failure to identify idioms often leads to unnatural, even hilarious outputs. This paper investigates the treatment of idioms in state-of-the-art SMT systems involving English and Croatian. First we introduce the concept of idioms. Then we construct three short stories abundant with idioms per each language, and translate them into the other language by two state-of-the-art SMT systems. Next we manually inspect the outputs and present results. For the purpose of conducting analysis, we devise an error taxonomy for handling idioms.

Section two clarifies the specificities of idioms. Section three gives an overview of related work. Section four describes our experimental study. The results are presented in section five. Section six highlights the main findings of our work.

II. IDIOMS

According to their structure, idioms can be divided into three categories. First category is comprised of sequences of words that consist of at least two independent words (e.g. gold mine). Second category are phonetic words. These sets of words consist of only one independent unit (e.g. out of sight). Finally, third category is comprised of idioms that acquired a form of a sentence (e.g. the place is getting too hot).

Idioms can also be categorized in accordance to their origin. First category, thus, would consist of biblical idioms. Considering the importance of the Bible and its tremendous influence since the beginning of the Middle ages, it is not surprising that biblical idioms found their equivalents in various languages. Examples of this category of idioms include: Judas kiss, the lost sheep, to cast pearls before swine. Second category consists of literature idioms. These are idioms that have origin in literature or mythology and are commonly used in language (e.g. to be or not to be, Sisyphean task, Tantalus’ agony). There are also idioms that originated from various human professions (e.g. mathematics, music, theatre, nautics) and are used in everyday communication. Some of the examples include: bring sth under the common denominator, have an ear for sth, behind the scenes.

In addition to previously mentioned categories, there are also historical idioms. These idioms are related to historical people and events which left a strong impact in the society where they are still used in everyday communication. Some of the examples include: die is cast, like sheep without a shepherd, meet your Waterloo [5]. The last idiom has a national background and is unknown among other cultures. The translation cannot be found outside the culture in which this idiom has occurred. Even if one tried to translate it, the message would never be truly transmitted.
Consequently, idioms can also be differentiated according to the time and place of their emergence. Phraseology divides its constituents on national and international idioms. While former are almost impossible to translate, the latter can be transferred between languages [5].

Some idioms have both identical meaning and identical components (e.g. swallow the bait which is translated into Croatian as “progutati manac”). In some instances, it is possible to come across idioms that have the same meaning but slightly different form (e.g. get out of the bed on the wrong side which is translated as “ustati na lijevu nogu”). Sometimes it is possible to find an idiom in the target language that has equivalent meaning in the source language, but a completely different form (e.g. piece of cake which is translated as “mačji kašalj”). Example translations listed are in Croatian.

One of the biggest mistakes when dealing with idioms is translating its components literally, word by word. Translator must be familiar with culture and language of both source and target language in order to recognize idioms and transfer them to the target language appropriately [5].

III. RELATED WORK

A study in [6] illustrates differing patterns between human and machine translations, but also between two different machine translation (MT) systems. Error analysis, as [7] puts it, gives a qualitative view on the MT system and should be an integral part of MT development. It can point to strengths and problem areas for a certain MT system, which is not possible using automatic evaluation metrics [8]. Automatic metrics, as well as some forms of human evaluation such as fluency and adequacy scoring or system ranking, provide quantitative system evaluation [7]. Research community would like to get answers to what kind of errors the system makes most often, whether a particular modification improves some aspect of translation, although the overall score is intact, whether one system is superior in all aspects of translation or just in some, etc. [9]. Idioms are usually explicitly tackled in MT error taxonomies, i.e. as expression in [10, 11], and as idioms in [12, 13, 14].

Standard statistical machine translation (SMT) systems do not model idioms explicitly [15]. The term phrase in PBSMT does not refer to a linguistic unit, but to a sequence of words. Although phrasal translations might indirectly capture multiword expressions (MWE), which is a more general concept, they are not distinguished from any other n-gram [15]. A rising interest has been detected in explicitly modelling MWEs within the SMT framework. The authors in [16] note that highly fixed expressions (e.g. by and large) can be represented as words-with-spaces in Natural Language Processing (NLP) applications. This, however, does not hold for semi-fixed and syntactically flexible expressions. Semi-fixed expressions adhere to strict constraints on word order and composition, but undergo some degree of lexical variation, e.g. inflection, variation in reflexive form, or determiner selection [16].

The authors in [17] show a simple approach to extract domain bilingual multiword expressions (MWE) and three methods to integrate them to Moses, the state-of-the-art PBSMT. The first method adds MWEs to the training corpus, the second adds one feature which has the value of 1 if the source language phrase contains a MWE and the target language phrase contains its translation, or the value of 0 otherwise, and the third method includes an additional phrase table containing automatically extracted MWEs.

A study in [15] proposes two different integration strategies for MWEs in SMT. In the first strategy they identify MWEs and turn them into a single unit. Therefore, from the perspective of SMT, all MWEs are considered frozen. In their second strategy they add a count feature which represents the number of MWEs in the input language phrase and integrate MWE knowledge as a feature in the translation lexicon. In that way the system is biased towards using phrases that do not break MWEs. This is sort of a generalization of a binary strategy from [17].

MWEs are integrated into the phrase table in two different ways in [18]. After identifying MWEs, the translation pairs are extracted from the corpus. In the first approach the aligner probability is kept, while in the second it is set to 1 in both translation directions. The factored model is used, which enables using lemmas beside surface forms of words.

A study in [19] shows that different MWE types require different integration methods in the SMT framework. Beside the two approaches proposed in [15], they also take zone integration approach in which they define reordering zones for all MWEs found in the test data. In that way the decoder is forced to respect the boundaries while constructing the hypothesis. However, although it is not allowed to translate out of zone phrases unless it fully finished translating the words in the zone, it is allowed to divide the zone into any combination of phrases and translate them individually and in any order. That is why the approach does not help to increase automatic scores.

The impact of idioms on SMT is evaluated in [20]. Unlike in this study, the authors focus on idiomatic expressions formed from the combination of a verb and a noun as its direct object (e.g. lose head). They show that even in that limited scenario idiomatic expressions pose a challenge to PBSMT systems, as witnessed by a drop in the BLEU score (BLEU score is proposed and presented in [21]).

A substitution based technique for improving SMT on idiomatic MWEs is evaluated in [22]. The method first performs substitution on the original idiom with its literal meaning before translation, and then replaces literal meanings with idioms following translation. Although a statistically significant improvement is reported, the authors conclude that there is still a lot of work to be done to solve the problems posed by idioms to SMT.
IV. EXPERIMENTAL SETUP

We compare the way that two online translation systems, i.e. GT1 and Assistent2, manipulate texts, more precisely idioms, in English-Croatian and Croatian-English language directions. The texts used in this analysis are constructed by hand and care was taken to ensure that the texts are abundant with idioms but make up coherent stories. More details on the test sets are given in Table I.

In the analysis of generated translations, we ignore punctuation errors, inappropriate upper case and lower case letters and discordance in gender, number and case. The focus is primarily on the translations of idioms3. For the purpose of analysis, we divide machine translations of idioms into the following categories: Equivalent, Appropriate meaning, Literal translation, Anomaly in form, Untranslated or partially translated, Wrong idiom, and Other.

V. RESULTS

The results are presented in Table II. For the purpose of comparison of translation directions, the distribution of error categories in percentages is given in Figure 1.

The results consist mostly of literal translations of idioms, i.e. word by word translations (stretch a dollar is translated into Croatian as “produžim dolar”).

Some of the idioms are not translated into their equivalents in the target language, but their translation conveys appropriate meaning, which is in accordance with the context (cold hearted is translated into Croatian as “hladnog srca”, instead of “mrtav hladan”). For some of the idioms in this category it is not possible to use an equivalent idiom because it does not exist in the target language (Jack of all trades is translated into Croatian as “dobar u svemu”).

To a lesser extent, we identify idioms that are translated using an equivalent idiom in the target language (armed to the teeth is translated into Croatian as “naoružan do zuba”), as well as idioms with some sort of anomaly in their form. The latter are idioms that are recognizable and translated appropriately, but have some sort of anomaly (an extra word, inappropriate preposition, wrong word). For example, idiom crying like the rain is translated as “plakala kao kiša s”, where the preposition s is unnecessary, but the rest of the idiom is translated appropriately.

The translations contain several idioms that are translated using an inappropriate idiom (is down for the count is translated into Croatian as “manji od makova zrna”). Additionally, some idioms are not even translated, i.e. they remain in their original form (“pomsrio konce” is translated into English as pomsrio strings), because of training data sparsity, which is mainly caused by rich morphology. We group these idioms into separate categories.

VI. CONCLUSION

Although one would expect Croatian-English translations to be better, as English is well resourced, the opposite proves to be true. We attribute this to the fact that English texts are more prevalent on the Internet than texts in Croatian, and therefore, translations from English into Croatian are much more accessible. Moreover, in our analysis we ignore discordance in gender, number and

case, which could also greatly affect results when translating from morphologically poor to morphologically rich language. Furthermore, due to a great number of existing idioms in both the source and target language, it was impossible to include them all in our corpus. This could have affected our final analysis.

The majority of generated translations are literal translations of idioms and other elements of the texts. This leads to the conclusion that the systems involved do not have special treatment for MWEs. The last three categories, namely Untranslated or partially translated, Wrong idiom and Other are so poorly represented that they can be dismissed from further investigations.

In some instances, GT achieves better results, while in others Asistent offers much better translations. Both give similar translations although we observe slight superiority of Asistent especially in English-Croatian translations.

The main conclusion that can be deducted from this study is that PBSMT systems do not capture MWEs to a sufficient degree and special attention needs to be paid first to their detection, and afterwards to finding appropriate integration method. Since literal translations predominate, back translations would yield similar if not even worse results.

Contactless control of sanitary water flow and temperature
Dominik Gečević, Toni Bjažić
Tehničko veleučilište u Zagrebu
Vrbik 8, 10000 Zagreb, Croatia
e-mail: dgecevic@tvz.hr

Abstract—An innovative embedded computer system for contactless control of sanitary water flow and temperature is described in this paper. The innovative component of this embedded system is in its ability to control the flow and temperature of sanitary water, without the need for physical contact with a tap. In this way, the transfer of bacteria from the surface of the tap to a user is avoided, which significantly contributes to the preservation of health and cleanliness, i.e. hygiene. A hardware and software components required for the functioning of this embedded computer system are described in this paper. A design and production of printed circuit boards (PCBs), for control of servo valves using an analog infrared proximity sensors, a digital infrared proximity sensor and signal LEDs, are included as the hardware part of the paper. The software part is consisted of description of a class for linearization characteristics of the analog infrared proximity sensor, and description of a class for noise filtering, as essential software components of the program, which ensure comfortable use of the system for the end user.

I. INTRODUCTION

One of the most basic hygiene procedure is hand washing. Proverb that said: "Hygiene is a half way to health" is old, but it is true! Therefore, in this paper, special attention will be dedicated to health care, and how it is possible to improve the existing mixing water system and health care for the purpose of general living improvement and health standards. Classic taps requires physical contact to regulate flow control and temperature of sanitary water. The biggest drawback of this system is hygiene. Eventually a newer system that detects the presence of hand have appeared. The system does not require hand contact to start the flow of sanitary water, which prevents the transfer of bacteria from the tap surface such as Streptococcus, Staphylococcus, E. coli, shigella, hepatitis A virus, cold virus, etc. This revolutionary system was implemented around the world in public toilets, but has major drawbacks are the inability to control the flow rate of water, temperature change and excessive (unnecessary) use of water.

II. DESIGNING THE PRINTED CIRCUIT BOARD

In this section are shown and explained components that are built on the PCB, as it follows: built-in microcontroller Nucleo-F303RE and shift register SN74HC595N.

A. Embedded microcontroller Nucleo-F303RE

Nucleo-F303RE the development platform from the manufacturer STMicroelectronics [1] is based on 32-bit ARM® microcontroller Cortex®-M4. Nucleo-F303RE (See table I) communicates via USB (2.0 full speed), SPI, I2C and CAN. Programming is done through the USB interface with its own decoder. The programming uses online mbed developer [2] and the code is written in object oriented programming language C++.

B. Shift register SN74HC595N

Shift registers are integrated circuits that consist of flip flop bistables. Bistable has only two states, which means that it can only remember one bit of data (0 or 1). Flip flops in an integrated circuit can be connected in series and parallel entering and outputting data. Shift register SN74HC595N (See table II) from the manufacturer Texas Instruments [3] in 16 PDIP (Plastic Dual Inline Package) version with serial and parallel output of entering data.

1) Principle of operation: A minimum of three pins at Nucleo development platform are needed to successfully use the shift registers: SER, RCLK and SRCLK. At the beginning SRCLK and RCLK input initiate to a low logic state, and the input SER brings (the first bit) data. After the SRCLK make the state change from low to a high

</tbody>
</table>
logic state, i.e. on the rising edge, data that was previously brought is saved in the first bit register as shown in Fig. 1.

Since the SER was in a high logical state, the high logic state was brought to the register. Now, if the SER is put in a low logic state and the state of SRCLK is changed from a low logic state to high, the data from the first register will move to another register, and to its previous place comes a logical zero as shown in Fig. 2.

This process can be repeated as many times as necessary until the desired combination of data within flip flops is achieved as shown in Fig. 3.

If the state of RCLK is changed from low to high logic state it will parallelly send data from flip flops to output, and every odd LED will light up as shown in Fig. 4.

The big advantage is the serial growing number of registry (to a maximum of 40) can be connected and operated with a much larger number of digital outputs. Shift register 74HC595 is compatible with low voltage Schottky TTL (Transistor - Transistor Logic).

The maximum total output current must not be higher than 70 mA and each output can be set up to a maximum of 35 mA. The Dependence of frequency to voltage is shown in Tab. III.

C. Printed circuit board

The printed circuit board (See figure 5) is designed using CircuitMaker software [4], and is shaped as a 100x100 mm square. It is made by the ShenZhen2U [5] service from a 1.6 mm thick standard double-sided FR4 epoxy (fiberglass-reinforced) material with 0.036 mm thick copper layers.

Printed circuit board is covered with a green protective thermal resistant varnish (solder mask) and all copper surfaces are surface treated using HASL method (hot air solder leveling), which is an addition to the protection and makes it easier to solder SMD components. Printed circuit board meets the requirements by European Directive 2002/95/EC - the RoHS standard (Restriction of Hazardous Substances), which means that during its production no mercury, lead, chromium (VI), cadmium and other harmful substances were used. The width of the power trace is an average of 0.5 mm for signal traces and...

1.0 mm for the control outputs of bipolar stepper motor. Three holes with open contact ring for mounting and grounding screw were added to prevent electromagnetic interference and parasitic capacity. All electrical traces have been carefully checked and are chamfered at 45° to eliminate "hot spots" (sharp turn edges where electrons travel the shortest route for which generate heat and damping) as shown in Fig. 6.

All grounding traces and unused space are covered in the Polygon Pour feature so that the maximum area of the circuit board absorbs all electromagnetic interference and parasitic capacity that could harm Nucleo development platform during program execution.

III. INPUTS AND OUTPUTS ON PCB

In this section are shown and explained all the devices used in the system, as it follows: two phase stepper motor driver, analog infrared proximity sensor, digital infrared proximity sensor and bipolar stepper motor.

A. Two phase stepper motor driver HY-DIV268N-5A

The HY-DIV268N-5A (See table IV) subdivision type is a PWM chopper type integrated driver which is used for controlling two phase hybrid stepping motor up to 4 A. This driver is using a current loop subdivision control. The motor torque noise is very small. The big advantage of this driver is high positioning accuracy.

The micro stepping (See table V) mode can be selected from the following eight operating modes using the S1, S2 and S3 inputs. The operation mode is set to standby mode if the S1=S2=S3=OFF. The power consumption in standby mode is minimized, while only protection operation is active.

The current regulation (See table VI) mode can be selected from the following eight operating modes using the S4, S5 and S6 inputs.

1) Function: To start the bipolar stepper motor it is necessary to configure the ENABLE pin high, to turn off the motor and configure the ENABLE pin low. The ENABLE pin is turning on or off all FET outputs. When the ENABLE pin is set high and the PULSE is on

rising edge, the system will rotate the motor by one increment.

B. Analog infrared proximity sensor Sharp GP2Y0A21YK0F

The proximity sensor is an optical sensor that works without the use of any external force, reveals the presence of nearby objects from which reflected light was reflected.

1) Principle of operation: Diffuse optical proximity sensor is a sensor in which the transmitter and receiver are integrated in a single housing. If an object comes close to the sensor its transmitted light will be reflected back to the receiver that will detect it. Such sensors are used for short distances, providing a distance reading from objects that have a good reflecting surface. The Sharp GP2Y0A21YK0F [6] sensor has an integrated electronic circuit for filtering noise and signal processing and analog output. The characteristics of the analog infrared sensor are shown in Tab. VII.

Sharp GP2Y0A21YK0F [6] the first measurement is performed in the range from 28.7 to 47.9 milliseconds. While the sensor performs the first measurement it is necessary to add a maximum of 5 milliseconds that would allow the signal to be measured and sent to output. Infrared proximity sensor is designed using paired infrared diode and photo-sensitive diodes. The principle of operation of the infrared sensor is relatively simple. The infrared diode emits infrared light waves that is received by a photo diode after reflection from obstacles (body).

2) Linearization of the sensor characteristics: Characteristic of the Sharp GP2Y0A21YK0F [6] sensor gives a

\[
y = 27.57 \cdot x^{1.192}.
\]

C. Digital infrared proximity sensor Sharp GP2Y0D815Z0F

Sharp GP2Y0D815Z0F [8] is a digital infrared proximity sensor used for measuring distances in the range from 0.5 to 15 centimeters. It consists of an integrated combination of the PSD (Position Sensitive Detector), IRED (InfraRed Emitting Diode) and processor unit for signal processing. The characteristics of the digital infrared sensor are shown in Tab. VIII.

D. Bipolar stepper motor 42STH38-1304AF

Stepper motors are electromechanical transducers of energy. Converted pulsed of electrical excitation are transferred to the rotational mechanical movement. The stepper motor may have 4, 5, 6, or 8 wires. Bipolar stepper 42STH38-1304AF produced by Suncor Engine [9] have only 4 wires. The characteristics of a bipolar stepper motor are shown in Tab. IX.

Normal mode to be used on a stepper motor is a full step mode. Half-step is a dividing method, which is more precise than full steps. The principle of operation is that the current flows through two motor windings. This way higher voltage to the reaction at a short distance, and at a lower voltage at a longer distance so in order to have a more accurate reading the characteristic needs to be linearized. The first step is to manually type in a meter reading from the image to Excel [7] table. Then choose the "scatter plot" that would replace the axle. The "Add Trendline" will allow the mathematical function of nonlinear characteristics to select the "Power" function as obtained in the enclosed Figure 7

half of the rotor is held in position between two stator poles. The principle of operation is similar to the half-step microstepping, but the only difference is that the value of the current in the coil is adjustable because half of the rotor can be in a number of discrete positions between the stator [10].

IV. DESIGN AND TESTING RESULT

Total power dissipation is shown in Tab. X, flowchart is shown in Fig. 8 and first prototype testing photos are shown in Fig. 9, 10, 11, 12,

V. IN GENERAL OF WRITING CODE

The code is written in C++ object-oriented programming language for the Nucleo-F303RE [1] development platform which is the main part of the processing electronics for signal processing in this final work. Programming the microcontroller was done from an mbed [2] integrated development environment. The code is translated using the online compiler [2] that is available for Linux, Mac and Windows operating system in the object-oriented programming language C++. Microcontroller runs a program that is stored in its flash memory.

1) Linearization of analog infrared proximity sensor: Mbed developer is made to easily share codes (open source). The linearization signal class used in this project was written by Thomas Johansen [11], and is protected under the license of MIT Institute. For the proper use of this class a non-linear function of the infrared analog proximity sensor should be described as we did at III-B2. The resulting function (1) must be described within the class to determine the minimum and maximum voltage value of the sensor. Class SHARPIR can return values in centimeters or inches, depending on the user’s needs.

2) Noise filtering using PT 1 element: The used class is written by a member of the TVZ Mechatronics Team [12]. For proper use of this class is necessary to determine the gain K, time constant T_1 and sampling time T_d. Low Pass Filter PT 1 is used to filter the noise of the analog infrared proximity sensor using the given transfer function. Transfer function PT 1 element is simulated in the software package Simulink, MATLAB from publisher MathWorks® [13].

VI. CONCLUSION

An innovative embedded computer system enables the user to contactless control sanitary water flow and temperature depending on the distance of a hand to the position of the infrared proximity sensor. The offset position of the hand is shown by signaling LEDs. The use of this embedded system is very simple. If the user wants to select the desired flow and temperature of sanitary water, it is necessary to stabilize hands at the desired height to the infrared proximity sensor and then the signaling LEDs will flash twice. After setting the desired value, control valves will open to the desired flow and temperature of sanitary water as long as the user’s hands are near to the mixer tap. This embedded system has the ability to remember the last value in order to allow the easier use and to reduce water consumption. Two LED rows are used to visualize the cold or hot water flow and temperature, each containing 20 LEDs. For example by activating 20 red LEDs, control valves are fully opening, the same logic hold true for cold water.

REFERENCES

ABSTRACT – In this paper we describe a technical system for DC motor speed control. The speed of DC motor is controlled using Arduino programming platform and MATLAB’s Simulink coder. This paper contains introduction to using an Arduino board and Simulink PI controller in closed loop system. It will be described how to program Arduino with Simulink coder and in the end we present the results of PI controller for DC motor speed will be given.

I. INTRODUCTION

Short settling time and minimized steady state error are desired in technical system of speed controlled DC motor. To accomplish these goals, closed control loop must contain a PI controller, DC-DC power converter and a negative feedback/speed sensor. Testing was done on laboratory model of small DC motor coupled with DC generator that is used as a load on the motor. Model is shown in Fig. 1.

That model also includes the tachogenerator that was used as negative feedback/speed sensor. Arduino Uno board was used as controller in this closed loop. To accomplish short settling time and a small steady-state error regulator have to be adjusted to the rest of the closed loop.

An Arduino board is used due to low cost, simplicity and flexibility. MATLAB Simulink is used to create control algorithm and convert that algorithm in C++ code that can be uploaded in Arduino board. PC computer with Windows OS is required to make the model of controller in Simulink and to upload that model on Arduino board.

II. ARDUINO UNO

Arduino Uno is microcontroller board with Atmega328p that has been used as a digital PI controller. This board is used to test the controller. It has 14 digital input/output pins, and 6 of them can be used as a PWM output pins. It also has 6 analog inputs, 16MHz clock crystal, a USB connection that is used to connect it to the PC and it operates at 5 Volts. Various Arduino boards can be used instead of Arduino Uno board.
III. ARDUINO AND SIMULINK

Arduino boards are usually programmed by writing C/C++ code in Arduino IDE window, but in this example it will be programmed using MATLAB Simulink package for Arduino. Simulink is a block diagram based environment for simulating mathematical models and it can be used to program some of the Arduino boards. To use Simulink with Arduino a support package is needed. It can be downloaded from Mathworks website with instructions how to install it and start using it. After installation is done correctly, a new library is now ready for use in Simulink library browser. In this paper analog input, digital input and PWM output blocks will be explained and shown.

IV. TESTING ARDUINO AND SIMULINK

Figure 4 Block diagram of sine wave generator

This section explains how to use Simulink blocks to read analog signals from real world and how to use PWM output signals to control some kind of electric device. Figure 4 shows simple block diagram made in Simulink. Its purpose is to generate a sine wave signal from Arduino using only Simulink. First block is a sine wave block. This block outputs sine wave signal of amplitude 0.5 and frequency of 10Hz. In sum block that signal is added to the constant of 0.5. Sum block now outputs sine wave that has “DC” component of 0.5, and amplitude of 0.5. Because Arduino Uno does not have analog output, the PWM output is used with corresponding RC filter. That signal is connected to the gain block of 255 value of gain, and outputs sine signal that has amplitude of 255/2.

In the PWM block, pin number needs to be entered. The PWM block will generate a PWM signal on the specified pin. The duty cycle of that PWM signal depends on input signal. In this case pin 5 is used and generated sine wave signal with amplitude of 255 is on input. When that block diagram is compiled and uploaded in Arduino Uno board by clicking on “build model” icon (normal mode), on pin 5 of the Arduino board you can measure PWM signal and by using RC filter that PWM signal can be filtered and that is shown on Fig 5.

Figure 5 Sine wave generated with Arduino

For demonstration how to use analog input block and Arduino Uno and Simulink in real time, another block diagram is uploaded on Arduino board (Fig. 6) but this time in “external mode”. “External mode” is used when you have to monitor any of the signals in block diagram.

Figure 6 Block diagram of sine wave generator and analog read

Top part of this diagram is the same as on Figure 4. This time analog input block is defined by selecting analog pin 4 as an input pin. For demonstration PWM pin 5 is connected with analog input pin 4 via the RC filter. In this example Arduino generates sine wave signal and reads that same signal. Transfer Fcn block simulates the same RC filter but represented as first order filter with time constant of 0.1 s. When diagram is uploaded using external mode on scope block generated sine wave signal can be monitored as shown in Fig 7. Input block converts input voltage in uint16 type number in range from 0 to 1023.

Figure 7 Sine wave read by Arduino
V. TESTING THE CONTROLLER WITH DC MOTOR

In order to apply the controller on DC motor model, the parameters of the controller need to be set. The parameters of the controller depend on the rest of closed loop components, so transfer functions must be known. Transfer functions of the motor, DC-DC power converter and speed sensor characteristics must be known to determine their transfer functions.

The motor is tested on load and data is collected. On Fig. 8 load characteristics is shown. Moment of inertia is determined with motor stopping experiment.

Resistance of armature coil is determined as well as motor constant “k”. In Fig. 9 time response of armature circuit is shown and inductance of armature coil is determined.

Motor now can be simulated in Simulink using block diagram shown in Fig. 10.

Because Arduino Uno does not have analog output, the PWM output is used and therefore chopper is used as DC-DC power converter. This is convenient because an RC filter is not needed to convert PWM to analog signal. DC-DC converter i.e. the chopper is shown in Fig. 11.

Transfer function of the speed sensor will be approximated by the first order filter.

Control block diagram is shown in Fig. 13. PI control algorithms will be tested and PID block is used. In PID block window various parameters can be changed. In “controller” drop menu, type of controller can be selected, and in the main window proportional and integral constants can be changed. In “form” drop menu window ideal or parallel algorithms can be selected. In Fig. 12 the function block parameters for PID block are shown.
Controller diagram (Fig. 13) represents how reference and negative feedback are accomplished and used as input signals to the controller itself. Speed sensor is connected to the analog input pin 0. 5V pin on Arduino board is connected to the digital input pin 7 via the button and resistor. When button is pressed on pin 7, 5 volts appears. Speed sensor that is mounted on the motor shaft gives 1.14V for the speed of 1000 RPM. Analog input block convert voltage that is connected to the pin 0 in to number, so data conversion block is used to adapt number type. In this case it is 237. In order to initialize the motor speed of 1000 RPM the reference value has to be 237 so Gain2 block has value of 237.

When button is not pressed motor is not spinning. When button is pressed digital input block outputs 1 and multiplies it by 237. Still motor is not spinning so speed sensor connected to analog input gives 0V and value that analog input block gives is also 0. Now PID controller block has 237 on its input and starts to give signal to the PWM block. PWM output pin is connected to the DC-DC power converter and motor starts to spin. Depending on the controller parameters the motor will get to 1000 RPM in around 3 seconds. To test the speed response on load disturbance a generator coupled with motor is used. Motor will be spinning at 1000 RPM and the load will be switched on. When controller compensates that load disturbance and gets up to 1000 RPM again, the load will be switched off, as shown in Fig. 16.

Steady state speed is around 1000 RPM as shown in Fig. 14. The time response graph is recorded with unloaded motor and using PI controller that is set to parallel form, proportional gain (P) set to 1 and integral gain (I) set to 1. In Fig. 15 parallel model of controller is shown.

In this example, where P=1 and I=1, the motor will get to 1000 RPM in around 3 seconds. To test the speed response on load disturbance a generator coupled with motor is used. Motor will be spinning at 1000 RPM and the load will be switched on. When controller compensates that load disturbance and gets up to 1000 RPM again, the load will be switched off, as shown in Fig. 16.

It takes 3 seconds to get back to wanted motor speed. To get more dynamic response of the motor controller parameters must be changed. Speed and load disturbance time response is shown in Fig. 17. In that case the proportional gain is set to 1 and integral gain to 20.
With this set up of controller the speed response is underdamped but much faster. In this case motor spins up to 1000 RPM in 0.62 seconds and time needed for the controller to compensate the load is 0.36 seconds.

All tests of the controller were done in normal simulation mode and all sample times were the same. Sample time is a very important parameter of the model and must be set at 0.0001 s for examples shown in this paper. This model of speed controlled motor will be used in laboratory exercises, and so it is convenient to use external simulation mode. In this mode user can monitor any of the signals in the model. For example in Fig. 18 and Fig. 19 two signals are being monitored in real time.

VI. CONCLUSION

Using Simulink and Arduino is one of the simplest ways to make satisfying controller for many purposes in variety of technical systems. Tests that were done in this paper show that Arduino can be very flexible for programming a control algorithms using MATLAB’s Simulink. One purpose of this kind of controller is using it in laboratory exercises where students can easily modify controller’s parameters and see what is going on with output value of the system that they are studying. Sample time of this controller can be changed and adapted to the system requirements. Using external mode, parameters of the controller can be changed in real time and user can see what has changed in the output signal almost instantly. The model was already tested on laboratory exercises and it has yielded good results. The students were very interested how to program the controller with Simulink.

ABSTRACT - This paper presents methods for regulating the elevator's cabin speed and position for purposes of traffic control. It contains four stations. On every station there are two position sensors and cabin call button. Cabin speed regulation is realized with microcontroller, incremental encoder and chopper, where chopper controls DC motor speed. A simple traffic control is written for ARDUINO platform.

I. INTRODUCTION

This paper will show how to regulate elevator's cabin speed and position for purpose of traffic control. It is necessary to achieve speed regulation due to speed limitations, acceleration and deceleration. In that way a cabin snatch can be solved. Position regulation is needed because the cabin needs to stop on preferred position. All functions are realized with two ARDUINO development boards (Pro Mini and Mega board) they are easy to program and they easily control another elements of control systems. The elevator model was made with the aim of acquiring knowledge of automation and regulation. The picture of model is given in Fig 1.

II. DC MOTOR SPEED REGULATION

The speed control loop contains microcontroller ATmega328p, which is a part of ARDUINO Pro Mini development board, chopper and small DC motor with permanent magnets.

A. Controller

ARDUINO Pro Mini (Fig 2.) development board is used as a PI controller. PI controller is implemented using the PID library. The process has only one dominant pole so it can be controlled quite well with a PI controller. PI controller parameters are obtained with experimental method, and uses difference between reference value which is set by another microcontroller and feedback value as an input. First the proportional gain is increased to get a little overshoot and then the integral constant is decreased from large value to small to obtain the response with given overshoot. Output is a PWM signal with modifiable duty-cycle.

Figure 1. Laboratory model of the Elevator

Figure 2. Overview of an ARDUINO Pro Mini board
PI transfer function is as follows \([3, 5]\):

\[
F(s) = K \cdot \frac{1 + sT}{sT} = 0.5 \cdot \frac{1 + 0.25s}{0.25s} = 0.5 \left( \frac{1}{0.25s} + 1 \right) = 0.5 + \frac{2}{s} \quad (1)
\]

B. H-Bridge

H-bridge is used to control direction and speed of DC motor. Inputs of H-bridge are connected to ARDUINO Pro Mini which controls direction and PWM duty-cycle. Output of an H-bridge is a voltage between 0 V and 12 V, and which depends on input’s duty-cycle. It is connected to a DC motor armature.

Transfer function of a H-bridge is as follows:

\[
F(s) = \frac{u_{\text{OUT}}(s)}{u_{\text{IN}}(s)} = K = 2.43 \quad (2)
\]

and its characteristic is shown on Fig.5.

C. DC Motor

DC motor with permanent magnets is used as an operating machine. The only known data about the motor are armature voltage which is 12 V and rotation speed which is 120 rpm. To get the transfer function of this motor, this data was insufficient. Dependence between rotation speed and armature voltage was measured with tachogenerator, and transfer function was obtained with MATLAB’s System Identification Toolbox \([4]\):

\[
F(s) = \frac{\omega(s)}{v_a(s)} = \frac{K_p}{1+s(T_{p1})(1+sT_{p2})} = \frac{K_p}{1+s(T_{p1}+T_{p2}) + s^2T_{p1}T_{p2}} = 0.9124 \quad (3)
\]

D. Incremental Encoder

DC motor rotation speed is measured with incremental encoder (Fig 7.). Incremental encoder gives 600 impulses per rotation. Output is connected to ARDUINO Pro Mini which counts impulses in time and is used as a regulation circuit feedback. Maximum input in encoder is 13.51 rad/s and maximum output is 5 V.
Therefore the transfer function of incremental encoder is:

\[
F(s) = \frac{y(s)}{\omega(s)} = \frac{5}{13.51} = 0.37
\]  \hspace{1cm} (4.)

III. SPEED REGULATION FEEDBACK LOOP

Reference value is voltage between 0 V and 5 V. It is set on analog input of microcontroller. If the reference value is set to 5 V, then DC motor rotation speed is 13.5 rad/s. Output of measuring element is value between 0 and 5. Regulator input uses difference between referent value and output of measuring element. Depending on the difference, on the output of the regulator 500 Hz PWM signal with modifiable duty-cycle appears. PWM signal is used as an input value to H-bridge. DC motor rotation direction is chosen by Arduino Mega which sends information of direction to ARDUINO Pro Mini. Arduino Pro Mini generates PWM signal with which controls DC motor speed via H-bridge. DC motor is connected on the output of the H-bridge. Motor speed depends on PWM’s duty cycle.

IV. POSITION AND TRAFFIC REGULATION

A. ARDUINO Mega

ARDUINO Mega development board (Fig 10.) is chosen for position and traffic control. This board is chosen because it has enough digital inputs and outputs to connect outputs of 8 position sensors, 8 buttons for cabin calling and few pins to communicate with ARDUINO Pro Mini.

</tbody>
</table>

B. Cabin position sensor

Cabin position sensor is an optocoupler. Paper flag is mounted on the cabin, and it goes through sensors. When the flag is between IR diode and photo transistor, sensor output is 0 V, else output is 5 V. Depending on sensors outputs microcontroller determines cabin position. Elevator model has eight sensors, two on every station.
C. Traffic control

There is a call button (Fig. 12.) on every of four stations. Four buttons are mounted in the cabin. They are connected to digital inputs of microcontroller. Algorithms in microcontroller save every button call and send cabin to the first saved value.

An elevator has four stations and the cabin speed depends on difference between current position and position where cabin needs to go. If the cabin needs to go from the first to second station, referent speed needs to be minimal because the distance is small. Also, acceleration and deceleration depends on difference between stations. Algorithm in microcontroller calculates the difference and constantly sends parameters to second microcontroller. It sends reference value of speed and cabin direction. Reference value has the shape of PWM signal, because microcontroller does not have analog outputs. PWM signal is connected to RC filter (Fig 13). The output is approximately equal to average value of PWM signal and it is connected to ARDUINO Pro Mini analog input. Fig. 14 shows acceleration and deceleration speed reference ramps.

D. Principles of operation of the elevator system

If the system is turned on for the first time, microcontroller checks cabin position. If the cabin is not on the first station, microcontroller positions cabin on first station. After that, microcontroller constantly checks call button and position sensors change of state. When the call is active, microcontroller calculates difference between stations and sets reference value of speed and direction of moving cabin to the speed control circuit. When the cabin is on the wanted position, microcontroller sends zero as speed reference and the cabin stops.

V. CONCLUSION

The elevator model is made with the aim of acquiring knowledge of automation and regulation. It is useful for laboratory exercises because the parameters of regulator are easy to change. If the parameters are changed, then the speed of cabin will be different.

Benefits in using such system are:
- ARDUINO platform is easy to program and is compatible with many operating systems,
- it is easy to change elements and their parameters in code,
- it is possible to measure all signals between microcontrollers and other elements.

However, there are certain disadvantages. They include:
- low operating voltage and possible disturbances,
- ARDUINO Mini Pro and Mega have not enough interrupt pins, so microcontroller needs to have additional algorithm to constantly check changes of states on digital inputs,
- optocouplers are not resistant to dust. Electromagnetic sensors would be better.

In addition, some improvements to this system can be done:
- adding the cabin door,
- changing DC motor with gear unit with DC motor without gear unit because when the cabin goes down the motor would be in braking mode. In that way real elevators work [6].

REFERENCES

The article deals with the system and methods for determination of the pressure distribution around aerodynamically shaped body immersed in airflow and further calculations of aerodynamic characteristics. Measurements are conducted in the subsonic closed-loop wind tunnel AT-1, in Aerodynamics Laboratory of Department of Aeronautics at Faculty of Transport and Traffic Sciences. Pressure distribution around airfoil NACA 2421 is sensed by the system for acquisition of pressure data Intelligent Pressure Scanner 9016, produced by the Pressure Systems Company. Data are digitalized and transferred to the computer through the Ethernet link. Data are processed by NUSS and LabVIEW software. Measurement results are displayed and compared to those obtained from piezometric harp. Results of experiments are commented and recommendations for further research are given.

I. INTRODUCTION

Wind tunnels are devices or facilities for experimental measurements in aerodynamics and they are used from the early beginning of aviation. The tunnels are used to obtain high-quality experimental data, especially when certain data can’t be obtained by theoretical calculations. In the wind tunnel, a controlled flow of air is produced which is acting on the model - subject of research and physical quantities are felt and measured and physical phenomena arising from the interaction of the body and the air flow are observed and recorded.

The measurements were performed in the subsonic wind tunnel AT-1 on the model of wing made of airfoil NACA 2421. The aim of the experiment was the construction of the measuring system from the measuring model through the acquisition of pressure system to the computer with appropriate programs.

Intelligent pressure transducer of Pressure Systems company uses electrical resistance elements by which mechanical displacement caused by the pressure is converted into an electrical signal. It consists of two module of code 9016 each containing 16 measurement points, each with input for reference pressure which is equal to the atmospheric pressure of the ambient air. In addition to the two modules, there is pressure calibrator of code 9034. It is used to calibrate the measuring instrument to zero and for the range. The modules convert analog signal to digital and send it through the Ethernet connection to the computer where the signal is further processed.

The results are compared with the results of hydrostatic pressure measurements. Two softwares are used for data processing: NUSS and LabView. NUSS is a basic program used to calibrate and adjust the system, and LabView is used to obtain pressure distribution on the upper and lower wing surface and to calculate the lift and the drag force due to the pressure.

II. WIND TUNNELS

Wind tunnels are complex installations which in its test section simulate flow conditions similar to those around the actual object or model. Wind tunnels are divided in regard to the velocity in the test section (subsonic, transsonic, supersonic) and the shape of the airstream line (open- or closed-circuit). According to their purpose or operating mode, tunnels are divided into: tunnels with a controlled pressure, tunnels with variable density of the working fluid, tunnels for testing prototypes in full size, tunnels for flow visualization, tunnels for testing free flight (the model is not fixed on the sting), tunnels for testing of spiral maneuvers, testing the stability of the flight, testing icing conditions on aircraft or other vehicles, for testing V/STOL aircraft, for testing aerodynamic characteristics of cars and boats, as well as for other uses in civil engineering (wind load on the building), ecology (the spread of pollution by natural air flow, the boundary layer to the surface of the Earth), sports (car racing, sailing, ski jumping, cycling ...) and for many other purposes.

Wind tunnel AT-1 (Figure 1.) at the Faculty of Transport and Traffic Sciences is a closed-circuit tunnel with a single return line. The test section has elliptical cross-section and partly open. Other components of the wind tunnel are converging nozzle, corner sections with air routers, honeycomb and screens, diffuser, the electric motor and fan, and the return line. Scheme of the wind tunnel AT-1 is shown in Figure 2.

Figure 1. Wind tunnel AT-1
The test section is the most important part of the wind tunnel, the required form of flow is obtained there, model and measurement equipment is located inside and measurements carried out. Through convergent nozzle, air is accelerated to the required speed due to the narrowing of the cross section of nozzle. Honeycomb and screens have to give enough laminar flow.

Angle sections are fitted with blades for deflecting the air stream to minimize losses due to turbulence. The purpose of the diffuser is to decrease the flow velocity of the working fluid, and thus the minimize power losses which are proportional to the third power of the speed. The electric motor drives fan which causes the airflow. Electric motor's rotation speed can be controlled and thus determines the flow velocity in the test section. Speeds attained in the test section of the tunnel AT-1 are up to 50 m/s and Reynolds numbers of flow up to $10^6$. [1]

III. BODY MODEL AND PRESSURE DISTRIBUTION

The aerodynamic wind tunnel AT-1 at the Faculty of Transport and Traffic Sciences in Zagreb uses a wing model with 29 pressure measurement points. A model of “infinite” wing with constant length of chord line of 150 mm and standard airfoil shape NACA 2421 is used in this experiment. A model of the wing located in the test section of the wind tunnel is shown on Figure 3.

Static pressure on the surface of airfoil is measured on measurement points allocated on upper and lower surface of the wing. Figure 4. shows 15 measurement points on the upper surface of an airfoil from leading to trailing edge. The rest of measurement points are set over the lower surface from trailing to leading edge. Measurement points on airfoil are holes of small diameter (1 mm) which are placed perpendicular to the contour of the airfoil surface. From that place canals are installed inside the wing which are connected to the plastic pneumatic hoses.

Pneumatic hoses are connected on a two pressure measuring devices. Each hose from one measuring point is divided into two hoses which are connected on both U-tube manometer and Intelligent Pressure Scanner.

U-tube manometer, also called piezometric harp, measures the pressure on the surface of the wing by a set of U-tube gauges. (Figure 5.). Piezometer harp consists of as many gauges as measuring points on the test model, plus one measuring tube for the determination of a reference pressure. All measuring tubes have one end connected to a common reference pressure (usually the pressure of the surrounding atmosphere). Reading height of fluid in the tubes is done using a measuring tape, which is set in the immediate vicinity of the tubes.

That is one of the oldest methods for normal pressure measurement from measuring point on the contour of the airfoil through pneumatic lines to the hydrostatic pressure gauge. Such a method of pressure reading is outdated and very time-consuming due to slow processing of each measurement point on the contour of the airfoil. Newer methods use electro-mechanical pressure transducers described in chapter IV of this article. These electromechanical transducers are integrated into digital systems for the acquisition of pressure around the airfoil. Intelligent Pressure Scanner uses silicon electro resistive pressure transmitter.

Pressure distribution around an airfoil at some angle of attack is shown on Figure 6. Pressure is expressed as relative to the pressure at infinity and drawn as a vertical length above each elementary surface of the airfoil. All peaks are connected and that represents the pressure distribution around the airfoil. If the difference $p - p_s$ has a positive value in the observed point, pressure forces acts towards aerofoil and arrow is directed towards airfoil.
That happened on the lower surface of airfoil where airflow is slower than in infinity. On the upper surface due to increased speed static pressure will decrease and will be lower than \( p_r \). That difference \( p - p_r \) has a negative value which creates a vacuum that pulls the airfoil up. So overpressure on the lower surface and vacuum on the upper surface are lifting the model of the wing. [2]

![Pressure distribution around an airfoil](image1)

**Figure 6. Pressure distribution around an airfoil**

### IV. INTELLIGENT PRESSURE SCANNER

The system for data acquisition is used to collect data from various sensors and to convert that data into digital numerical value used by the computer. It converts analog signals to digital. Programs for systems acquisitions are made in various programming languages and the program that is used here is LabVIEW.

Measurement begins with pressure sensing. Pressure gauges used by this system are electro-resistive elements also called piezo-resistive pressure transmitters. These devices are measuring the elongation of piezo-resistive element which stretches under the influence of the diaphragm (Figure 7). If the thin electro-resistive element is loaded by force attributable to the action of pressure, it causes a change in the geometry of electrical conductor and therefore the electrical resistance of the wire.

![Piezo-resistive element](image2)

**Figure 7. Piezo-resistive element**

Bending (tension and compression) of piezo-element generates very small changes in resistance. Deformation and fracture of strips are the limit for greater elongation. Therefore, extremely small changes in resistance have to be measured with great accuracy. Such a need for precision resistance measurement requires bridge circuit, a Wheatstone bridge. [3]

The Model 9016 Pneumatic Intelligent Pressure Scanner is a pressure acquisition module for multiple measurements of dry, non-corrosive gases. The scanner integrates 16 silicon piezo-resistive pressure sensors of large pressure range. This scanner has scanning speed up to 100 measurements per second on a single measurement channel. Each has its own reference pressure input, in this case atmospheric. Each pressure sensor is individually separated and incorporates a temperature sensor and EEPROM memory which stores complete information on digital temperature compensation. Housing incorporates also calibration valve, 16 bit A/D converter and 32 bit processor (Figure 8). [4]

![Piezometer harpasad](image3)

**Figure 8. Piezometer harpasad[4]**

Scanner modules are connected with the computer via power supply unit and Ethernet interface (Figure 9). The computer communicates with measuring modules using 10 MBit TCP/IP and UDP/IP protocols. Each measuring module and the computer have a unique IP address which is used for identification. In this network, computer represents a customer who receives information about the data of pressure and the measurement modules are servers that generate information about the data pressure. In order to connect with the modules computer must have a proper setting of a static IP address.

![Intelligent Pressure Scanner connections](image4)

**Figure 9. Intelligent Pressure Scanner connections**

In order to reduce the length of the hoses and improve dynamic measurement characteristics, model 9016 is designed for installation close to the measuring point. The distance between the object which is used for pressure measurement and electronic pressure scanner can range from a meter to thirty meters. Larger hoses have an impact on dynamic characteristics of transferred measuring air pressure signal.

Electronics are located within a housing which is hermetically sealed against the entry of liquids and dirt. Housing and internal electronics are designed to withstand very high vibrations that are moving in vibrational envelope with peak acceleration of 30 \( G \).

The effect of temperature on the measurement error may be significant if the module is exposed to temperatures outside the range of \( 0 \) °C to \( 60 \) °C. In this temperature range algorithm acts to correct pressure, and any excess of the work area temperature means uncontrolled increase of errors. [5]
V. DATA ANALYSIS

After setting the correct network properties the Netscanner Unified Startup Software can be started. This program allows system calibration, testing, cleaning and changing the IP address. There is no equipment in the laboratory to calibrate system, only the accuracy can be checked. After checking and obtaining IP address, the program LabVIEW can be started.

Manufacturer designed an application inside LabVIEW that connects to module device and reads the pressure. That application was modified for wind tunnel purpose. There is an interface of the application used for pressure acquisition for Netscanner system. To start the application it is necessary to enter correct IP address.

Air characteristics:
- temperature: \( t = 26.2^\circ C, \ T = 299.35 \text{ K} \)
- pressure: \( p = 99580 \text{ Pa} \)
- density: \( \rho = 1.1589 \text{ kg/m}^3 \)
- viscosity: \( \mu = 1.8415 \text{e} - 05 \).

Measuring of surrounding flow speed around airfoil for motor frequency of 35 Hz:

- fluid level difference in U-tube: \( \Delta h = 62 \text{ mm} \)
- pressure difference: \( \Delta p = \rho_{H2O} \cdot g \cdot \Delta h = 1000 \cdot 9.81 \cdot 0.062 = 608.22 \text{ Pa} \)
- airspeed: \( v = \sqrt{2 \cdot \Delta p/\rho} = 32.403 \text{ m/s} \).

Using the sum of all pressure around measuring points, and lift formula we can get the normal component of the lift:

- \( F_N = 71.39 \text{ N} \)

Difference between piezometric harp and scanner is +/−5% because of errors in reading height of harp and inability to accurately measure a harp slope.

The Figures 10. and 11. show a graphs that represents the pressure distribution around airfoil and it is very similar to graphs obtained by manual calculating using piezometric harp. Y-axis shows pressure value in PSI and X-axis shows measurement point number. On the right side pressure is shown in decimal number.

VI. CONCLUSION

Use of the system for pressure data acquisition significantly shorten and simplify the process of pressure distribution determination. Measurement results obtained from piezometric harp and those from pressure acquisition module vary in acceptable extent. Intelligent pressure scanner is more accurate device and allows programming in various languages. There is no more need for manual calculations. Application for sensing the pressure created in the LabVIEW program could be upgraded so all pressure around the airfoil could be presented in one coordinate system. It is also possible to make the application to sense all the pressure around airfoil and, with given speed and conditions of the atmosphere, to calculate coefficient of pressure, lift and drag for given angle of attack. This system is independent of AT-1 wind tunnel and airfoil within it. In future experiments other airfoils could be used and in different wind tunnels for various testing.

Sažetak - U novoj eri industrijskih računalnih sustava ulazi se u tzv. četvrto generaciju sustava nadzora, upravljanja i prikupljanja podataka koji se baziraju na Cloud i Internet of Things tehnologijama. Odlikuju ih mnoge karakteristike koje pružaju prednost nad starijim generacijama SCADA sustava. Najveći napredak postignut je u okviru komunikacijske razinе ujedinjavajući proizvođače uređaja industrijske namjene kako bi mogli raditi u istom okruženju. Na taj način podupire se razvoj cyber-fizičkih sustava koji čine samu osnovu koncepta četvrte industrijske revolucije pod nazivom Industry 4.0. U okviru ovog rada prikazano je rješenje MyScada koje posjeduje sve karakteristike četvrte generacije SCADA sustava.

I. UVOD

SCADA (eng. Supervisory Control And Data Acquisition, dalje SCADA) općenito je naziv za sustave nadzora, upravljanja i prikupljanja podataka u postrojenjima [7]. Ove sustave koristimo u skoro svim većim industrijskim postrojenjima, zgradaštvu, energetskom sektoru, prometnom sektoru te mnogim drugima djelatnostima [7]. Operatoru postrojenja omogućuju naglavljanje i upravljanje procesom rada sustava.

Do danas su razvijene četiri generacije SCADA sustava. Razvijale su se paralelno s razvojem računalnih tehnologija budući da se zasnivaju na tehnologijama komunikacije, procesiranja i prikaza podataka tj. grafike. Softvera danas ima vrlo mnogo te se proizvođači uglavnom baziraju na općenitoj primjeni, ali postoje i softveri određene namjene, tj. primjene u samo jednoj grani npr. vježbene elektrarane. U radu prikazan je tipičan SCADA sustav četvrte generacije na primjeru komercijalnog rješenja mySCADA. Cilj je rada dobivati uvida osnovnih softverskih mogućnosti SCADA sustava četvrte generacije na primjeru.

II. GENERACIJE SCADA SUSTAVA

Razvojem računalnih tehnologija SCADA sustavi postaju sve napredniji. Povećava se procesorska moć, brzina, način komunikacije među uređajima, pouzdanost te efikasnost. Tako su se do danas razvile četiri generacije sustava nadzora upravljanja i prikupljanja podataka (eng. Supervisory Control And Data Acquisition, SCADA).

A. Prva generacija

Prva generacija SCADA sustava temelji se na monošiltovnoj arhitekturi jer u to vrijeme nije bila razvijena komunikacija među sustavima [5]. Jedina komunikacija se odvijala između glavne upravljačke stanice i upravljačkih uređaja u polju (eng. Remote Terminal Unit, RTU). Komunikacijske protokole određivali su proizvođači RTU opreme, a bazirali su se na sabirničkim protokolima (npr. Modbus, Profibus). Kontrolne sobe bile su limitirane brojem pokaznika koji su većinom bili analogni mjerni uređaji i zasloni CRT (eng. Cathode Ray Tube) tehnologije.

B. Druga generacija

Druga generacija SCADA sustava temelji se na uvođenju distribuirane arhitekture koja omogućuje povezivanje dva ili više prostorno udaljenih sustava u jedan zajednički upravljački sustav [5]. Prednost drugih generacija omogućena je uvećanjem masne proizvodnje i distribuiranju procesa rada sustava.

C. Treća generacija

Treća generacija SCADA sustava temelji se na otvorenoj mrežnoj arhitekturi i upotrebi WSN (eng. Wide Area Networks) širokopojasnih protokola [5]. Pod pojmom otvorene mrežne arhitekture podrazumijeva se da su proizvođači RTU uređaja omogućili komunikaciju njihovih uređaja sa uređajima drugih proizvođača u istom sustavu. Time je omogućen nesmetan razvoj SCADA rješenja koja više nisu ovisna o proizvođačima opreme. Veliki napredak dogodio se i u prikazu samog sustava jer su kontrolne sobe opremljene velikim zaslonima koji pokazuju stanje sustava u realnom tj. stvarnom vremenu. Rad u stvarnom vremenu omogućava brži rad procesa s većom točnošću. Pohranjena podatke gledaju i izračunaju omogućuju procesu samostalno odlučivanje i trenutno djelovanje na reakciju dobivenu od strane uređaja koji je promatrana pojedinje stanje polja (senzori, mikroprokidači) što povećava efikasnost proizvodnog procesa.

D. Četvrta generacija

Tehnologije koje predstavljaju platformu za razvoj SCADA sustava četvrte generacije su Internet of Things (dalje IoT) i Cloud [3]. IoT možemo razmatrati kao mrežu...

1822
MIPRO 2017/SP
fizičkih uređaja i objekata koji međusobno komuniciraju sa nekom Cloud aplikacijom. U kontekstu SCADA sustava četvrte generacije takav koncept omogućuje prikupljanje, analizu i donošenje zaključaka na temelju raznih podataka iz postrojenja. Analiza stanja uređaja tako omogućuje poduzimanje prediktivnih mjera u pogledu održavanja procesa čime se povećava životni vijek opreme u postrojenju. Stoga prediktivnost rada sustava u smislu održavanja jedan je od najvažnijih noviteta SCADA sustava četvrte generacije. Mogućnosti umrežavanja uređaja u postrojenju povećavaju se razvojem ovakvih komunikacijskih protokola (npr. OPC UA) koji omogućavaju rad sa PLC uređajima, HMI stanicama i operativnim sustavima raznih proizvođača. Konačni cilj SCADA sustava četvrte generacije je arhitektura koja se u potpunosti temelji na Cloud-u i pruža mogućnosti udaljenog spažanja na upravljačku mrežu na razini pogona (Sl. 1.). Međutim, razvojem ovakve arhitekture povećavaju se i rizici sa stajališta računalne sigurnosti [6]. Zbog toga se najveći izazovi SCADA sustavima četvrte generacije postavljaju u pogledu sigurnosti kako prikupljanja podataka tako i upravljanja uređajima pomoću Cloud baziranih aplikacija uz komunikaciju u realnom vremenu [7].

III. MYSCADA TECHNOLOGIES

MyScada je neovisno cloud rješenje SCADA sustava koje svojom univerzalnošću i otvorenosti prema raznim proizvođačima industrijske opreme prati Industry 4.0 strategiju. Rješenje se sastoji od nekoliko modula koji se mogu zasebno koristiti (Sl. 2.).

A. myDESIGNER

MyDESIGNER je razvojna platforma za brzu i jednostavnu izradu aplikacije za vizualizaciju [1]. Grafičko sučelje može se kreirati iz gotove baze komponenata ili prema želji korisnika. Pri izradi aplikacije omogućene su sljedeće funkcionalnosti SCADA sustava: alarmi i događaji, kreiranje baze povijesnih podataka, kontrola pristupa, kreiranje sučelja čovjek stoj statičkog i dinamičkog tipa, recepti, upotreba broja tagova po želji korisnika, itd. Dakle, sve funkcionalnosti koje moderni SCADA sustavi zahtijevaju.

![Slika 1. Primjer četvrte generacije SCADA sustava [6]](image1)

![Slika 2. Prikaz implementacije softverskih rješenja [1]](image2)

B. myPRO

MyPRO jest profesionalni SCADA sustav koji je primarno namijenjen za vizualizaciju i upravljanje industrijskih procesa [1]. Instalira se na stolna i serverska računala. Razvojni sustav je moguće instalirati na bilo kojem operativnom sustavu, a pritom je podržan rad sa raznim proizvođačima PLC uređaja i njihovim komunikacijskim protokolima kao što su Ethernet/IP, Siemens S7, Modbus i sl. Pristup gotovom HMI sučelju je jedino moguće putem web preglednika što omogućuje brz i jednostavan rad.

C. myREPORTS

MyREPORTS jest upravljački i analitički alat za pregled, procesiranje i analizu podataka iz projekta [1]. Omogućuje učitavanje podataka iz projekta te ekportiranje istih u MS Excel, CSV ili PDF format. Predstavljanje podataka u tabličnoj formi, plotiranje istih u dijagrame, pite ili crtično. Time je omogućen statistički pregled podataka iz proizvodnog pogona u jednostavnoj razumljivoj formi što pomaže odgovornom osoblju u donošenju odluka.

D. myMOBILE

MyMOBILE jest softver koji se može instalirati na sve mobilne pametne uređaje i tako omogućuje nadzor i upravljanje u industrijskoj okolini [1]. Projekt se pokreće kroz web preglednik.

E. mySMART HOUSE

MySMART HOUSE je dio paketa mySCADA koja se primjenjuje za projekte "pametnih" kuća.[1] Instalira se na Raspberry PI platformi koja služi kao centralna HMI jedinica.

F. myBOX

MyBOX univerzalni su serverski uređaji koje mySCADA nudi na tržištu [1]. Služe za spažanje PLC uređaja u SCADA sustav na jednostavan način. Postoje tri
uredaja koji se razlikuju prema procesorskoj jačini MyBOX LOGGER, OPTIUM i EXTREME. Uređaji imaju ethernet ulazni priključak i dva izlaza za komunikaciju s okolinom. GSM i GPRS priključak, priključak za SIM karticu te microSD karticu.

IV. PRIMJER IMPLEMENTACIJE MYSCADA

Primjer implementacije mySCADA softverskih rješenja izveden je u Laboratoriju za procesna računala Tehničkog Veleučilišta u Zagrebu. Primjer je kreiran na način da se SCADA kreira na glavnoj radnoj stanici (Sl. 3). U sustav su uključena dva PLC uređaja različitih proizvođača: Siemens serije Simatic S7 i Allen Bradley serije CompactLogix. HMI sučelja pokrenuta su na dva mjesta i to na mobilnom uređaju i računalu. Switch služi kao pjesnjovački svih uređaja u sustavu. Uređajima su prethodno u MyDesigner dodijelene fiksne IP adrese. Router služi kako bi povezali mobilni uređaj u SCADA sustav. Program MyPRO je instaliran na glavnoj radnoj stanici HMI-računalu, dok je myMOBILE program instaliran na mobilni uređaj (Android, iPhone). Svi projekti su pokretani kroz Internet Explorer web preglednik.

Unosom IP adrese uređaja s kojim trenutno radimo na projektu web preglednika otvara se projekt s kojim počinjemo raditi. Pokretanjem projekta kroz Firefox i Chrome web preglednik pojavile su se poteškoće u normalnom otvaranju projekta dok je na sustavu Internet Explorer sve nesmetano funkcioniralo.

Primjer jednostavne nadzorno upravljačke aplikacije u web pregledniku jasno pokazuje kako mySCADA kao softver otvorenih protokola može istovremeno raditi s dva PLC uređaja istog proizvođača (Sl. 5).

Kako bi bili sigurni da su uređaji povezani postoji opcija Test Device čime softver provjerava da li su svi uređaji u sustavu pod unesenim IP adresaama vidljivi. Nakon unosa gotovih grafičkih objekata unose se tagovi pod Data Logs poljem. Svaki tag ima svoj naziv, opis, te adresu koja se unosi u istom obliku kao što PLC uređaj zahtjeva. Zatim se određuje koja adresa pripada kojemu PLC uređaju prema nazivu koji je prethodno dodijeljen pod opcijom Connections. Opcija Tag Database služi za unos tagova koje smo prethodno definirali u Data Logs, a želimo njihove promjene trajno spremiti u bazu podataka te pratiti njihovu promjenu kroz myREPORTS.

Prilikom podešavanja sustava sa slike u myDESIGNER softveru prvo je potrebno pokrenuti novi projekt I unijeti osnovne podatke projekta. Jednom kada smo otvorili projekt ispred ekrana imamo prazno polje za crtanje željene grafičke (Sl. 4). S lijeve strane nalazi se izbornik kojim se određuju željeni parametre projekta i unose gotovi grafički objekti. Na alatnoj traci iznad praznog polja nalaze se funkcije za crtanje i izmjenu željene grafičke. U polju s desne strane od praznog polja nalazi se baza komponenata, korisnika i ikona te polje za podešenje svojstava komponenata kojima se služimo na našoj grafički.

Najvažnija je opcija Connections gdje se unose proizvođači, tipovi PLC uređaja te njihove IP adrese.
Unosom brojke od 0-100 u polje Input value na SCADA aplikaciji prvi zeleni stupić promijeni boju na vrijednost koja je zadana dok je unesena vrijednost odmah vidljiva u memoriji PLC uređaja odabranih proizvođača. mySCADA također omogućuje izravnu razmjenu podataka između korištenih PLC uređaja čime se dokazuje njegova "otvorenost" prema uređajima različitih proizvođača. Ova mogućnost se postiže podešavanjem funkcija Input i Output values u programu myDESIGNER.

V. ZAKLJUČAK

Budući da veliko najavljevana era koncepta Industry 4.0 još nije zaživjela, jednako tako postoji mnogo prostora za unapređenjem i testiranjem SCADA sustava četvrte generacije kao sastavnog dijela navedenog koncepta. Glavni cilj SCADA sustava temeljenih na IoT je povećati protok podataka između uređaja i računala te između ljudi i računala. Prednost ove tehnologije jest otvorenost sustava prema svim PLC proizvođačima, rad u stvarnom vremenu s vrlo brzim odživom, rad na svim operacijskim sustavima, rad sa svim uređajima u polju, WAN komunikacija, predvidivost procesa i prediktivnost stanja uređaja.

Izazovi koji će pratiti inženjere primjenom IoT tehnologije u SCADA sustavima je prilagoditi se novim SCADA softverima te odbaciti koncept rada sa hardverskim rješenjima samo jednog proizvođača. Nova industrijska proizvodna postrojenja će svoju tehnologiju zasnivati na SCADA sustavima četvrte generacije, a već postojeća će se prilagodavati ovisno o potrebi zamjene pojedinog starog proizvodnog dijela pogona sa novim. Ovakva prilagodba zahtijeva puno vremena i ulaganja, a moguće rješenje se krije dodatnom standardizacijom IoT koncepta u području industrijskih aplikacija. Implementirano rješenje mySCADA prikazuje da je otvorenost programske podrške prema opremi različitih proizvođača dobar korak u pravcu standardiziranih SCADA sustava četvrte generacije.

Osnove modeliranja bežičnog komunikacionog kanala za tjelesne mreže

Katjana Krhač*
*Fakultet elektrotehnike i računarstva, Zagreb, Hrvatska
katjana.krhac@gmail.com

Sažetak - IEEE 802.15.6 je standard za bežične komunikacije u blizini, na ili unutar ljudskog tijela koje prema fizičkom sloju mogu biti uskopojasne, širokopojasne ili HBC. Komunikaciju u okolici ili unutar ljudskog tijela karakteriziraju značajni gubitci i sjenjenje što predstavlja problem kod modeliranja komunikacionog kanala. Kako bi model komunikacionog kanala bio prihvatljiv, mora vrijediti za mnogobrojne scenarije i primjene. Statistički modeli prvog i drugog reda koriste se za točno modeliranje bežičnih BAN komunikacionih sustava. Širokopojasne BAN komunikacijske kanale najčešće opisuje log-normalna razdioba, dok je za opis uskopojasnih BAN komunikacionih kanala najčešće log-normalna ili gama razdioba.

I. UVOD

Bežične tjelesne mreže (engl. Body Area Network, BAN) za nadgledanje i očitavanje signala tjelesnih funkcija jedne su od najbrže rastućih bežičnih komunikacijskih sustava koji obećavaju revoluciju zdravstva. Posljednji napredci u mikro i nano elektronici omogućili su izradu malih uređaja uz minimalnu potrošnju snage prilagodni radu unutar, na ili u okolici ljudskog tijela. Podaci iz implantata unutar ljudskog tijela ili senzora na površini ljudskog tijela nude mogućnost boljih dijagnoza i terapija.

IEEE 802.15.6 standard za bežične BAN mreže je temelj modeliranja komunikacijskog kanala koji daje mogućnost odabira između tri propagacijska modela: uskopojasne komunikacije, širokopojasne komunikacije, te HBC (engl. Human Body Communication) odnosno komunikacija kod koje je medij širenja signala ljudsko tijelo. Također, komunikacijski kanal kod bežičnih BAN mreža može biti na ljudskom tijelu, u okolini ljudskog tijela, unutar ljudskog tijela ili između dva ljudska tijela (engl. on-body, off-body, in-body, body-to-body).

Statističke prvog i drugog reda daju uvid u odabir odgovarajućeg modela za BAN komunikacijski kanal, kod kojih log-normalna razdioba i gama razdioba najbolje odgovaraju bežičnim BAN mrežama.

Poglavlje II. prikazuje navažnije karakteristike IEEE 802.15.6. standarda, dok su u poglavljima III. navedeni komunikacijski scenariji za BAN mreže. U poglavlju IV. objašnjene su statistike prvog i drugog reda koje pomažu pri modeliranju BAN komunikacijskog kanala. Primjer BAN komunikacijskog kanala s primjenom u medicini dan je u poglavlju V, dok su glavni zaključci rada navedeni u poglavlju VI.

II. IEEE 802.15.6 BODY AREA NETWORK STANDARD

Bežične BAN mreže su posljednja generacija osobnih mreža (engl. Personal Area Network, PAN), te opisuju mrežu uređaja koji međusobno komuniciraju unutar, na ili u okolini ljudskog tijela na ISM (engl. Industrial Scientific and Medical) pojasi ili drugim frekvencijskim pojasevima koji su dozvoljeni u tu svrhu.

IEEE 802.15.6 standard dozvoljava da uređaji rade s vrlo malom snagom u svrhu sigurnosti kako bi se minimiziralas specifična konstanta apsorpcije (engl. Specific absorption rate, SAR), te produžio život baterije koja napaja uređaj. Svrha standarda je pružiti internacionalnu normu za kratki domet, nisku snagu i veliku pouzdanost bežične komunikacije unutar ili u blizini ljudskog tijela. Postojeće PAN mreže ne podržavaju medicinske komunikacijske propise, te kombinaciju pouzdanosti, kvalitete usluge, niske snage, brzine prijenosa podataka i spriječavanje interferencije koja je potrebna u svrhu brojnih mogućnosti BAN mreže.

Glavna primjena BAN mreža je u zdravstvene svrhe, te je zbog toga dugotrajno i pouzdano djelovanje uz nisku potrošnju snage od velike značajnosti.

A. Tehnički zahtjevi za BAN mreže

IEEE 802.15.6 standard daje brojne smjernice za BAN mreže. Čime se daje uvid u način rada BAN mreža te njihov značajan utjecaj na modeliranje komunikacijskog kanala. Navedene smjernice odnose se na fizički sloj i propagaciju unutar kanala [1].

- BAN mreže mogu sadržavati do 256 čvorova.
- BAN link može podržati brzine prijenosa podataka od 10 kb/s do 10 MB/s.
- Omjer pogreške paketa (engl. Packet Error Rate) mora biti ≤10% za korisničke informacije od 256 okteta.
- Maksimalna izračena snaga ne smije prelaziti 0 dBm (1 mW), te svi uređaji moraju imati mogućnost odašiljavanja na 10 dBm (10 mW). Time se ujedno postiže i ograničenje za SAR koja ne smije prelaziti 0,0016 W/g po 1 g ljudskog tkiva.
• Dodavanje ili uklanjanje čvorova sa ili u BAN mrežu ne smije trajati dulje od 3 sekunde.
• Primjena BAN mreža mora podrzavati pouzdanost, kašnjenje i treperenje (engl. jitter) signala. Kašnjenje mora biti manje od 125 ms za medicinske primjene i manje od 250 ms za ne-medicinske svrhe. Treperenje ne smije prelaziti 50 ms.
• Mehanizmi za očuvanje snage moraju biti omogućeni.
• Fizički sloj mora podrzavati rad najmanje 10 nasumice raspodijeljenih BAN mreža (2560 čvorova).

B. Metode propagacije kod BAN mreža

Unutar IEEE 802.15.6 standarda definirane su tri propagacijske metode temeljene na fizičkom sloju [1]. To su uskopojasne komunikacije, širokopojasne (engl. Ultra Wide Band, UWB) komunikacije, te komunikacije kroz ljudsko tijelo - HBC. Frekvencijski pojasi i širine komunikacijskih kanala za navedene metode propagacije prikazane su u tablici 1.

1) **Uskopojasne komunikacije**

Uskopojasne komunikacije pogodne su za većinu medicinskih aplikacija. Pošto imaju nisku frekvenciju nosioca pod manjim su utjecajem atenuacije zbog ljudskog tijela. Širina pojasa od 1 MHz ili manje također spriječava intemisimalnu interferenciju (engl. Intersymbol Interference, ISI) koju uzrokuje višestazno širenje signala.

2) **Širokopojasne (UWB) komunikacije**

IEEE 802.15.6 standard podržava UWB komunikaciju s modulacijom frekvencije (engl. Frequency Modulation UWB, FM-UWB) i s radioimpulsom (engl. Impulse Radio UWB, IR-UWB), time da je IR-UWB pogodniji za BAN mrežu. UWB pruža veću propusnost kao posljedicu veće širine pojasa. Prema 802.15.6 standardu, svaki UWB komunikacijski kanal ima širinu pojasa od 499 MHz.

3) **HBC komunikacije**

HBC komunikacija omogućena je vezom signala preko površine ljudskog tijela. Prijenos signala ostvaruje se elektrodama koje su u kontaktu s ljudskom kožom.

III. **BAN KOMUNIKACIJSKI SCENARIJI**

BAN mreže nude jedan od navedenih scenarija za ostvarenje bežičnog komunikacijskog kanala [2]:

1. Š. – body: komunikacija između dvije točke na površini ljudskog tijela.
2. In – body: komunikacija između implantata unutar ljudskog tijela do senzora koji se najčešće nalazi na površini ljudskog tijela.
3. Off – body: komunikacija između točke na površini ljudskog tijela i uređaja u blizini ljudskog tijela, najčešće u okolici od 3m.

U sljedećim poglavljima su objašnjene karakteristike svakog od navedenih scenarija za ostvarenje komunikacijskog kanala koristeći BAN mreže.

Slika 1. Prikaz on-body, in-body, off-body i body-to-body komunikacijskih scenarija za BAN komunikacijske mreže, preuzeto iz [2]

4. **On–body komunikacijski kanal**

On-body kanal je najčešće korišten komunikacijski kanal za bežične BAN mreže. Kanal radi u različitim okruženjima, te na njega utječe sporo promjenjiva dinamika i varijacije u sjenjenju signala zbog ljudskog tijela. Iako se kod dizajniranja takvog radio sustava susreće s potrešća zbog utjecaja ljudskog tijela, on-body komunikacijski kanal ima i svoje prednosti.

Pri radu s uređajima male potrošnje snage poželjan je dugi vijek trajanja senzora koji je omogućen malom potrošnjom snage baterije, kao i nisko elektromagnetsko zračenje čime se postiže mala specifična konstanta apsorpcije. Time se postiže željena snaga zračenja koja je znatno manja od 0 dBm (1 mW). Kod frekvencija koje su dodijeljene BAN mrežama ljudsko tijelo uzrokuje značajne gubitke kod propagacije signala.
S druge strane, uskopojasne komunikacije u svakodnevnom okruženju nude nekoliko prednosti pri modeliranju on-body komunikacijskog kanala.

• Komunikacijski kanal je recipročan, odnosno kanal koji se koristi za prijenos podataka od točke a do točke b jednak je komunikacijskom kanalu koji prenosi podatke od točke b do točke a.

• Komunikacijski kanal je stabilan najmanje stočin milisekundi, tipično dulje od 0,5 sekundi, čime su omogućena relativno točna predviđanja kanala kroz višestruke komunikacijske okvire.

• Iako direktna veza između senzora može biti prekinuta, pošto je kanal na ljudskom tijelu sporo promjenjivi pojavit će se novi link preko višestaznog zračenja signala transmtera.

• On-body BAN komunikacijski kanal podržava velike brzine prijenosa, međutim u većini slučajeva, primjerice u medicinske svrhe, nije potrebna tolika brzina prijenosa već najčešće tek nekoliko desetaka kb/s.

• On-body BAN komunikacijski kanal za uskopojasne sustave sporo se mijenja s vremenom, međutim ne ovisi o frekvenciji te ne nudi rješenja za višestazo širenje signala. Pošto ima samo jedan kanal ne javljuju se smetnje zbog intersimbolne interferencije.

B. In–body komunikacijski kanal

Kod primjena u medicini, in-body komunikacijski kanal uglavnom radi na nižim prijenosnim frekvencijama. Najčešće je to MICS frekvencijski pojas od 402 MHz do 405 MHz. In-body komunikacijski sustav sastoji se od implantata s odasljačem koji prenosi signal do prijamnika na površini ili u okolici ljudskog tijela. Prijenos signala od odasljača unutar tijela do prijamnika koji se također nalazi u tijelu je neuobičajeno. Prigušenje signala koji putuje kroz ljudsko tijelo ima veliki utjecaj kod in-body komunikacijskog kanala.

In-body kanal susreće se sa sličnim izazovima i prednostima kao i on-body kanal. Dodatno, in-body komunikacijski kanal zahtjeva veća ograničenja snage zračenja kao i manju potrošnju snage baterijskog napajanja. Poželjno je da napajanje unutar ljudskog tijela ima životni vijek od nekoliko godina, kao i umanjenu apsorpciju radio valova unutar ljudskih tkiva kojima signal prolazi.

C. Off–body komunikacijski kanal

Ovaj komunikacijski kanal je najsličniji osobnoj mreži (PAN – Personal Area Network). Međutim, prijenos signala od točke na površini ljudskog tijela do pristupnika na maloj udaljenosti od ljudskog tijela pod velikim je utjecajem sjenjenja signala, slično kao i kod on-body komunikacijskog kanala. Kod medicinskih aplikacija, točno određeni položaj radio uređaja u okolici tijela može povećati dobitak kanala kod željenog off–body komunikacijskog prijenosa. Također, off-body komunikacijski kanal može imati manje energetsko ograničene releje nego on-body komunikacijski kanal. Za off-body komunikacijski kanal vrijede sve prednosti pri modeliranju kanala kao i kod on-body sustava kao što je na primjer recipročnost sustava, no brzine prijenosa podataka mogu u nekim slučajevima biti veće nego kod on-body komunikacijskog sustava.

D. Body–to–body komunikacijski kanal

U većini bežičnih BAN mreža, mala je vjerojatnost komunikacijskog sustava koji se sastoji od komunikacije između nekoliko ljudskih tijela. S druge strane, zbog mobilnosti, može se dogoditi da se nekoliko ljudi koji nose BAN mreže nade na istom mjestu te je stoga važno razumjeti karakteristike body-to-body komunikacijskog kanala.

Interferencijski kanal ima manje gubitke od on-body komunikacijskog kanala pošto se pri body-to-body kanalu ne javlja sjenjenje signala. Također, kod body-to-body komunikacijskog kanala ne javljaju se gubici slobodnog prostora, iako je kanal sporo vremenski promjenjiv i frekvencijski neovisan za uskopojasne komunikacije. BAN mreže mogu imati poboljšane karakteristike kada se nalaze u okolici ostalih BAN mreža koje karakterizira body-to-body interferencija.

IV. STATISTIČKI MODELI POGODNI ZA BAN

A. Statistički modeli prvog reda

Kako bi se dobio statistički model prvog reda malih razmjera za uskopojasne kanale radi se podešavanje funkcije gustoće statističkih razdioba koje se koriste za karakterizaciju sjenjenja (Rayleigh, normalna (Gauss), log-normalna, Ricean, Nakagami, Weibull, gama) prema izmjenjenim ili simuliranim dobitcima kanala. Graf na slici 2 prikazuje statističke razdiobe te se vidi koliko je puta određena razdioba odgovarala dobitku kanala. Usprobom im se dva stapca za svaku od prikazanih razdioba vidi se da log-normalna, gama i Weibull razdiobe najbolje odgovaraju dobitcima kanala, dok Rayleigh razdioba izrazito loše opisuje dobitak kanala u svakom okruženju.

Slika 2. Prikaz statističkih razdioba koje odgovaraju dobitku kanala za sva okruženja, preuzeto iz [2]
B. Model prvog reda za UWB BAN komunikacijski kanal

Dobitak kanala za UWB BAN najbolje opisuje log-
normalna razdioba te se ona i najčešće koristi. Širokopojasni kanali susreću se s brojnim preprekama koje doprinose smanjenju odašilačkog signala (difrakcija, refleksija, apsorpcija, gubitci antene, itd.) koji se u logaritamskom domeni zbrajaju. U isuprlici s uskopojasnim BAN kanalom, kod UWB kanala javlja se i sjenjenje većih razmjera kao posljedica većih gubitaka zbog viših frekvencija nosioca.

C. Statistički modeli drugog reda za BAN mreže

Pošto BAN kanal nije statičan, na njega značajno
utječu kretanje osobe koja na sebi ima BAN mrežu. Zbog te dinamike, statistike drugog reda također su važne za karakterizaciju BAN komunikacijskih kanala. U nastavku su navedene glavne značajke statistika drugog reda za BAN radio propagaciju [2].

Raspon kašnjenja i profil kašnjenja snage BAN kanala mogu se iskoristiti kako bi se odredio broj korištenih kanala i time postojanje intersimbolne interferencije. Višestano širenje karakteristika je UWB BAN kanala, te se stoga ISI, čiji se utjecaj povećava sa širinom frekvencijskog pojasa, javlja samo pri UWB komunikacijskim kanalima.

Prosjek trajanja sjenjenja, odnosno prosječno vrijeme kod kojeg je snaga primljenog signala manja od određene vrijednosti, može se iskoristiti kako bi se odredio vremenski okvir kod kojeg nije moguće ostvariti paketski prijenos između odašilača i prijavnika. Prosjek trajanja sjenjenja uvelike ovisi o dinamici komunikacijskog kanala, pošto na sjenjenje utječe brzina i količina kretanja ljudskog tijela. Tipično kod BAN kanala prosječno trajanje sjenjenja iznosi 300 ms ili više.

Autokorelacija vremenski ovisnog dobitka kanala, koja se može iskoristiti za određivanje koherencije, za
bilo koji BAN komunikacijski link može odrediti vremenski okvir kod kojeg je mogući uspješni paketski prijenos podataka uz prisutnost sjenjenja. Dugo vrijeme koherencije, do 1 s za uskopojasni on-body kanal, omogućuje uspješnu kontrolu snage odašilačanja. Uz kontinuirano kretanje, vrijeme koherencije kanala može pasti između 70 ms i 25 ms, čime se dobiva znatno manji vremenski okvir za uspješno slanje paketskog prijenosa.

V. PRIMJENA BAN KOMUNIKACIJSKOG KANALA U MEDICINI

BAN mreže imaju najvažniju primjenu u zdravstvene
svrhe, s ciljem razvoja novih, naprednijih metoda
aplikacije lijekova i smanjivanja invazivnosti raznih pretrag i postupaka. Jedan od zanimljivijih primjera BAN komunikacijskog sustava je endoskopia bežičnim kapsulom. Postupak endoskopije kapsulom uključuje unos kapsule u provabiv sustav gutanjem nakon čega kapsula pomoću peristaltike putuje kroz provabiv sustav oko dvaenaest sati. U tom periodu kapsula bilježi i odašilje veliki broj slika prema prijavniku koji je na površini ljudskog tijela gdje se podaci sprejuju u memoriju. Bežična endoskopska kapsula, (eng. Wireless Capsule Endoscopy – WCE), je uređaj u obliku pilule koji se sastoji od CMOS kamere, izvora svjetlosti, baterije i
radio transmziera. Kapsule su cilindričnog oblika, obično duljine oko 26 mm i promjera oko 11 mm. Izazov u dizajniranju kapsule leži u tome što volumen kapsule treba biti što manji kako bi pacijent lakše protuagio kapsulu, a istovremeno je u taj volumen potrebno smjestiti sve komponente kapsule kod kojih veličina utječe na učinkovitost i iskoristivost.

Iako model BAN kanala za endoskopiju kapsulom još uvijek nije realiziran, iako je zaključiti da određivanje modela nije jednostavno zbog brojnih izazova. Ljudsko tijelo problematičan je medij za RF propagaciju pošto je djelomično vodljivo te se sastoji od raznih materijala različitih veličina, dielektričnih konstanta i karakterističnih impedancija. Ovisno o odbrajanj frekvenciji, ljudsko tijelo može prouzročiti značajne gubitke temeljene na apsorpciji snage, pomaknu centralne frekvencije ili promjeni kod smjera radijacije. Također, još uvijek nisu riješene sve prepreke koje se tiču veličine, cijene, napajanja i samog dizajn komponenata. Na kraju, potrebno je ispitati i izmjeriti sigurnost i pouzdano endoskopske kapsule unutar ljudskog tijela. Važno je analizirati RF propagacijske signale iz endoskopske kapsule izvan ljudskog tijela kako bi se izbjegla interferencija. Navedeni izazovi i prepreke utječu na modeliranje propagacijskog kanala, te je prije same izrade modela BAN kanala potrebno razrješiti sve nejasnoće koje se javljaju pri endoskopiji kapsulum.

VI. ZAKLJUČAK

Bežične BAN mreže nova su generacija komunikacijskih mreža sa specifičnim propagacijskim karakteristikama opisane IEEE 802.15.6 standardom. Unutar standarda definirane su tri propagacijske metode temeljene na fizičkom sloju; uskopojasne komunikacije, širokopojasne (UWB) komunikacije, te komunikacije pomoću ljudskog tijela (HBC).

Propagaciju najčešće opisuju značajni gubici i sjenjenje koji otežavaju komunikaciju, posebice zbog zahtjeva IEEE 802.15.6 standarda za nisku izračenu snagu kod korištenih uređaja. S druge strane, BAN komunikacijski kanal karakterizira recipročnost i privremena stabilnost. Dobar model za komunikacijski kanal trebao bi vrijediti za mnogobrojne scenarije i aplikacije a ne samo za jedan komunikacijski kanal i jednu osobu pošto svaka osoba ima svoje karakteristike (visina, težina) i različite tjelesne aktivnosti. Međutim veliki izbor modela i tehnika modeliranja kanala otežava izbor najpogodnijeg i najboljeg modela za BAN mreže.

Zahtjevi bežičnog BAN komunikacijskog standarda te osnovne karakteristike propagacije, mogu se točno modelirati statistikama prvog i drugog reda. Sjenjenje kod širokopojasnijih BAN komunikacijskih kanala najčešće opisuje log-normalna razdioba, dok je za opis uskopojasnih BAN komunikacijskih kanala najčešća log-normalna ili gama razdioba. Model također mora vrijediti za bilo koji od BAN komunikacijskih scenarija; on-body, in-body, off-body, body-to-body.
